

MPLS VPN—Carrier Supporting Carrier

Feature History

Release	Modification
12.0(14)ST	This feature was introduced in Cisco IOS Release 12.0(14)ST.
12.0(16)ST	Support for the Cisco 12000 series routers (Engine 0) for the Cisco IOS 12.0 ST release was added.
12.2(8)T	This feature was integrated into Cisco IOS Release 12.2(8)T. Support was added for the Cisco 12.2 T release for the following platforms: Cisco 3640 series, Cisco 3660 series, Cisco 4500 series, Cisco uBR7200 series, and the Cisco MGX Route Processor Module.
12.0(21)ST	This feature was integrated into Cisco IOS Release 12.0(21)ST. Support for the Cisco 12000 series routers was added (for specific line cards supported, see Table 5).
12.0(22)S	This feature was integrated into Cisco IOS Release 12.0(22)S. Support for the Cisco 12000 series routers was added (for specific line cards supported, see Table 5).
12.0(23)S	This feature was integrated into Cisco IOS Release 12.0(23)S. Support was added for the Cisco 12000 Series Eight-Port OC-3c/STM-1c ATM Line Card (8-Port OC-3 ATM) and the Cisco 12000 Series Three-Port Gigabit Ethernet Line Card (3-Port GbE).
12.2(14)S	This feature was integrated into Cisco IOS Release 12.2(14)S and implemented on Cisco 7200 and Cisco 7500 series routers.

The carrier supporting carrier feature enables one MPLS VPN-based service provider to allow other service providers to use a segment of its backbone network. This document includes the following sections:

- [Feature Overview, page 2](#)
- [Supported Platforms, page 11](#)
- [Supported Standards, MIBs, and RFCs, page 12](#)
- [Prerequisites, page 13](#)
- [Configuration Tasks, page 13](#)
- [Configuration Examples, page 14](#)
- [Command Reference, page 60](#)
- [Glossary, page 61](#)

Feature Overview

Carrier supporting carrier is a term used to describe a situation where one service provider allows another service provider to use a segment of its backbone network. The service provider that provides the segment of the backbone network to the other provider is called the backbone carrier. The service provider that uses the segment of the backbone network is called the customer carrier.

This feature module focuses on a backbone carrier that offers Border Gateway Protocol and Multiprotocol Label Switching (BGP/MPLS) VPN services. The customer carrier can be either

- An Internet service provider (ISP)
- A BGP/MPLS VPN service provider

This feature module describes both types of customer carrier.

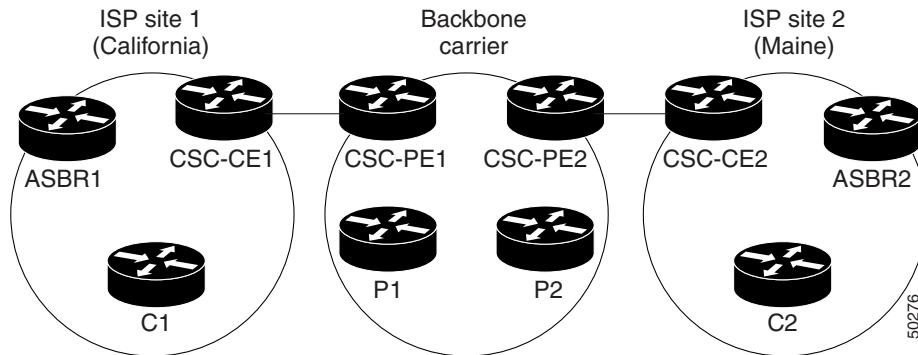

Providing a Backbone Network to a Customer Carrier Who Is an ISP

This section explains how a BGP/MPLS VPN service provider (backbone carrier) can provide a segment of its backbone network to a customer who is an ISP.

Consider the following example:

An ISP has two sites: one in California, the other in Maine. Each site is a point of presence (POP). The ISP wants to connect these sites using a VPN service provided by a backbone carrier. [Figure 1](#) illustrates this situation.

Figure 1 Sample BGP/MPLS Backbone Carrier Supporting an ISP

Note The CE routers in the figures in this feature module are CE routers to the backbone carrier. However, they are PE routers to the customer carrier.

Note This document uses the following abbreviations:

CE router: A customer edge router is part of a customer network and interfaces to a provider edge (PE) router. In this document, the CE router sits on the edge of the customer carrier network.

PE router: A provider edge router is part of a service provider's network connected to a customer edge (CE) router. In this document, the PE routers sits on the edge of the backbone carrier network.

ASBR: In this document, an autonomous system boundary router connects one autonomous system to another.

In this example, only the backbone carrier uses MPLS. The customer carrier (ISP) uses only IP. As a result, the backbone carrier must carry all the Internet routes of the customer carrier, which could be as many as 100,000 routes. This poses a scalability problem for the backbone carrier. To solve the scalability problem, the backbone carrier is configured as follows:

- The backbone carrier allows only internal routes of the customer carrier (IGP routes) to be exchanged between the CE routers of the customer carrier and the PE routers of the backbone carrier.
- MPLS is enabled on the interface between the CE router of the customer carrier and the PE router of the backbone carrier.

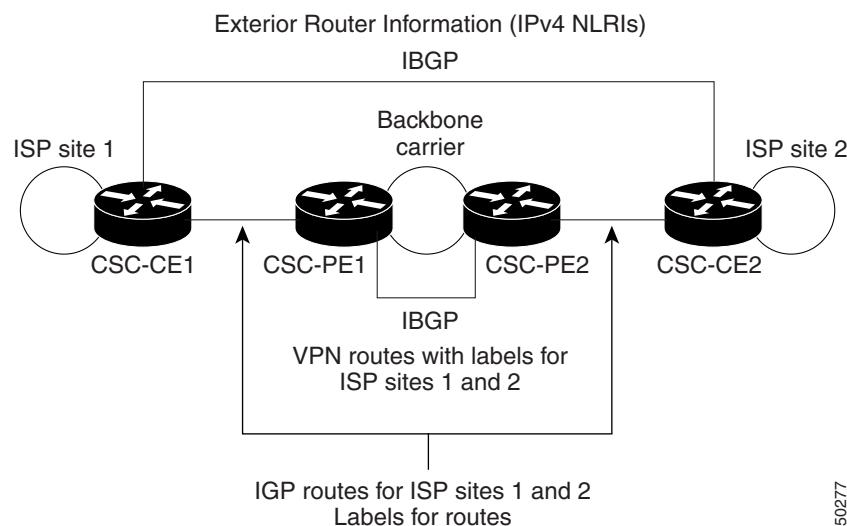

Internal and external routes are differentiated this way:

- Internal routes go to any of the routers within the ISP.
- External routes go to the Internet.

The number of internal routes is much smaller than the number of external routes. Restricting the routes between the CE routers of the customer carrier and the PE routers of the backbone carrier significantly reduces the number of routes that the PE router needs to maintain.

Since the PE routers do not have to carry external routes in the VRF routing table, they can use the incoming label in the packet to forward the customer carrier Internet traffic. Adding MPLS to the routers provides a consistent method of transporting packets from the customer carrier to the backbone carrier. MPLS allows the exchange of an MPLS label between the PE and the CE routers for every internal customer carrier route. The routers in the customer carrier have all the external routes either through IBGP or route redistribution to provide Internet connectivity. [Figure 2](#) shows how information is exchanged when the network is configured in this manner.

Figure 2 Backbone Carrier Exchanging Routing Information with a Customer Carrier Who Is an ISP

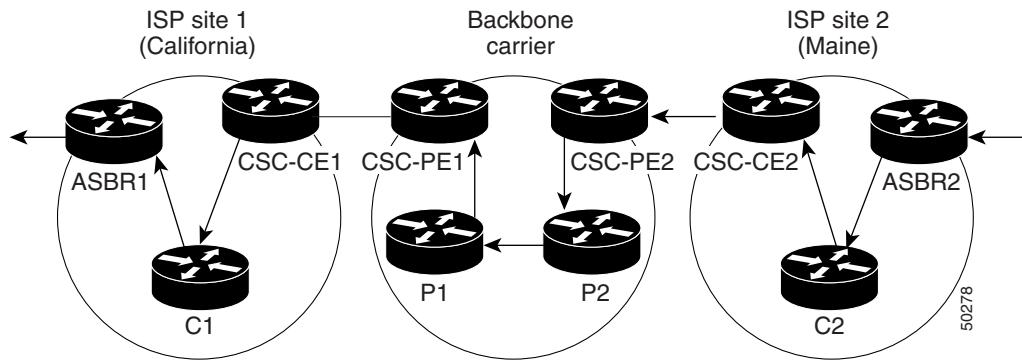

50277

Establishing a Route Between the Backbone Carrier and the Customer Carrier Who Is an ISP

In the example shown in [Figure 3](#), routes are created between the backbone carrier and the customer carrier sites. ASBR2 receives an Internet route that originated outside the network. All routers in the ISP sites have all the external routes through IBGP connections among them.

Figure 3 Establishing a Route Between a Backbone Carrier and a Customer Carrier Who Is an ISP

[Table 1](#) describes the process of establishing the route, which can be divided into two distinct steps:

- The backbone carrier propagates the IGP information of the customer carrier, which enables the customer carrier routers to reach all the customer carrier routers in the remote sites.
- Once the routers of the customer carriers in different sites are reachable, external routes can be propagated in the customer carrier sites, using IBGP without using the backbone carrier routers.

Table 1 Establishing a Route Between the Backbone Carrier and the Customer Carrier ISP

Step	Description
1	CSC-CE2 sends the internal routes within site 2 to CSC-PE2. The routes include the route to ASBR2.
2	CSC-PE2 sends the routing information for site 2 to CSC-PE1, using MPLS VPN processes. CSC-PE1 gets one label (called L3), which is associated with the route to the VPN-IP address for ASBR2. CSC-PE1 gets another label (called L2), which is associated with the route to CSC-PE2.
3	CSC-PE1 sends the routing information associated with internal routes from site 2 to CSC-CE1. CSC-PE1 also sends the label binding information. As a result, CSC-CE1 gets the route to ASBR2 with CSC-PE1 as the next hop. The label associated with that route is called L1.
4	CSC-CE1 distributes the routing information through site 1. Every router in site 1 gets a route for every internal destination in site 2. Therefore, every router in site 1 can reach routers in site 2 and learn external routes through IBGP.
5	ASBR2 receives an Internet route.
6	The IBGP sessions exchange the external routing information of the ISP, including a route to the Internet. Every router in site 1 knows a route to the Internet, with ASBR2 as the next hop of that route.

Transporting a Packet Through a Network of a Backbone Carrier and Customer Carrier Who Is an ISP

Table 2 explains each step in the process of transporting a packet. The following conventions are used in **Table 2**:

- The D in the Label Stack and Destination Address column represents an address that is outside the network, such as an Internet address.
- The notation $X(Y)$ means “the label distributed by Y , which represents the route to X .”
- In the Label Stack and Destination Address column, when a label stack is present, the top label is listed first; the destination address is listed last.

Table 2 Transporting Packets From a Customer Carrier Who is an ISP Through a BGP/MPLS Backbone Carrier

Step	The Packet Is Received By	Label Stack and Destination Address	Label Stack Operation	How the Label Was Learned	Next Hop
1	ASBR1	D	None	—	C1
2	C1	D	None	—	CSC-CE1
3	CSC-CE1	D	Move ASBR2(CSC-PE1) onto the stack	LDP	CSC-PE1
4	PE1	ASBR2(CSC-PE1) D	Replace the top label with ASBR2(CSC-PE2) Push the IGP label for CSC-PE2 CSC-PE2(P1)	BGP	P1
5	P1	CSC-PE2(P1) ASBR2(CSC-PE2) D	Replace the top label with CSC-PE2(P2)	LDP	P2
6	P2	CSC-PE2(P2) ASBR2(CSC-PE2) D	Remove a label from the stack	LDP	CSC-PE2
7	CSC-PE2	ASBR2(CSC-CE2) D	Replace the top label from the stack	LDP	CSC-CE2
9	CSC-CE2	D	Remove a label from the stack	—	C2
9	C2	D	None	—	ASBR2
10	ASBR2	D			

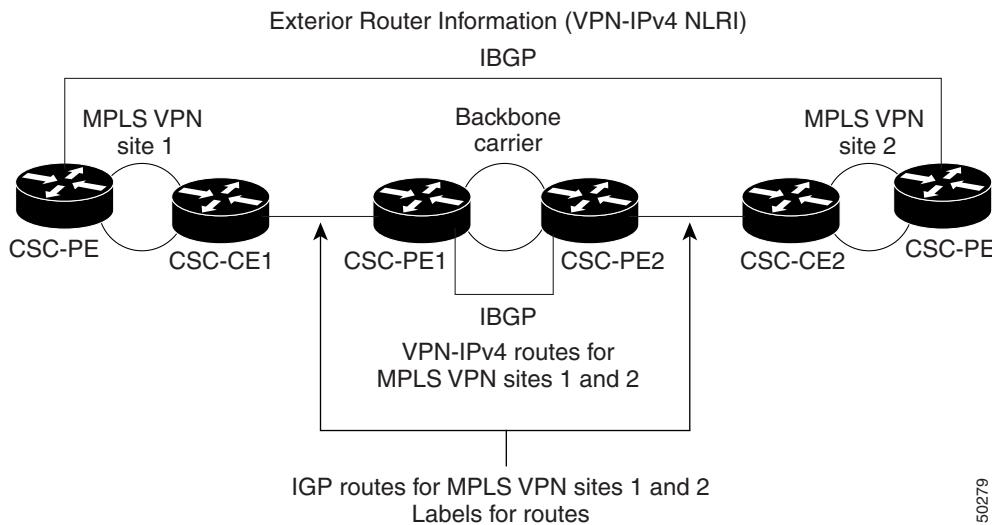

Providing a Backbone Network to a Customer Carrier Who Is a BGP/MPLS VPN Service Provider

When a backbone carrier and the customer carrier both provide BGP/MPLS VPN services, the method of transporting data is different from when a customer carrier provides only ISP services. The following list highlights those differences.

- When a customer carrier provides BGP/MPLS VPN services, its external routes are VPN-IPv4 routes. When a customer carrier is an ISP, its external routes are IP routes.
- When a customer carrier provides BGP/MPLS VPN services, every site within the customer carrier must use MPLS. When a customer carrier is an ISP, the sites do not need to use MPLS.

[Figure 4](#) shows how information is exchanged when MPLS VPN services reside on all customer carrier sites and on the backbone carrier.

Figure 4 *Backbone Carrier Exchanging Information with a Customer Carrier Who Is an MPLS VPN Service Provider*

Establishing a Route Between the Backbone Carrier and the Customer Carrier Who Is an MPLS VPN Service Provider

In the example shown in [Figure 5](#), routes are created between the backbone carrier and the customer carrier sites.

50279

Figure 5 Establishing a Route Between a Backbone Carrier and a Customer Carrier Who Is an MPLS VPN Service Provider

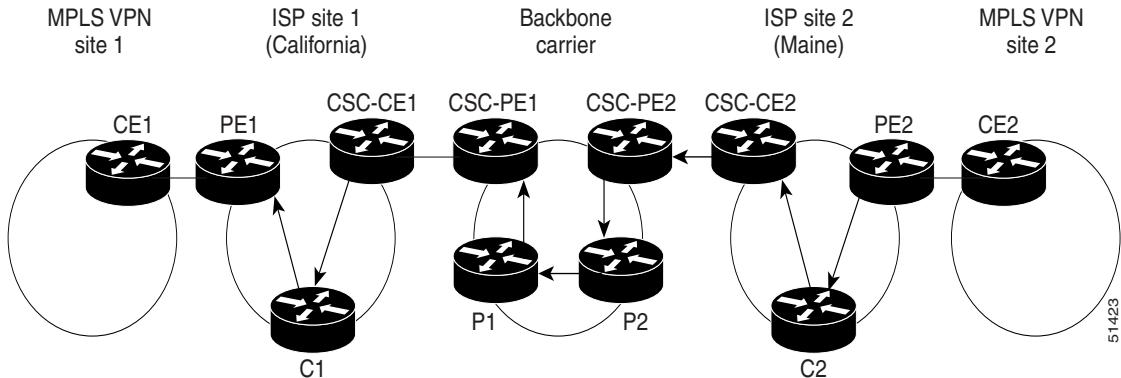

Table 3 describes the process of establishing the route.

Table 3 Establishing a Route Between the Backbone Carrier and Customer Carrier Site

Step	Description
1	CE2 sends all the internal routes within site 2 to CSC-PE2.
2	CSC-PE2 sends the routing information for site 2 to CSC-PE1, using MPLS VPN processes. CSC-PE1 gets one label (called L3), which is associated with the route to the VPN-IP address for PE2. CSC-PE1 gets another label (called L2), which is associated with the route to CSC-PE2.
3	CSC-PE1 sends the routing information associated with internal routes from site 2 to CSC-CE1. CSC-PE1 also sends the label binding information. As a result, CSC-CE1 gets the route to PE2 with CSC-PE1 as the next hop. The label associated with that route is called L1.
4	CE1 distributes the routing and labeling information through site 1. Every router in site 1 gets a route for every internal destination in site 2. Therefore, PE1 can establish an MP-IBGP session with PE2.
5	CE2 advertises the internal routes of MPLS VPN site 2 to PE2.
6	PE2 allocates labels for all the VPN routes (regular MPLS VPN functionality) and advertises it to PE1, using MP-IBGP.
7	PE1 can forward traffic from VPN site 1 that is destined for VPN site 2.

Transporting a Packet Through a Network of a Backbone Carrier and Customer Carrier Who Is an MPLS VPN Service Provider

Table 4 explains each step in the process of transporting the packet. The following conventions are used in Table 4:

- The D in the Label Stack and Destination Address column represents an address that is outside the network, such as an Internet address.
- The notation $X(Y)$ means “the label distributed by Y , which represents the route to X .”
- In the Label Stack and Destination Address column, when a label stack is present, the top label is listed first; the destination address is listed last.

Table 4 Transporting Packets From a Customer Carrier Running BGP/MPLS VPN Service Through a BGP/MPLS Backbone Carrier

Step	The Packet Is Received By	Label Stack and Destination Address	Label Stack Operation	How the Label Was Learned	Next Hop
1	PE1	D	Move D(PE2) onto the stack Move PE2(C1) onto the stack	BGP LDP	C1
2	C1	PE2(C1) D(PE2) D	Replace the top label with PE2(CSC-CE1)	LDP	CSC-CE1
3	CSC-CE1	PE2(CSC-CE1) D(PE2) D	Replace the top label with PE2(CSC-PE1)	LDP	CSC-PE1
4	CSC-PE1	PE2(CSC-PE1) D(PE2) D	Replace the top label with PE2(CSC-PE2) Move CSC-PE2(P1) onto the stack	BGP	P1
5	P1	CSC-PE2(P1) PE2(CSC-PE2) D(PE2) D	Replace the top label with CSC-PE2(P2)	LDP	P2
6	P2	CSC-PE2(P2) PE2(P2) D(PE2) D	Remove a label from the stack	LDP	CSC-PE2
7	CSC-PE2	PE2(CSC-PE2) D(PE2) D	Replace the top label with PE2(CSC-CE2)	BGP	CSC-CE2
8	CSC-CE2	PE2(CSC-CE2) D(PE2) D	Replace the top label with PE2(C2)	LDP	C2
9	C2	PE2(C2) D(PE2) D	Remove a label from the stack	LDP	PE2
10	PE2	D(PE2) D			

Benefits

The MPLS VPN carrier supporting carrier feature provides the benefits listed in the following paragraphs to service providers who are backbone carriers and customer carriers.

Benefits to the Backbone Carrier

Implementing the MPLS VPN carrier supporting carrier feature enables the backbone carrier to realize the following benefits:

- The backbone carrier can accommodate many customer carriers and give them access to its backbone. The backbone carrier does not need to create and maintain separate backbones for its customer carriers. Using one backbone network to support multiple customer carriers simplifies the backbone carrier's VPN operations. The backbone carrier uses a consistent method for managing and maintaining the backbone network. This is also cheaper and more efficient than maintaining separate backbones.
- The MPLS VPN carrier supporting carrier feature is scalable. Carrier supporting carrier can change the VPN to meet changing bandwidth and connectivity needs. The feature can accommodate unplanned growth and changes. The carrier supporting carrier feature enables tens of thousands of VPNs to be set up over the same network, and it allows a service provider to offer both VPN and Internet services.
- The MPLS VPN carrier supporting carrier feature is a flexible solution. The backbone carrier can accommodate many types of customer carriers. The backbone carrier can accept customer carriers who are ISPs or VPN service providers or both. The backbone carrier can accommodate customer carriers that require security and various bandwidths.

Benefits to the Customer Carrier

Implementing the MPLS VPN carrier supporting carrier feature enables the customer carrier to realize the following benefits:

- The MPLS VPN carrier supporting carrier feature removes from the customer carrier the burden of configuring, operating, and maintaining its own backbone. The customer carrier uses the backbone network of a backbone carrier, but the backbone carrier is responsible for network maintenance and operation.
- Customer carriers who use the VPN services provided by the backbone carrier receive the same level of security that Frame Relay or ATM-based VPNs provide. Customer carriers can also use IPSec in their VPNs for a higher level of security; it is completely transparent to the backbone carrier.
- Customer carriers can use any link layer technology (SONET, DSL, Frame Relay, and so on) to connect the CE routers to the PE routers and the PE routers to the P routers. The MPLS VPN carrier supporting carrier feature is link layer independent. The CE routers and PE routers use IP to communicate, and the backbone carrier uses MPLS.
- The customer carrier can use any addressing scheme and still be supported by a backbone carrier. The customer address space and routing information are independent of the address space and routing information of other customer carriers or the backbone provider.

Requirements

The carrier supporting carrier feature includes the following requirements:

- The PE routers of the backbone carrier require 128 MB of memory.
- The backbone carrier must enable the PE router to check that the packets it receives from the CE router contain only the labels that the PE router advertised to the CE router. This prevents data spoofing, which occurs when a packet from an unrecognized IP address is sent to a router.
- A routing protocol is required between the PE and CE routers that connect the backbone carrier to the customer carrier. The routing protocol enables the customer carrier to exchange IGP routing information with the backbone carrier. Use the same routing protocol that the customer carrier uses. You can choose RIP, OSPF, or static routing as the routing protocol. BGP is not supported.
- Label distribution protocol (LDP) is required between the PE and CE routers that connect the backbone carrier to the customer carrier. LDP is also required on the PE to CE interface for VPN routing/forwarding (VRF). LDP is available on Cisco IOS Release 12.0(10)ST or later.
- All PE routers that link the backbone carrier to the customer carrier must run this IOS software image. Other PE routers, CE routers, and P routers do not need to run this software image, but, they must run a version of Cisco IOS software that supports MPLS VPNs (Cisco IOS Release 12.0(5)T or later).
- Every packet that crosses the backbone carrier must be encapsulated, so that the packet includes MPLS labels. To ensure that the packets are encapsulated, issue the following command on the PE routers that connect to CE routers:

```
(config-if)# mpls ip
```

For more information, see the IOS Command Reference Guide.

The following features are not supported in the carrier supporting carrier feature:

- ATM MPLS
- Carrier supporting carrier traffic engineering
- Carrier supporting carrier class of service (CoS)
- RSVP aggregation
- VPN Multicast between the customer carrier and the backbone carrier network

Related Features and Technologies

The carrier supporting carrier feature is used with the VPN capabilities of MPLS. (MPLS VPNs were introduced in Cisco IOS Release 12.0(5)T.)

Supported Platforms

The following router platforms are supported on the edge:

- Cisco 7200 series
- Cisco 7500 series
- Cisco 12000 series

See [Table 5](#) for Cisco 12000 series line card support added for Cisco IOS Releases.

Table 5 Cisco I2000 Series Line Card Support Added for Cisco IOS Releases

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported on specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

■ Supported Standards, MIBs, and RFCs

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

No new or modified standards are supported by this feature.

MIBs

No new or modified MIBs are supported by this feature.

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

RFCs

- RFC 1171, *A Border Gateway Protocol 4*
- RFC 1164, *Application of the Border Gateway Protocol in the Internet*
- RFC 2283, *Multiprotocol Extensions for BGP-4*
- RFC 2547, *BGP/MPLS VPNs*

Prerequisites

The backbone carrier must be properly configured for MPLS VPN operation before the customer carriers can access the backbone network. Refer to the [MPLS Virtual Private Networks \(VPNs\)](#) and the [MPLS Virtual Private Network Enhancements](#) feature modules.

Configuration Tasks

See the following sections to enable a backbone carrier to share its backbone network with a customer carrier. Each task entry in the list indicates if the task is optional or required.

- [Configuring the Backbone Carrier PE Router](#) (required)
- [Configuring the Customer Carrier CE Routers](#) (required)
- [Verifying the Carrier Supporting Carrier Configuration](#) (optional)

Configuring the Backbone Carrier PE Router

To configure the backbone carrier PE route that links to the edge router of the customer carrier, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# mpls label protocol ldp	Sets the default label distribution protocol for all interfaces to be LDP.
Step 2	Router(config-if)# mpls ip	Enables MPLS on the VRF interface.

Configuring the Customer Carrier CE Routers

To configure the CE router on the customer carrier that links to the edge router of the backbone carrier, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# mpls label protocol ldp	Sets the default label distribution protocol for all interfaces to LDP.
Step 2	Router(config-if)# mpls ip	Enables MPLS on the VRF interface.

Verifying the Carrier Supporting Carrier Configuration

The following commands helps to verify the status of LDP sessions that were configured between the backbone carrier and customer carrier. Now the customer carrier ISP sites appear as a VPN customer to the backbone carrier.

This command shows the LDP sessions in VRF VPN1 of the PE router of the backbone carrier.

```
Router# show mpls ldp discovery vrf vpn1
```

■ Configuration Examples

```

Local LDP Identifier:
  139.0.0.0:0
Discovery Sources:
  Interfaces:
    Ethernet1/0 (ldp): xmit/recv
      LDP Id: 55.0.0.1:0
    POS6/0 (ldp): xmit
  
```

This command lists all LDP sessions in a router.

```

Router# show mpls ldp discovery all

Local LDP Identifier:
  141.141.141.141:0
Discovery Sources:
  Interfaces:
    Ethernet1/5 (ldp): xmit/recv
      LDP Id: 5.5.5.5:0
  VRF vpn1: Local LDP Identifier:
    139.0.0.1:0
Discovery Sources:
  Interfaces:
    Ethernet1/0 (ldp): xmit/recv
      LDP Id: 55.0.0.1:0
    POS6/0 (ldp): xmit
  
```

The Local LDP Identifier field shows the LDP identifier for the local label switching router for this session. The Interfaces field displays the interfaces engaging in LDP discovery activity:

- xmit indicates that the interface is transmitting LDP discovery hello packets.
- recv indicates that the interface is receiving LDP discovery hello packets.

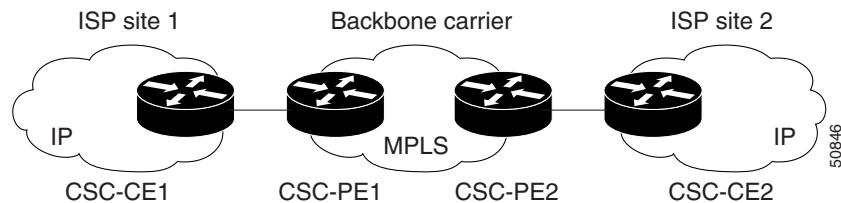

Configuration Examples

This section provides the following configuration examples:

- [Configuring a Carrier Supporting Carrier Network with a Customer Who Is an ISP](#)
- [Configuring a Carrier Supporting Carrier Network with a Customer Who Is an MPLS VPN Provider](#)
- [Configuring a Carrier Supporting Carrier Network That Contains Route Reflectors](#)
- [Configuring a Carrier Supporting Carrier Network with a Customer Who Has VPNs at the Network's Edge](#)

Configuring a Carrier Supporting Carrier Network with a Customer Who Is an ISP

[Figure 6](#) shows a carrier supporting carrier network configuration where the customer carrier is an ISP. The customer carrier has two sites, each of which is a point of presence (POP). The customer carrier connects these sites using a VPN service provided by the backbone carrier. The backbone carrier uses MPLS. The ISP sites use IP. To enable packet transfer between the ISP sites and the backbone carrier, the CE routers that connect the ISPs to the backbone carrier run MPLS.

Figure 6 Carrier Supporting Carrier Network with a Customer Carrier Who Is an ISP

The following configuration examples show the configuration of each router in the carrier supporting carrier network. OSPF is the protocol used to connect the customer carrier to the backbone carrier.

Configuring a Carrier Supporting Carrier Network with a Customer Who Is an MPLS VPN Provider

Figure 7 shows a carrier supporting carrier network configuration where the customer carrier is an MPLS VPN provider. The customer carrier has two sites. The backbone carrier and the customer carrier use MPLS. The IBGP sessions exchange the external routing information of the ISP.

Figure 7 Carrier Supporting Carrier Network with a Customer Carrier Who Is an MPLS VPN Provider

The following configuration examples show the configuration of each router in the carrier supporting carrier network. OSPF is the protocol used to connect the customer carrier to the backbone carrier.

Configuring a Carrier Supporting Carrier Network That Contains Route Reflectors

Figure 8 shows a carrier supporting carrier network configuration that contains route reflectors. The customer carrier has two sites.

Figure 8 Carrier Supporting Carrier Network that Contains Route Reflectors

Note A connection between route reflectors (RR) is not necessary.

The following configuration examples show the configuration of each router in the carrier supporting carrier network. Note the following:

- The router IP addresses are abbreviated for ease of reading. For example, the loopback address for PE 1 is 25, which is equivalent to 25.25.25.25.
- The following list shows the loopback addresses for the CSC-PE routers:
 - CSC-PE1 (75K-37-3): loopback 0 = 15.15.15.15, loopback 1 = 18.18.18.18
 - CSC-PE2 (75K-38-3): loopback 0 = 16.16.16.16, loopback 1 = 20.20.20.20

Command Reference

The feature requires no new or modified commands. All commands used with this feature are documented in the Cisco IOS Release 12.2 command reference publications.

Glossary

AS—autonomous system. A collection of networks under a common administration sharing a common routing strategy.

ASBR—autonomous system boundary router. An edge router located between an Open Shortest Path First (OSPF) autonomous system and a non-OSPF network. ASBRs run both OSPF and another routing protocol, such as RIP.

BGP—Border Gateway Protocol. A routing protocol that exchanges network reachability information with other BGP systems, which may be within the same autonomous system or between multiple autonomous systems.

CE router—customer edge router. A router that is part of a customer network and that interfaces to a provider edge (PE) router.

EBGP—External Border Gateway Protocol. A Border Gateway Protocol between routers located in different autonomous systems.

IBGP—Internal Border Gateway Protocol. A Border Gateway Protocol between routers within the same autonomous system.

LDP—label distribution protocol. A standard protocol used by MPLS-enabled routers to assign the labels (addresses) used to forward packets.

LSP—label-switched path. A sequence of hops in which a packet travels from one router to another router by means of label switching mechanisms. A label-switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

LSR—label switching router. An LSR forwards packets in an MPLS network by looking only at the fixed-length label.

MPLS—Multiprotocol Label Switching. MPLS is a method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels.

Multihop BGP—A Border Gateway Protocol between two routers in different autonomous systems that are more than one hop away from each other.

NLRI—Network Layer Reachability Information. BGP routers exchange network layer reachability information, which includes the full route (BGP AS numbers) to reach the destination network.

PE router—provider edge router. A router that is part of a service provider's network connected to a customer edge (CE) router. All MPLS VPN processing occurs in the PE router.

POP—point of presence. An access point to the Internet. A POP has a unique IP address. The ISP or online service provider (such as AOL) has one or more POPs on the Internet. ISP users dial into the POP to connect to the Internet. A POP can reside in rented space owned by the telecommunications carrier (such as Sprint) to which the ISP is connected. A POP usually includes routers, digital/analog call aggregators, servers, and frequently frame relay or ATM switches.

RD—route distinguisher. An 8-byte value that is concatenated with an IPv4 prefix to create a unique VPN-IPv4 prefix.

RIP—Routing Information Protocol. An internal gateway protocol used to exchange routing information within an autonomous system. RIP uses hop count as a routing metric.

VPN—Virtual Private Network. VPNs connect branch offices and remote users through a shared or public network, such as the Internet, and provide the same security and availability as a private network. Because VPNs use an existing shared WAN infrastructure, costs are lower and deployment is faster than

is the case with traditional private networks. A VPN can consist of sites (or systems) that are all from the same enterprise (intranet) or from different enterprises (extranet); it can consist of sites (or systems) that all attach to the same service provider backbone or to different service provider backbones.

VPN-IPv4—A prefix that consists of a customer VPN address that has been made unique by the addition of an 8-byte route distinguisher.

VRF table—VPN routing/forwarding table. A VRF table includes the routing information that defines a customer VPN site that is attached to a PE router. A VRF table consists of the following elements:

- An IP routing table
- A derived forwarding table
- A set of interfaces that use the forwarding table
- A set of rules and routing protocols that determine what goes into the forwarding table
