| <a href="#">hostname dynamic disable, on page 745</a> | Enables the IS-IS routing protocol to dynamically update the mapping of router names to system IDs. |

# show isis interface

To display information about the Intermediate System-to-Intermediate System (IS-IS) interfaces, use the **show isis interface** command in EXEC mode.

**show isis interface** [*type interface-path-id*] **level** {**1** | **2**} [**brief**]

## Syntax Description

|                                      |                                                                                                                                                                                                                                                                                   |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type                                 | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                           |
| interface-path-id                    | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Displays IS-IS interface information for Level 1 or Level 2 independently.                                                                                                                                                                                             |
| brief                                | (Optional) Displays brief interface output.                                                                                                                                                                                                                                       |

## Command Default

Displays all IS-IS interfaces.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis interface** command:

```
RP/0/0/CPU0:router#show isis interface
GigabitEthernet 0/3/0/2
Gi 0/3/0/2 Enabled
Adjacency Formation: Enabled
Prefix Advertisement: Enabled
BFD: Disabled
BFD Min Interval: 150
BFD Multiplier: 3

Circuit Type: level-2-only
Media Type: P2P
Circuit Number: 0
Extended Circuit Number: 67111168
Next P2P IIH in: 4 s
LSP Rermit Queue Size: 0

Level-2
Adjacency Count: 1
LSP Pacing Interval: 33 ms
PSNP Entry Queue Size: 0

CLNS I/O
Protocol State: Up
MTU: 4469

IPv4 Unicast Topology: Enabled
Adjacency Formation: Running
Prefix Advertisement: Running
Metric (L1/L2): 10/100
MPLS LDP Sync (L1/L2): Disabled/Disabled
IPv6 Unicast Topology: Disabled (Not cfg on the intf)

IPv4 Address Family: Enabled
Protocol State: Up
Forwarding Address(es): 10.3.10.143
Global Prefix(es): 10.3.10.0/24
IPv6 Address Family: Disabled (No topology enabled which uses IPv6)

LSP transmit timer expires in 0 ms
LSP transmission is idle
Can send up to 9 back-to-back LSPs in the next 0 ms
```

This table describes the significant fields shown in the display.

**Table 68: show isis interface Field Descriptions**

| Field                  | Description                                                                     |
|------------------------|---------------------------------------------------------------------------------|
| GigabitEthernet0/6/0/0 | Status of the interface, either enabled or disabled.                            |
| Adjacency formation:   | Status of adjacency formation, either enabled or disabled.                      |
| Prefix Advertisement:  | Status of advertising connected prefixes, either enabled or disabled.           |
| BFD:                   | Status of Bidirectional Forwarding Detection (BFD), either enabled or disabled. |

| Field                    | Description                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| BFD Min Interval:        | BFD minimum interval.                                                                                                                          |
| BFD Multiplier:          | BFD multiplier.                                                                                                                                |
| Circuit Type:            | Levels the interface is running on (circuit-type configuration) which may be a subset of levels on the router.                                 |
| Media Type:              | Media type on which IS-IS is running.                                                                                                          |
| Circuit Number:          | Unique ID assigned to a circuit internally (8-bit integer).                                                                                    |
| Extended Circuit Number: | Valid only for point-to-point interfaces (32-bit integer).                                                                                     |
| LSP Rermit Queue Size:   | Number of LSPs pending retransmission on the interface.                                                                                        |
| Adjacency Count:         | Number of adjacencies formed with a neighboring router that supports the same set of protocols.                                                |
| PSNP Entry Queue Size:   | Number of SNP entries pending inclusion in the next PSNP.                                                                                      |
| LAN ID:                  | ID of the LAN.                                                                                                                                 |
| Priority (Local/DIS):    | Priority of this interface or priority of the Designated Intermediate System.                                                                  |
| Next LAN IIH in:         | Time (in seconds) in which the next LAN hello message is sent.                                                                                 |
| LSP Pacing Interval:     | Interval at which the link-state packet (LSP) transmission rate (and by implication the reception rate of other systems) is to be reduced.     |
| Protocol State:          | Running state of the protocol (up or down).                                                                                                    |
| MTU:                     | Link maximum transmission unit (MTU).                                                                                                          |
| SNPA:                    | Data-link address (also known as the Subnetwork Point of Attachment [SNPA]) of the neighbor.                                                   |
| All Level-n ISs:         | Status of interface membership in Layer 2 multicast group. The status options are Yes or reason for not being a member of the multicast group. |
| IPv4 Unicast Topology:   | Status of the topology, either enabled or disabled.                                                                                            |

| Field                         | Description                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Adjacency Formation:          | Status of adjacency formation. The status options are Running or a reason for not being ready to form adjacencies.                                                                                                                                                                                     |
| Prefix Advertisement:         | Status of advertising prefixes, either enabled or disabled.                                                                                                                                                                                                                                            |
| Metric (L1/L2):               | IS-IS metric for the cost of the adjacency between the originating router and the advertised neighbor, or the metric of the cost to get from the advertising router to the advertised destination (which can be an IP address, an end system (ES), or a connectionless network service (CLNS) prefix). |
| MPLS LDP Sync (L1/L2)         | Status of LDP IS-IS synchronization, either enabled or disabled. When enabled, the state of synchronization (Sync Status) is additionally displayed as either achieved or not achieved.                                                                                                                |
| IPv4 Address Family:          | Status of the address family, either enabled or disabled.                                                                                                                                                                                                                                              |
| Protocol State:               | State of the protocol.                                                                                                                                                                                                                                                                                 |
| Forwarding Address(es):       | Addresses on this interface used by the neighbor for next-hop forwarding.                                                                                                                                                                                                                              |
| Global Prefix(es):            | Prefixes for this interface included in the LSP.                                                                                                                                                                                                                                                       |
| LSP transmit timer expires in | LSP transmission expiration timer interval (in milliseconds).                                                                                                                                                                                                                                          |
| LSP transmission is           | State of LSP transmission. Valid states are: <ul style="list-style-type: none"> <li>• idle</li> <li>• in progress</li> <li>• requested</li> <li>• requested and in progress</li> </ul>                                                                                                                 |

The following is sample output from the **show isis interface** command with the **brief** keyword:

```
RP/0/0/CPU0:router# show isis interface brief
```

| Interface | All<br>OK | Adjs<br>L1 L2 | Adj Topos<br>Run/Cfg | Adv Topos<br>Run/Cfg | CLNS | MTU  | Prio<br>L1 L2 |
|-----------|-----------|---------------|----------------------|----------------------|------|------|---------------|
| PO0/5/0/0 | Yes       | 1 1           | 1/1                  | 1/1                  | Up   | 4469 | - -           |
| Gi0/6/0/0 | Yes       | 1* 1*         | 1/1                  | 1/1                  | Up   | 1497 | 64 64         |

This table describes the significant fields shown in the display.

**Table 69: show isis interface brief Field Descriptions**

| Field             | Description                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface         | Name of the interface.                                                                                                                           |
| All OK            | Everything is working as expected for this interface.                                                                                            |
| Adjs L1 L2        | Number of L1 and L2 adjacencies over this interface.                                                                                             |
| Adj Topos Run/Cfg | Number of topologies that participate in forming adjacencies. Number of topologies that were configured to participate in forming adjacencies.   |
| Adv Topos Run/Cfg | Number of topologies that participate in advertising prefixes. Number of topologies that were configured to participate in advertising prefixes. |
| CLNS              | Status of the Connectionless Network Service. Status options are Up or Down.                                                                     |
| MTU               | Maximum transfer unit size for the interface.                                                                                                    |
| Prio L1 L2        | Interface L1 priority. Interface L2 priority.                                                                                                    |

# show isis lsp-log

To display link-state packet (LSP) log information, use the **show isis lsp-log** command in EXEC mode.

**show isis** [**instance** *instance-id*] **lsp-log** [**level** {**1** | **2**}] [**last** *number* | **first** *number*]

## Syntax Description

|                                      |                                                                                                                                                                                                                                                         |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i>   | (Optional) Displays the LSP log information for the specified IS-IS instance only. <ul style="list-style-type: none"><li>The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command.</li></ul> |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Displays the Intermediate System-to-Intermediate System (IS-IS) link-state database for Level 1 or Level 2 independently.                                                                                                                    |
| <b>last</b> <i>number</i>            | (Optional) Specifies that the output be restricted to the last <i>number</i> of entries. Range is 1 to 20.                                                                                                                                              |
| <b>first</b> <i>number</i>           | (Optional) Specifies that the output be restricted to the first <i>number</i> of entries. Range is 1 to 20.                                                                                                                                             |

## Command Default

No instance ID specified displays the LSP log information for all the IS-IS instances.  
Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis lsp-log** command with the **instance** and *instance-id* values specified:

```
RP/0/0/CPU0:router# show isis instance isp lsp-log

ISIS isp Level 1 LSP log
  When      Count      Interface      Triggers
00:02:36    1
00:02:31    1
00:02:26    1      PO4/1      LSPREGEN
00:02:24    1      PO4/1      DELADJ
00:02:23    1      Gi5/0      NEWADJ
00:02:23    1      Gi5/0      DIS
00:01:27    1      Lo0        IPDOWN
00:01:12    1      Lo0        IPUP

ISIS isp Level 2 LSP log
  When      Count      Interface      Triggers
00:02:36    1
00:02:30    1
00:02:26    1      PO4/1      LSPREGEN
00:02:24    1      PO4/1      DELADJ
00:02:23    1      Gi5/0      NEWADJ
00:02:21    1      Gi5/0      DIS
00:02:21    1      Gi5/0      AREASET
00:01:27    1      Lo0        IPDOWN
00:01:12    1      Lo0        IPUP
```

This table describes the significant fields shown in the display.

**Table 70: show isis instance isp lsp-log Field Descriptions**

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level     | IS-IS level of the router.                                                                                                                                                                                                                                                                                                                                                           |
| When      | How long ago (in hh:mm:ss) an LSP rebuild occurred. The last 20 occurrences are logged.                                                                                                                                                                                                                                                                                              |
| Count     | Number of events that triggered this LSP run. When there is a topology change, often multiple LSPs are received in a short period. A router waits 5 seconds before running a full LSP, so it can include all new information. This count denotes the number of events (such as receiving new LSPs) that occurred while the router was waiting its 5 seconds before running full LSP. |
| Interface | Interface that corresponds to the triggered reasons for the LSP rebuild.                                                                                                                                                                                                                                                                                                             |

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

# show isis mesh-group

To display Intermediate System-to-Intermediate System (IS-IS) mesh group information, use the **show isis mesh-group** command in EXEC mode.

**show isis** [*instance instance-id*] **mesh-group**

## Syntax Description

**instance** *instance-id* (Optional) Displays the mesh group information for the specified IS-IS instance only.

- The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No instance ID specified displays the IS-IS mesh group information for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis mesh-group** command with the **instance** and *instance-id* values specified:

```
RP/0/0/CPU0:router# show isis instance isp mesh-group

ISIS isp Mesh Groups

Mesh group 6:
GigabitEthernet 0/4/0/1
```

This table describes the significant fields shown in the display.

**Table 71: show isis instance isp mesh-group Field Descriptions**

| Field                  | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mesh group             | Mesh group number to which this interface is a member. A mesh group optimizes link-state packet (LSP) flooding in nonbroadcast multiaccess (NBMA) networks with highly meshed, point-to-point topologies. LSPs that are first received on interfaces that are part of a mesh group are flooded to all interfaces except those in the same mesh group. |
| GigabitEthernet0/4/0/1 | Interface belonging to mesh group 6.                                                                                                                                                                                                                                                                                                                  |

# show isis mpls traffic-eng adjacency-log

To display a log of Multiprotocol Label Switching traffic engineering (MPLS TE) adjacency changes for an Intermediate System-to-Intermediate System (IS-IS) instance, use the **show isis mpls traffic-eng adjacency-log** command in EXEC mode.

**show isis** [**instance** *instance-id*] **mpls traffic-eng adjacency-log** [**last** *number*] [**first** *number*]

## Syntax Description

|                                    |                                                                                                                                                                                                                        |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the MPLS TE adjacency changes for the specified IS-IS instance only.<br><br>• The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command. |
| <b>last</b> <i>number</i>          | (Optional) Specifies that the output is restricted to last <i>number</i> of entries. Range is 1 to 20.                                                                                                                 |
| <b>first</b> <i>number</i>         | (Optional) Specifies that the output is restricted to first <i>number</i> of entries. Range is 1 to 20.                                                                                                                |

## Command Default

No instance ID specified displays MPLS TE adjacency changes for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show isis mpls traffic-eng adjacency-log** command to display the status of MPLS TE adjacencies.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis mpls traffic-eng adjacency-log** command with the **instance** and **instance-id** values specified:

```
RP/0/0/CPU0:router# show isis instance isp mpls traffic-eng adjacency-log

IS-IS isp Level-2 MPLS Traffic Engineering adjacency log
When      Neighbor ID      IP Address      Interface Status
00:03:36  router-6          172.17.1.6      PO0/3/0/1 Up
00:03:36  router-6          172.17.1.6      PO0/3/0/1 Down
00:02:38  router-6          172.17.1.6      PO0/3/0/1 Up
```

This table describes the significant fields shown in the display.

**Table 72: show isis instance isp mpls traffic-eng adjacency-log Field Descriptions**

| Field       | Description                                                 |
|-------------|-------------------------------------------------------------|
| When        | Time (in hh:mm:ss) since the entry was recorded in the log. |
| Neighbor ID | Identification value of the neighbor.                       |
| IP Address  | Neighbor IP Version 4 (IPv4) address.                       |
| Interface   | Interface from which a neighbor is learned.                 |
| Status      | Up (active) or Down (disconnected).                         |

## Command Default

No instance ID specified displays the latest flooded record from MPLS TE for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show isis mpls traffic-eng advertisements** command to verify that MPLS TE is flooding its record and that the bandwidths are correct.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis mpls traffic-eng advertisements** command with the **instance** and *instance-id* values specified:

```
RP/0/0/CPU0:router# show isis instance isp mpls traffic-eng advertisements
ISIS isp Level-2 MPLS Traffic Engineering advertisements
```

```

System ID: router-9
Router ID: 172.18.0.9
Link Count: 1
Link[0]
  Neighbor System ID: router-gsr6 (P2P link)
  Interface IP address: 172.18.0.9
  Neighbor IP Address: 172.18.0.6

| Field                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID            | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or if the <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used.                                                                                                                                                                                                                                                                        |
| Router ID            | MPLS TE router ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Link Count           | Number of links that MPLS TE advertised.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Neighbor System ID   | System ID of a neighbor number in an area. The six bytes directly preceding the n-selector are the system ID. The system ID length is a fixed size and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2). In an IS-IS routing domain, each router is represented by a 6-byte hexadecimal system ID. When network administrators maintain and troubleshoot networking devices, they must know the router name and corresponding system ID. |
| Interface IP address | IP address of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Neighbor IP Address  | IP address of the neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Admin. Weight        | Administrative weight associated with this link.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Physical BW          | Link bandwidth capacity (in bits per second).                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Field                     | Description                                                      |
|---------------------------|------------------------------------------------------------------|
| Reservable BW             | Reservable bandwidth on this link.                               |
| Global pool BW unreserved | Unreserved bandwidth that is available in the global pool.       |
| Sub pool BW unreserved    | Amount of unreserved bandwidth that is available in the subpool. |
| Affinity Bits             | Link attribute flags being flooded. Bits are MPLS-TE specific.   |

# show isis mpls traffic-eng tunnel

To display Multiprotocol Label Switching traffic engineering (MPLS TE) tunnel information for an Intermediate System-to-Intermediate System (IS-IS) instance, use the **show isis mpls traffic-eng tunnel** command in EXEC mode.

**show isis** [*instance instance-id*] **mpls traffic-eng tunnel**

## Syntax Description

**instance** *instance-id* (Optional) Displays the MPLS TE tunnel information for the specified IS-IS instance only.

- The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No instance ID specified displays the MPLS TE tunnel information for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show isis** command to find the current status of MPLS TE tunnels.

Tunnels are used in IS-IS next-hop calculations.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis mpls traffic-eng tunnel** command:

```
RP/0/0/CPU0:router# show isis mpls traffic-eng tunnel

ISIS isp Level-2 MPLS Traffic Engineering tunnels
System Id          Tunnel Name    Bandwidth    Nexthop      Metric      Mode
```

```
router-6          tu0          100000      172.18.1.6      0      Relative
```

This table describes the significant fields shown in the display.

**Table 74: show isis mpls traffic-eng tunnel Field Descriptions**

| Field       | Description                                                                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID   | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| Tunnel Name | Name of the MPLS TE tunnel interface.                                                                                                                                                                                          |
| Bandwidth   | MPLS TE-specified tunnel bandwidth of the tunnel.                                                                                                                                                                              |
| Nexthop     | MPLS TE destination IP address of the tunnel.                                                                                                                                                                                  |
| Metric      | MPLS TE metric of the tunnel.                                                                                                                                                                                                  |
| Mode        | MPLS TE metric mode of the tunnel. It can be relative or absolute.                                                                                                                                                             |

# show isis neighbors

To display information about Intermediate System-to-Intermediate System (IS-IS) neighbors, use the **show isis neighbors** command in EXEC mode.

**show isis** [**instance** *instance-id*] **neighbors** [*type interface-path-id*] **summary**] [**detail**] [**systemid** *system-id*]

## Syntax Description

| <b>summary</b>                     | (Optional) Displays neighbor status count for each level.                                                                                                                                                                                                                         |
| <b>detail</b>                      | (Optional) Displays additional details.                                                                                                                                                                                                                                           |
| <b>systemid</b> <i>system-id</i>   | (Optional) Displays the information for the specified neighbor only.                                                                                                                                                                                                              |

## Command Default

No instance ID specified displays neighbor information for all the IS-IS instances.  
Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis neighbors** command with the **instance** and *instance-id* values specified:

```
Total neighbor count: 3
RP/0/RP0/CPU0:router# show isis instance isp neighbors detail

IS-IS isp neighbors:
System Id      Interface      SNPA          State Holdtime Type IETF-NSF

**Table 75: show isis instance isp neighbors Field Descriptions**

| Field     | Description                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| Interface | Interface through which the neighbor is reachable.                                                                                                                                                                             |
| SNPA      | Data-link address (also known as the Subnetwork Point of Attachment [SNPA]) of the neighbor.                                                                                                                                   |

| Field               | Description                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| State               | Adjacency state of the neighboring interface. Valid states are: Down, Init, and Up.                               |
| Holdtime            | Hold time of the neighbor.                                                                                        |
| Type                | Type of adjacency.                                                                                                |
| IETF-NSF            | Specifies whether the neighbor can adhere to the IETF-NSF restart mechanism. Valid states are Capable and Unable. |
| Area Address(es)    | Number of area addresses on this router.                                                                          |
| IPv4 Address(es)    | IPv4 addresses configured on this router.                                                                         |
| Topologies          | Address and subaddress families for which IS-IS is configured.                                                    |
| Uptime              | Time (in hh:mm:ss) that the neighbor has been up.                                                                 |
| IPFRR: LFA Neighbor | IP fast reroute (IPFRR) loop-free alternate (LFA) neighbor.                                                       |
| LFA IPv4 address:   | Address of the LFA.                                                                                               |
| LFA Interface:      | LFA interface.                                                                                                    |

The following is sample output from the **show isis neighbors** command with the **summary** keyword specified:

```
RP/0/0/CPU0:router# show isis instance isp neighbors summary

ISIS isp neighbor summary:
  State      L1      L2      L1L2
  Up         0        0        2
  Init       0        0        0
  Failed     0        0        0
```

This table describes the significant fields shown in the display.

**Table 76: show isis neighbors summary Field Descriptions**

| Field | Description                                          |
|-------|------------------------------------------------------|
| State | State of the neighbor is up, initialized, or failed. |
| L1    | Number of Level 1 neighbors.                         |
| L2    | Number of Level 2 neighbors.                         |

| Field | Description                        |
|-------|------------------------------------|
| L1L2  | Number of Level 1 and 2 neighbors. |

# show isis protocol

To display summary information about an Intermediate System-to-Intermediate System (IS-IS) instance, use the **show isis protocol** command in EXEC mode.

**show isis** [*instance instance-id*] **protocol**

## Syntax Description

**instance** *instance-id* (Optional) Displays the IS-IS adjacencies for the specified IS-IS instance only.

- The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No instance ID specified displays IS-IS adjacencies for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis protocol** command:

```
RP/0/0/CPU0:router# show isis protocol

IS-IS Router: isp
  System Id: 0001.0000.0011
  IS Levels: level-1-2
  Manual area address(es):
    49

  Routing for area address(es):
    49
  Non-stop forwarding: Cisco Proprietary NSF Restart enabled
```

```

Process startup mode: Cold Restart
Topologies supported by IS-IS:
  IPv4 Unicast
    Level-1 iSPF status: Dormant (awaiting initial convergence)
    Level-2 iSPF status: Dormant (awaiting initial convergence)
    No protocols redistributed
    Distance: 115
Interfaces supported by IS-IS:
  Loopback0 is running passively (passive in configuration)
  GigabitEthernet 0/4/0/1 is running actively (active in configuration)
  GigabitEthernet 0/5/0/1 is running actively (active in configuration)

```

This table describes the significant fields shown in the display.

**Table 77: show isis protocol Field Descriptions**

| Field                       | Description                                                                                                                                                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID:                  | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| IS Levels:                  | IS-IS level of the router.                                                                                                                                                                                                     |
| Manual area address(es)     | Area addresses that are manually configured.                                                                                                                                                                                   |
| Routing for areaaddress(es) | Area addresses for which this router provides the routing.                                                                                                                                                                     |
| Non-stop forwarding:        | Status and name of nonstop forwarding (NSF).                                                                                                                                                                                   |
| Process startup mode:       | Mode in which the last process startup occurred. Valid modes are: <ul style="list-style-type: none"> <li>• Cisco Proprietary NSF Restart</li> <li>• IETF NSF Restart</li> <li>• Cold Restart</li> </ul>                        |

| Distance:                   | Administrative distance for this protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## show isis route

To display IP reachability information for an Intermediate System-to-Intermediate System (IS-IS) instance, use the **show isis route** command in EXEC mode.

**show isis** [**instance** *instance-id*] [**ipv4**|**ipv6**] **afi-all**] [**unicast**|**multicast**] [**topology** {**all**|*topo-name*}]| **safi-all**] **route** [*ip-address mask*|*ip-address/length*] [**longer-prefixes**] [**summary**] [**multicast-intact**] [**backup**] [**detail**]

### Syntax Description

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the IP reachability information for the specified IS-IS instance only.<br><br>• The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command.                                                                                                                                                                                                                                  |
| <b>ipv4</b>                        | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ipv6</b>                        | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>afi-all</b>                     | (Optional) Specifies all address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>unicast</b>                     | (Optional) Specifies unicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>multicast</b>                   | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>topology</b>                    | (Optional) Specifies IS-IS paths to intermediate systems.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>all</b>                         | (Optional) Specifies all topologies.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>topology</b> <i>topo-name</i>   | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>safi-all</b>                    | (Optional) Specifies all secondary address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>ip-address</i>                  | (Optional) Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                        |
| <i>mask</i>                        | (Optional) Network mask specified in either of two ways:<br><br>• Network mask can be a four-part, dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.<br><br>• Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are ones, and the corresponding bits of the address are the network address. |
| <i>/ length</i>                    | (Optional) Length of the IP prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value. Range is 0 to 32.                                                                                                                                                                                                           |

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| <b>longer-prefixes</b>  | (Optional) Displays route and more-specific routes.              |
| <b>summary</b>          | (Optional) Displays topology summary information.                |
| <b>multicast-intact</b> | (Optional) Displays multicast intact information for this entry. |
| <b>systemid</b>         | (Optional) Displays multicast information by system ID.          |
| <b>backup</b>           | (Optional) Displays backup information for this entry.           |
| <b>detail</b>           | (Optional) Displays link-state packet (LSP) details.             |

**Command Default** No instance ID specified displays the IP reachability information for all the IS-IS instances.

**Command Modes** EXEC

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>                                                 |
|------------------------|----------------|---------------------------------------------------------------------|
|                        | Release 3.2    | This command was introduced.                                        |
|                        | Release 3.3.0  | The <b>multicast-intact</b> keyword was added.                      |
|                        | Release 3.4.0  | The <b>safi-all</b> and <b>multicast</b> keywords were added.       |
|                        | Release 3.7.0  | The <b>topology</b> keyword was added for multicast routing tables. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| <b>Task ID</b> | <b>Task ID</b> | <b>Operations</b> |
|----------------|----------------|-------------------|
|                | isis           | read              |

**Examples** The following is sample output from the **show isis route** command:

```
RP/0/RP0/CPU0:router# show isis route

IS-IS isp IPv4 Unicast routes
Codes: L1 - level 1, L2 - level 2, ia - interarea (leaked into level 1)
df - level 1 default (closest attached router), su - summary null
C - connected, S - static, R - RIP, B - BGP, O - OSPF
i - IS-IS (redistributed from another instance)
```

```

Maximum parallel path count: 8

L2 10.76.240.6/32 [4/115]
via 10.76.245.252, SRP0/1/0/2, isp2
via 10.76.246.252, SRP0/1/0/0, isp2
C 10.76.240.7/32
is directly connected, Loopback0
L2 10.76.240.9/32 [256/115]
via 10.76.249.2, GigabitEthernet 0/3/0/0, isp3
L2 10.76.240.10/32 [296/115]
via 10.76.249.2, GigabitEthernet 0/3/0/0, isp3
C 10.76.245.0/24
is directly connected, SRP0/1/0/2
C 10.76.246.0/24
is directly connected, SRP0/1/0/0
C 10.76.249.0/26
is directly connected, GigabitEthernet 0/3/0/0
L2 10.101.10.0/24 [296/115]
via 10.76.249.2, GigabitEthernet 0/3/0/0, isp3

```

This table describes the significant fields shown in the display.

**Table 78: show isis route ipv4 unicast Field Descriptions**

| Field                 | Description                                            |
|-----------------------|--------------------------------------------------------|
| C172.18.0.0/24        | Connected route for GigabitEthernet interface 0/5/0/0. |
| C 172.19.1.0/24       | Connected route for GigabitEthernet interface 0/4/0/1. |
| L1 172.35.0.0/24 [10] | Level 1 route to network 172.35.0.0/24.                |
| C 172.18.0/24         | Connected route for loopback interface 0.              |

## show isis spf-log

To display how often and why the router has run a full shortest path first (SPF) calculation, use the **show isis spf-log** command in EXEC mode.

**show isis** [*instance instance-id*] [[*ipv4*|*ipv6*] **afi-all**] [**unicast**|**multicast**] [**topology** {**all**|*topo-name*}]| **safi-all**]]  
**spf-log** [*level* {**1**|**2**}] [**ispf**|**fspf**] [**prc**|**nhc**] [**detail**|**verbose**|**plfrr**|**ppfrr**] [*last number*|**first number**]

### Syntax Description

|                                               |                                                                                                                                                     |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i>            | (Optional) Displays the IS-IS SPF log for the specified IS-IS instance only.                                                                        |
| <b>ipv4</b>                                   | (Optional) Specifies IP Version 4 address prefixes.                                                                                                 |
| <b>ipv6</b>                                   | (Optional) Specifies IP Version 6 address prefixes.                                                                                                 |
| <b>afi-all</b>                                | (Optional) Specifies all address prefixes.                                                                                                          |
| <b>unicast</b>                                | (Optional) Specifies unicast address prefixes.                                                                                                      |
| <b>multicast</b>                              | (Optional) Specifies multicast address prefixes.                                                                                                    |
| <b>topology</b> <b>all</b>   <i>topo-name</i> | (Optional) Specifies topology table information for all topologies or for the specified topology table ( <i>topo-name</i> ).                        |
| <b>safi-all</b>                               | (Optional) Specifies all secondary address prefixes.                                                                                                |
| <b>level</b> { <b>1</b>   <b>2</b> }          | (Optional) Displays the IS-IS SPF log for Level 1 or Level 2 independently.                                                                         |
| <b>ispf</b>                                   | (Optional) Specifies incremental SPF entries only.                                                                                                  |
| <b>fspf</b>                                   | (Optional) Specifies full SPF entries only.                                                                                                         |
| <b>prc</b>                                    | (Optional) Specifies partial route calculations only.                                                                                               |
| <b>nhc</b>                                    | (Optional) Specifies next-hop route calculations only.                                                                                              |
| <b>detail</b>                                 | (Optional) Specifies detailed output. Includes a breakdown of the time taken to perform the calculation and changes resulting from the calculation. |
| <b>verbose</b>                                | (Optional) Specifies verbose output.                                                                                                                |
| <b>last</b> <i>number</i>                     | (Optional) Specifies that the output is restricted to the last <i>number</i> of entries. Range is 1 to 210.                                         |
| <b>first</b> <i>number</i>                    | (Optional) Specifies that the output is restricted to the first <i>number</i> of entries. Range is 1 to 210.                                        |

### Command Default

No instance ID specified displays IS-IS adjacencies for all the IS-IS instances.

Both Level 1 and Level 2 are configured if no level is specified.  
Displays all types of route calculation (not just fspf, ispf and prc).

**Command Modes**

EXEC

**Command History**

| Release       | Modification                                                                                            |
|---------------|---------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                            |
| Release 3.3.0 | The <b>nhc</b> and <b>verbose</b> keywords were added.                                                  |
| Release 3.4.0 | The <b>safi-all</b> and <b>multicast</b> keywords were added.                                           |
| Release 3.7.0 | The <b>topology</b> keyword was added for <b>multicast spf-log</b> on the Cisco XR 12000 Series Router. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis spf-log** command:

```
RP/0/0/CPU0:router# show isis spf-log

IS-IS 1 Level 1 IPv4 Unicast Route Calculation Log
      Time  Total Trig

```

This table describes the significant fields shown in the display.

**Table 79: show isis spf-log ipv4 unicast Field Descriptions**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level             | IS-IS level of the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp         | Time when the SPF calculation started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Duration          | Number of milliseconds taken to complete this SPF run. Elapsed time is wall clock time, not CPU time.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Nodes             | Number of routers and pseudonodes (LANs) that make up the topology calculated in this SPF run.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Trig Count        | Number of events that triggered this SPF run. When there is a topology change, often multiple link-state packets (LSPs) are received in a short time. Depending on the configuration of the <b>spf-interval</b> command, a router may wait for a fixed period of time before running a router calculation. This count denotes the number of triggering events that occurred while the router was waiting to run the calculation. For a full description of the triggering events, see <i>List of Triggers</i> . |
| First Trigger LSP | LSP ID stored by the router whenever a full SPF calculation is triggered by the arrival of a new LSP. The LSP ID can suggest the source of routing instability in an area. If multiple LSPs are causing an SPF run, only the LSP ID of the first received LSP is remembered.                                                                                                                                                                                                                                    |
| Triggers          | List of all reasons that triggered a full SPF calculation. For a list of possible triggers, see <i>List of Triggers</i> .                                                                                                                                                                                                                                                                                                                                                                                       |

This table lists triggers of a full SPF calculation.

**Table 80: List of Triggers**

| Trigger       | Description                                          |
|---------------|------------------------------------------------------|
| PERIODIC      | Runs a full SPF calculation every 15 minutes.        |
| NEWLEVEL      | Configured new level (using is-type) on this router. |
| RTCLEARED     | Cleared IS-IS topology on the router.                |
| MAXPATHCHANGE | Changed IP maximum parallel path.                    |
| NEWMETRIC     | Changed link metric.                                 |

| Trigger     | Description                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| ATTACHFLAG  | Changed Level 2 Attach bit.                                                                                                              |
| ADMINDIST   | Configured another administrative distance for the IS-IS instance on this router.                                                        |
| NEWADJ      | Created a new adjacency to another router.                                                                                               |
| DELADJ      | Deleted adjacency.                                                                                                                       |
| BACKUP      | Installed backup route.                                                                                                                  |
| SEEDISPF    | Seed incremental SPF.                                                                                                                    |
| NEXTHOP     | Changed IP next-hop address.                                                                                                             |
| NEWLSP0     | New LSP 0 appeared in the topology.                                                                                                      |
| LSPEXPIRED  | Some LSP in the link-state database (LSDB) has expired.                                                                                  |
| LSPHEADER   | Changed important LSP header fields.                                                                                                     |
| TLVCODE     | Type, length, and value (TLV) objects code mismatch, indicating that different TLV objects are included in the newest version of an LSP. |
| LINKTV      | Changed Link TLV content.                                                                                                                |
| PREFIXTLV   | Changed Prefix TLV content.                                                                                                              |
| AREAADDRTLV | Changed Area address TLV content.                                                                                                        |
| IP ADDR TLV | Changed IP address TLV content.                                                                                                          |
| TUNNEL      | Changed RRR tunnel.                                                                                                                      |

This table describes the significant fields shown in the display.

**Table 81: show isis spf-log first Field Descriptions**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level             | IS-IS level of the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp         | Time at which the SPF calculation started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Type              | Type of route calculation. The possible types are incremental SPF (iSPF), full SPF (FSPF), or partial route calculation (PRC).                                                                                                                                                                                                                                                                                                                                                                                  |
| Time (ms)         | Number of milliseconds taken to complete this SPF run. Elapsed time is wall clock time, not CPU time.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Nodes             | Number of routers and pseudonodes (LANs) that make up the topology calculated in this SPF run.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Trig Count        | Number of events that triggered this SPF run. When there is a topology change, often multiple link-state packets (LSPs) are received in a short time. Depending on the configuration of the <b>spf-interval</b> command, a router may wait for a fixed period of time before running a router calculation. This count denotes the number of triggering events that occurred while the router was waiting to run the calculation. For a full description of the triggering events, see <i>List of Triggers</i> . |
| First Trigger LSP | LSP ID stored by the router whenever a full SPF calculation is triggered by the arrival of a new LSP. The LSP ID can suggest the source of routing instability in an area. If multiple LSPs are causing an SPF run, only the LSP ID of the first received LSP is remembered.                                                                                                                                                                                                                                    |
| Triggers          | List of all reasons that triggered a full SPF calculation. For a list of possible triggers, see <i>List of Triggers</i> .                                                                                                                                                                                                                                                                                                                                                                                       |

| Trig Count | Number of events that triggered this SPF run. When there is a topology change, often multiple link-state packets (LSPs) are received in a short time. Depending on the configuration of the <b>spf-interval</b> command, a router may wait for a fixed period of time before running a router calculation. This count denotes the number of triggering events that occurred while the router was waiting to run the calculation. For a full description of the triggering events, see <i>List of Triggers</i> . |

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| First Trigger LSP  | LSP ID stored by the router whenever a full SPF calculation is triggered by the arrival of a new LSP. The LSP ID can suggest the source of routing instability in an area. If multiple LSPs are causing an SPF run, only the LSP ID of the first received LSP is remembered.                                                                                                                                                  |
| Triggers           | List of all reasons that triggered a full SPF calculation. For a list of possible triggers, see <i>List of Triggers</i> .                                                                                                                                                                                                                                                                                                     |
| Delay              | Two different delays exist: <ol style="list-style-type: none"> <li>1 The delay between the time when the route calculation was first triggered and the time when it was run.</li> <li>2 The delay between the end of the last route calculation and the start of this one. This is used to verify that the SPF-interval timers are working correctly, and is only reported for calculations after the first delay.</li> </ol> |
| CPU Time           | Two different CPU times exist: <ol style="list-style-type: none"> <li>1 CPU time (in milliseconds) taken to calculate the shortest path tree (SPT).</li> <li>2 CPU time (in milliseconds) taken to perform the prefix updates.</li> </ol>                                                                                                                                                                                     |
| Real Time          | Two different real times exist: <ol style="list-style-type: none"> <li>1 Real time (in milliseconds) taken to calculate the shortest path tree (SPT).</li> <li>2 Real time (in milliseconds) taken to perform the prefix updates.</li> </ol>                                                                                                                                                                                  |
| New LSP Arrivals   | Number of LSP arrivals since the start of this route calculation.                                                                                                                                                                                                                                                                                                                                                             |
| Next Wait Interval | Enforced delay until the next route calculation can be run, based on the <b>spf-interval</b> command configuration.                                                                                                                                                                                                                                                                                                           |
| Reach              | Number of reachable nodes or prefixes.                                                                                                                                                                                                                                                                                                                                                                                        |
| Unreach            | Number of unreachable nodes or prefixes.                                                                                                                                                                                                                                                                                                                                                                                      |
| Total              | Total number of nodes or prefixes at various priorities.                                                                                                                                                                                                                                                                                                                                                                      |

# show isis statistics

To display Intermediate System-to-Intermediate System (IS-IS) traffic counters, use the **show isis statistics** command in EXEC mode.

**show isis** [**instance** *instance-id*] **statistics** [*type interface-path-id*]

## Syntax Description

|                                    |                                                                                                                                                                                                                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the IS-IS traffic statistics for the specified IS-IS instance only. <ul style="list-style-type: none"><li>The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command.</li></ul>                  |
| <i>type</i>                        | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i>           | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

## Command Default

No instance ID specified displays IS-IS traffic statistics for all the IS-IS instances.  
IS-IS traffic statistics are displayed for all interfaces.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show isis statistics** command displays IS-IS traffic counters for the specified interface or all traffic counters if no interface is specified.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis statistics** command that shows all traffic counters:

```
RP/0/0/CPU0:router#show isis statistics
IS-IS isp statistics:
  Fast PSNP cache (hits/tries): 164115/301454

**Table 83: show isis statistics Field Descriptions**

| Field                            | Description                                                                                                                                                                                                                                                                    |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast PSNP cache (hits/tries):    | Number of successful lookups (hits) along with the number of lookup attempts (tries). To save time or processing power when receiving multiple copies of the same LSP, IS-IS attempts to look up incoming LSPs to see if they have been received recently.                     |
| Fast CSNP cache (hits/tries):    | Number of successful lookups (hits) along with the number of lookup attempts (tries). To reduce CSNP construction time, IS-IS maintains a cache of CSNPs and attempts to look up CSNP in this cache before transmission on the interface.                                      |
| Fast CSNP cache updates:         | Number of times the CSNP cache has been updated since the last clearing of statistics. The cache is updated on LSP addition or removal from the database.                                                                                                                      |
| LSP checksum errors received:    | Number of internal checksum errors received in LSPs.                                                                                                                                                                                                                           |
| IIH (LSP/SNP) dropped:           | Number of hello, LSP, and SNP messages dropped.                                                                                                                                                                                                                                |
| IIH (UPD) Max Queue size:        | Maximum number of queued packets.                                                                                                                                                                                                                                              |
| Average transmit times and rate: | Average time taken to transmit the pdu type across all interfaces and the corresponding rate at which the pdu type is being transmitted.                                                                                                                                       |
| Average process times and rate:  | Average time taken to process an incoming pdu type across all interfaces and the corresponding rate at which the pdu type is being received.                                                                                                                                   |
| LSPs sourced (new/refresh):      | Number of LSPs this IS-IS instance has created or refreshed. To find more details on these LSPs, use the <b>show isis lsp-log</b> command.                                                                                                                                     |
| SPF calculations:                | Number of shortest path first (SPF) calculations. SPF calculations are performed only when the topology changes. They are not performed when external routes change. The interval at which SPF calculations are performed is configured using the <b>spf-interval</b> command. |
| iSPF calculations:               | Number of incremental shortest path first (iSPF) calculations. iSPF calculations are performed only when ISPF has been configured in the isis address family configuration submode.                                                                                            |

| Field                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Partial Route Calculations:                        | Number of partial route calculations (PRCs). PRCs are processor intensive. Therefore, it may be useful to limit their number, especially how often a PRC is done, especially on slower networking devices. Increasing the PRC interval reduces the processor load on the router, but might slow the rate of convergence. The interval at which PRC calculations are performed is configured using the <b>spf-interval</b> command. |
| Level-(1/2) (LSPs/CSNPs/PSNPs/Hellos) (sent/rcvd): | Number of LSPs, Complete Sequence Number Packets (CSNPs), Partial Sequence Number Packets (PSNPs), and hello packets sent or received on this interface.                                                                                                                                                                                                                                                                           |
| PTP Hellos (sent/rcvd):                            | Point-to-point (PTP) hellos sent and received.                                                                                                                                                                                                                                                                                                                                                                                     |
| LSP Retransmissions:                               | Total number of retransmissions on each IS-IS LSP on a point-to-point interface. The LSP retransmission interval can be configured using the <b>retransmit-throttle-interval</b> command.                                                                                                                                                                                                                                          |
| Level-(1.2) DRElections:                           | Total number of Designated Intermediate System elections that have taken place. These counts are maintained on an individual level basis.                                                                                                                                                                                                                                                                                          |
| LSP Flooding Duplicates:                           | Number of duplicate LSPs filtered from flooding to the neighbor. In case of parallel interfaces to the same neighbor, IS-IS optimizes the flooding by avoiding sending the same LSP copy on other interfaces.                                                                                                                                                                                                                      |

### Related Commands

| Command                                        | Description                                                           |
|------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">show isis spf-log, on page 887</a> | Displays how often and why the router has run a full SPF calculation. |
| <a href="#">spf-interval, on page 911</a>      | Sets IS-IS throttling of shortest path first (SPF) calculations.      |

# show isis topology

To display a list of connected Intermediate System-to-Intermediate System (IS-IS) routers in all areas, use the **show isis topology** command in EXEC mode.

```
show isis [instance instance-id] [[ipv4|ipv6] afi-all] [unicast|multicast [topology {all|topo-name}]]
safi-all]] summary|level {1|2} [multicast-intact] [systemid system-id] [detail]
```

## Syntax Description

|                                    |                                                                                                                                                                                                             |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the IS-IS topology for the specified IS-IS instance only.<br><br>• The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command. |
| <b>ipv4</b>                        | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                         |
| <b>ipv6</b>                        | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                         |
| <b>afi-all</b>                     | (Optional) Specifies all address prefixes.                                                                                                                                                                  |
| <b>unicast</b>                     | (Optional) Specifies unicast address prefixes.                                                                                                                                                              |
| <b>multicast</b>                   | (Optional) Specifies multicast address prefixes.                                                                                                                                                            |
| <b>topology</b> <i>topo-name</i>   | (Optional) Specifies topology table information and name of the topology table.                                                                                                                             |
| <b>safi-all</b>                    | (Optional) Specifies all secondary address prefixes.                                                                                                                                                        |
| <b>summary</b>                     | (Optional) Displays a brief list of the IS-IS topology.                                                                                                                                                     |
| <b>level</b> { 1   2 }             | (Optional) Displays the IS-IS link-state topology for Level 1 or Level 2 independently.                                                                                                                     |
| <b>multicast-intact</b>            | (Optional) Displays multicast intact information on the IS-IS topology.                                                                                                                                     |
| <b>systemid</b> <i>system-id</i>   | (Optional) Displays the information for the specified router only.                                                                                                                                          |
| <b>detail</b>                      | (Optional) Displays detailed information on the IS-IS topology.                                                                                                                                             |

## Command Default

No instance ID specified displays a list of connected routers in all areas for all the IS-IS instances.  
Both Level 1 and Level 2 is configured if no level is specified.

## Command Modes

EXEC

**Command History**

| Release       | Modification                                                           |
|---------------|------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                           |
| Release 3.3.0 | The <b>detail</b> and <b>multicast-intact</b> keywords were added.     |
| Release 3.4.0 | The <b>safi-all</b> and <b>multicast</b> keywords were added.          |
| Release 3.7.0 | The <b>topology</b> keyword was added to the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show isis topology** command to verify the presence and connectivity among all routers in all areas.

**Task ID**

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis topology** command:

```
RP/0/0/CPU0:router# show isis topology

IS-IS isp paths to (Level-1) routers
System Id      Metric  Next-hop Interface  SNPA
ensoft-5       10      ensoft-5    PO0/4/0/1      *PtoP*
ensoft-5       10      ensoft-5    Gi0/5/0/0      0003.6cff.0680
ensoft-11      --

IS-IS isp paths to (Level-2) routers
System Id      Metric  Next-hop Interface  SNPA
ensoft-5       10      ensoft-5    PO0/4/0/1      *PtoP*
ensoft-5       10      ensoft-5    Gi0/5/0/0      0003.6cff.0680
ensoft-11      --
```

**Table 84: show isis topology ipv4 unicast Field Descriptions**

| Field     | Description                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |

| Field     | Description                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metric    | Metric assigned to the link and used to calculate the cost from each router using the links in the network to other destinations. Range is 1 to 16777214. Default is 1 to 63 for narrow metric and 1 to 16777214 for wide metric. 0 is set internally if no metric has been specified by the user. |
| Next-hop  | Address of the next-hop.                                                                                                                                                                                                                                                                           |
| Interface | Interface used to reach the neighbor.                                                                                                                                                                                                                                                              |
| SNPA      | Data-link address (also known as the Subnetwork Point of Attachment [SNPA]) of the neighbor.                                                                                                                                                                                                       |

The following is sample output from the **show isis topology** command with the **summary** keyword specified:

```
RP/0/0/CPU0:router# show isis topology summary

IS-IS 10 IS Topology Summary IPv4 Unicast
              L1
      Reach  UnReach  Total
-----
Router nodes:      1       1       2
Pseudo nodes:      0       0       0
Total nodes:       1       1       2

              L2
      Reach  UnReach  Total
-----
Router nodes:      1       1       2
Pseudo nodes:      0       0       0
Total nodes:       1       1       2
```

This table describes the significant fields shown in the display.

**Table 85: show isis topology summary Field Descriptions**

| Field   | Description                                                 |
|---------|-------------------------------------------------------------|
| L1/L2   | IS-IS level of the router.                                  |
| Reach   | Number of router nodes or pseudonodes that are reachable.   |
| UnReach | Number of router nodes or pseudonodes that are unreachable. |
| Total   | Total number of reachable and unreachable nodes.            |

# show protocols (IS-IS)

To group a number of protocol show commands according to the specified address family, use the **show protocols** command in EXEC mode.

**show protocols** [**afi-all**| **ipv4**| **ipv6**] [**all**| *protocol*]

## Syntax Description

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>afi-all</b>  | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ipv4</b>     | (Optional) Specifies an IPv4 address family.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ipv6</b>     | (Optional) Specifies an IPv6 address family.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>all</b>      | (Optional) Specifies all protocols for a given address family.                                                                                                                                                                                                                                                                                                                                                               |
| <i>protocol</i> | <p>(Optional) Specifies a routing protocol. For the IPv4 address family, the options are:</p> <ul style="list-style-type: none"> <li>• <b>bgp</b></li> <li>• <b>isis</b></li> <li>• <b>ospf</b></li> <li>• <b>rip</b></li> <li>• <b>eigrp</b></li> </ul> <p>For the IPv6 address family, the options are:</p> <ul style="list-style-type: none"> <li>• <b>bgp</b></li> <li>• <b>isis</b></li> <li>• <b>ospfv3</b></li> </ul> |

## Command Default

If no address family is specified, the default is IPv4.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If IPv6 is enabled on an IS-IS instance, the instance is displayed in the **show protocols ipv6** command output. IPv4 IS-IS instances are displayed in the **show protocols ipv4** command output.

When using the **show protocols** command with the **ipv6** or **ipv4** keyword, you get all routing instances in that particular address family—not only IS-IS instances.

**Task ID**

| Task ID | Operations |
|---------|------------|
| isis    | read       |
| rib     | read       |

**Examples**

The following example shows the output for the **show protocols** command :

```
RP/0/0/CPU0:router# show protocols ipv4

IS-IS Router: uut
  System Id: 0000.0000.12a8
  IS Levels: level-1-2
  Manual area address(es):
    49.1515.1515
  Routing for area address(es):
    49.1515.1515
  Non-stop forwarding: Disabled
  Most recent startup mode: Cold Restart
  Topologies supported by IS-IS:
    IPv4 Unicast
      Level-1
        Metric style (generate/accept): Narrow/Narrow
        ISPF status: Disabled
      Level-2
        Metric style (generate/accept): Narrow/Narrow
        ISPF status: Disabled
    Redistributing:
      static
      Distance: 115
    IPv6 Unicast
      Level-1
        ISPF status: Disabled
      Level-2
        ISPF status: Disabled
      No protocols redistributed
      Distance: 45
  Interfaces supported by IS-IS:
    GigabitEthernet 0/6/0/0 is running actively (active in configuration)
```

This table describes the significant fields shown in the display.

**Table 86: show protocols ipv4 Field Descriptions**

| Field                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System ID                     | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used.                                                                                                                                                                                                                                                                                                                                                                                           |
| IS Levels                     | IS-IS level of the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Manual area address(es)       | Area addresses configured manually on the originating router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Routing for area address(es)  | Area addresses for which this router provides the routing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Non-stop forwarding           | Status and name of NSF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Most recent startup mode      | Mode in which the most recent startup was performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Topologies supported by IS-IS | Address and subaddress family IS-IS are configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Metric style                  | Type, length, and value (TLV) objects accepted by IS-IS. To configure this value, see the <a href="#">metric-style narrow, on page 781</a> , <a href="#">metric-style transition, on page 783</a> , or <a href="#">metric-style wide, on page 785</a> command.                                                                                                                                                                                                                                                                                                                                                           |
| ISPF status                   | State of iSPF configuration for this IS-IS instance. Four states exist: <ul style="list-style-type: none"> <li>• Disabled if iSPF has not been configured but is awaiting a full SPF to compile the topology for use by the iSPF algorithm.</li> <li>• Dormant if iSPF has been configured but is awaiting initial convergence before initializing.</li> <li>• Awake if iSPF has been configured but is awaiting a full SPF to compile the topology for use by the iSPF algorithm.</li> <li>• Active if IS-IS is ready to consider using the iSPF algorithm whenever a new route calculation needs to be run.</li> </ul> |
| Redistributing                | IS-IS is configured to redistribute IP static routes into Level 1 or Level 2. The <b>redistribute</b> command is used to configure redistribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Distance                      | Administrative distance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Field                         | Description                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Interfaces supported by IS-IS | Interfaces and their states currently supported by IS-IS. Both operational and configuration status are displayed. |

The following example shows how to disable the IPv4 address family, with no output shown for IS-IS IPv4 instances from the **show protocols ipv4** command:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router isis uut
RP/0/0/CPU0:router(config-isis)# no address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis)# commit

RP/0/0/CPU0:router# show protocols ipv4
```

|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <a href="#">metric-style narrow, on page 781</a>     | Configures the IS-IS software to generate and accept old-style type, length, and value (TLV) objects.                   |
| <a href="#">metric-style transition, on page 783</a> | Configures the IS-IS software to generate and accept both old-style and new-style type length, and value (TLV) objects. |
| <a href="#">metric-style wide, on page 785</a>       | Configures the IS-IS software to generate and accept only new-style type, length, and value (TLV) objects.              |
| <a href="#">redistribute (IS-IS), on page 818</a>    | Redistributes routes from one IS-IS instance into another instance.                                                     |

## shutdown (IS-IS)

To disable the Intermediate System-to-Intermediate System (IS-IS) protocol on a particular interface, use the **shutdown** command in interface configuration mode. To re-enable the IS-IS protocol, use the **no** form of this command.

**shutdown**

**no shutdown**

### Command Default

IS-IS protocol is enabled.

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example disables the IS-IS protocol on GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# shutdown
```

# single-topology

To configure the link topology for IP Version 4 (IPv4) when IP Version 6 (IPv6) is configured, use the **single-topology** command in address family configuration mode. To remove the **single-topology** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**single-topology**

**no single-topology**

|                        |                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Command Default</b> | Performs in multitopology mode in which independent topologies for IPv4 and IPv6 are running in a single area or domain. |
|------------------------|--------------------------------------------------------------------------------------------------------------------------|

|                | isis           | read, write       |

## Examples

The following example shows how to enable single-topology mode for IPv6:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# net 49.0000.0000.0001.00  
RP/0/0/CPU0:router(config-isis)# address-family ipv6 unicast  
RP/0/0/CPU0:router(config-isis-af)# single-topology
```

## snmp-server traps isis

To enable the Simple Network Management Protocol (SNMP) server notifications (traps) available for IS-IS, use the **snmp-server traps isis** command in global configuration mode. To disable all available SNMP notifications, use the **no** form of this command.

**snmp-server traps isis** {all| *traps set*}

**no snmp-server traps isis** {all| *traps set*}

### Syntax Description

|           |                                        |
|-----------|----------------------------------------|
| all       | Specifies all IS-IS SNMP server traps. |
| traps set | Specify any set of trap names.         |

### Command Default

SNMP server traps notification is disabled.

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following examples show how to enable all SNMP server traps available for isis:

```
RP/0/0/CPU0:router(config)# snmp-server traps isis?
```

|                                |                                |
|--------------------------------|--------------------------------|
| adjacency-change               | isisAdjacencyChange            |
| all                            | Enable all IS-IS traps         |
| area-mismatch                  | isisAreaMismatch               |
| attempt-to-exceed-max-sequence | isisAttemptToExceedMaxSequence |
| authentication-failure         | isisAuthenticationFailure      |
| authentication-type-failure    | isisAuthenticationTypeFailure  |

|                              |                                |
|------------------------------|--------------------------------|
| corrupted-lsp-detected       | isisCorruptedLSPDetected       |
| database-overload            | isisDatabaseOverload           |
| id-len-mismatch              | isisIDLenMismatch              |
| lsp-error-detected           | isisLSPErrorDetected           |
| lsp-too-large-to-propagate   | isisLSPTooLargeToPropagate     |
| manual-address-drops         | isisManualAddressDrops         |
| max-area-addresses-mismatch  | isisMaxAreaAddressesMismatch   |
| orig-lsp-buff-size-mismatch  | isisOrigLSPBuffSizeMismatch    |
| own-lsp-purge                | isisOwnLSPPurge                |
| protocols-supported-mismatch | isisProtocolsSupportedMismatch |
| rejected-adjacency           | isisRejectedAdjacency          |
| sequence-number-skip         | isisSequenceNumberSkip         |
| version-skew                 | isisVersionSkew                |

```
RP/0/0/CPU0:router(config)#snmp-server traps isis all
```

The following example shows how to enable area-mismatch lsp-error-detected trap:

```
RP/0/0/CPU0:router(config)# snmp-server traps isis area-mismatch  
lsp-error-detected
```

# spf-interval

To customize IS-IS throttling of shortest path first (SPF) calculations, use the **spf-interval** command in address family configuration mode. To restore default values, use the **no** form of this command.

**spf-interval** [**initial-wait** *initial*] **secondary-wait** *secondary*] **maximum-wait** *maximum*] ... [**level** {**1** | **2**}]  
**no spf-interval** [[**initial-wait** *initial*] **secondary-wait** *secondary*] **maximum-wait** *maximum*] ...] [**level** {**1** | **2**}]

## Syntax Description

|                                        |                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>initial-wait</b> <i>initial</i>     | Initial SPF calculation delay (in milliseconds) after a topology change. Range is 0 to 120000.     |
| <b>secondary-wait</b> <i>secondary</i> | Hold time between the first and second SPF calculations (in milliseconds). Range is 0 to 120000.   |
| <b>maximum-wait</b> <i>maximum</i>     | Maximum interval (in milliseconds) between two consecutive SPF calculations. Range is 0 to 120000. |
| <b>level</b> { <b>1</b>   <b>2</b> }   | (Optional) Enables the SPF interval configuration for Level 1 or Level 2 independently.            |

## Command Default

**initial-wait** *initial* : 50 milliseconds  
**secondary-wait** *secondary* : 200 milliseconds  
**maximum-wait** *maximum* : 5000 milliseconds

## Command Modes

Address family configuration

## Command History

| Release     | Modification             |
|-------------|--------------------------|
| Release 3.2 | This command introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

SPF calculations are performed only when the topology changes. They are not performed when external routes change.

Use the **spf-interval** command to control how often the software can perform the SPF calculation. The SPF calculation is processor intensive. Therefore, it may be useful to limit how often this calculation is done,

especially when the area is large and the topology changes often. Increasing the SPF interval reduces the processor load of the router, but potentially slows the rate of convergence.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to set the initial SPF calculation delay to 10 milliseconds and the maximum interval between two consecutive SPF calculations to 5000 milliseconds:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-af)# spf-interval initial-wait 10 maximum-wait 5000
```

## spf prefix-priority (IS-IS)

To assign a priority to an ISIS prefix for customizing the RIB update sequence, use the **spf prefix-priority** command in address family configuration mode. To restore default values, use the **no** form of this command.

**spf prefix-priority** [**level** {**1** | **2**}] {**critical** | **high** | **medium**} [*access-list-name* | **tag** *tag*]

**no spf prefix-priority** [**level** {**1** | **2**}] {**critical** | **high** | **medium**} [*access-list-name* | **tag** *tag*]

### Syntax Description

|                                      |                                                                                         |
|--------------------------------------|-----------------------------------------------------------------------------------------|
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Enables the assignment of a priority to Level 1 or Level 2 independently.    |
| <b>critical</b>                      | Assigns a critical priority.                                                            |
| <b>high</b>                          | Assigns a high priority.                                                                |
| <b>medium</b>                        | Assigns a medium priority.                                                              |
| <i>access-list-name</i>              | Name of an access list.                                                                 |
| <b>tag</b> <i>tag</i>                | Specifies a tag to indicate priority. The <i>tag</i> argument range is 1 to 4294967295. |

### Command Default

By default, IPv4 prefixes with a length of 32 and IPv6 prefixes with a length of 128 are given medium priority. The remaining prefixes are given low priority.

### Command Modes

Address family configuration

### Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
| Release 3.4.0 | The <b>tag</b> <i>tag</i> keyword and argument were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **spf prefix-priority** command to change the sequence of prefix updates to the RIB after an SPF is run. ISIS installs prefixes in the RIB according to the following priority order:

Critical > High > Medium > Low

The **spf prefix-priority** command supports prefix lists for the first three priorities. The unmatched prefixes are updated with low priority.

If a **spf prefix-priority** is specified, the default behavior of prioritizing either length 32 or 128 prefixes for IPv4 or IPv6, respectively, as **medium** is disabled.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to set the prefix priorities:

```
RP/0/0/CPU0:router(config)# ipv4 prefix-list isis-critical-acl
RP/0/0/CPU0:router(config-ipv4_pfx)# 10 permit 0.0.0.0/0 eq 32
!
RP/0/0/CPU0:router(config)# ipv4 prefix-list isis-med-acl
RP/0/0/CPU0:router(config-ipv4_pfx)# 10 permit 0.0.0.0/0 eq 29
!
RP/0/0/CPU0:router(config)# ipv4 prefix-list isis-high-acl
RP/0/0/CPU0:router(config-ipv4_pfx)# 10 permit 0.0.0.0/0 eq 30
!
RP/0/0/CPU0:router(config)# router isis ring
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# spf prefix-priority critical isis-critical-acl
RP/0/0/CPU0:router(config-isis-af)# spf prefix-priority high isis-high-acl
RP/0/0/CPU0:router(config-isis-af)# spf prefix-priority medium isis-med-acl
```

## summary-prefix (IS-IS)

To create aggregate addresses for the Intermediate System-to-Intermediate System (IS-IS) protocol, use the **summary-prefix** command in address family configuration mode. To restore the default behavior, use the **no** form of this command.

### Syntax Description

|                               |                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>address</b>                | Summary address designated for a range of IPv4 addresses. The <i>address</i> argument must be in four-part, dotted-decimal notation.                                                                                         |
| <b>/ <i>prefix-length</i></b> | Length of the IPv4 or IPv6 prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value. |
| <b>ipv6-prefix</b>            | Summary prefix designated for a range of IPv6 prefixes. The <i>ipv6-prefix</i> argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons.     |
| <b>level { 1   2 }</b>        | (Optional) Redistributes routes into Level 1 or Level 2 and summarizes them with the configured address and mask value.                                                                                                      |
| <b>tag <i>tag</i></b>         | Sets a tag value. The value range is 1- 4294967295.                                                                                                                                                                          |

### Command Default

All redistributed routes are advertised individually.  
Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.2   | This command was introduced. |
| Release 3.9.0 | Tag keyword was added        |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Multiple groups of addresses can be summarized for a given level. Routes learned from other routing protocols can also be summarized. The metric used to advertise the summary is the smallest metric of all the more-specific routes. Use the **summary-prefix** command to help reduce the size of the routing table.

This command also reduces the size of the link-state packets (LSPs) and thus the link-state database. It also helps ensure stability, because a summary advertisement depends on many more specific routes. If one more-specific route flaps, in most cases, this flap does not cause a flap of the summary advertisement.

The drawback of summary addresses is that other routes might have less information to calculate the most optimal routing table for all individual destinations.

**Note**

When IS-IS advertises a summary prefix, it automatically inserts the summary prefix into the IP routing table but labels it as a “discard” route entry. Any packet that matches the entry is discarded to prevent routing loops. When IS-IS stops advertising the summary prefix, the routing table entry is removed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to redistribute Open Shortest Path First (OSPF) routes into IS-IS. In the OSPF routing table, IPv6 routes exist for 3ffe:f000:0001:0000::/64, 3ffe:f000:0002:0000::/64, 3ffe:f000:0003:0000::/64, and so on. This example shows only 3ffe:f000::/24 advertised into IPv6 IS-IS Level 2.

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv6 unicast
RP/0/0/CPU0:router(config-isis-af)# redistribute ospfv3 2 level-2
RP/0/0/CPU0:router(config-isis-af)# summary-prefix 3ffe:f000::/24 level-2
RP/0/0/CPU0:router(config-isis-af)# summary-prefix 3ffe:f000::/24 tag
```

# suppressed

To allow an IS-IS interface to participate in forming adjacencies without advertising connected prefixes in the system link-state packets (LSPs), use the **suppressed** command in interface configuration mode. To enable advertising connected prefixes, use the **no** form of this command.

**suppressed**

**no suppressed**

**Command Default** Interface is active.

**Command Modes** Interface configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **suppressed** command to reduce the number of routes that IS-IS has to maintain, improving convergence times after an isolated failure. Improvement is noticeable if the command is used widely throughout the network. Other routers in the domain do not install routes to the affected connected prefixes.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The following example shows how to disable the advertisement of connected prefixes on GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# suppressed
```

| Related Commands | Command                                      | Description                              |
|------------------|----------------------------------------------|------------------------------------------|
|                  | <a href="#">passive (IS-IS), on page 812</a> | Suppresses S-IS packets on an interface. |

 suppressed

## tag (IS-IS)

To associate and advertise a tag with the prefix of an IS-IS interface, use the **tag** command in interface address family configuration mode. To restore the default behavior, use the **no** form of this command.

**tag** *tag*

**no tag** [*tag*]

### Syntax Description

|            |                                          |
|------------|------------------------------------------|
| <i>tag</i> | Interface tag. Range is 1 to 4294967295. |
|------------|------------------------------------------|

### Command Default

Default is that no tag is associated and advertised.

### Command Modes

Interface address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to associate and advertise an interface tag:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# tag 234
```

**Related Commands**

| Command                                                   | Description                                                                   |
|-----------------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">spf prefix-priority (IS-IS)</a> , on page 913 | Assigns a priority to an ISIS prefix for customizing the RIB update sequence. |

# topology-id

To differentiate one topology in the domain from another while configuring a multicast routing table, use the **topology-id** command in Intermediate System-to-Intermediate System (IS-IS) address family configuration submode. To disable the topology use the **no** form of the command.

**topology-id** *isis-multicast-topology-id-number*

**no topology-id** *isis-multicast-topology-id-number*

## Syntax Description

|                                          |                                                                        |
|------------------------------------------|------------------------------------------------------------------------|
| <i>isis-multicast-topology-id-number</i> | ID number for a specific IS-IS multicast topology. Range is 6 to 4095. |
|------------------------------------------|------------------------------------------------------------------------|

## Command Default

No topology is associated with a routing table by default.

## Command Modes

IS-IS address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to differentiate a topology from another in the multicast routing table in IS-IS routing:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 multicast topology green
RP/0/0/CPU0:router(config-isis-af)# topology-id 2666
```

**Related Commands**

| Command                                                                | Description                                                                                                                                                                 |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">address-family multicast topology (IS-IS), on page 697</a> | Used in conjunction with the <b>topology-id</b> command, enables a multicast topology globally when configuring Intermediate System-to-Intermediate System (IS-IS) routing. |

## trace (IS-IS)

To set the the IS-IS buffer size, use the **trace** command in router configuration mode. To return to the default value, use the **no** form of this command.

**trace** [**detailed**| **severe**| **standard**] *max-trace-entries*

**no trace** [**detailed**| **severe**| **standard**]

### Syntax Description

|                          |                                                            |
|--------------------------|------------------------------------------------------------|
| <b>detailed</b>          | Specifies the buffer size for detailed traces. Range is    |
| <b>severe</b>            | Specifies the buffer size for severe traces. Range is      |
| <b>standard</b>          | Specifies the buffer size for standard traces. Range is    |
| <i>max-trace-entries</i> | Sets the maximum number of trace entries. Range is 1-20000 |

### Command Default

None

### Command Modes

Router IS-IS configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to set the isis buffer size for severe traces to 1200:

```
RP/0/0/CPU0:router(config)#router isis isp  
RP/0/0/CPU0:router(config-isis)#trace sever 1200
```

## OSPF Commands

---

This module describes the commands used to configure and monitor the Open Shortest Path First (OSPF) routing protocol.

For detailed information about OSPF concepts, configuration tasks, and examples, see the *Implementing OSPF on Cisco IOS XR Software* module in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

# address-family (OSPF)

To enter address family configuration mode for Open Shortest Path First (OSPF), use the **address-family** command in the appropriate mode. To disable address family configuration mode, use the **no** form of this command.

**address-family ipv4 [unicast]**

**no address-family ipv4 [unicast]**

## Syntax Description

|                |                                                 |
|----------------|-------------------------------------------------|
| <b>ipv4</b>    | Specifies IP Version 4 (IPv4) address prefixes. |
| <b>unicast</b> | (Optional) Specifies unicast address prefixes.  |

## Command Default

An address family is not specified.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF version 2 automatically provides routing services for IPv4 unicast topologies, so this command is redundant.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the OSPF router process with IPv4 unicast address prefixes:

```
RP/0/0/CPU0:router(config)# router ospf 1
```

```
RP/0/0/CPU0:router(config-ospf)# address-family ipv4 unicast
```

# adjacency stagger

To configure staggering of OSPF adjacency during reload, process restart, and process clear, use the **adjacency stagger** command in router configuration mode. To turn off adjacency staggering, either use the **disable** keyword or use the **no** form of this command.

**adjacency stagger** {**disable**| *initial-num-nbr max-num-nbr*}  
**no adjacency stagger**

## Syntax Description

|                        |                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b>         | Disables adjacency staggering.                                                                                                                                                                                     |
| <i>initial-num-nbr</i> | The initial number of simultaneous neighbors allowed to form adjacency to FULL in any area to bring up to FULL after a router reload, OSPF process restart, or OSPF process clear. Range is 1-65535. Default is 2. |
| <i>max-num-nbr</i>     | The subsequent number of simultaneous neighbors allowed to form adjacency, per OSPF instance, after the initial set of OSPF neighbors have become FULL. Range is 1-65535. Default is 64.                           |

## Command Default

OSPF adjacency staggering is enabled.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Staggering of the OSPF adjacency during reload, process restart (without NSR or graceful-restart), and process clear reduces the overall adjacency convergence time.

Initially, allow 2 (configurable) neighbors to form adjacency to FULL per area. After the first adjacency reaches FULL, up to 64 (configurable) neighbors can form adjacency simultaneously for the OSPF instance (all areas). However, areas without any FULL adjacency is restricted by the initial area limit.

### Note

Adjacency stagger and OSPF nonstop forwarding (NSF) are mutually exclusive. Adjacency stagger will not be activated if **nsf** is configured under router ospf configuration.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure adjacency stagger for a 2 neighbors initially and for a maximum of 3 neighbors:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# adjacency stagger 2 3
```

# area (OSPF)

To configure an Open Shortest Path First (OSPF) area, use the **area** command in the appropriate mode. To terminate an OSPF area, use the **no** form of this command.

**area** *area-id*

**no area** *area-id*

## Syntax Description

|                |                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>area-id</i> | Identifier of an OSPF area. The <i>area-id</i> argument can be specified as either a decimal value or an IP address (dotted decimal) format. Range is 0 to 4294967295. |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No OSPF area is defined.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **area** command to explicitly configure an area. Commands configured under the area configuration mode (such as the **interface** [OSPF] and **authentication** commands), are automatically bound to that area.

To modify or remove the area, the *area-id* argument format must be the same as the format used when creating the area. Otherwise, even if the actual 32-bit value matches, the area is not matched. For example, if you create an area with an *area-id* of 10 it would not match an *area-id* of 0.0.0.10.

### Note

To remove the specified area from the router configuration, use the **no area** *area-id* command. The **no area** *area-id* command removes the area and all area options, such as **authentication** , **default-cost** , **nssa** , **range** , **stub** , **virtual-link** , and **interface**.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure area 0 and GigabitEthernet interface 0/2/0/0. GigabitEthernet interface 0/2/0/0 is bound to area 0 automatically.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/2/0/0
```

## authentication (OSPF)

To enable plain text, Message Digest 5 (MD5) authentication, or null authentication for an Open Shortest Path First (OSPF) interface, use the **authentication** command in the appropriate mode. To remove such authentication, use the **no** form of this command.

**authentication** [**message-digest** [**keychain** *keychain*]] **null**

**no authentication**

### Syntax Description

|                                 |                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>message-digest</b>           | (Optional) Specifies that MD5 is used.                                                                                               |
| <b>keychain</b> <i>keychain</i> | (Optional) Specifies a keychain name.                                                                                                |
| <b>null</b>                     | (Optional) Specifies that no authentication is used. Useful for overriding password or MD5 authentication if configured for an area. |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the authentication parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the authentication parameter specified for the process.

If this command is not specified at any level, then the interface does not use authentication.

If no keyword is specified, plain text authentication is used.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
Virtual-link configuration  
VRF configuration  
Multi-area interface configuration  
Sham-link configuration

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |

| Release       | Modification                                                             |
|---------------|--------------------------------------------------------------------------|
| Release 3.5.0 | The <b>keychain</b> <i>keychain</i> keyword and argument pair was added. |
| Release 3.6.0 | This command was added under sham-link configuration mode.               |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **authentication** command to specify an authentication type for the interface, which overrides the authentication specified for the area to which this interface belongs. If this command is not included in the configuration file, the authentication configured in the area to which the interface belongs is assumed (as specified by the area **authentication** command).

The authentication type and password must be the same for all OSPF interfaces that are to communicate with each other through OSPF. If you specified plain text authentication, use the **authentication-key** command to specify the plain text password.

If you enable MD5 authentication with the **message-digest** keyword, you must configure a key with the **message-digest-key** interface command.

To manage the rollover of keys and enhance MD5 authentication for OSPF, you can configure a container of keys called a keychain with each key comprising the following attributes: generate/accept time, key identification, and authentication algorithm. The keychain management feature is always enabled.

### Note

Changes to the system clock will impact the validity of the keys in the existing configuration.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to set authentication for areas 0 and 1 of OSPF routing process 201. Authentication keys are also provided.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# authentication
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# authentication-key mykey
RP/0/0/CPU0:router(config-ospf-ar-if)# exit
RP/0/0/CPU0:router(config-ospf)# area 1
RP/0/0/CPU0:router(config-ospf-ar)# authentication
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# authentication-key mykey1
```

The following example shows how to configure use of an authentication keychain:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-ospf)# authentication message-digest keychain mykeychain
```

#### Related Commands

| Command                                                | Description                                                                                                     |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <a href="#">authentication-key (OSPF), on page 938</a> | Assigns a password to be used by neighboring routers that are using the simple password authentication of OSPF. |
| <a href="#">message-digest-key, on page 1015</a>       | Specifies a key used with OSPF MD5 authentication.                                                              |

# authentication-key (OSPF)

To assign a password to be used by neighboring routers that are using the Open Shortest Path First (OSPF) simple password authentication, use the **authentication-key** command in the appropriate mode. To remove a previously assigned OSPF password, use the **no** form of this command.

**authentication-key** [**clear**| **encrypted**] *password*

**no authentication-key**

## Syntax Description

|                  |                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>clear</b>     | (Optional) Specifies that the key be clear text.                                                                        |
| <b>encrypted</b> | (Optional) Specifies that the key be encrypted using a two-way algorithm.                                               |
| <i>password</i>  | Any contiguous string up to 8 characters in length that can be entered from the keyboard. For example, <i>mypswd2</i> . |

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the OSPF password parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the OSPF password parameter specified for the process.

If this command is not specified at any level, then no password is specified.

Clear is the default if the **clear** or **encrypted** keyword is not specified.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
Virtual-link configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.6.0 | This command was added under sham-link configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The password created by this command is inserted directly into the OSPF header when the Cisco IOS XR software originates routing protocol packets. A separate password can be assigned to each network on an individual interface basis. All neighboring routers on the same network must have the same password to be able to exchange OSPF information.

The **authentication-key** command must be used with the **authentication** command. If the **authentication** command is not configured, the password provided by the **authentication-key** command is ignored and no authentication is adopted by the OSPF interface.

#### Note

The **authentication-key** command cannot be used with the **authentication** command when the **message-digest** or **null** keyword is configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to configure an authentication password as the string yourpass:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# authentication-key yourpass
```

### Related Commands

| Command                                            | Description                    |
|----------------------------------------------------|--------------------------------|
| <a href="#">authentication (OSPF), on page 935</a> | Specifies authentication type. |

## auto-cost (OSPF)

To control how the Open Shortest Path First (OSPF) protocol calculates default metrics for the interface, use the **auto-cost** command in the appropriate mode. To revert to the default reference bandwidth, use the **no** form of this command.

**auto-cost** {**reference-bandwidth** *mbps*| **disable**}

**no auto-cost** {**reference-bandwidth**| **disable**}

### Syntax Description

|                                        |                                                              |
|----------------------------------------|--------------------------------------------------------------|
| <b>reference-bandwidth</b> <i>mbps</i> | Specifies a rate in Mbps (bandwidth). Range is 1 to 4294967. |
| <b>disable</b>                         | Assigns a cost based on interface type.                      |

### Command Default

*mbps* : 100 Mbps

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default OSPF calculates the OSPF metric for an interface according to the bandwidth of the interface.

The OSPF metric is calculated as the *mbps* value divided by bandwidth, with *mbps* equal to 108 by default.

If you have multiple links with high bandwidth (such as OC-192), you might want to use a larger number to differentiate the cost on those links. That is, the metric calculated using the default *mbps* value is the same for all high-bandwidth links.

Recommended usage of cost configuration for OSPF interfaces with high bandwidth is to be consistent: Either explicitly configure (by using the **cost** command) or choose the default (by using the **auto-cost** command).

The value set by the **cost** command overrides the cost resulting from the **auto-cost** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the reference value for the auto cost calculation to 1000 Mbps:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# auto-cost reference-bandwidth 1000
```

**Related Commands**

| Command                                                   | Description                                                                         |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">cost (OSPF)</a> , <a href="#">on page 953</a> | Explicitly specifies the cost of the interface (network) for OSPF path calculation. |

# capability opaque disable

To prevent Multiprotocol Label Switching traffic engineering (MPLS TE) topology information flooded to the network through opaque LSAs, use the **capability opaque disable** command in the appropriate mode. To restore MPLS TE topology information flooded through opaque LSAs to the network, use the **no** form of the command.

**capability opaque disable**

**no capability opaque disable**

## Command Default

Opaque LSAs are allowed.

## Command Modes

Router configuration

VRF configuration

## Command History

| Release       | Modification                                                        |
|---------------|---------------------------------------------------------------------|
| Release 3.2   | This command was introduced. The <b>enable</b> keyword was removed. |
| Release 3.3.0 | This command was added under the VRF configuration mode.            |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **capability opaque disable** command prevents flooded MPLS TE information (Types 1 and 4) through opaque LSAs of all scope (Types 9, 10, and 11).

Control opaque LSA support capability must be enabled for OSPF to support MPLS TE.

The MPLS TE topology information is flooded to the area through opaque LSAs by default.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to prevent OSPF from supporting opaque services:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# capability opaque disable
```

# clear ospf process

To reset an Open Shortest Path First (OSPF) router process without stopping and restarting it, use the **clear ospf process** command in EXEC mode.

**clear ospf** [*process-name* [**vrf** {*vrf-name*| **all**}]] **process**

## Syntax Description

|                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only the specified routing process is affected. Otherwise, all OSPF processes are reset. |
| <b>vrf</b>          | (Optional) An OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                           |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF instance to be reset.                                                                                                                                                                                                   |
| <b>all</b>          | (Optional) Resets all OSPF VRF instances.                                                                                                                                                                                                               |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.3.0 | The <b>vrf</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the OSPF router process is reset, OSPF releases all resources allocated, cleans up the internal database, and shuts down and restarts all interfaces that belong to the process.

### Note

The **clear ospf process** command may change the router ID unless the OSPF router ID is explicitly configured through the **router-id (OSPF)**, [on page 1079](#) command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to reset all OSPF processes:

```
RP/0/0/CPU0:router# clear ospf process
```

The following example shows how to reset the OSPF 1 process:

```
RP/0/0/CPU0:router# clear ospf 1 process
```

**Related Commands**

| Command                                        | Description                                  |
|------------------------------------------------|----------------------------------------------|
| <a href="#">router ospf, on page 1081</a>      | Configures an OSPF routing process.          |
| <a href="#">router-id (OSPF), on page 1079</a> | Configures a router ID for the OSPF process. |

# clear ospf redistribution

To clear all routes redistributed from other protocols out of the Open Shortest Path First (OSPF) routing table, use the **clear ospf redistribution** command in EXEC mode.

**clear ospf** [*process-name* [**vrf** {*vrf-name*| **all**}]] **redistribution**

## Syntax Description

|                     |                                                                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only the specified routing process is affected. Otherwise, all OSPF routes are cleared. |
| <b>vrf</b>          | (Optional) OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                             |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF instance to be reset.                                                                                                                                                                                                  |
| <b>all</b>          | (Optional) Resets all OSPF VRF instances.                                                                                                                                                                                                              |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear ospf redistribution** command to cause the routing table to be read again. OSPF regenerates and sends Type 5 and Type 7 link-state advertisements (LSAs) to its neighbors. If an unexpected route has appeared in the OSPF redistribution, using this command corrects the issue.

**Note**

Use of this command can cause a significant number of LSAs to flood the network. We recommend that you use this command with caution.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to clear all redistributed routes across all processes from other protocols:

```
RP/0/0/CPU0:router# clear ospf redistribution
```

# clear ospf routes

To clear all Open Shortest Path First (OSPF) routes from the OSPF routing table, use the **clear ospf routes** command in EXEC mode.

**clear ospf** [*process-name* [**vrf** {*vrf-name*| **all**}]] **routes**

## Syntax Description

|                     |                                                                                                                                                                                                                                                        |

|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to clear all OSPF routes from the OSPF routing table and recompute valid routes. When the OSPF routing table is cleared, OSPF routes in the global routing table are also recalculated.

```
RP/0/0/CPU0:router# clear ospf routes
```

| <a href="#">clear ospf statistics, on page 949</a> | Clears the Open Shortest Path First (OSPF) statistics of neighbor state transitions. |

# cost (OSPF)

To explicitly specify the interface (network) for Open Shortest Path First (OSPF) path calculation, use the **cost** command in the appropriate mode. To remove the cost, use the **no** form of this command.

**cost** *cost*

**no cost**

## Syntax Description

|             |                                                                                 |
|-------------|---------------------------------------------------------------------------------|
| <i>cost</i> | Unsigned integer value expressed as the link-state metric. Range is 1 to 65535. |
|-------------|---------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the cost parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the cost parameter specified for the process.

If this command is not specified at any level, then the cost is calculated by the **auto-cost** command.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | This command was added under sham-link configuration mode.                |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The link-state metric is advertised as the link cost in the router link advertisement. Cisco IOS XR software does not support type of service (ToS), so you can assign only one cost for each interface.

In general, the path cost is calculated using the following formula:

$108 / \text{bandwidth}$  (the default auto cost is set to 100 Mbps)

This calculation is the default reference bandwidth used by the auto-costing calculation which establishes the interface auto-cost. The **auto-cost** command can set this reference bandwidth to some other value. The **cost** command is used to override the auto-costing calculated default value for interfaces.

Using this formula, the default path cost is 1 for any interface that has a link bandwidth of 100 Mbps or higher. If this value does not suit the network, configure the reference bandwidth for auto calculating costs based on the link bandwidth.

The value set by the **cost** command overrides the cost resulting from the **auto-cost (OSPF)** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to set the cost value to 65 for GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# cost 65
```

## Related Commands

| Command                                        | Description                                                                  |
|------------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">auto-cost (OSPF)</a> , on page 940 | Controls how the OSPF protocol calculates default metrics for the interface. |

# cost-fallback (OSPF)

To apply higher cost than the normal interface cost when the cumulative bandwidth of a bundle interface goes below the threshold specified and to revert to the original cost if the cumulative bandwidth goes above the configured threshold, use the cost-fallback command. To remove the cost-fallback, use the **no** form of this command.

**cost-fallback cost threshold bandwidth**

**no cost-fallback**

## Syntax Description

|                              |                                                                                                                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cost</i> <b>threshold</b> | Unsigned integer value expressed as the link-state metric. Range is 1 to 65535, but typically, cost-fallback value is supposed to be set to a value higher than the normal cost. |
| <i>bandwidth</i>             | Unsigned integer value expressed in Mbits per second. Range is 1 to 4294967.                                                                                                     |

## Command Default

If this command is not specified in interface configuration mode, the currently effective interface cost takes effect even when the cumulative bandwidth goes down below the maximum bandwidth. Unlike the interface cost command, this cost-fallback command is available only under interface configuration mode; it is not available in area or process level. Unlike other interface specific parameters, no inheritance will take place from area or process level if this command is not specified at interface level.

## Command Modes

Interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The fallback cost must be set to a higher value than the normal interface cost. The motivation of setting the fallback cost is to cost out an interface or disfavor an interface without shutting it down when its cumulative bandwidth goes below the user specified threshold, so that the traffic can take an alternative path. The normal interface cost will take over when the cumulative bandwidth reaches or exceeds user-specified threshold.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to set the cost-fallback value for Packet-over-SONET/SDH (POS):

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 100
RP/0/0/CPU0:router(config-ospf)# router-id 2.2.2.2
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface bundle-pos1
RP/0/0/CPU0:router(config-ospf-ar-if)# cost-fallback 1000 threshold 300
```

## Related Commands

| Command                                        | Description                                                                  |
|------------------------------------------------|------------------------------------------------------------------------------|
| <a href="#">auto-cost (OSPF)</a> , on page 940 | Controls how the OSPF protocol calculates default metrics for the interface. |
| <a href="#">cost (OSPF)</a> , on page 953      | Specifies the cost of the interface (network) for OSPF path calculation.     |

## database-filter all out (OSPF)

To filter outgoing link-state advertisements (LSAs) to an Open Shortest Path First (OSPF) interface, use the **database-filter all out** command in the appropriate mode. To restore the forwarding of LSAs to the interface, use the **disable** form of the command.

**database-filter all out** [**disable**| **enable**]

### Syntax Description

|                |                                |
|----------------|--------------------------------|
| <b>disable</b> | (Optional) Disables filtering. |
| <b>enable</b>  | (Optional) Enables filtering.  |

### Command Default

The database filter is disabled.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration  
Multi-area configuration

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **database-file all out** command to perform the same function that the [neighbor database-filter all out](#), on page 1036 command performs on a neighbor basis.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to prevent flooding of OSPF LSAs to broadcast, nonbroadcast, and point-to-point networks reachable through GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# database-filter all out
```

## Related Commands

| Command                                                         | Description                                 |
|-----------------------------------------------------------------|---------------------------------------------|
| <a href="#">neighbor database-filter all out</a> , on page 1036 | Filters outgoing LSAs to an OSPF interface. |

# dead-interval (OSPF)

To set the interval after which a neighbor is declared dead when no hello packets are observed, use the **dead-interval** command in the appropriate mode. To return to the default time, use the **no** form of this command.

**dead-interval** *seconds*  
**no dead-interval**

## Syntax Description

|                |                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Integer that specifies the interval (in seconds). Range is 1 to 65535. The value must be the same for all nodes on the network. |
|----------------|---------------------------------------------------------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the dead interval parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the dead interval parameter specified for the process.

If this command is not specified at any level, then the dead interval is four times the interval set by the **hello-interval** (OSPF) command.

## Command Modes

Interface configuration  
 Area configuration  
 Router configuration  
 Virtual-link configuration  
 VRF configuration  
 Multi-area configuration  
 Sham-link configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | This command was added under sham-link configuration mode.                |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The dead interval value must be the same for all routers and access servers on a specific network.

If the hello interval is configured, the dead interval value must be larger than the hello interval value. The dead interval value is usually configured four times larger than the hello interval value.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the OSPF dead interval to 40 seconds:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# dead-interval 40
```

**Related Commands**

| Command                                             | Description                                                                                         |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">hello-interval (OSPF)</a> , on page 993 | Specifies the interval between hello packets that the Cisco IOS XR software sends on the interface. |

## default-cost (OSPF)

To specify a cost for the default summary route sent into a stub area or not-so-stubby area (NSSA), use the **default-cost** command in area configuration mode. To remove the assigned default route cost, use the **no** form of this command.

**default-cost** *cost*

**no default-cost** *cost*

### Syntax Description

|             |                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------|
| <i>cost</i> | Cost for the default summary route used for a stub or NSSA area. The acceptable value is a 24-bit number. |
|-------------|-----------------------------------------------------------------------------------------------------------|

### Command Default

*cost* : 1

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-cost** command only on an Area Border Router (ABR) attached to a stub or an NSSA area.

In all routers and access servers attached to the stub area, the area should be configured as a stub area using the **stub** command in the area submode. Use the **default-cost** command only on an ABR attached to the stub area. The **default-cost** command provides the metric for the summary default route generated by the ABR into the stub area.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to assign a default cost of 20 to a stub area. The GigabitEthernet interface 0/4/0/3 is also configured in the stub area):

```
RP/0/0/CPU0:router# configure
```

```
RP/0/0/CPU0:router(config)# router ospf 201  
RP/0/0/CPU0:router(config-ospf)# area 10.15.0.0  
RP/0/0/CPU0:router(config-ospf-ar)# stub  
RP/0/0/CPU0:router(config-ospf-ar)# default-cost 20  
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/4/0/3
```

**Related Commands**

| Command                                   | Description                     |
|-------------------------------------------|---------------------------------|
| <a href="#">stub (OSPF), on page 1160</a> | Defines an area as a stub area. |

# default-information originate (OSPF)

To generate a default external route into an Open Shortest Path First (OSPF) routing domain, use the **default-information originate** command in the appropriate mode. To disable this feature, use the **no** form of this command.

**default-information originate** [**always**] [**metric** *metric-value*] [**metric-type** *type-value*] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no default-information originate**

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                       |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>always</b>                          | (Optional) Always advertises the default route regardless of whether the routing table has a default route.                                                                                                                                                           |
| <b>metric</b> <i>metric-value</i>      | (Optional) Specifies the metric used for generating the default route. The default metric value is 1. Range is 1 to 16777214.                                                                                                                                         |
| <b>metric-type</b> <i>type-value</i>   | (Optional) Specifies the external link type associated with the default route advertised into the OSPF routing domain. It can be one of the following values:<br><br>1—Type 1 external route<br>2—Type 2 external route                                               |
| <b>tag</b> <i>tag-value</i>            | (Optional) 32-bit dotted-decimal value attached to each external route. This is not used by the OSPF protocol itself. It may be used to communicate information between autonomous system boundary routers (ASBRs). If a tag is not specified, then zero (0) is used. |
| <b>route-policy</b> <i>policy-name</i> | (Optional) Specifies that a routing policy be used and the routing policy name.                                                                                                                                                                                       |

## Command Default

When you do not use this command in router configuration mode, no default external route is generated into an OSPF routing domain.

*metric-value* : 1

*type-value* : 2

*tag-value*: 0

## Command Modes

Router configuration

VRF configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                                                                               |
|---------------|----------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was added under the VRF configuration mode.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Whenever you use the **redistribute** or **default-information originate** command to redistribute routes into an OSPF routing domain, the software automatically becomes an Autonomous System Boundary Router (ASBR). However, an ASBR does not, by default, generate a default route into the OSPF routing domain. The software still must have a default route for itself before it generates one, except when you have specified the **always** keyword.

The **default-information originate** route-policy attach point conditionally injects the default route 0.0.0.0/0 into the OSPF link-state database, and is done by evaluating the attached policy. If any routes specified in the policy exist in the global RIB, then the default route is inserted into the link-state database. If there is no match condition specified in the policy, the policy passes and the default route is generated into the link-state database.

For information about the default-information originate attach point, see the *OSPF Policy Attach Points* section in the *Implementing Routing Policy* chapter in *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

For information about routing policies, see the *Routing Policy Commands* chapter in the *Cisco IOS XR Routing Command Reference for the Cisco XR 12000 Series Router*.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to specify a metric of 100 for the default route redistributed into the OSPF routing domain and an external metric type of Type 1:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 109
RP/0/0/CPU0:router(config-ospf)#redistribute igmp 108 metric 100
RP/0/0/CPU0:router(config-ospf)#default-information originate metric 100 metric-type 1
```

### Related Commands

| Command                                            | Description                                                                 |
|----------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">redistribute (OSPF)</a> , on page 1070 | Redistributes routes from one routing domain into a specified OSPF process. |

# default-metric (OSPF)

To set default metric values for routes redistributed from another protocol into the Open Shortest Path First (OSPF) protocol, use the **default-metric** command in the appropriate mode. To return to the default state, use the **no** form of this command.

**default-metric** *value*

**no default-metric** *value*

## Syntax Description

|              |                                                                                              |
|--------------|----------------------------------------------------------------------------------------------|
| <i>value</i> | Default metric value appropriate for the specified routing protocol. Range is 1 to 16777214. |
|--------------|----------------------------------------------------------------------------------------------|

## Command Default

Built-in, automatic metric translations, as appropriate for each routing protocol.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced                              |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-metric** command with the **redistribute** command to cause the current routing protocol to use the same metric value for all redistributed routes. A default metric helps solve the problem of redistributing routes with incompatible metrics. Whenever metrics do not convert, use a default metric to provide a reasonable substitute and enable the redistribution to proceed.

The default-metric value configured in OSPF configuration does not apply to connected routes that are redistributed to OSPF using the **redistribute connected** command. To set a non-default metric for connected routes, configure OSPF with the **redistribute connected metric** *metric-value* command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to advertise Intermediate System-to-Intermediate System (IS-IS) protocol-derived routes into OSPF and assign a metric of 10:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# default-metric 10
RP/0/0/CPU0:router(config-ospf)# redistribute isis IS-IS_isp
```

## Related Commands

| Command                                                            | Description                                                                 |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">redistribute (OSPF)</a> , <a href="#">on page 1070</a> | Redistributes routes from one routing domain into a specified OSPF process. |

## demand-circuit (OSPF)

To configure the Open Shortest Path First (OSPF) protocol to treat the interface as an OSPF demand circuit, use the **demand-circuit** command in the appropriate mode. To remove the demand circuit designation from the interface, use the **no** form of this command.

**demand-circuit** [**disable**| **enable**]

**no demand-circuit**

### Syntax Description

|                |                                                              |
|----------------|--------------------------------------------------------------|
| <b>disable</b> | (Optional) Disables the interface as an OSPF demand circuit. |
| <b>enable</b>  | (Optional) Enables the interface as an OSPF demand circuit.  |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the demand circuit parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the demand circuit parameter specified for the process.

If this command is not specified at any level, then the circuit is not a demand circuit.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

On point-to-point interfaces, only one end of the demand circuit must be configured with this command. Periodic hello messages are suppressed and periodic refreshes of link-state advertisements (LSAs) do not flood the demand circuit. Use the **demand-circuit** command to allow the underlying data link layer to be closed when the topology is stable. In point-to-multipoint topology, only the multipoint end must be configured with this command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the configuration for an OSPF demand circuit:

```
RP/0/RP0/CPU0:router# configure  
RP/0/RP0/CPU0:router(config)# router ospf 1  
RP/0/RP0/CPU0:router(config-ospf)# demand-circuit
```

# disable-dn-bit-check

To specify that down bits should be ignored, use the **disable-dn-bit-check** command in VPN routing and forwarding (VRF) configuration mode. To specify that down bits should be considered, use the **no** form of this command.

**disable-dn-bit-check**

**no disable-dn-bit-check**

**Command Default** Down bits are considered.

**Command Modes** VRF configuration mode

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** The following example shows how to specify that down bits be ignored:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# vrf v1
RP/0/0/CPU0:router(config-ospf-vrf)# disable-dn-bit-check
```

## distance (OSPF)

To define an administrative distance, use the **distance** command in an appropriate configuration mode. To remove the **distance** command from the configuration file and restore the system to its default condition in which the software removes a distance definition, use the **no** form of this command.

**distance** *weight* [*ip-address wildcard-mask* [ *access-list-name* ]]

**no distance** *weight ip-address wildcard-mask* [ *access-list-name* ]

### Syntax Description

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>weight</i>           | Administrative distance. Range is 10 to 255. Used alone, the <i>weight</i> argument specifies a default administrative distance that the software uses when no other specification exists for a routing information source. Routes with a distance of 255 are not installed in the routing table. lists the default administrative distances. <a href="#">Table 87: Default Administrative Distances, on page 971</a> |
| <i>ip-address</i>       | (Optional) IP address in four-part, dotted-decimal notation.                                                                                                                                                                                                                                                                                                                                                          |
| <i>wildcard-mask</i>    | (Optional) Wildcard mask in four-part, dotted decimal format. A bit set to 1 in the <i>mask</i> argument instructs the software to ignore the corresponding bit in the address value.                                                                                                                                                                                                                                 |
| <i>access-list-name</i> | (Optional) Name of an IP access list to be applied to incoming routing updates.                                                                                                                                                                                                                                                                                                                                       |

### Command Default

If this command is not specified, then the administrative distance is the default, as specified in [Table 87: Default Administrative Distances, on page 971](#).

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An administrative distance is an integer from 10 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means that the routing information source cannot be trusted at all and should be ignored. Weight values are subjective; no quantitative method exists for choosing weight values.

If an access list is used with this command, it is applied when a network is being inserted into the routing table. This behavior allows you to filter networks based on the IP prefix supplying the routing information. For example, you could filter possibly incorrect routing information from networking devices not under your administrative control.

The order in which you enter **distance** commands can affect the assigned administrative distances in unexpected ways (see the “Examples” section for further clarification).

This table lists default administrative distances.

**Table 87: Default Administrative Distances**

| Route Source                  | Default Distance |
|-------------------------------|------------------|
| Connected interface           | 0                |
| Static route out on interface | 0                |
| State route to next-hop       | 1                |
| EIGRP Summary Route           | 5                |
| External BGP                  | 20               |
| Internal EIGRP                | 90               |
| OSPF                          | 110              |
| IS-IS                         | 115              |
| RIP version 1 and 2           | 120              |
| External EIGRP                | 170              |
| Internal BGP                  | 200              |
| Unknown                       | 255              |

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

In the following example, the **router ospf** command sets up OSPF routing instance1. The first **distance** command sets the default administrative distance to 255, which instructs the software to ignore all routing

updates from networking devices for which an explicit distance has not been set. The second **distance** command sets the administrative distance for all networking devices on the Class C network 192.168.40.0 0.0.0.255 to 90.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# distance 255
RP/0/0/CPU0:router(config-ospf)# distance 90 192.168.40.0 0.0.0.255
```

|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>distance bgp</b>                       | Allows the use of external, internal, and local administrative distances that could be a better route to a BGP node.   |
| <b>distance ospf</b>                      | Allows the use of external, internal, and local administrative distances that could be a better route to an OSPF node. |
| <a href="#">router ospf, on page 1081</a> | Configures the OSPF routing process.                                                                                   |

# distance ospf

To define Open Shortest Path First (OSPF) route administrative distances based on route type, use the **distance ospf** command in router configuration mode. To restore the default value, use the **no** form of this command.

**distance ospf** {intra-area| inter-area| external} *distance*  
**no distance ospf**

## Syntax Description

|                                                         |                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>intra-area</b>   <b>inter-area</b>   <b>external</b> | <p>Sets the type of area. It can be one of the following values:</p> <p><b>intra-area</b> —All routes within an area.</p> <p><b>inter-area</b> —All routes from one area to another area.</p> <p><b>external</b> —All routes from other routing domains, learned by redistribution. Any combination of the above areas is allowed.</p> |
| <i>distance</i>                                         | Route administrative distance.                                                                                                                                                                                                                                                                                                         |

## Command Default

*distance* : 110

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must specify one of the keywords.

Use the **distance ospf** command to perform the same function as the **distance** command used with an access list. However, the **distance ospf** command sets a distance for an entire group of routes, rather than a specific route that passes an access list.

A common reason to use the **distance ospf** command is when you have multiple OSPF processes with mutual redistribution, and you want to prefer internal routes from one over external routes from the other.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to change the external distance to 200, making the route less reliable:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# redistribute ospf 2
RP/0/0/CPU0:router(config-ospf)# distance ospf external 200
RP/0/0/CPU0:router(config-ospf)# exit
RP/0/0/CPU0:router(config)# router ospf 2
RP/0/0/CPU0:router(config-ospf)# redistribute ospf 1
RP/0/0/CPU0:router(config-ospf)# distance ospf external 200
```

## Related Commands

|----------------------------------------------------|-------------------------------------|
| <a href="#">disable-dn-bit-check</a> , on page 969 | Defines an administrative distance. |

# distribute-list

To filter networks received or transmitted in Open Shortest Path First (OSPF) updates, use the **distribute-list** command in the appropriate mode. To change or cancel the filter, use the **no** form of this command.

**distribute-list** {*access-list-name* {**in**|**out** [**bgp number**|**connected**|**ospf instance**|**static**] }| **route-policy** *route-policy-name* **in**}

**no distribute-list** {*access-list-name* {**in**|**out**}| **route-policy** *route-policy-name* **in**}

## Syntax Description

|                                                 |                                                                                                                                     |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list-name</i>                         | Standard IP access list name. The list defines which networks are to be received and which are to be suppressed in routing updates. |
| <b>in</b>                                       | Applies the access list or route-policy to incoming routing updates.                                                                |
| <b>out</b>                                      | Applies the access list to outgoing routing updates. The <b>out</b> keyword is available only in router configuration mode.         |
| <b>bgp</b>                                      | (Optional) Applies the access list to BGP routes.                                                                                   |
| <b>connected</b>                                | (Optional) Applies the access list to connected routes.                                                                             |
| <b>ospf</b>                                     | (Optional) Applies the access list to OSPF routes (not the current OSPF process).                                                   |
| <b>static</b>                                   | (Optional) Applies the access list to statically configured routes.                                                                 |
| <b>route-policy</b><br><i>route-policy-name</i> | Specifies the route-policy to filter OSPF prefixes.                                                                                 |

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the distribute list parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the distribute list parameter specified for the process.

If this command is not specified at any level, then the distribute list is disabled.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration  
Multi-area configuration

## Command History

| Release       | Modification                                                                                                                             |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                             |
| Release 3.3.0 | This command was added in the VRF configuration mode.                                                                                    |
| Release 3.4.1 | This command was added in the multi-area interface configuration mode.                                                                   |
| Release 4.2.1 | The <b>route-policy</b> <i>route-policy-name</i> keyword and argument were added to allow use of route policies to filter OSPF prefixes. |
| Release 4.3.1 | Support was added for "if tag..." statements in <b>distribute-list in</b> <i>route-policy</i> .                                          |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **distribute-list** command to limit which OSPF routes are installed on this router. The **distribute-list** command does not affect the OSPF protocol itself.

The **distribute-list in** is configurable at instance (process), area, and interface levels. Regular OSPF configuration inheritance applies. Configuration is inherited from instance > area > interface levels.

Use the **route-policy** *route-policy-name* keyword and argument to allow use of route policies to filter OSPF prefixes.

### Note

Either an access-list, or a route-policy can be used in a single command, not both. Configuring the command with access-list removes the route-policy configuration, and vice versa.

The "if tag..." statements can be used in **distribute-list in** *route-policy*. The matching on route tag supports operators "eq/ge/is/le". Operator "in" is not supported.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to prevent OSPF routes from the 172.17.10.0 network from being installed if they are learned in area 0:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# ipv4 access-list 3
RP/0/0/CPU0:router(config-ipv4-acl)# deny 172.17.10.0 0.0.0.255
RP/0/0/CPU0:router(config-ipv4-acl)# permit any any
!
RP/0/0/CPU0:router(config)# router ospf 1
```

```
RP/0/0/CPU0:router(config-ospf)# area 0  
RP/0/0/CPU0:router(config-ospf-ar)# distribute-list 3 in  
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
```

## domain-id (OSPF)

To specify the Open Shortest Path First (OSPF) VPN routing and forwarding (VRF) domain ID, use the **domain-id** command in VRF configuration mode. To remove an OSPF VRF domain ID, use the **no** form of this command.

**domain-id** [**secondary**] **type** [0005| 0105| 0205| 8005] **value** *value*

**no domain-id** [**secondary**] **type** [0005| 0105| 0205| 8005] **value** *value*

### Syntax Description

|                           |                                                  |
|---------------------------|--------------------------------------------------|
| <b>secondary</b>          | (Optional) OSPF secondary domain ID.             |
| <b>type</b>               | Primary OSPF domain ID in hex format.            |
| <b>value</b> <i>value</i> | OSPF domain ID value in hex format (six octets). |

### Command Default

No domain ID is specified.

### Command Modes

VRF configuration mode

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An OSPF domain id must be explicitly configured. The OSPF domain ID helps OSPF determine how to translate a prefix received through Border Gateway Protocol (BGP) from the remote provider edge (PE). If the domain IDs match, OSPF generates a Type 3 link state advertisement (LSA). If the domain IDs do not match, OSPF generates a Type 5 LSA.

There is only one primary domain ID. There can be multiple secondary domain IDs.

#### Note

When an IOS XR router and an IOS router are configured as peers, the two Domain IDs must match. Manually configure the IOS XR Domain ID value to match the IOS default Domain ID value. This ensures that the routes have route code "OIA" because they are learned as inter-area routes. If the Domain IDs do not match, the routes have route code, "O-E2" because they are learned as external routes. Use the **show ip ospf** command to get the OSPF Domain ID from the IOS router. Then, set the IOS XR Domain ID to the same value using the **domain-id** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to specify a domain ID:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# router ospf 01  
RP/0/0/CPU0:router(config-ospf)# vrf v1  
RP/0/0/CPU0:router(config-ospf-vrf)# domain-id type 0105 value AABBCDDEEFF
```

# domain-tag

To specify the Open Shortest Path First (OSPF) VPN routing and forwarding (VRF) domain tag, use the **domain-tag** command in VRF configuration mode. To remove an OSPF VRF domain tag, use the **no** form of this command.

**domain-tag** *tag*

**no domain-tag**

## Syntax Description

|            |                                                                        |
|------------|------------------------------------------------------------------------|
| <i>tag</i> | OSPF domain tag as a 32-bit value. The valid range is 0 to 4294967295. |
|------------|------------------------------------------------------------------------|

## Command Default

No OSPF VRF domain tag is specified.

## Command Modes

VRF configuration mode

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The domain tag is added to any Type 5 link state advertisements (LSAs) generated as a result of VPN-IP routes received from Border Gateway Protocol (BGP). The domain-tag is derived from BGP autonomous system number (ASN).

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to specify the domain tag:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 01
RP/0/0/CPU0:router(config-ospf)# domain-tag 234
```

# fast-reroute (OSPFv2)

To enable IP fast reroute loop-free alternate (LFA) computation, use the **fast-reroute** command in the appropriate OSPF configuration mode. To disable the IP fast reroute loop-free alternate computation, use the **no** form of this command.

To disable loop-free alternate computation that is enabled on a higher level, use the **fast-reroute** command with **disable** keyword.

**fast-reroute** {per-link| per-prefix} [disable]

**no fast-reroute**

## Syntax Description

|                   |                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------|
| <b>per-link</b>   | Enables per-link loop-free alternate computation.                                       |
| <b>per-prefix</b> | Enables per-prefix loop-free alternate computation.                                     |
| <b>disable</b>    | (Optional) Disables loop-free alternate computation that was enabled on a higher level. |

## Command Default

IP fast-reroute LFA computation is disabled.

## Command Modes

Area configuration  
Interface configuration  
Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Only one mode of computation can be configured on an interface - per-link or per-prefix. Different modes of computations can be enabled on different interfaces; one set of interface using per-link and other set using per-prefix computation. Based on the outgoing interface of the primary path, per-link or per-prefix backup path will be computed.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

**Examples**

This example shows how to enable per-link computation of loop-free alternates under interface POS 0/3/0/0:

```
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface POS 0/3/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# fast-reroute per-link
```

This example shows how to enable per-prefix computation of loop-free alternates under area 0:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 1
RP/0/0/CPU0:router(config-ospf)#area 0
RP/0/0/CPU0:router(config-ospf-ar)#fast-reroute per-prefix
```

This example shows how to disable computation of loop-free alternates that was configured under area 0:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 1
RP/0/0/CPU0:router(config-ospf)#area 0
RP/0/0/CPU0:router(config-ospf-ar)#fast-reroute per-prefix
RP/0/0/CPU0:router(config-ospf-ar)#interface POS 0/3/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)#fast-reroute disable
```

# fast-reroute per-link exclude interface

To excludes specified interface to be used as a backup during (IPFRR) loop-free alternate (LFA) computation, use the **fast-reroute per-link exclude interface** command, in the appropriate OSPF configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-link exclude interface** *type interface-path-id*

**no fast-reroute per-link exclude interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |

## Command Default

No interfaces are excluded.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to exclude an interface from IP fast reroute loop-free alternate (LFA) computation:

```
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf-ar-if)# fast-reroute per-link exclude interface POS 0/3/2/1
```

## Related Commands

| Command                                            | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">fast-reroute (OSPFv2), on page 981</a> | Enables IP fast reroute loop-free alternate (LFA) computation. |

## fast-reroute per-prefix exclude interface (OSPFv2)

To exclude interface to be used as a backup path from fast-reroute loop-free alternate per-prefix computation, use the **fast-reroute per-prefix exclude interface** command in the appropriate OSPF configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix exclude interface** *type interface-path-id*

**no fast-reroute per-prefix exclude interface** *type interface-path-id*

### Syntax Description

|                          |                                                                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                    |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the show interfaces command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark (?) online help function. |

### Command Default

No interfaces are excluded.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Backup paths via the excluded interfaces will not be computed.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

## Examples

This example shows how to exclude interface POS0/6/0/1 from being used as a backup path:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#fast-reroute per-prefix exclude interface POS0/6/0/1
```

## fast-reroute per-prefix lfa-candidate (OSPFv2)

To add interfaces to the LFA candidate list, use the **fast-reroute per-prefix lfa-candidate** command in interface configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix lfa-candidate** [ *interface-name* ]

**no fast-reroute per-prefix lfa-candidate** [ *interface-name* ]

### Syntax Description

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| <i>interface-name</i> | Specifies name of the interface to add to the LFA candidate list. |
|-----------------------|-------------------------------------------------------------------|

### Command Default

No interfaces are added to the candidate list.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

### Examples

This example shows how to add an interface to LFA candidates:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#fast-reroute per-prefix lfa-candidate interface POS0/6/0/0
```

## fast-reroute per-prefix remote-lfa (OSPFv2)

To configure fast-reroute per-prefix remote loop-free alternate (rLFA) computation for an OSPFv2 process, use the **fast-reroute per-prefix remote-lfa** command in the appropriate OSPF configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix remote-lfa** {**disable**| **maximum-cost** *path-cost*| **tunnel mpls-ldp**}

**no fast-reroute per-prefix remote-lfa**

### Syntax Description

|                                      |                                                                                                 |
|--------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>remote-lfa</b>                    | Enables remote LFA backup computation                                                           |
| <b>maximum-cost</b> <i>path-cost</i> | Sets the cost option to limit the range of remote LFAs. Range for path-cost is 1 to 4294967295. |
| <b>tunnel mpls-ldp</b>               | Enables remote LFA computation using tunnel interfaces.                                         |
| <b>disable</b>                       | Selectively disables remote LFA calculation under one or more areas.                            |

### Command Default

Remote LFA FRR computation is disabled.

### Command Modes

Router configuration  
Area configuration  
Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.3.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Fast-reroute per-prefix LFA must be enabled for remote LFA to be operational. The OSPF configuration hierarchy at process level and area level are applicable for remote LFA configuration. For example, it is possible to enable remote-LFA for all OSPF areas and selectively disable (using **disable** keyword) the computation under one or more area.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

## Examples

This example shows how to enable fast-reroute per-prefix remote LFA computation for tunnel interfaces:

```
RP/0/0/CPU0:router(config)#router ospf 1
RP/0/0/CPU0:router(config-ospf)#fast-reroute per-prefix remote-lfa tunnel mpls-ldp
```

This example shows how to configure cost option to limit the range of remote LFAS:

```
RP/0/0/CPU0:router(config)#router ospf 1
RP/0/0/CPU0:router(config-ospf)#fast-reroute per-prefix remote-lfa maximum-cost 2
```

## Related Commands

| Command                                            | Description                                                    |
|----------------------------------------------------|----------------------------------------------------------------|
| <a href="#">fast-reroute (OSPFv2), on page 981</a> | Enables IP fast reroute loop-free alternate (LFA) computation. |

## fast-reroute per-prefix use-candidate-only (OSPFv2)

To restrict the backup interfaces to those that are present on the LFA candidate list, use the **fast-reroute per-prefix use-candidate-only** command in router OSPF configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix use-candidate-only** [enable| disable]

**fast-reroute per-prefix use-candidate-only**

### Syntax Description

|                |                                                     |
|----------------|-----------------------------------------------------|
| <b>enable</b>  | Enables backup selection from candidate-list only.  |
| <b>disable</b> | Disables backup selection from candidate-list only. |

### Command Default

Disabled.

### Command Modes

Router OSPF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

### Examples

This example shows how to restrict the backup interfaces to those that are present on the LFA candidate list:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#fast-reroute per-prefix use-candidate-only
```

# flood-reduction (OSPF)

To suppress the unnecessary flooding of link-state advertisements (LSAs) in stable topologies, use the **flood-reduction** command in the appropriate mode. To remove this functionality from the configuration, use the **no** form of this command.

**flood-reduction** [enable| disable]

**no flood-reduction** [enable| disable]

## Syntax Description

|                |                                                              |
|----------------|--------------------------------------------------------------|
| <b>enable</b>  | (Optional) Turns on this functionality at a specific level.  |
| <b>disable</b> | (Optional) Turns off this functionality at a specific level. |

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the flood reduction parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the flood reduction parameter specified for the process.

If this command is not specified at any level, then flood reduction is disabled.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

## Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was added in the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

All routers supporting the OSPF demand circuit are compatible and can interact with routers supporting flooding reduction.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to reduce the flooding of unnecessary LSAs for area 0:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# flood-reduction
```

**Related Commands**

| Command                                           | Description                                                          |
|---------------------------------------------------|----------------------------------------------------------------------|
| <a href="#">show ospf interface, on page 1109</a> | Displays OSPF-related interface information.                         |
| <a href="#">show ospf neighbor, on page 1121</a>  | Displays OSPF neighbor information on an individual interface basis. |

# hello-interval (OSPF)

To specify the interval between consecutive hello packets that are sent on the Open Shortest Path First (OSPF) interface, use the **hello-interval** command in the appropriate mode. To return to the default time, use the **no** form of this command.

**hello-interval** *seconds*

**no hello-interval**

## Syntax Description

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Interval (in seconds). The value must be the same for all nodes on a specific network. Range is 1 to 65535. |
|----------------|-------------------------------------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the hello interval parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the hello interval parameter specified for the process.

If this command is not specified at any level, then the hello interval is 10 seconds (broadcast) or 30 seconds (nonbroadcast).

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
Virtual-link configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

## Command History

| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | This command was added under sham-link configuration mode.                |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The hello interval value is advertised in the hello packets. The shorter the hello interval, the faster topological changes are detected, but more routing traffic occurs. This value must be the same for all routers and access servers on a specific network.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the interval between hello packets to 15 seconds:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# hello-interval 15
```

**Related Commands**

| Command                                                            | Description                                                                                          |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">dead-interval (OSPF)</a> , <a href="#">on page 959</a> | Sets the time period for which hello packets are suspended before neighbors declare the router down. |

# ignore lsa mospf

To suppress the sending of syslog messages when the router receives link-state advertisement (LSA) Type 6 multicast Open Shortest Path First (MOSPF) packets, which are unsupported, use the **ignore lsa mospf** command in an appropriate configuration mode. To restore the sending of syslog messages, use the **no** form of this command.

**ignore lsa mospf**

**no ignore lsa mospf**

This command has no keywords or arguments.

## Command Default

When you do not specify this command in router configuration mode, each MOSPF packet received by the router causes the router to send a syslog message.

## Command Modes

Router configuration

VRF configuration

## Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Cisco routers do not support LSA Type 6 (MOSPF), and they generate syslog messages if they receive such packets. If the router is receiving many MOSPF packets, you might want to configure the router to ignore the packets and thus prevent a large number of syslog messages.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the router to suppress the sending of syslog messages when it receives MOSPF packets:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
```

```
RP/0/0/CPU0:router(config-ospf)# ignore lsa mospf
```

# interface (OSPF)

To define the interfaces on which the Open Shortest Path First (OSPF) protocol runs, use the **interface** command in area configuration mode. To disable OSPF routing for interfaces, use the **interface** form of this command.

**interface** *type interface-path-id*

**no interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |

## Command Default

When you do not specify this command in configuration mode, OSPF routing for interfaces is not enabled.

## Command Modes

Area configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **interface** command to associate a specific interface with an area. The interface remains associated with the area even when the IP address of the interface changes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how the OSPF routing process 109 defines four OSPF areas (0, 2, 3, and 10.9.50.0), and associates an interface with each area:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 4/0/0/3
!
RP/0/0/CPU0:router(config-ospf)# area 2
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
!
RP/0/0/CPU0:router(config-ospf)# area 3
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 3/0/0/2
!
RP/0/0/CPU0:router(config-ospf)# area 10.9.50.0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 3/0/0/1
```

# log adjacency changes (OSPF)

To configure the router to send a syslog message when the state of an Open Shortest Path First (OSPF) neighbor changes, use the **log adjacency changes** command in router configuration mode. To turn off this function, use the **disable** keyword. To log all state changes, use the **detail** keyword.

**log adjacency changes** {**detail**|**disable**}

## Syntax Description

|                |                                                                                            |
|----------------|--------------------------------------------------------------------------------------------|
| <b>detail</b>  | Provides all (DOWN, INIT, 2WAY, EXSTART, EXCHANGE, LOADING, FULL) adjacency state changes. |
| <b>disable</b> | Disables sending adjacency change messages.                                                |

## Command Default

The router sends a syslog message when the state of an OSPF neighbor changes.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                                          |
|---------------|---------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                          |
| Release 3.6.0 | The <b>detail</b> and <b>disable</b> keywords were changed from optional to required. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **log adjacency changes** command to display high-level changes to the state of the peer relationship. Configure this command if you want to know about OSPF neighbor changes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the software to send a syslog message for any OSPF neighbor state changes:

```
RP/0/0/CPU0:router# configure
```

```
RP/0/0/CPU0:router(config)# router ospf 109  
RP/0/0/CPU0:router(config-ospf)# log adjacency changes detail
```

# loopback stub-network

To enable advertising loopback as stub networks, use the **loopback stub-network** command in an appropriate configuration mode. To disable advertising loopback as stubnetworks, use the **no** form of this command.

**loopback stub-network** [**enable**| **disable**]

**no loopback stub-network**

## Syntax Description

|                |                                                             |
|----------------|-------------------------------------------------------------|
| <b>enable</b>  | (Optional) Enables advertising loopbacks as stub networks.  |
| <b>disable</b> | (Optional) Disables advertising loopbacks as stub networks. |

## Command Default

By default, OSPF advertises loopbacks as stub hosts.

## Command Modes

OSPF interface configuration  
OSPF router configuration  
OSPF area configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

In the interface submode, the command can be enabled only on loopback interfaces.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to enable advertising loopback as a stub network, under OSPF interface configuration:

```
RP/0/0/CPU0:router(config)#router ospf 100  
RP/0/0/CPU0:router(config-ospf)#loopback stub-network enable
```

**Related Commands**

| <a href="#">show ospf interface</a> , on page 1109 | Displays Open Shortest Path First (OSPF) interface information. |

# max-lsa

To limit the number of nonself-generated link-state advertisements (LSAs) that an Open Shortest Path First (OSPF) routing process can keep in the OSPF link-state database (LSDB), use the **max-lsa** command in router configuration mode. To remove the limit of non self-generated LSAs that an OSPF routing process can keep in the OSPF LSDB, use the **no** form of this command.

**max-lsa** *max* [ *threshold* ] [ **warning-only** ] [ **ignore-time** *value* ] [ **ignore-count** *value* ] [ **reset-time** *value* ]

**no max-lsa** *max* [ *threshold* ] [ **warning-only** ] [ **ignore-time** *value* ] [ **ignore-count** *value* ] [ **reset-time** *value* ]

## Syntax Description

|                                  |                                                                                                                                                                    |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>max</i>                       | Maximum number of nonself-generated LSAs the OSPF process can keep in the OSPF LSDB.                                                                               |
| <i>threshold</i>                 | (Optional) The percentage of the maximum LSA number, as specified by the maximum-number argument, at which a warning message is logged. The default is 75 percent. |
| <b>warning-only</b>              | (Optional) Specifies that only a warning message is sent when the maximum limit for LSAs is exceeded. Disabled by default.                                         |
| <b>ignore-time</b> <i>value</i>  | (Optional) Specifies the time, in minutes, to ignore all neighbors after the maximum limit of LSAs has been exceeded. The default is 5 minutes.                    |
| <b>ignore-count</b> <i>value</i> | (Optional) Specifies the number of times the OSPF process can consecutively be placed into the ignore state. The default is 5 times.                               |
| <b>reset-time</b> <i>value</i>   | (Optional) Specifies the time, in minutes, after which the ignore count is reset to zero. The default is 2 times <b>ignore-time</b> .                              |

## Command Default

Disabled

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command allows you to protect the OSPF routing process from the large number of received LSAs that can result from a misconfiguration on another router in the OSPF domain (for example, the redistribution of a large number of IP prefixes to OSPF).

When this feature is enabled, the router keeps count of the number of all received (nonself-generated) LSAs. When the configured *threshold* value is reached, an error message is logged. When the configured *max* number of received LSAs is exceeded, the router stops accepting new LSAs.

If the count of received LSAs is higher than the configured *max* number after one minute, the OSPF process disables all adjacencies in the given context and clears the OSPF database. This state is called the ignore state. In this state, all OSPF packets received on all interfaces belonging to the OSPF instance are ignored and no OSPF packets are generated on its interfaces. The OSPF process remains in the ignore state for the duration of the configured **ignore-time**. When the **ignore-time** expires, the OSPF process returns to normal operation and starts building adjacencies on all its interfaces.

To prevent the OSPF instance from endlessly oscillating between its normal state and the ignore state, as a result of the LSA count immediately exceeding the *max* number again after it returns from the ignore state, the OSPF instance keeps a count of how many times it has been in the ignore state. This counter is called the **ignore-count**. If the **ignore-count** exceeds its configured value, the OSPF instance remains in the ignore state permanently.

To return the OSPF instance to its normal state, you must issue the **clear ip ospf** command. The **ignore-count** is reset to zero if the LSA count does not exceed the *max* number again during the time configured by the **reset-time** keyword.

If you use the **warning-only** keyword, the OSPF instance never enters the ignore state. When LSA count exceeds the *max* number, the OSPF process logs an error message and the OSPF instance continues in its normal state operation.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the OSPF instance to accept 12000 nonself-generated LSAs in the global routing table, and 1000 nonself-generated LSAs in VRF V1.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 0
RP/0/0/CPU0:router(config-ospf)# max-lsa 12000
RP/0/0/CPU0:router(config-ospf)# vrf V1
RP/0/0/CPU0:router(config-ospf)# max-lsa 1000
```

The following example shows how to display the current status of the OSPF instance:

```
RP/0/0/CPU0:router# show ospf 0

Routing Process "ospf 0" with ID 10.0.0.2
NSR (Non-stop routing) is Disabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
It is an area border router
Maximum number of non self-generated LSA allowed 12000
Current number of non self-generated LSA 1
Threshold for warning message 75%
```

```
Ignore-time 5 minutes, reset-time 10 minutes  
Ignore-count allowed 5, current ignore-count 0
```

**Related Commands**

## max-metric

To configure the Open Shortest Path First (OSPF) protocol to signal other networking devices not to prefer the local router as an intermediate hop in their shortest path first (SPF) calculations, use the **max-metric** command in router configuration mode. To disable this function, use the **no** form of this command.

**max-metric router-lsa** [*external-lsa overriding metric*] [**include-stub**] [**on-proc-migration**] [**on-proc-restart**] [**on-startup**] [**on-switchover**] [**wait-for-bgp**] [**summary-lsa**]

**no max-metric router-lsa**

### Syntax Description

|                                              |                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>router-lsa</b>                            | Always originates router link-state advertisements (LSAs) with the maximum metric.                                                                                                                                                                                                                                                                                                    |
| <b>external-lsa</b> <i>overriding metric</i> | (Optional) Overrides the external-lsa metric with the max-metric value. The <i>overriding metric</i> argument specifies the number of in-summary-LSAs. The range is 1 to 16777215. The default is 16711680.                                                                                                                                                                           |
| <b>include-stub</b>                          | (Optional) Advertises stub links in router-LSA with the max-metric value (0xFFFF).                                                                                                                                                                                                                                                                                                    |
| <b>on-proc-migration</b> <i>time</i>         | (Optional) Sets the maximum metric temporarily after a process migration to originate router-LSAs with the max-metric value. The <i>time</i> range is 5 to 86400 seconds.                                                                                                                                                                                                             |
| <b>on-proc-restart</b> <i>time</i>           | (Optional) Sets the maximum metric temporarily after a process restart to originate router-LSAs with the max-metric value. The <i>time</i> range is 5 to 86400 seconds.                                                                                                                                                                                                               |
| <b>on-startup</b> <i>time</i>                | (Optional) Sets the maximum metric temporarily after a reboot to originate router-LSAs with the max-metric value. The <i>time</i> range is 5 to 86400 seconds.                                                                                                                                                                                                                        |
| <b>on-switchover</b> <i>time</i>             | (Optional) Sets the maximum metric temporarily after a switchover to originate router-LSAs with the max-metric value. The <i>time</i> range is 5 to 86400 seconds.<br><b>Note</b> OSPF will not populate maximum metric on the router's generated LSAs, when the OSPF routing process is configured to support Nonstop Routing (NSR) or Nonstop Forwarding/Graceful restart (NSF/GR). |
| <b>wait-for-bgp</b>                          | (Optional) Causes OSPF to originate router LSAs with the maximum metric and allows Border Gateway Protocol (BGP) to decide when to start originating router LSAs with a normal metric instead of the maximum metric.                                                                                                                                                                  |
| <b>summary-lsa</b>                           | (Optional) specifies the number of in summary-LSAs. The range is 1 to 16777215. The default is 16711680.                                                                                                                                                                                                                                                                              |

### Command Default

Router LSAs are originated with normal link metrics.

*overriding-metric* :16711680

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                                                                     |

| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                                                                                                     |
| Release 3.3.0 | This command was added under the VRF configuration mode.                                                                                                                                                                                                                                                                                                                                                         |
| Release 3.6.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>external-lsa</b></li> <li>• <i>overriding-metric</i></li> <li>• <b>include-stub</b></li> <li>• <b>summary-lsa</b></li> </ul>                                                                                                                                                                                        |
| Release 3.7.0 | Modifications to the following keywords and arguments were made: <ul style="list-style-type: none"> <li>• <b>router-lsa</b></li> <li>• <b>external-lsa</b> <i>overriding metric</i></li> <li>• <b>include-stub</b></li> <li>• <b>on-proc-migration</b> <i>time</i></li> <li>• <b>on-proc-restart</b> <i>time</i></li> <li>• <b>on-startup</b> <i>time</i></li> <li>• <b>on-switchover</b> <i>time</i></li> </ul> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **max-metric** command to cause the software to originate router LSAs with router link metrics set to LSInfinity (0XFFFF). This feature can be useful in Internet backbone routers that run both OSPF and BGP because OSPF converges more quickly than BGP and may begin attracting traffic before BGP has converged, resulting in dropped traffic.

If this command is configured, the router advertises its locally generated router LSAs with a metric of 0XFFFF. This action allows the router to converge but not attract transit traffic if there are better, alternative paths around this router. After the specified *announce-time* value or notification from BGP has expired, the router advertises the local router LSAs with the normal metric (interface cost).

If this command is configured with the **on-startup** keyword, then the maximum metric is temporarily set only after reboot is initiated. If this command is configured without the **on-startup** keyword, then the maximum metric is permanently used until the configuration is removed.

If the **include-stub** keyword is enabled, the stub-links in the router LSA will be sent with the max-metric. If the **summary-lsa** keyword is enabled, all self-generated summary LSAs will have a metric set to 0xFF0000, unless the metric value is specified with the max-metric value parameter. If the **external-lsa** keyword is enabled, all self-generated external LSAs will have a metric set to 0xFF0000, unless the metric value is specified with the max-metric value parameter.

This command might be useful when you want to connect a router to an OSPF network, but do not want real traffic flowing through it if there are better, alternative paths. If there are no alternative paths, this router still accepts transit traffic as before.

Some cases where this command might be useful are as follows:

- During a router reload, you prefer that OSPF wait for BGP to converge before accepting transit traffic. If there are no alternative paths, the router still accepts transit traffic.
- A router is in critical condition (for example, it has a very high CPU load or does not have enough memory to store all LSAs or build the routing table).
- When you want to gracefully introduce or remove a router to or from the network.
- When you have a test router in a lab, connected to a production network.

#### Note

For older OSPF implementations (RFC 1247), router links in received router LSAs with a metric and cost of LSInfinity are not used during SPF calculations. Hence, no transit traffic is set to the routers originating such router LSAs.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

The following example shows how to configure OSPF to originate router LSAs with the maximum metric until BGP indicates that it has converged:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# max-metric router-lsa on-startup wait-for-bgp
```

## maximum interfaces (OSPF)

To limit the number of interfaces that can be configured for an Open Shortest Path First (OSPF) process, use the **maximum interfaces** command in the appropriate mode. To return to the default limit, use the **no** form of this command.

**maximum interfaces** *number-interfaces*

**no maximum interfaces**

### Syntax Description

|                          |                                                 |
|--------------------------|-------------------------------------------------|
| <i>number-interfaces</i> | Number of interfaces. Range is 1 to 4294967295. |
|--------------------------|-------------------------------------------------|

### Command Default

If the command is not specified, the default is 1024.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                     |
| Release 3.3.0 | This command was added under the VRF configuration mode.                                                                                         |
| Release 4.1.1 | The range for number of interfaces was changed to 1 to 4294967295 from 1 to 1024. The default number of interfaces was changed to 1024 from 255. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum interface** command to increase or decrease the limit on the number of interfaces configured for an OSPF process.

You cannot configure a limit lower than the number of interfaces currently configured for the OSPF process. To lower the limit, remove interfaces from the OSPF configuration until the number of configured interfaces is at or below the desired limit. You may then apply the new, lower limit.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

This example shows how to configure a maximum interface limit of 1500 on a router:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# maximum interfaces 1500
```

## Related Commands

| Command                                           | Description                          |
|---------------------------------------------------|--------------------------------------|
| <a href="#">show ospf interface, on page 1109</a> | Displays OSPF interface information. |

## maximum paths (OSPF)

To control the maximum number of parallel routes that the Open Shortest Path First (OSPF) protocol can support, use the **maximum paths** command in an appropriate configuration mode. To remove the **maximum paths** command from the configuration file and restore the system to its default condition with respect to the routing protocol, use the **no** form of this command.

**maximum paths** *maximum-routes-number*

**no maximum paths**

### Syntax Description

|                              |                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------|
| <i>maximum-routes-number</i> | Maximum number of parallel routes that OSPF can install in a routing table. Range is 1 to 32. |
| <b>Note</b>                  | The maximum number of paths that can be configured is 16.                                     |

### Command Default

16 paths

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the maximum number of parallel routes is reduced, all existing paths are pruned and paths reinstalled at the new maximum number. During this route-reduction period, you may experience some packet loss for a few seconds. This may impact route traffic.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to allow a maximum of two paths to a destination:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# maximum paths 2
```

## maximum redistributed-prefixes (OSPF)

To limit the aggregate number of prefixes that can be redistributed into an Open Shortest Path First (OSPF) process, use the **maximum redistributed-prefix** command in the appropriate mode. To return to the default limit, use the **no** form of this command.

**maximum redistributed-prefixes** *maximum* [ *threshold-value* ] [**warning-only**]

**no maximum redistributed-prefixes**

### Syntax Description

|                        |                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------|
| <i>maximum</i>         | Number of routes. Range is 1 to 4294967295.                                                             |
| <i>threshold-value</i> | (Optional) Threshold value (as a percentage) at which to generate a warning message. Range is 1 to 100. |
| <b>warning-only</b>    | (Optional) Gives only a warning when the limit is exceeded.                                             |

### Command Default

If the command is not specified, the default is 10000.

The threshold value defaults to 75 percent.

### Command Modes

Router configuration

VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum redistributed-prefixes** command to increase or decrease the maximum number of prefixes (also referred to as routes) redistributed for an OSPF process.

If the *maximum* value is less than the existing number of routes, existing routes remain configured, but no new routes are redistributed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure a maximum number of routes that can be redistributed for an OSPF routing process:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# maximum redistributed-prefixes 15000
```

**Related Commands**

|-----------------------------------------------------------------|-----------------------------------|
| <a href="#">show ospf routes</a> , <a href="#">on page 1135</a> | Displays the OSPF topology table. |

# message-digest-key

To specify a key used with Open Shortest Path First (OSPF) Message Digest 5 (MD5) authentication, use the **message-digest-key** command in the appropriate mode. To remove an old MD5 key, use the **no** form of this command.

**message-digest-key** *key-id* **md5** {*key*| **clear** *key*| **encrypted** *key*}  
**no message-digest-key** *key-id*

## Syntax Description

|                  |                                                                |
|------------------|----------------------------------------------------------------|
| <i>key-id</i>    | Key number. Range is 1 to 255.                                 |
| <b>md5</b>       | Enables OSPF MD5 authentication.                               |
| <i>key</i>       | Alphanumeric string of up to 16 characters.                    |
| <b>clear</b>     | Specifies that the key be clear text.                          |
| <b>encrypted</b> | Specifies that the key be encrypted using a two-way algorithm. |

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the message digest key parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the message digest key parameter specified for the process.

If this command is not specified at any level, then OSPF MD5 authentication is disabled.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
Virtual-link configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

|---------------|---------------------------------------------------------------------------|
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | This command was added under sham-link configuration mode.                |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Usually, one key individual interface is used to generate authentication information when packets are sent and to authenticate incoming packets. The same key identifier on the neighbor router must have the same *key* value.

For authentication to be enabled, you must configure the **message-digest-key** command together with the **authentication** command and its **message-digest** keyword. Both the **message-digest-key** and **authentication** commands can be inherited from a higher configuration level.

The process of changing keys is as follows. Suppose the current configuration is:

```
interface GigabitEthernet 0/3/0/2
 message-digest-key 100 md5 OLD
```

You change the configuration to the following:

```
interface GigabitEthernet 0/3/0/2
 message-digest-key 101 md5 NEW
```

The system assumes its neighbors do not have the new key yet, so it begins a rollover process. It sends multiple copies of the same packet, each authenticated by different keys. In this example, the system sends out two copies of the same packet—the first one authenticated by key 100 and the second one authenticated by key 101.

Rollover allows neighboring routers to continue communication while the network administrator is updating them with the new key. Rollover stops after the local system finds that all its neighbors know the new key. The system detects that a neighbor has the new key when it receives packets from the neighbor authenticated by the new key.

After all neighbors have been updated with the new key, the old key should be removed. In this example, you would enter the following:

```
interface ethernet 1
 no ospf message-digest-key 100
```

Then, only key 101 is used for authentication on interface 1.

We recommend that you not keep more than one key individual interface. Every time you add a new key, you should remove the old key to prevent the local system from continuing to communicate with a hostile system that knows the old key. Removing the old key also reduces overhead during rollover.

**Note**

The MD5 key is always stored in encrypted format on the router. The **clear** and **encrypted** keywords inform the router whether the value that is entered is encrypted or unencrypted.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set a new key 19 with the password *8ry4222* :

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# area 0

RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# message-digest-key 19 md5 8ry4222
```

**Related Commands**

# mpls ldp auto-config (OSPF)

To enable Label Distribution Protocol (LDP)-Interior Gateway Protocol (IGP) interface automatic configuration, use the **mpls ldp auto-config** command in the appropriate mode. To disable LDP-IGP interface automatic configuration, use the **no** form of this command.

**mpls ldp auto-config**

**no mpls ldp auto-config**

**Command Default** LDP-IGP interface automatic configuration is disabled for OSPF.

**Command Modes**

- Interface configuration
- Area configuration
- Router configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.6.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples**

The following example shows how to enable LDP-IGP interface automatic configuration:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 01
RP/0/0/CPU0:router(config-ospf)# mpls ldp auto-config
```

## mpls ldp sync (OSPF)

To enable Label Distribution Protocol (LDP)-Interior Gateway Protocol (IGP) synchronization, use the **mpls ldp sync** command in the appropriate mode. To disable LDP-IGP synchronization, use the **no** form of this command.

**mpls ldp sync [disable]**

**no mpls ldp sync**

### Syntax Description

|                |                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Disables MPLS LDP synchronization from within the OSPF interface and area configuration submodes only. For the OSPF router configuration mode, use the <b>no</b> form of the command. |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

LDP-IGP synchronization is disabled for OSPF.

### Command Modes

Interface configuration

Area configuration

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to enable LDP-IGP synchronization:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 01
RP/0/0/CPU0:router(config-ospf)# mpls ldp sync
```

## mpls ldp sync-igp-shortcuts

To configure and enable Label Distribution Protocol- Interior Gateway Protocol (LDP-IGP) synchronization on Multiprotocol Label Switching (MPLS) shortcuts (auto-route announced tunnels) only, use the **mpls ldp sync-igp-shortcuts** command in the appropriate OSPF configuration mode. To disable the use of LDP-IGP synchronization on MPLS shortcuts, use the **no** form of this command.

**mpls ldp sync-igp-shortcuts [disable]**

**no mpls ldp sync-igp-shortcuts**

### Syntax Description

|                |                                                                                                                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Disables MPLS LDP synchronization with IGP shortcuts from within the OSPF interface and area configuration submodes only. For the OSPF router configuration mode, use the <b>no</b> form of the command. |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

LDP-IGP synchronization is disabled on MPLS tunnels.

### Command Modes

OSPF interface configuration  
OSPF router configuration  
OSPF area configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.4 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When **mpls ldp sync-igp-shortcuts** is configured at a higher mode (area or instance level), you can selectively disable LDP-IGP synchronization on specific interfaces or areas by using the **disable** form of the command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to enable LDP-IGP synchronization shortcuts under OSPF interface configuration, using the **mpls ldp sync-igp-shortcuts** command on a tunnel-te interface. However, the command applies to all interfaces under the applicable configuration mode.

```
RP/0/0/CPU0:router(config)# router ospf 100
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface tunnel-te 1
RP/0/0/CPU0:router(config-ospf-ar-if)# mpls ldp sync-igp-shortcuts
```

When **mpls ldp sync-igp-shortcuts** is configured at a higher mode (area or instance level), you can selectively disable LDP-IGP synchronization on specific interfaces or areas by using the **disable** form of the command.

The following example shows how to enable the use of LDP-IGP synchronization across all interfaces in all areas except area 10:

```
RP/0/0/CPU0:router(config)# router ospf foo
RP/0/0/CPU0:router(config-ospf)# mpls ldp sync-igp-shortcuts
RP/0/0/CPU0:router(config-ospf)# area 10
RP/0/0/CPU0:router(config-ospf-ar)# mpls ldp sync-igp-shortcuts disable
```

## Related Commands

| Command                                            | Description                                                                                |
|----------------------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">mpls ldp sync (OSPF), on page 1019</a> | Enables Label Distribution Protocol (LDP)-Interior Gateway Protocol (IGP) synchronization. |

## mpls traffic-eng (OSPF)

To configure an Open Shortest Path First (OSPF) area for Multiprotocol Label Switching traffic engineering (MPLS TE), use the **mpls traffic-eng** command in the appropriate configuration mode. To remove the MPLS TE from an area, use the **no** form of this command.

**mpls traffic-eng**

**no mpls traffic-eng**

### Syntax Description

This command has no keywords or arguments.

### Command Default

MPLS TE is not configured for OSPF.

### Command Modes

Area configuration

VRF configuration

### Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced                                    |
| Release 3.3.0 | This command was added under the VRF configuration mode.       |
| Release 3.4.0 | The <b>area area-id</b> keyword and argument pair was removed. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must configure the **mpls traffic-eng** command for OSPF to support MPLS traffic engineering. OSPF provides the flooding mechanism that is used to flood TE link information.

#### Note

This command is supported only in the default VRF mode.

We recommend that you configure the **mpls traffic-eng router-id** command instead of using the **router-id** command in global configuration mode.

OSPF support for MPLS TE is a component of the overall MPLS TE feature. Other MPLS TE software components must also be configured for this feature to be fully supported.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to associate loopback interface 0 with area 0, and area 0 is declared to be an MPLS area:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# router-id 10.10.10.10
RP/0/0/CPU0:router(config-ospf)# mpls traffic-eng router-id loopback 0
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf)# mpls traffic-eng
RP/0/0/CPU0:router(config-ospf-ar)# interface loopback 0
```

**Related Commands**

| Command                                                                | Description                                                                                                                |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">capability opaque disable, on page 942</a>                 | Controls the OSPF opaque LSA support capability.                                                                           |
| <a href="#">mpls traffic-eng multicast-intact (OSPF), on page 1026</a> | Specifies that the traffic engineering router identifier for the node is the IP address associated with a given interface. |
| <a href="#">router-id (OSPF), on page 1079</a>                         | Configures a router ID for the OSPF process.                                                                               |

# mpls traffic-eng igp-intact (OSPF)

To ensure that the OSPF protocol installs at least one IPv4 next-hop when it adds the tunnel next-hops (igp-shortcuts), use the **mpls traffic-eng igp-intact** command in the router configuration mode. To disable IGP-intact, use the **no** form of this command.

**mpls traffic-eng igp-intact**

**no mpls traffic-eng igp-intact**

## Command Default

IGP-intact is disabled.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The OSPF protocol adds both tunnel next-hops (igp-shortcuts) and IPv4 next-hops to the next-hop list in the Routing Information Base (RIB), until it reaches the maximum number of paths. When IGP-intact is enabled, it ensures that the Routing Information Base (RIB) always has at least one IPv4 next-hop present in the list of next-hops when the number of paths is at maximum.

### Note

IGP-intact should be used only when Policy-Based Tunnel Selection (PBTS) is in use.

Configure IGP-intact only when Policy-Based Tunnel Selection (PBTS) is in use. This ensures that at least one IPv4 next-hop is available for the default Differentiated Services Code Point (DSCP) traffic class. It also prevents traffic loss for other DSCP traffic classes by diverting such traffic to an IPv4 next-hop when the corresponding tunnel is unavailable for forwarding.

When Policy-Based Tunnel Selection (PBTS) is in use, traffic that is not policy-based is forwarded to an IGP path that may not have fast reroute (FRR) protection. Configuring IGP-intact when PBTS is not in use, causes traffic to be forwarded indiscriminately to an IGP path that may not have FRR protection.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to enable IGP-intact:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# mpls traffic-eng igp-intact
```

| <a href="#">maximum paths (OSPF), on page 1011</a> | Configures the maximum number of parallel routes that the Open Shortest Path First (OSPF) protocol can support. |

# **mpls traffic-eng multicast-intact (OSPF)**

To enable multicast-intact for Open Shortest Path First (OSPF) routes so that multicast-intact paths are published to the Routing Information Base (RIB), use the **mpls traffic-eng multicast-intact** command in the appropriate configuration mode. To remove the MPLS TE area, use the **no** form of this command.

**mpls traffic-eng multicast-intact**

**no mpls traffic-eng multicast-intact**

**Syntax Description** This command has no keywords or arguments.

**Command Default** MPLS TE is not configured for OSPF.

**Command Modes** Router configuration  
VRF configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF support for MPLS TE is a component of the overall MPLS TE feature. Other MPLS TE software components must also be configured for this feature to be fully supported.

**Note**

This command is supported only in the default VRF mode.

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples** The following example shows how to enable publishing of multicast-intact paths to RIB:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
```

```
RP/0/0/CPU0:router(config-ospf)# mpls traffic-eng multicast-intact
```

## mpls traffic-eng router-id (OSPF)

To specify that the traffic engineering router identifier for the node is the IP address associated with a given Open Shortest Path First (OSPF) interface, use the **mpls traffic-eng router-id** command in the appropriate configuration mode. To disable this feature, use the **no** form of this command.

**mpls traffic-eng router-id** {*router-id*| *type interface-path-id*}

**no mpls traffic-eng router-id** {*router-id*| *type interface-path-id*}

### Syntax Description

|                          |                                                                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>router-id</i>         | The 32-bit router ID value specified in four-part, dotted-decimal notation (must be in the valid IP address range of 0.0.0.0 to 255.255.255.255).                                                                                                                       |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                   |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br>Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark (?) online help function. |

### Command Default

If this command is specified in router configuration mode, then the traffic engineering router identifier for the node is the IP address associated with a given interface.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This identifier of the router acts as a stable IP address for the traffic engineering configuration. This IP address is flooded to all nodes. For all traffic engineering tunnels originating at other nodes and ending at this node, you must set the tunnel destination to the traffic engineering router identifier of the destination node, because that is the address that the traffic engineering topology database at the tunnel head uses for its path calculation.

**Note**

We recommend that loopback interfaces be used for Multiprotocol Label Switching traffic engineering (MPLS TE), because they are more stable than physical interfaces.

**Note**

This command is supported only in the default VRF mode.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to specify the traffic engineering router identifier as the IP address associated with loopback interface 0:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# mpls traffic-eng router-id loopback 0
```

**Related Commands**

| Command                                               | Description                          |
|-------------------------------------------------------|--------------------------------------|
| <a href="#">mpls traffic-eng (OSPF), on page 1022</a> | Configures an OSPF area for MPLS TE. |

## mtu-ignore (OSPF)

To prevent Open Shortest Path First (OSPF) from checking whether neighbors are using the same maximum transmission unit (MTU) on a common interface when exchanging database descriptor (DBD) packets, use the **mtu-ignore** command in the appropriate mode. To reset to default, use the **no** form of this command.

**mtu-ignore** [**disable**| **enable**]

**no mtu-ignore**

### Syntax Description

|                |                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Enables checking for whether OSPF neighbors are using the MTU on a common interface.  |
| <b>enable</b>  | (Optional) Disables checking for whether OSPF neighbors are using the MTU on a common interface. |

### Command Default

The default is **mtu-ignore** with no keywords, which disables MTU checking.

If this command is not specified in interface configuration mode, then the interface adopts the MTU ignore parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the MTU ignore parameter specified for the process.

If this command is not specified at any level, then OSPF checks the MTU received from neighbors when exchanging DBD packets.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration  
Multi-area configuration

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF checks whether OSPF neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the MTU configured on the incoming interface, OSPF adjacency is not established.

The keywords, **disable** and **enable**, do not need to be used. If no keywords are used, the **mtu-ignore** command disables MTU checking. You can then use the **no mtu-ignore** command to activate MTU checking.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to disable MTU mismatch detection on receiving DBD packets:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# mtu-ignore
```

# multi-area-interface

To enable multiple adjacencies for different Open Shortest Path First (OSPF) areas and enter multi-area interface configuration mode, use the **multi-area-interface** command in the area configuration mode. To reset to the default, use the **no** form of this command.

**multi-area-interface** *type interface-path-id*

**no multi-area-interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |

## Command Default

An OSPF network is enabled for one area only.

## Command Modes

Area configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **multi-area-interface** command to enable area border routers (ABRs) to establish multiple adjacencies for different OSPF areas.

Each multiple area adjacency is announced as a point-to-point unnumbered link in the configured area. This point-to-point link provides a topological path for that area. The first or primary adjacency using the link advertises the link consistent with draft-ietf-ospf-multi-area-adj-06.txt.

You can configure multi-area adjacency on any interface where only two OSPF speakers are attached. In the case of native broadcast networks, the interface must be configured as an OSPF point-to-point type using the **network point-to-point** command to enable the interface for a multi-area adjacency.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to enable multiple area adjacency for OSPF 109:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# area 1
RP/0/0/CPU0:router(config-ospf-ar)# multi-area-interface GigabitEthernet 0/1/0/3
RP/0/0/CPU0:router(config-ospf-ar-mif) # ?

authentication          Enable authentication
authentication-key      Authentication password (key)
commit                 Commit the configuration changes to running
cost                   Interface cost
database-filter         Filter OSPF LSA during synchronization and flooding
dead-interval          Interval after which a neighbor is declared dead
describe               Describe a command without taking real actions
distribute-list        Filter networks in routing updates
do                     Run an exec command
exit                   Exit from this submode
hello-interval         Time between HELLO packets
message-digest-key     Message digest authentication password (key)
mtu-ignore             Enable/Disable ignoring of MTU in DBD packets
no                     Negate a command or set its defaults

## neighbor (OSPF)

To configure Open Shortest Path First (OSPF) routers interconnecting to nonbroadcast networks, use the **neighbor** command in interface configuration mode. To remove a configuration, use the **no** form of this command.

**neighbor** *ip-address* [**cost** *number*] [**priority** *number*] [**poll-interval** *seconds*]

**no neighbor** *ip-address* [**cost** *number*] [**priority** *number*] [**poll-interval** *seconds*]

### Syntax Description

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>                   | Interface IP address of the neighbor.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>cost</b> <i>number</i>           | (Optional) Assigns a cost to the neighbor, in the form of an integer from 1 to 65535. Neighbors with no specific cost configured assume the cost of the interface, based on the <b>cost</b> command. On point-to-multipoint interfaces, <b>cost</b> <i>number</i> is the only keyword and argument combination that works. The <b>cost</b> keyword does not apply to nonbroadcast multiaccess (NBMA) networks. |
| <b>priority</b> <i>number</i>       | (Optional) Specifies an 8-bit number indicating the router priority value of the nonbroadcast neighbor associated with the IP address specified. The <b>priority</b> keyword does not apply to point-to-multipoint interfaces.                                                                                                                                                                                 |
| <b>poll-interval</b> <i>seconds</i> | (Optional) Specifies an unsigned integer value (in seconds) reflecting the poll interval. RFC 1247 recommends that this value be much larger than the hello interval. The <b>poll-interval</b> keyword does not apply to point-to-multipoint interfaces.                                                                                                                                                       |

### Command Default

No configuration is specified.

**priority** *number* : 0

**poll-interval** *seconds* : 120 seconds (2 minutes)

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must include one neighbor entry in the software configuration for each known nonbroadcast network neighbor. The neighbor address must be on the primary address of the interface.

If a neighboring router has become inactive (hello packets have not been received for the router dead interval period), it may still be necessary to send hello packets to the dead neighbor. These hello packets are sent at a reduced rate called the *poll interval*.

When the router starts up, it sends only hello packets to those routers with nonzero priority; that is, routers that are eligible to become designated routers (DRs) and backup designated routers (BDRs). After the DR and BDR are selected, the DR and BDR start sending hello packets to all neighbors to form adjacencies.

To filter all outgoing OSPF link-state advertisement (LSA) packets for the neighbor, use the **neighbor database-filter all out** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to declare a router at address 172.16.3.4 on a nonbroadcast network, with a priority of 1 and a poll interval of 180 seconds:

```
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.4 priority 1 poll-interval 180
```

The following example illustrates a network with nonbroadcast:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface GigabitEthernet1/0/0/3
RP/0/0/CPU0:router(config-if)# ip address 172.16.3.10 255.255.255.0

RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet1/0/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# network nonbroadcast
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.4 priority 1 poll-interval 180
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.5 cost 10 priority 1 poll-interval 180
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.6 cost 15 priority 1 poll-interval 180
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.7 priority 1 poll-interval 180
```

## Related Commands

# neighbor database-filter all out

To filter all outgoing link-state advertisements (LSAs) to an Open Shortest Path First (OSPF) neighbor, use the **neighbor database-filter all out** command in interface configuration mode. To restore the forwarding of LSAs to the neighbor, use the **no** form of this command.

**neighbor** *ip-address* **database-filter all out**

**no neighbor** *ip-address* **database-filter all out**

## Syntax Description

|                   |                                                                |
|-------------------|----------------------------------------------------------------|
| <i>ip-address</i> | IP address of the neighbor to which outgoing LSAs are blocked. |
|-------------------|----------------------------------------------------------------|

## Command Default

Instead of all outgoing LSAs being filtered to the neighbor, they are flooded to the neighbor.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **neighbor database-filter all out** command to filter all outgoing OSPF LSA packets during synchronization and flooding for point-to-multipoint neighbors on nonbroadcast networks. More neighbor options are available with the **neighbor** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to prevent flooding of OSPF LSAs from point-to-multipoint networks to the neighbor at IP address 10.2.3.4:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet1/0/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 10.2.3.4 database-filter all out
```

**Related Commands**

| Command                                       | Description                                                       |

| <a href="#">neighbor (OSPF), on page 1034</a> | Configures OSPF routers interconnecting to nonbroadcast networks. |

## network (OSPF)

To configure the Open Shortest Path First (OSPF) network type to a type other than the default for a given medium, use the **network** command in the appropriate mode. To return to the default value, use the **no** form of this command.

**network** {**broadcast**| **non-broadcast**| {**point-to-multipoint** [**non-broadcast**]| **point-to-point**}}  
**no network**

### Syntax Description

|                            |                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>broadcast</b>           | Sets the network type to broadcast.                                                                                                   |
| <b>non-broadcast</b>       | Sets the network type to nonbroadcast multiaccess (NBMA).                                                                             |
| <b>point-to-multipoint</b> | Sets the network type to point-to-multipoint.                                                                                         |
| <b>non-broadcast</b>       | (Optional) Sets the point-to-multipoint network to be nonbroadcast. If you use this keyword, the <b>neighbor</b> command is required. |
| <b>point-to-point</b>      | Sets the network type to point-to-point.                                                                                              |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the network parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the network parameter specified for the process.

If this command is not specified at any level, then the OSPF network type is the default of the given medium. POS interfaces default to point-to-point and GigabitEthernet and TenGigEthernet interfaces default to broadcast.

### Command Modes

Interface configuration  
 Area configuration  
 Router configuration  
 VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced                              |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **network** command to configure broadcast networks as NBMA networks when, for example, routers in your network do not support multicast addressing.

Configuring NBMA networks as either broadcast or nonbroadcast assumes that there are virtual circuits from every router to every router or fully meshed network. However, there are other configurations where this assumption is not true; for example, a partially meshed network. In these cases, you can configure the OSPF network type as a point-to-multipoint network. Routing between two routers that are not directly connected go through the router that has virtual circuits to both routers. You need not configure neighbors when using this command.

If this command is issued on an interface that does not allow it, this command is ignored.

OSPF has two features related to point-to-multipoint networks. One feature applies to broadcast networks; the other feature applies to nonbroadcast networks:

- On point-to-multipoint, broadcast networks, you can use the **neighbor** command, and you must specify a cost to that neighbor.
- On point-to-multipoint, nonbroadcast networks, you must use the **neighbor** command to identify neighbors. Assigning a cost to a neighbor is optional.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure the OSPF network as a nonbroadcast network:

```
RP/0/RP0/CPU0:router# configure
RP/0/RP0/CPU0:router(config)# router ospf 1
RP/0/RP0/CPU0:router(config-ospf)# area 0
RP/0/RP0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/3
RP/0/RP0/CPU0:router(config-ospf-ar-if)# network non-broadcast
RP/0/RP0/CPU0:router(config-ospf-ar-if)# neighbor 172.16.3.4 priority 1 poll-interval 180
```

**Related Commands**

| <a href="#">neighbor (OSPF), on page 1034</a> | Configures OSPF routers interconnecting to nonbroadcast networks. |

## nsf (OSPF)

To configure nonstop forwarding (NSF) for the Open Shortest Path First (OSPF) protocol, use the **nsf** command in the appropriate mode. To remove this command from the configuration file and restore the system to its default condition, use the **no nsf** form of this command.

**nsf** {**cisco** [**enforce global**]| **ietf** [**helper disable**]}

**no nsf** {**cisco** [**enforce global**]| **ietf** [**helper disable**]}

### Syntax Description

|                       |                                                                                    |
|-----------------------|------------------------------------------------------------------------------------|
| <b>cisco</b>          | Enables Cisco Nonstop Forwarding.                                                  |
| <b>enforce global</b> | (Optional) Cancels NSF restart when non-NSF network device neighbors are detected. |
| <b>ietf</b>           | Enables Internet Engineering Task Force (IETF) graceful restart.                   |
| <b>helper disable</b> | (Optional) Disables router helper support.                                         |

### Command Default

NSF is disabled.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The NSF feature allows for the forwarding of data packets to continue along known routes while routing protocol information (such as OSPF) is being restored following a switchover.

Use the **nsf** command if the router is expected to perform NSF during restart. To experience the full benefits of this feature, configure all neighboring routers with NSF.

When this command is used without the optional **cisco enforce global** keywords and non-NSF neighbors are detected, the NSF restart mechanism aborts on the interfaces of those neighbors and functions properly on others.

When this command is used with the optional **cisco enforce global** keywords and non-NSF neighbors are detected, NSF restart is canceled for the entire OSPF process.

IETF graceful restart provides an NSF mechanism to allow data traffic to flow seamlessly with no packet drops during the transient period when OSPF attempts to recover after a process restart or RP failover, within the guidelines of RFC 3623.

By default, neighbors in helper mode listen to both the NSF Cisco- and NSF IETF-type LSAs. The **nsf** command enables one type of mechanism that would undergo an RP failover or, anticipating an OSPF process restart. If the **cisco** or **ietf** keyword is not entered, NSF is not enabled, irrespective of neighbors in listening mode for both NSF Cisco and NSF IETF.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

The following example shows how to cancel NSF restart for the entire OSPF process if non-NSF neighbors are detected on any network interface during restart:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# nsf cisco enforce global
```

## nsf flush-delay-time (OSPF)

To configure the maximum time allowed for nonstop forwarding (NSF) external route queries for the Open Shortest Path First (OSPF) protocol, use the **nsf flush-delay-time** command in the appropriate mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsf flush-delay-time** *seconds*

**no nsf flush-delay-time** *seconds*

### Syntax Description

|                |                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Length of time (in seconds) allowed for NSF external route queries. Range is 1 to 3600 seconds. |
|----------------|-------------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 300

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to configure the maximum time for NSF to learn external routes for OSPF at 60 seconds:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# nsf flush-delay-time 60
```

## nsf interval (OSPF)

To configure the minimum time between consecutive nonstop forwarding (NSF) restart attempts for the Open Shortest Path First (OSPF) protocol, use the **nsf interval** command in the appropriate mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsf interval** *seconds*

**no nsf interval** *seconds*

### Syntax Description

|                |                                                                                                |
|----------------|------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Length of time (in seconds) between consecutive restart attempts. Range is 90 to 3600 seconds. |
|----------------|------------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 90

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.6.0 | Minimum number for the <i>seconds</i> argument was changed from 95 to 90. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When you use the **nsf interval** command, the OSPF process must be up for at least 90 seconds before OSPF attempts to perform an NSF restart.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the minimum time between consecutive NSF restart attempts at 120 seconds:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# nsf interval 120
```

## nsf lifetime (OSPF)

To configure the maximum time that routes are held in the Routing Information Base (RIB) following an Open Shortest Path First (OSPF) process restart, use the **nsf lifetime** command in the appropriate mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsf lifetime** *seconds*

**no nsf lifetime** *seconds*

### Syntax Description

|                |                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------|
| <i>seconds</i> | The length of time (in seconds) that routes are held in the RIB. Range is 90 to 3600 seconds. |
|----------------|-----------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 95

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced                              |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When you use this command, the OSPF process must reconverge within the maximum length of time configured. If the convergence exceeds this length of time, routes are purged from RIB and nonstop forwarding (NSF) restart may fail.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the maximum lifetime for OSPF NSF at 120 seconds:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# router ospf 1  
RP/0/0/CPU0:router(config-ospf)# nsf lifetime 120
```

## nsr (OSPF)

To configure nonstop routing (NSR) for the Open Shortest Path First (OSPF) protocol, use the **nsr** command in OSPF router configuration mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsr**

**no nsr**

**Command Default** NSR is not defined.

**Command Modes** Router configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.6.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The NSR feature allows an OSPF process on the active RP to synchronize all necessary data and states with the OSPF process on the standby RP. When the switchover happens, the OSPF process on the newly active RP has all the necessary data and states to continue running and does not require any help from its neighbors.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** The following example shows how to configure NSR:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# nsr
```

## nssa (OSPF)

To configure an area as a not-so-stubby area (NSSA), use the **nssa** command in area configuration mode. To remove the NSSA distinction from the area, use the **no** form of this command.

**nssa** [**no-redistribution**] [**default-information-originate** [**metric** *metric-value*] [**metric-type** *type-value*]] [**no-summary**]

**no nssa**

### Syntax Description

|                                      |                                                                                                                                                                                                                         |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>no-redistribution</b>             | (Optional) Imports routes only into the normal areas, but not into the NSSA area, by the <b>redistribute</b> command when the router is an NSSA Area Border Router (ABR).                                               |
| <b>default-information-originate</b> | (Optional) Generates a Type 7 default into the NSSA area. This keyword takes effect only on an NSSA ABR or NSSA Autonomous System Boundary Router (ASBR).                                                               |
| <b>metric</b> <i>metric-value</i>    | (Optional) Specifies the metric used for generating the default route. If you omit a value and do not specify a value using the <b>defaultmetric</b> command, the default metric value is 10. Range is 1 to 16777214.   |
| <b>metric-type</b> <i>type-value</i> | (Optional) Specifies the external link type associated with the default route advertised into the OSPF routing domain. It can be one of the following values:<br><br>1—Type 1 external route<br>2—Type 2 external route |
| <b>no-summary</b>                    | (Optional) Prevents an ABR from sending summary link advertisements into the NSSA.                                                                                                                                      |

### Command Default

No NSSA area is defined.

### Command Modes

Area configuration

### Command History

| Release       | Modification                                         |
|---------------|------------------------------------------------------|
| Release 3.2   | This command was introduced.                         |
| Release 3.3.0 | Added <b>metric</b> and <b>metric-type</b> keywords. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An NSSA does not flood Type 5 external LSAs from the core into the area, but can import autonomous system external routes in a limited fashion within the area.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure area 1 as an NSSA area:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 1
RP/0/0/CPU0:router(config-ospf-ar)# nssa
```

# ospf name-lookup

To configure the Open Shortest Path First (OSPF) protocol to look up Domain Name System (DNS) names, use the **ospf name-lookup** command in global configuration mode. To disable this function, use the **no** form of this command.

**ospf name-lookup**

**no ospf name-lookup**

**Command Default** Routers are displayed by router ID or neighbor ID.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **ospf name-lookup** command to easily identify a router when executing all OSPF **show** command displays. The router is displayed by name rather than by its router ID or neighbor ID.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** The following example shows how to configure OSPF to identify a router by name:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# ospf name-lookup
```

## packet-size (OSPF)

To configure the size of Open Shortest Path First (OSPF) packets up to the size specified by the maximum transmission unit (MTU), use the **packet-size** command in the appropriate configuration mode. To disable this function and reestablish the default packet size, use the **no** form of this command.

**packet-size** *bytes*

**no packet-size**

### Syntax Description

*bytes*

Size, in bytes. Range is 576 to 10000 bytes.

### Command Default

If the command is not specified, the default packet size is either the interface IP MTU size (if that is lower than 9000 bytes) or 9000 bytes.

### Command Modes

Router configuration  
Area configuration  
Interface configuration  
VRF configuration  
Multi-area configuration

### Command History

| Release       | Modification                                                                               |
|---------------|--------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                               |
| Release 3.3.0 | This command was added under the VRF configuration mode.                                   |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode.                  |
| Release 3.9.0 | The default packet size was changed to minimum of the interface IP MTU size or 9000 bytes. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **packet-size** command to customize the size of OSPF packets. The OSPF protocol compares the packet size and the MTU size and uses the lower packet size value.

If the command is not configured, the default packet size is equal to the interface IP MTU size (if that is lower than 9000 bytes) or 9000 bytes. For example, if the interface IP MTU size is 1500 bytes, OSPF uses packet size of 1500 bytes on the interface because the byte size is lower than 9000 bytes. If the interface IP MTU size is 9500 bytes, OSPF uses packet size of 9000 bytes on the interface because the byte size exceeds 9000 bytes. The interface IP MTU size depends on the interface and the platform. In most cases, the default interface IP MTU value will be lower than 9000 bytes.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure the packet size on an interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 1/0/0/2
RP/0/0/CPU0:router(config-ospf-ar-if)# packet-size 3500
```

## passive (OSPF)

To suppress the sending of Open Shortest Path First (OSPF) protocol operation on an interface, use the **passive** command in the appropriate mode. To remove the passive configuration, use the **no** form of this command.

**passive** [**disable**| **enable**]

**no passive**

### Syntax Description

|                |                                           |
|----------------|-------------------------------------------|
| <b>disable</b> | (Optional) Sends OSPF updates.            |
| <b>enable</b>  | (Optional) Disables sending OSPF updates. |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the passive parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the passive parameter specified for the process.

If this command is not specified at any level, then the passive parameter is disabled and OSPF updates are sent on the interface.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |
| Release 3.6.0 | The <b>enable</b> keyword was added.                     |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF routing information is neither sent nor received through the specified interface. The interface appears as a stub network in the OSPF router (Type 1) link-state advertisement (LSA).

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows that GigabitEthernet interface 1/0/0/2 reduces OSPF updates because passive mode is enabled; however, GigabitEthernet interface 0/1/0/3 receives normal OSPF traffic flow:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet1/0/0/2
RP/0/0/CPU0:router(config-ospf-ar-if)# passive
RP/0/0/CPU0:router(config-ospf-ar-if)# exit
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet1/0/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# end
```

# priority (OSPF)

To set the router priority for an interface, which helps determine the designated router for an Open Shortest Path First (OSPF) link, use the **priority** command in the appropriate mode. To return to the default value, use the **no** form of this command.

**priority** *value*

**no priority** *value*

## Syntax Description

|              |                                                                                 |
|--------------|---------------------------------------------------------------------------------|
| <i>value</i> | 8-bit unsigned integer indicating the router priority value. Range is 0 to 255. |
|--------------|---------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the priority parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the priority parameter specified for the process.

If this command is not specified at any level, then the default priority is 1.

## Command Modes

Interface configuration  
Area configuration  
Router configuration  
VRF configuration

## Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When two routers attached to a network both attempt to become the designated router, the one with the higher router priority takes precedence. If there is a tie, the router with the higher router ID takes precedence. A router with a router priority set to zero is ineligible to become the designated router or backup designated router. Router priority is configured only for interfaces to multiaccess networks (in other words, not point-to-point networks).

This priority value is used when you configure the Open Shortest Path First (OSPF) protocol for nonbroadcast networks using the **neighbor** command for OSPF.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows that priority is set through the **priority** and **neighbor** commands for Routers A and B and that the neighbor priority value must reflect that of the neighbor router:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-if)# ipv4 address 10.0.0.2 255.255.255.0
RP/0/0/CPU0:router(config-if)# exit
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# network non-broadcast
RP/0/0/CPU0:router(config-ospf-ar-if)# priority 4
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 10.0.0.1 priority 6

RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface GigabitEthernet POS 0/2/0/1
RP/0/0/CPU0:router(config-if)# ipv4 address 10.0.0.1 255.255.255.0
RP/0/0/CPU0:router(config-if)# exit
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# network non-broadcast
RP/0/0/CPU0:router(config-ospf-ar-if)# priority 6
RP/0/0/CPU0:router(config-ospf-ar-if)# neighbor 10.0.0.2 priority 4
```

## Related Commands

| Command                                       | Description                                                                           |
|-----------------------------------------------|---------------------------------------------------------------------------------------|
| <a href="#">neighbor (OSPF), on page 1034</a> | Configures OSPF routers interconnecting to nonbroadcast networks.                     |
| <a href="#">network (OSPF), on page 1038</a>  | Configures the OSPF network type to a type other than the default for a given medium. |

# protocol shutdown

To disable an instance of the Open Shortest Path First (OSPF) protocol so that it cannot form an adjacency on any interface, use the **protocol shutdown** command in the router configuration mode. To reenable the OSPF protocol, use the **no** form of this command.

**protocol shutdown**

**no protocol shutdown**

**Command Default** No default behavior or values

**Command Modes** Router configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **protocol shutdown** command to disable the OSPF protocol for a specific routing instance without removing any existing OSPF configuration parameters.

The OSPF protocol continues to run on the router and you can use the current OSPF configuration, but OSPF does not form any adjacencies on any interface.

This command is similar to performing the **no router ospf** command.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | ospf    | read, write |

## Examples

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# protocol shutdown
```

# queue dispatch flush-lsa

To change the number of LSAs scheduled (rate-limited) for flushing, that are processed in each iteration, use the **queue dispatch flush-lsa** command in router configuration mode. To return to the system default value, use the **no** form of this command.

**queue dispatch flush-lsa** *count*

**no queue dispatch flush-lsa**

## Syntax Description

|              |                                                              |
|--------------|--------------------------------------------------------------|
| <i>count</i> | Maximum number of LSAs flushed per run. Range is 30 to 3000. |
|--------------|--------------------------------------------------------------|

## Command Default

The default LSAs flushed per run is 150 (when the count is not configured).

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to limit the number of LSAs flushed per run to 30:

```
RP/0/0/CPU0:router(config-ospf)# queue dispatch flush-lsa 30
```

Use the [show ospf message-queue](#), [on page 1118](#) command to see the queue dispatch values, peak lengths, and limits.

| <a href="#">show ospf message-queue, on page 1118</a>      | Displays the information about the queue dispatch values, peak lengths, and limits.                                                     |

## queue dispatch spf-lsa-limit

To change the maximum number of Type 3-4 and Type 5-7 link-state advertisements (LSAs) processed per shortest path first (SPF) iteration within a single SPF run, use the **queue dispatch spf-lsa-limit** command in router configuration mode. To return to the system default value, use the **no** form of this command.

**queue dispatch spf-lsa-limit** *count*

**no queue dispatch spf-lsa-limit**

### Syntax Description

|              |                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i> | Maximum number of continuous Type 3-4 and Type 5-7 LSAs processed per SPF in each scheduled iteration within a single SPF run. Range is 30 to 3000. |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

The default number of Type 3-4 and Type 5-7 processed per run is 150 LSAs (when this command is not configured).

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to limit the number of continuous Type 3-4 and Type 5-7 LSAs processed by SPF per scheduling run, to 100:

```
RP/0/0/CPU0:router(config-ospf)# queue dispatch spf-lsa-limit 100
```

**Related Commands**

| Command                                                       | Description                                                                                |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <a href="#">queue dispatch incoming, on page 1060</a>         | Limits the number of continuous incoming events processed.                                 |
| <a href="#">queue dispatch rate-limited-lsa, on page 1062</a> | Sets the maximum number of rate-limited link-state advertisements (LSAs) processed per run |
| <a href="#">queue limit, on page 1066</a>                     | Sets the high watermark for incoming priority events.                                      |
| <a href="#">show ospf message-queue, on page 1118</a>         | Displays the information about the queue dispatch values, peak lengths, and limits.        |

# queue limit

To set the high watermark for incoming events by priority, use the **queue limit** in router configuration mode. To return to the system default values, use the **no** form of this command.

**queue limit** {**high**| **medium**| **low**} *count*

**no queue limit** {**high**| **medium**| **low**}

## Syntax Description

|               |                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>high</b>   | High watermark for incoming high-priority events (state-changing Hellos).                                                       |
| <b>medium</b> | High watermark for incoming medium-priority events (LSA ACK).                                                                   |
| <b>low</b>    | High watermark for incoming low-priority events (DBD/LSUpd/LSReq).                                                              |
| <i>count</i>  | Maximum number of events per queue. Events are dropped when the priority queue size exceeds this value. Range is 1000 to 30000. |

## Command Default

High watermark: 9500 (when the corresponding configuration is not present).  
 Medium watermark: 9000 (when the corresponding configuration is not present).  
 Low watermark: 8000 (when the corresponding configuration is not present).

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Always keep the limits in the following order of priority:

Limit for High > Limit for Medium > Limit for Low

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following examples show how to set the maximum number of events per queue:

```
RP/0/0/CPU0:router(config-ospf)# queue limit high 11000
RP/0/0/CPU0:router(config-ospf)# queue limit medium 10000
RP/0/0/CPU0:router(config-ospf)# queue limit low 9000
```

## Related Commands

|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">queue dispatch incoming, on page 1060</a>         | Limits the number of continuous incoming events processed.                                                                              |
| <a href="#">queue dispatch rate-limited-lsa, on page 1062</a> | Sets the maximum number of rate-limited link-state advertisements (LSAs) processed per run.                                             |
| <a href="#">queue dispatch spf-lsa-limit, on page 1064</a>    | Limits the number of summary or external Type 3 to Type 7 link-state advertisements (LSAs) processed per shortest path first (SPF) run. |
| <a href="#">show ospf message-queue, on page 1118</a>         | Displays the information about the queue dispatch values, peak lengths, and limits.                                                     |

## range (OSPF)

To consolidate and summarize routes at an area boundary, use the **range** command in area configuration mode. To disable this function, use the **no** form of this command.

**range** *ip-address mask* [**advertise**|**not-advertise**]

**no range** *ip-address mask* [**advertise**|**not-advertise**]

### Syntax Description

|                      |                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>    | IP address in four-part, dotted-decimal notation.                                                                                                              |
| <i>mask</i>          | IP address mask.                                                                                                                                               |
| <b>advertise</b>     | (Optional) Sets the address range status to advertise and generates a Type 3 summary link-state advertisement (LSA).                                           |
| <b>not-advertise</b> | (Optional) Sets the address range status to DoNotAdvertise. The Type 3 summary LSA is suppressed and the component networks remain hidden from other networks. |

### Command Default

When this command is not specified for Area Border Routers (ABRs), routes at an area boundary are not consolidated or summarized.

Advertise is the default.

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **range** command only with Area Border Router (ABRs). Use the command to consolidate or summarize routes for an area. The result is that a single summary route is advertised to other areas by the ABR. Routing information is condensed at area boundaries. External to the area, a single route is advertised for each address range. This process is called *route summarization*.

Multiple **range** configurations specifying the **range** command can be configured. Thus, the OSPF protocol can summarize addresses for many different sets of address ranges.

The summarized route uses the maximum cost of the routes assumed in the range.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows area 36.0.0.0 consisting of interfaces whose IP addresses have “10.31.x.x” as the first two octets. The **range** command summarizes interfaces. Instead of advertising eight networks individually, the single route 10.31.0.0 255.255.0.0 is advertised:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet 0/3/0/2
!
RP/0/0/CPU0:router(config-ospf)# area 36.0.0.0
RP/0/0/CPU0:router(config-ospf-ar)# range 10.31.0.0 255.255.0.0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/1/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/1/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/1/0/2
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/1/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/2/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/2/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/2/0/2
RP/0/0/CPU0:router(config-ospf-ar-if)# interface GigabitEthernet0/2/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# end
```

## Directed-attached gateway redundancy (DAGR)

**redistribute dagr** [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute dagr** [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

## Enhanced Interior Gateway Routing Protocol (EIGRP)

**redistribute eigrp** *process-id* [**match** {external [1| 2]| internal}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute eigrp** *process-id* [**match** {external [1| 2]| internal}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

## Intermediate System-to-Intermediate System (IS-IS)

**redistribute isis** *process-id* [**level-1**| **level-2**| **level-1-2**] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute isis** *process-id* [**level-1**| **level-2**| **level-1-2**] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

## Open Shortest Path First (OSPF)

**redistribute ospf** *process-id* [**match** {external [1| 2]| internal| nssa-external [1| 2]}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute ospf** *process-id* [**match** {external [1| 2]| internal| nssa-external [1| 2]}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**Routing Information Protocol (RIP)**

**redistribute rip** [*metric metric-value*] [**metric-type** {**1** | **2**}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute rip** [*metric metric-value*] [**metric-type** {**1** | **2**}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**IP Static Routes**

**redistribute static** [*metric metric-value*] [**metric-type** {**1** | **2**}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**no redistribute static** [*metric metric-value*] [**metric-type** {**1** | **2**}] [**route-policy** *policy-name*] [**tag** *tag-value*]

**Syntax Description**

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgp</b>                                 | Distributes routes from the BGP protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>process-id</i>                          | <p>For the <b>bgp</b> keyword, an autonomous system number has the following ranges:</p> <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> <p>For the <b>isis</b> keyword, an IS-IS instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p> <p>For the <b>ospf</b> keyword, an OSPF instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p> |
| <b>preserve-med</b>                        | (Optional) Preserves the Multi Exit Discriminator (MED) of BGP routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>metric</b> <i>metric-value</i>          | (Optional) Specifies the metric used for the redistributed route. Range is 1 to 16777214. Use a value consistent with the source protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>metric-type</b> { <b>1</b>   <b>2</b> } | <p>(Optional) Specifies the external link type associated with the route advertised into the OSPF routing domain. It can be one of two values:</p> <ul style="list-style-type: none"> <li>• <b>1</b> —Type 1 external route</li> <li>• <b>2</b> —Type 2 external route</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>tag</b> <i>tag-value</i>                | (Optional) Specifies the value attached to each external route. This value is not used by the OSPF protocol itself, but is carried in the external LSAs. Range is 0 to 4294967295.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>route-policy</b> <i>policy-name</i>     | (Optional) Specifies the identifier of a configured policy. A policy is used to filter the importation of routes from this source routing protocol to OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>connected</b>                           | Distributes routes that are established automatically by virtue of having enabled IP on an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                                    |
| Release 3.3.0 | This command was added under the VRF configuration mode.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> .<br>The <b>eigrp</b> and <b>rip</b> keywords were added.                                                                                                                                                              |
| Release 3.6.0 | The following keywords and arguments were added to the <b>redistribute eigrp</b> command: [ <b>metric</b> <i>metric-value</i> ] [ <b>metric-type</b> { <b>1</b>   <b>2</b> } ] [ <b>route-policy</b> <i>policy-name</i> ] [ <b>tag</b> <i>tag-value</i> ].<br>The <b>preserve-med</b> keyword was added to the <b>redistribute bgp</b> command. |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.<br>Support was added for redistribution from directed-attached gateway redundancy (DAGR). The keyword <b>dagr</b> was added.<br>The <b>instance</b> keyword and <i>instance-name</i> argument were added for connected routes                                       |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

When redistributing routes (into OSPF) using both command keywords for setting or matching of attributes and a route policy, the routes are run through the route policy first, followed by the keyword matching and setting.

Redistributed routing information should always be filtered by the **policy** *policy-name* keyword and argument. This filtering ensures that only those routes intended by the administrator are redistributed into OSPF.

For information about routing policies, see the *Routing Policy Commands on the Cisco IOS XR Software* Cisco IOS XR module of *Cisco IOS XR Routing Command Reference for the Cisco XR 12000 Series Router*.

Whenever you use the **redistribute** or [default-information originate \(OSPF\)](#), on page 963 command to redistribute routes into an OSPF routing domain, the router automatically becomes an ASBR. However, an ASBR does not, by default, generate a default route into the OSPF routing domain.

When routes are redistributed between OSPF processes, no OSPF metrics are preserved.

When routes are redistributed into OSPF and no metric is specified with the **metric** keyword, OSPF uses 20 as the default metric for routes from all protocols except BGP routes, which get a metric of 1.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to cause BGP routes to be redistributed into an OSPF domain:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 110
RP/0/0/CPU0:router(config-ospf)# redistribute bgp 100
```

The following example shows how to redistribute the specified IS-IS process routes into an OSPF domain. The IS-IS routes are redistributed with a metric of 100.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# redistribute isis 108 metric 100
```

In the following example, network 10.0.0.0 appears as an external link-state advertisement (LSA) in OSPF 1:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-if)# ip address 10.0.0.0 255.0.0.0
!
RP/0/0/CPU0:router(config)# interface GigabitEthernet 0/2/0/2
RP/0/0/CPU0:router(config)# ip address 10.99.0.0 255.0.0.0
!
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# redistribute ospf 2
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/2/0/2
!
RP/0/0/CPU0:router(config)# router ospf 2
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/1/0/1
```

**Related Commands**

|------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">default-information originate (OSPF)</a> , <a href="#">on page 963</a> | Generates a default external route into an OSPF routing domain. |

## retransmit-interval (OSPF)

To specify the time between link-state advertisement (LSA) retransmissions for adjacencies belonging to the Open Shortest Path First (OSPF) interface, use the **retransmit-interval** command in the appropriate mode. To return to the default value, use the **no** form of this command.

**retransmit-interval** *seconds*

**no retransmit-interval**

### Syntax Description

|                |                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Time (in seconds) between retransmissions. It must be greater than the expected round-trip delay between any two routers on the attached network. Range is 1 to 65535 seconds. |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the retransmit interval parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the retransmit interval parameter specified for the process.

If this command is not specified at any level, then the default retransmit interval is 5 seconds.

### Command Modes

Interface configuration  
Area configuration  
Router configuration  
Virtual-link configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | This command was added under sham-link configuration mode.                |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA.

The setting of this parameter should be conservative, or needless retransmission results. The value should be larger for serial lines and virtual links.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the retransmit interval value to 8 seconds in interface configuration mode:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-ospf-ar-if)# retransmit-interval 8
```

## route-policy (OSPF)

To specify a routing policy to filter Type 3 link-state advertisements (LSA), use the **route-policy** command in area configuration mode. To disable the routing policy, use the **no** form of this command.

**route-policy** *route-policy-name* {**in**|**out**}

**no route-policy** *route-policy-name* {**in**|**out**}

### Syntax Description

|                          |                                    |
|--------------------------|------------------------------------|
| <i>route-policy-name</i> | Name of route policy.              |
| <b>in</b>                | Applies policy to inbound routes.  |
| <b>out</b>               | Applies policy to outbound routes. |

### Command Default

No policy is applied.

### Command Modes

Area configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-policy** command to specify an OSPF routing policy for an inbound or outbound route. The policy can be used to filter routes or modify route attributes.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to specify an OSPF route policy for inbound routes in area 0:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-area)# route-policy area0_in in
```

# router-id (OSPF)

To configure a router ID for the Open Shortest Path First (OSPF) process, use the **router-id** command in the appropriate mode. To cause the software to use the default method of determining the router ID, use the **no** form of this command after clearing or restarting the OSPF process.

**router-id router-id**

**no router-id router-id**

## Syntax Description

|                  |                                                                         |
|------------------|-------------------------------------------------------------------------|
| <i>router-id</i> | 32-bit router ID value specified in four-part, dotted-decimal notation. |
|------------------|-------------------------------------------------------------------------|

## Command Default

If this command is not configured, the router ID is the highest IP version 4 (IPv4) address for an interface on the router, with any loopback interface taking precedence.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                                 |
|---------------|--------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                 |
| Release 3.3.0 | This command was added under the VRF configuration mode.     |
| Release 3.4.0 | The <i>type interface-path-id</i> argument pair was removed. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

It is good practice to use the **router-id** command to explicitly specify a unique 32-bit numeric value for the router ID. This action ensures that OSPF can function regardless of the interface address configuration. Clear the OSPF process using the **clear ospf process** command or restart the OSPF process for the **no router-id** command to take effect.

OSPF attempts to obtain a router ID in the following ways (in order of preference):

- 1 By default, when the OSPF process initializes, it checks if there is a router-id in the checkpointing database.
- 2 The 32-bit numeric value specified by the OSPF **router-id** command in router configuration mode. (This value can be any 32-bit value. It is not restricted to the IPv4 addresses assigned to interfaces on this router, and need not be a routable IPv4 address.)
- 3 The ITAL selected router-id.

- 4 The primary IPv4 address of an interface over which this OSPF process is running. The first interface address in the OSPF interface is selected.

**Note**

Unlike OSPF version 3, OSPF version 2 is guaranteed to have at least one interface with an IPv4 address configured.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to assign the IP address of 172.20.10.10 to the OSPF process 109:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config-ospf)# router-id 172.20.10.10
```

**Related Commands**

| Command                                         | Description                                                       |
|-------------------------------------------------|-------------------------------------------------------------------|
| <a href="#">clear ospf process, on page 943</a> | Resets an OSPF router process without stopping and restarting it. |
| <b>ipv4 address</b>                             | Sets a primary IPv4 address for an interface.                     |

# router ospf

To configure an Open Shortest Path First (OSPF) routing process, use the **router ospf** command in global configuration mode. To terminate an OSPF routing process, use the **no** form of this command.

**router ospf** *process-name*

**no router ospf** *process-name*

## Syntax Description

|                     |                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | Name that uniquely identifies an OSPF routing process. The process name is any alphanumeric string no longer than 40 characters without spaces. |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No OSPF routing process is defined.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can specify multiple OSPF routing processes in each router. Up to 10 processes can be configured. The recommendation is not to exceed 4 OSPF processes.

All OSPF configuration commands must be configured under an OSPF routing process. For example, two of these commands are the **default-metric** command and the **router-id** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |
| rib     | read, write |

## Examples

The following example shows how to instantiate an OSPF routing process called 109:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 109
```

**Related Commands**

| <a href="#">router-id (OSPF), on page 1079</a>     | Configures a router ID for the OSPF process.                                                      |

# security ttl (OSPF)

To set the security time-to-live (TTL) value in the IP header for Open Shortest Path First (OSPF) packets, use the **security ttl** command in the appropriate configuration mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**security ttl** [**hops** *hops-number*]

**no security ttl**

|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>The <b>security ttl</b> command is used for the Generalized TTL Security Mechanism (GTSM) feature to prevent network attacks.</p> <p>During the act of receiving Link State Advertisement (LSA) from neighbors, network attacks can occur because there are no checks that unicast or multicast packets are originating from a neighbor that is one hop away or multiple hops away over virtual links.</p> <p>For virtual links, OSPF packets travel multiple hops across the network; hence, the TTL value can be decremented several times. For these type of links, a minimum TTL value must be allowed and accepted for multiple-hop packets.</p> <p>To filter network attacks originating from invalid sources traveling over multiple hops, the GTSM, RFC 3682, is used to prevent the attacks. GTSM filters link-local addresses and allows for only one-hop neighbor adjacencies through the configuration of TTL value 255. The TTL value in the IP header is set to when OSPF packets are originated and checked on the received OSPF packets against the default GTSM TTL value 255</p> |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

or the user configured GTSM TTL value, blocking unauthorized OSPF packets originated from TTL hops away.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to set the security TTL for an interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet0/6/0/3
RP/0/0/CPU0:router(config-ospf-ar-if)# security ttl 2
```

# sham-link

To configure an Open Shortest Path First OSPF sham link between two provider edge routers, use the **sham-link** command in VRF area configuration mode. To terminate an (OSPF) sham link, use the **no** form of this command.

**sham-link** *source-address destination-address*

**no sham-link**

## Syntax Description

|                            |                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------|
| <i>source-address</i>      | IP address of the local (source) sham-link endpoint specified in four-part, dotted-decimal notation.       |
| <i>destination-address</i> | IP address of the remote (destination) sham-link endpoint specified in four-part, dotted-decimal notation. |

## Command Default

No sham link is configured.

## Command Modes

VRF area configuration.

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **sham-link** command to configure a point-to-point connection between two provider edge (PE) routers creating an interconnect between two VPN sites (VPN backbone). Sham links are configured on PE provider edge (PE) routers in a Multiprotocol Label Switching (MPLS) VPN backbone.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure an OSPF sham link:

```
RP/0/0/CPU0:router# configure
```

```

RP/0/0/CPU0:router(config)# router ospf 109
RP/0/0/CPU0:router(config_ospf)# vrf vrf_a
RP/0/0/CPU0:router(config_ospf_vrf)# area 0
RP/0/0/CPU0:router(config_ospf_vrf_ar)# sham-link 192.168.40.0 172.16.30.0
RP/0/0/CPU0:router(config_ospf_vrf_ar_sl)# cost 23

```

## Related Commands

|------------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">area (OSPF), on page 933</a> | Configures an OSPF area.                                                            |
| <a href="#">cost (OSPF), on page 953</a> | Explicitly specifies the cost of the interface (network) for OSPF path calculation. |
| <a href="#">vrf (OSPF), on page 1179</a> | Configures an OSPF VPN routing and forwarding (VRF) instance.                       |

# show ospf

To display general information about Open Shortest Path First (OSPF) routing processes, use the **show ospf** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*|**all**}] [**summary**]

## Syntax Description

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved values of the <i>vrf-name</i> argument.                                     |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |
| <b>summary</b>      | (Optional) Displays OSPF summary information.                                                                                                                                                                                   |

## Command Default

IPv4 and unicast address prefixes

## Command Modes

EXEC

## Command History

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.6.0 | The <b>all</b> keyword was added.                                                                                                                                                                                                    |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf** command to provide basic information about the OSPF processes running on the router. Additional options provide in-depth information.

Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

Examples

The following is sample output from the **show ospf** command:

```
RP/0/0/CPU0:router#show ospf

Routing Process "ospf 1" with ID 1.1.1.1
  Supports only single TOS(TOS0) routes
  Supports opaque LSA
  It is an area border router
  Initial SPF schedule delay 5000 msec
  Minimum hold time between two consecutive SPF's 10000 msec
  Maximum wait time between two consecutive SPF's 10000 msec
  Initial LSA throttle delay 500 msec
  Minimum hold time for LSA throttle 5000 msec
  Maximum wait time for LSA throttle 5000 msec
  Minimum LSA interval 5000 msec. Minimum LSA arrival 1 sec
  Maximum number of configured interfaces 255
  Number of external LSA 0. Checksum Sum 00000000
  Number of opaque AS LSA 0. Checksum Sum 00000000
  Number of DCbitless external and opaque AS LSA 0
  Number of DoNotAge external and opaque AS LSA 0
  Number of areas in this router is 2. 2 normal 0 stub 0 nssa
  External flood list length 0
  Non-Stop Forwarding enabled
    Area BACKBONE(0) (Inactive)
      Number of interfaces in this area is 2
      SPF algorithm executed 8 times
      Number of LSA 2. Checksum Sum 0x01ba83
      Number of opaque link LSA 0. Checksum Sum 00000000
      Number of DCbitless LSA 0
      Number of indication LSA 0
      Number of DoNotAge LSA 0
      Flood list length 0
    Area 1
      Number of interfaces in this area is 1
      SPF algorithm executed 9 times
      Number of LSA 2. Checksum Sum 0x0153ea
      Number of opaque link LSA 0. Checksum Sum 00000000
      Number of DCbitless LSA 0
      Number of indication LSA 0
      Number of DoNotAge LSA 0
      Flood list length 0
```

This table describes the significant fields shown in the display.

Table 88: show ospf Field Descriptions

| Field                                             | Description                                                     |
|---------------------------------------------------|-----------------------------------------------------------------|
| Routing Process "ospf 201" with ID 172.22.110.200 | OSPF process name.                                              |
| Supports only                                     | Number of types of service supported (Type 0 only).             |
| It is                                             | Types are internal, area border, or autonomous system boundary. |

| Field                               | Description                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------|
| Redistributing External Routes from | Lists of redistributed routes, by protocol.                                                   |
| SPF schedule delay                  | Delay time of SPF calculations.                                                               |
| Minimum LSA interval                | Minimum interval between LSAs.                                                                |
| Minimum LSA arrival                 | Minimum elapsed time between accepting an update for the same link-state advertisement (LSA). |
| external LSA                        | Total number of Type 5 LSAs in the LSDB.                                                      |
| opaque LSA                          | Total number of Type 10 LSAs in the LSDB.                                                     |
| DCbitless...AS LSA                  | Total number of Demand Circuit Type 5 and Type 11 LSAs.                                       |
| DoNotAge...AS LSA                   | Total number of Type 5 and Type 11 LSAs with the DoNotAge bit set.                            |
| Number of areas                     | Number of areas in router, area addresses, and so on.                                         |
| Area BACKBONE                       | Backbone is area 0.                                                                           |

# show ospf border-routers

To display the internal Open Shortest Path First (OSPF) routing table entries to an Area Border Router (ABR) and Autonomous System Boundary Router (ASBR), use the **show ospf border-routers** command in EXEC mode.

**show ospf** [ *process-name* ] [ **vrf** {*vrf-name*| **all**} ] **border-routers** [ *router-id* ]

## Syntax Description

|                     |                                                                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) OSPF process name. If this argument is included, only information for the specified routing process is included.                                                                              |
| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                  |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings "default" and "all" are reserved vrf-names.                                           |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                             |
| <i>router-id</i>    | (Optional) Router ID associated with the border router. The value of the <i>router-id</i> argument can be any 32-bit router ID value specified in four-part, dotted-decimal notation. No default exists. |

## Command Default

IPv4 and unicast address prefixes

## Command Modes

EXEC

## Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.6.0 | The <b>all</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf border-routers** command to list all OSPF border routers visible to the specified processes and to ascertain the OSPF topology of the router.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf border-routers** command:

```
RP/0/0/CPU0:router# show ospf border-routers
OSPF 1 Internal Routing Table
Codes: i - Intra-area route, I - Inter-area route
i 172.31.97.53 [1] via 172.16.1.53, GigabitEthernet POS 3/0/0/0, ABR/ASBR , Area 0, SPF
3
```

This table describes the significant fields shown in the display.

**Table 89: show ospf border-routers Field Descriptions**

| Field                   | Description                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| i                       | Type of this route; i indicates an intra-area route, I an interarea route.                                                    |
| 172.31.97.53            | Router ID of destination.                                                                                                     |
| [1]                     | Cost of using this route.                                                                                                     |
| 172.16.1.53             | Next-Next hop toward the destination.                                                                                         |
| GigabitEthernet 3/0/0/0 | Packets destined for 172.16.1.53 are sent over GigabitEthernet interface 3/0/0/0.                                             |
| ABR/ASBR                | Router type of the destination; it is either an Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) or both. |
| Area 0                  | Area ID of the area from which this route is learned.                                                                         |
| SPF 3                   | Internal number of the shortest path first (SPF) calculation that installs this route.                                        |

# show ospf database

To display lists of information related to the Open Shortest Path First (OSPF) database for a specific router, use the **show ospf database** command in EXEC mode.

```

show ospf [ process-name ] [ vrf {vrf-name| all} ] [ area-id ] database
show ospf [ process-name ] [ vrf {vrf-name| all} ] [ area-id ] database [ adv-router ip-address ]
show ospf [ process-name ] [ vrf {vrf-name| all} ] [ area-id ] database [ asbr-summary ] [ link-state-id ]

## Syntax Description

|                                     |                                                                                                                                                                                                                                                        |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>                 | (Optional) OSPF process name that uniquely identifies an OSPF routing process. The process name is any alphanumeric string no longer than 40 characters. If this argument is included, only information for the specified routing process is included. |
| <b>vrf</b>                          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                |
| <i>vrf-name</i>                     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                                         |
| <b>all</b>                          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                           |
| <i>area-id</i>                      | (Optional) Area number used to define the particular area.                                                                                                                                                                                             |
| <b>adv-router</b> <i>ip-address</i> | (Optional) Displays all LSAs of the specified router.                                                                                                                                                                                                  |
| <b>asbr-summary</b>                 | (Optional) Displays information only about the Autonomous System Boundary Router (ASBR) summary LSAs.                                                                                                                                                  |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>link-state-id</i>    | <p>(Optional) Portion of the Internet environment that is being described by the advertisement. The value entered depends on the link-state type of the advertisement. It must be entered in the form of an IP address.</p> <p>When the link-state advertisement (LSA) is describing a network, the <i>link-state-id</i> can take one of two forms:</p> <ul style="list-style-type: none"> <li>• The network IP address (as in Type 3 summary link advertisements and in autonomous system external link advertisements).</li> <li>• A derived address obtained from the link-state ID.</li> </ul> <p><b>Note</b> Masking the link-state ID of a network link advertisement with the subnet mask of the network yields the IP address of the network.</p> <p>When the LSA is describing a router, the link-state ID is always the OSPF router ID of the described router.</p> <p>When an autonomous system external advertisement (LS Type = 5) is describing a default route, its link-state ID is set to Default Destination (0.0.0.0).</p> |
| <b>internal</b>         | (Optional) Displays internal LSA information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>self-originate</b>   | (Optional) Displays only self-originated LSAs (from the local router).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>database-summary</b> | (Optional) Displays how many of each type of LSA for each area there are in the database and the total.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>external</b>         | (Optional) Displays information only about the external LSAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>network</b>          | (Optional) Displays information only about the network LSAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nssa-external</b>    | (Optional) Displays information only about the not-so-stubby area (NSSA) external LSAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>opaque-area</b>      | (Optional) Displays information about the opaque Type 10 LSAs. Type 10 denotes an area-local scope. Refer to RFC 2370 for more information on the opaque LSA options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>opaque-as</b>        | (Optional) Displays information about the opaque Type 11 LSAs. Type 11 denotes that the LSA is flooded throughout the autonomous system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>opaque-link</b>      | (Optional) Displays information about the opaque Type 9 LSAs. Type 9 denotes a link-local scope.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>router</b>           | (Optional) Displays information only about the router LSAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>summary</b>          | (Optional) Displays information only about the summary LSAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Release 3.6.0 | The <b>internal</b> keyword was added.<br>The <b>all</b> keyword was added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The various forms of the **show ospf database** command deliver information about different OSPF link-state advertisements. This command can be used to examine the link-state database (LSD) and its contents. Each router participating in an area having identical database entries pertaining to that area (with the exception of LSAs that are being flooded). Numerous options (such as **network** and **router**) are used to display portions of the database.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf database** command when no arguments or keywords are used:

```
RP/0/0/CPU0:router# show ospf database

OSPF Router with ID (172.20.1.11) (Process ID 1)

    Router Link States (Area 0)

Link ID        ADV Router    Age      Seq#           Checksum Link count
172.20.1.8     172.20.1.8    1381     0x8000010D    0xEF60    2
172.20.1.11    172.20.1.11    1460     0x800002FE    0xEB3D    4
172.20.1.12    172.20.1.12    2027     0x80000090    0x875D    3
172.20.1.27    172.20.1.27    1323     0x800001D6    0x12CC    3

    Net Link States (Area 0)

Link ID        ADV Router    Age      Seq#           Checksum
172.22.1.27    172.20.1.27    1323     0x8000005B    0xA8EE
172.22.1.11    172.20.1.11    1461     0x8000005B    0x7AC

    Type-10 Opaque Link Area Link States (Area 0)

Link ID        ADV Router    Age      Seq#           Checksum Opaque ID
10.0.0.0       172.20.1.11    1461     0x800002C8    0x8483    0
10.0.0.0       172.20.1.12    2027     0x80000080    0xF858    0
10.0.0.0       172.20.1.27    1323     0x800001BC    0x919B    0
```

```
10.0.0.1      172.20.1.11      1461      0x8000005E      0x5B43      1
```

**Table 90: show ospf database Field Descriptions**

| Field      | Description                                                 |
|------------|-------------------------------------------------------------|
| Link ID    | Router ID number.                                           |
| ADV Router | ID of the advertising router.                               |
| Age        | Link-state age.                                             |
| Seq#       | Link-state sequence number (detects old or duplicate LSAs). |
| Checksum   | Fletcher checksum of the complete contents of the LSA.      |
| Link count | Number of interfaces detected for the router.               |
| Opaque ID  | Opaque LSA ID number.                                       |

The following is sample output from the **show ospf database** command with the **asbr-summary** keyword:

```
RP/0/RP0/CPU0:router# show ospf database asbr-summary
OSPF Router with ID (192.168.0.1) (Process ID 300)
Summary ASB Link States (Area 0.0.0.0)
  LS age: 1463
  Options: (No TOS-capability)
  LS Type: Summary Links (AS Boundary Router)
  Link State ID: 172.17.245.1 (AS Boundary Router address)
  Advertising Router: 172.17.241.5
  LS Seq Number: 80000072
  Checksum: 0x3548
  Length: 28
  Network Mask: /0
  TOS: 0 Metric: 1
```

This table describes the significant fields shown in the display.

**Table 91: show ospf database asbr-summary Field Descriptions**

| Field               | Description        |
|---------------------|--------------------|
| OSPF Router with ID | Router ID number.  |
| Process ID          | OSPF process name. |
| LS age              | Link-state age.    |

| Field              | Description                                                                  |
|--------------------|------------------------------------------------------------------------------|
| Options            | Type of service options (Type 0 only).                                       |
| LS Type            | Link-state type.                                                             |
| Link State ID      | Link-state ID (ASBR).                                                        |
| Advertising Router | ID of the advertising router.                                                |
| LS Seq Number      | Link-state sequence (detects old or duplicate LSAs).                         |
| Checksum           | Link-state checksum (Fletcher checksum of the complete contents of the LSA). |
| Length             | Length (in bytes) of the LSAs.                                               |
| Network Mask       | Network mask implemented.                                                    |
| TOS                | Type of service.                                                             |
| Metric             | Link-state metric.                                                           |

The following is sample output from the **show ospf database** command with the **external** keyword:

```
RP/0/0/CPU0:router# show ospf database external
OSPF Router with ID (192.168.0.1) (Process ID 300)
Type-5 AS External Link States

LS age: 280
Options: (No TOS-capability)
LS Type: AS External Link
Link State ID: 172.17.0.0 (External Network Number)
Advertising Router: 172.17.70.6
LS Seq Number: 80000AFD
Checksum: 0xC3A
Length: 36
Network Mask: 255.255.0.0
Metric Type: 2 (Larger than any link state path)
TOS: 0
Metric: 1
Forward Address: 0.0.0.0
External Route Tag: 0
```

This table describes the significant fields shown in the display.

**Table 92: show ospf database external Field Descriptions**

| Field                      | Description        |
|----------------------------|--------------------|
| OSPF Router with Router ID | Router ID number.  |
| Process ID                 | OSPF process name. |

| Field              | Description                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LS age             | Link-state age.                                                                                                                                                                                                      |
| Options            | Type of service options (Type 0 only).                                                                                                                                                                               |
| LS Type            | Link-state type.                                                                                                                                                                                                     |
| Link State ID      | Link-state ID (external network number).                                                                                                                                                                             |
| Advertising Router | ID of the advertising router.                                                                                                                                                                                        |
| LS Seq Number      | Link-state sequence number (detects old or duplicate LSAs).                                                                                                                                                          |
| Checksum           | Link-state checksum (Fletcher checksum of the complete contents of the LSA).                                                                                                                                         |
| Length             | Length (in bytes) of the LSA.                                                                                                                                                                                        |
| Network Mask       | Network mask implemented.                                                                                                                                                                                            |
| Metric Type        | External type.                                                                                                                                                                                                       |
| TOS                | Type of service.                                                                                                                                                                                                     |
| Metric             | Link-state metric.                                                                                                                                                                                                   |
| Forward Address    | Forwarding address. Data traffic for the advertised destination is forwarded to this address. If the forwarding address is set to 0.0.0.0, data traffic is forwarded instead to the originator of the advertisement. |
| External Route Tag | External route tag, a 32-bit field attached to each external route. This tag is not used by the OSPF protocol itself.                                                                                                |

The following is sample output from the **show ospf database** command with the **network** keyword:

```
RP/0/0/CPU0:router# show ospf database network

OSPF Router with ID (192.168.0.1) (Process ID 300)

Net Link States (Area 0.0.0.0)

  LS age: 1367
  Options: (No TOS-capability)
  LS Type: Network Links
  Link State ID: 172.23.1.3 (address of Designated Router)
  Advertising Router: 192.168.0.1
  LS Seq Number: 800000E7
  Checksum: 0x1229
```

```

Length: 52
Network Mask: /24
    Attached Router: 192.168.0.1
    Attached Router: 172.23.241.5
    Attached Router: 172.23.1.1
    Attached Router: 172.23.54.5
    Attached Router: 172.23.1.5

```

This table describes the significant fields shown in the display.

**Table 93: show ospf database network Field Descriptions**

| Field               | Description                                                                  |
|---------------------|------------------------------------------------------------------------------|
| OSPF Router with ID | Router ID number.                                                            |
| Process ID          | OSPF process name.                                                           |
| LS age              | Link-state age.                                                              |
| Options             | Type of service options (Type 0 only).                                       |
| LS Type             | Link-state type.                                                             |
| Link State ID       | Link-state ID of the designated router.                                      |
| Advertising Router  | ID of the advertising router.                                                |
| LS Seq Number       | Link-state sequence number (detects old or duplicate LSAs).                  |
| Checksum            | Link-state checksum (Fletcher checksum of the complete contents of the LSA). |
| Length              | Length (in bytes) of the LSA.                                                |
| Network Mask        | Network mask implemented.                                                    |
| Attached Router     | List of routers attached to the network, by IP address.                      |

The following is sample output, carrying Multiprotocol Label Switching traffic engineering (MPLS TE) specification information, from the **show ospf database** command with the **opaque-area** keyword and a *link-state-id* of adv-router:

```

RP/0/0/CPU0:router# show ospf database opaque-area adv-router 172.20.1.12

OSPF Router with ID (172.20.1.11) (Process ID 1)

    Type-10 Opaque Link Area Link States (Area 0)

    LS age: 224
    Options: (No TOS-capability, DC)
    LS Type: Opaque Area Link
    Link State ID: 1.0.0.0
    Opaque Type: 1

```

```

Opaque ID: 0
Advertising Router: 172.20.1.12
LS Seq Number: 80000081
Checksum: 0xF659
Length: 132
Fragment number : 0

MPLS TE router ID : 172.20.1.12

Link connected to Point-to-Point network
Link ID : 172.20.1.11
Interface Address : 172.21.1.12
Neighbor Address : 172.21.1.11
Admin Metric : 10
Maximum bandwidth : 193000
Maximum reservable bandwidth : 125000
Number of Priority : 8
Priority 0 : 125000      Priority 1 : 125000
Priority 2 : 125000      Priority 3 : 125000
Priority 4 : 125000      Priority 5 : 125000
Priority 6 : 125000      Priority 7 : 100000
Affinity Bit : 0x0

Number of Links : 1

```

The following is sample output from the **show ospf database** command that displays a Type 10, Router Information LSA:

```

RP/0/0/CPU0:router# show ospf database opaque-area 4.0.0.0

OSPF Router with ID (3.3.3.3) (Process ID orange)

Type-10 Opaque Link Area Link States (Area 0)

LS age: 105
Options: (No TOS-capability, DC)
LS Type: Opaque Area Link
Link State ID: 4.0.0.0
Opaque Type: 4
Opaque ID: 0
Advertising Router: 3.3.3.3
LS Seq Number: 80000052
Checksum: 0x34e2
Length: 52
Fragment number: 0

Router Information TLV: Length: 4
Capabilities:
  Graceful Restart Helper Capable
  Traffic Engineering enabled area
  All capability bits: 0x50000000

PCE Discovery TLV: Length: 20
IPv4 Address: 3.3.3.3
PCE Scope: 0x20000000
Compute Capabilities:
  Inter-area default (Rd-bit)
Compute Preferences:
  Intra-area: 0   Inter-area: 0
  Inter-AS: 0   Inter-layer: 0

```

This table describes the significant fields shown in the display.

**Table 94: show ospf database opaque-area Field Descriptions**

| Field                        | Description                                                                  |
|------------------------------|------------------------------------------------------------------------------|
| OSPF Router with ID          | Router ID number.                                                            |
| Process ID                   | OSPF process name.                                                           |
| LS age                       | Link-state age.                                                              |
| Options                      | Type of service options (Type 0 only).                                       |
| LS Type                      | Link-state type.                                                             |
| Link State ID                | Link-state ID.                                                               |
| Opaque Type                  | Opaque link-state type.                                                      |
| Opaque ID                    | Opaque ID number.                                                            |
| Advertising Router           | ID of the advertising router.                                                |
| LS Seq Number                | Link-state sequence (detects old or duplicate LSAs).                         |
| Checksum                     | Link-state checksum (Fletcher checksum of the complete contents of the LSA). |
| Length                       | Length (in bytes) of the LSA.                                                |
| Fragment number              | Arbitrary value used to maintain multiple traffic engineering LSAs.          |
| Link ID                      | Link ID number.                                                              |
| Interface Address            | ID address of the interface.                                                 |
| Neighbor Address             | IP address of the neighbor.                                                  |
| Admin Metric                 | Administrative metric value used by MPLS TE.                                 |
| Maximum bandwidth            | Specifies maximum bandwidth (in kbps).                                       |
| Maximum reservable bandwidth | Specifies maximum reservable bandwidth (in kbps).                            |
| Number of Priority           | Priority number.                                                             |
| Affinity Bit                 | Used by MPLS TE.                                                             |
| Router Information TLV       | Router capabilities are advertised in this TLV.                              |

| Field                       | Description                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Capabilities                | Some router capabilities include stub router, traffic engineering, graceful restart, and graceful restart helper.        |
| PCE Discovery TLV           | PCE address and capability information is advertised in this TLV.                                                        |
| IPv4 Address                | Configured PCE IPv4 address.                                                                                             |
| PCE Scope                   | Computation capabilities of the PCE.                                                                                     |
| Compute Capabilities        | Compute capabilities and preferences of the PCE.                                                                         |
| Inter-area default (RD-bit) | PCE compute capabilities such as intra-area, inter-area, inter-area default, inter-AS, inter-AS default and inter-layer. |
| Compute Preferences         | Order or preference of path computation that includes intra-area, inter-area, inter-AS, and inter-layer preferences.     |

The following is sample output from the **show ospf database** command with the **router** keyword:

```
RP/0/0/CPU0:router# show ospf database router

OSPF Router with ID (192.168.0.1) (Process ID 300)

Router Link States (Area 0.0.0.0)

This table describes the significant fields shown in the display.

**Table 97: show ospf database database-summary Field Descriptions**

| Field    | Description                                                     |
|----------|-----------------------------------------------------------------|
| LSA Type | Link-state type.                                                |
| Count    | Number of advertisements in that area for each link-state type. |
| Delete   | Number of LSAs that are marked “Deleted” in that area.          |
| Maxage   | Number of LSAs that are marked “Maxaged” in that area.          |

# show ospf flood-list

To display a list of Open Shortest Path First (OSPF) link-state advertisements (LSAs) waiting to be flooded over an interface, use the **show ospf flood-list** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*| **all**}] [*area-id*] **flood-list** [*type interface-path-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) OSPF process name that uniquely identifies an OSPF routing process. The process name is any alphanumeric string no longer than 40 characters. If this argument is included, only information for the specified routing process is included.                          |
| <b>vrf</b>               | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                         |
| <i>vrf-name</i>          | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                                                                  |
| <b>all</b>               | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                                                    |
| <i>area-id</i>           | (Optional) Area number used to define the particular area.                                                                                                                                                                                                                      |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |

## Command Default

## Command History

| Release       | Modification                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced                                                                                              |
| Release 3.6.0 | The <i>type interface-path-id</i> arguments were changed from required to optional.<br>The <b>all</b> keyword was added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf flood-list** command to display LSAs in flood queue and queue length.

Flood list information is transient and normally the flood lists are empty.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf flood-list** command for interface GigabitEthernet 3/0/0/0:

```
RP/0/0/CPU0:router# show ospf flood-list GigabitEthernet 3/0/0/0

Interface GigabitEthernet3/0/0/0, Queue length 20
Link state retransmission due in 12 msec
Displaying 6 entries from flood list:

Type  LS ID          ADV RTR          Seq NO          Age          Checksum
  5    10.2.195.0        200.0.0.163      0x80000009      0            0xFB61
  5    10.1.192.0        200.0.0.163      0x80000009      0            0x2938
  5    10.2.194.0        200.0.0.163      0x80000009      0            0x757
  5    10.1.193.0        200.0.0.163      0x80000009      0            0x1E42
  5    10.2.193.0        200.0.0.163      0x80000009      0            0x124D
  5    10.1.194.0        200.0.0.163      0x80000009      0            0x134C
```

This table describes the significant fields shown in the display.

**Table 98: show ospf flood-list Field Descriptions**

| Field                            | Description                                                           |
|----------------------------------|-----------------------------------------------------------------------|
| GigabitEthernet3/0/0/0           | Interface for which information is displayed.                         |
| Queue length                     | Number of LSAs waiting to be flooded.                                 |
| Link state retransmission due in | Length of time (in milliseconds) before next link-state transmission. |
| Type                             | Type of LSA.                                                          |
| LS ID                            | Link-state ID of the LSA.                                             |
| ADV RTR                          | IP address of the advertising router.                                 |
| Seq NO                           | Sequence number of the LSA.                                           |
| Age                              | Age of the LSA (in seconds).                                          |

| Field    | Description          |
|----------|----------------------|
| Checksum | Checksum of the LSA. |

# show ospf interface

To display Open Shortest Path First (OSPF) interface information, use the **show ospf interface** command in EXEC mode.

**show ospf** [ *process-name* ] [ **vrf** { *vrf-name* | **all** } ] [ *area-id* ] **interface** [**brief**] [*type interface-path-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) OSPF process name that uniquely identifies an OSPF routing process. The process name is any alphanumeric string no longer than 40 characters. If this argument is included, only information for the specified routing process is included.                  |
| <b>vrf</b>               | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                 |
| <i>vrf-name</i>          | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                                                          |
| <b>all</b>               | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                                            |
| <i>area-id</i>           | (Optional) Area number used to define the particular area.                                                                                                                                                                                                              |
| <b>brief</b>             | (Optional) Displays brief interface information.                                                                                                                                                                                                                        |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                   |

| Release 3.4.1 | Show output was modified to display multiple area adjacency information configured on an interface. |
| Release 3.6.0 | The <b>brief</b> keyword was added.<br>The <b>all</b> keyword was added.                            |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf interface** command:

```
RP/0/0/CPU0:router# show ospf interface

GigabitEthernet0/2/0/1 is up, line protocol is up
  Internet Address 121.10.10.2/24, Area 2
  Process ID 1, Router ID 200.2.2.2, Network Type POINT_TO_POINT, Cost: 1
  Transmit Delay is 1 sec, State POINT_TO_POINT,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:04
  Index 1/3, flood queue length 0
  Next 0(0)/0(0)
  Last flood scan length is 3, maximum is 10
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 101.3.3.3
  Suppress hello for 0 neighbor(s)
  Multi-area interface Count is 1
    Multi-Area interface exist in area 1 Neighbor Count is 1
GigabitEthernet0/3/0/0 is up, line protocol is up
  Internet Address 145.10.10.2/16, Area 3
  Process ID 1, Router ID 200.2.2.2, Network Type POINT_TO_POINT, Cost: 1
  Transmit Delay is 1 sec, State POINT_TO_POINT,
  BFD enabled, BFD interval 15 msec, BFD multiplier 3
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
  Index 1/5, flood queue length 0
  Next 0(0)/0(0)
  Last flood scan length is 3, maximum is 11
  Last flood scan time is 0 msec, maximum is 1 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 101.3.3.3
  Suppress hello for 0 neighbor(s)
  Message digest authentication enabled
  Youngest key id is 1
  Multi-area interface Count is 0
```

The following is sample output when MPLS LDP Sync is configured on the OSPF routing process and MPLS LDP is configured on Packet-over-SONET/SDH (POS) interface 0/2/0/1:

```
RP/0/0/CPU0:router#show ospf 1 interface

pos 0
/2
/1
/0
POS0/2/1/0 is up, line protocol is up
  Internet Address 10.111.4.11/24, Area 0
  Process ID 100, Router ID 10.11.11.11, Network Type POINT_TO_POINT, Cost: 1
  Interface is multi-area adjacency
```

```

LDP Sync Enabled, Sync Status: Achieved
Transmit Delay is 1 sec, State POINT_TO_POINT,
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Non-Stop Forwarding (NSF) enabled
  Hello due in 00:00:09
Index 5/5, flood queue length 0
Next 0(0)/0(0)
Last flood scan length is 4, maximum is 7
Last flood scan time is 0 msec, maximum is 1 msec
Neighbor Count is 1, Adjacent neighbor count is 1
  Adjacent with neighbor 10.1.1.1
Suppress hello for 0 neighbor(s)
Multi-area interface Count is 0
Loopback0 is up, line protocol is up
Internet Address 200.2.2.2/32, Area 1
Process ID 1, Router ID 200.2.2.2, Network Type LOOPBACK, Cost: 1
Loopback interface is treated as a stub Host
RP/0/RSP0/CPU0:router#

```

This table describes the significant fields shown in the display.

**Table 99: show ospf interface Field Descriptions**

| Field                         | Description                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| POS                           | Status of the physical link.                                                                                               |
| line protocol                 | Operational status of the protocol.                                                                                        |
| Internet Address              | Interface IP address, subnet mask, and area address.                                                                       |
| Process ID                    | OSPF process ID, router ID, network type, and link-state cost.                                                             |
| LDP Sync Enabled, Sync Status | LDP Sync configuration state and operational status. Displayed only when the OSPF process is configured for MPLS LDP Sync. |
| Transmit Delay                | Transmit delay, interface state, and router priority.                                                                      |
| Timer intervals configured    | Configuration of timer intervals.                                                                                          |
| Hello                         | Number of seconds until next hello packet is sent over this interface.                                                     |
| Index 1/1                     | Area and autonomous system flood indexes.                                                                                  |
| Next 0x0(0)                   | Next area and autonomous system flood information, data pointer, and index.                                                |
| Last flood scan length        | Length of last flood scan.                                                                                                 |
| Last flood scan time          | Time (in milliseconds) of last flood scan.                                                                                 |
| Neighbor Count                | Count of network neighbors and list of adjacent neighbors.                                                                 |

| Field                | Description                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------|
| Suppress hello       | Count of neighbors suppressing hello messages.                                                           |
| Multi-area interface | Multiple area interface information for the primary interface, such as count and area/neighbor location. |

## show ospf mpls traffic-eng

To display information about the links and fragments available on the local router for traffic engineering, use the **show ospf mpls traffic-eng** command in EXEC mode.

**show ospf** [ *process-name* ] [ **vrf** { *vrf-name* | **all** } ] [ *area-id* ] [ *type interface-path-id* ] **mpls traffic-eng** { **link** | **fragment** }

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) OSPF process name that uniquely identifies an OSPF routing process. The process name is any alphanumeric string no longer than 40 characters. If this argument is included, only information for the specified routing process is included.                          |
| <b>vrf</b>               | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                         |
| <i>vrf-name</i>          | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                                                                  |
| <b>all</b>               | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                                                    |
| <i>area-id</i>           | (Optional) Area number used to define the particular area.                                                                                                                                                                                                                      |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <b>link</b>              | Provides detailed information about the links over which traffic engineering is supported on the local router.                                                                                                                                                                  |
| <b>fragment</b>          | Provides detailed information about the traffic engineering fragments on the local router.                                                                                                                                                                                      |

### Command Default

All links or fragments

### Command Modes

EXEC

### Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.6.0 | The <b>all</b> keyword was added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf mpls traffic-eng** command when the **link** keyword is specified:

```
RP/0/0/CPU0:router# show ospf mpls traffic-eng link

      OSPF Router with ID (10.10.10.10) (Process ID 1)

Area 0 has 2 MPLS TE links. Area instance is 67441.

Links in hash bucket 3.
  Link is associated with fragment 1. Link instance is 67441
    Link connected to Point-to-Point network
    Link ID : 10.10.10.8
    Interface Address : 10.10.10.2
    Neighbor Address : 10.10.10.3
    Admin Metric : 0
    Maximum bandwidth : 19440000
    Maximum global pool reservable bandwidth : 25000000
    Maximum sub pool reservable bandwidth : 3125000
    Number of Priority : 8
    Global pool unreserved BW
    Priority 0 : 25000000 Priority 1 : 25000000
    Priority 2 : 25000000 Priority 3 : 25000000
    Priority 4 : 25000000 Priority 5 : 25000000
    Priority 6 : 25000000 Priority 7 : 25000000
    Sub pool unreserved BW
    Priority 0 : 3125000 Priority 1 : 3125000
    Priority 2 : 3125000 Priority 3 : 3125000
    Priority 4 : 3125000 Priority 5 : 3125000
    Priority 6 : 3125000 Priority 7 : 3125000
    Affinity Bit : 0

Links in hash bucket 8.
  Link is associated with fragment 0. Link instance is 67441
    Link connected to Point-to-Point network
    Link ID : 10.1.1.1
    Interface Address : 10.10.25.4
    Neighbor Address : 10.10.25.5
    Admin Metric : 0
    Maximum bandwidth : 19440000
    Maximum global pool reservable bandwidth : 25000000
    Maximum sub pool reservable bandwidth : 3125000
    Number of Priority : 8
    Global pool unreserved BW
    Priority 0 : 25000000 Priority 1 : 25000000
    Priority 2 : 25000000 Priority 3 : 25000000
    Priority 4 : 25000000 Priority 5 : 25000000
    Priority 6 : 25000000 Priority 7 : 25000000
    Sub pool unreserved BW
    Priority 0 : 3125000 Priority 1 : 3125000
```

```

Priority 2 :    3125000  Priority 3 :    3125000
Priority 4 :    3125000  Priority 5 :    3125000
Priority 6 :    3125000  Priority 7 :    3125000
Affinity Bit : 0

```

This table describes the significant fields shown in the display.

**Table 100: show ospf mpls traffic-eng link Field Descriptions**

| Field                                    | Description                                                                                                                                                                                                                       |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Link ID                                  | Link type.                                                                                                                                                                                                                        |
| Interface address                        | IP address of the interface.                                                                                                                                                                                                      |
| Neighbor address                         | IP address of the neighbor.                                                                                                                                                                                                       |
| Admin Metric                             | Administrative distance metric value used by Multiprotocol Label Switching traffic engineering (MPLS TE).                                                                                                                         |
| Maximum bandwidth                        | Bandwidth capacity of the link (in kbps).                                                                                                                                                                                         |
| Maximum global pool reservable bandwidth | Maximum amount of bandwidth that is available for reservation in the global pool.                                                                                                                                                 |
| Maximum sub pool reservable bandwidth    | Maximum amount of bandwidth that is available for reservation in the subpool.                                                                                                                                                     |
| Number of Priority                       | Priority number.                                                                                                                                                                                                                  |
| Global pool unreserved BW                | Amount of unreserved bandwidth that is available in the global pool.                                                                                                                                                              |
| Sub pool unreserved BW                   | Amount of unreserved bandwidth that is available in the subpool.                                                                                                                                                                  |
| Affinity Bit                             | Used by MPLS TE. Attribute values required for links carrying this tunnel. A 32-bit dotted-decimal number. Valid values are from 0x0 to 0xFFFFFFFF, representing 32 attributes (bits), where the value of an attribute is 0 or 1. |

The following is sample output from the **show ospf mpls traffic-eng** command when the **fragment** keyword is specified:

```

RP/0/0/CPU0:router# show ospf mpls traffic-eng fragment

      OSPF Router with ID (10.10.10.10) (Process ID 1)

Area 0 has 2 MPLS TE fragment. Area instance is 67441.
MPLS router address is 10.10.10.10
Next fragment ID is 2

```

```

Fragment 0 has 1 link. Fragment instance is 67441.
Fragment has 1 link the same as last update.
Fragment advertise MPLS router address
Link is associated with fragment 0. Link instance is 67441
Link connected to Point-to-Point network
Link ID : 10.1.1.1
Interface Address : 10.10.25.4
Neighbor Address : 10.10.25.5
Admin Metric : 0
Maximum bandwidth : 19440000
Maximum global pool reservable bandwidth : 25000000
Maximum sub pool reservable bandwidth : 3125000
Number of Priority : 8
Global pool unreserved BW
Priority 0 : 25000000 Priority 1 : 25000000

This table describes the significant fields shown in the display.

**Table 101: show ospf mpls traffic-eng fragment Field Descriptions**

| Field             | Description                                                          |
|-------------------|----------------------------------------------------------------------|
| Area instance     | Number of times traffic engineering information or any link changed. |
| Link instance     | Number of times any link changed.                                    |
| Link ID           | Link type.                                                           |
| Interface address | IP address of the interface.                                         |

| Field                                    | Description                                                                                                                                                                                                                       |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor address                         | IP address of the neighbor.                                                                                                                                                                                                       |
| Admin Metric                             | Administrative distance metric value used by MPLS TE.                                                                                                                                                                             |
| Maximum bandwidth                        | Bandwidth capacity of the link (in kbps).                                                                                                                                                                                         |
| Maximum global pool reservable bandwidth | Maximum amount of bandwidth that is available for reservation in the global pool.                                                                                                                                                 |
| Maximum sub pool reservable bandwidth    | Maximum amount of bandwidth that is available for reservation in the subpool.                                                                                                                                                     |
| Number of Priority                       | Priority number.                                                                                                                                                                                                                  |
| Global pool unreserved BW                | Amount of unreserved bandwidth that is available in the global pool.                                                                                                                                                              |
| Sub pool unreserved BW                   | Amount of unreserved bandwidth that is available in the subpool.                                                                                                                                                                  |
| Affinity Bit                             | Used by MPLS TE. Attribute values required for links carrying this tunnel. A 32-bit dotted-decimal number. Valid values are from 0x0 to 0xFFFFFFFF, representing 32 attributes (bits), where the value of an attribute is 0 or 1. |

# show ospf message-queue

To display the information about the queue dispatch values, peak lengths, and limits, use the **show ospf message-queue** command in EXEC mode.

## show ospf message-queue

This command has no arguments or keywords.

### Command Default

No default behavior or values

### Command Modes

EXEC

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

### Examples

The following is sample output from the **show ospf message-queue** command:

```
RP/0/0/CPU0:router# show ospf 1 message-queue

OSPF 1
  Hello Input Queue:
    Current queue length: 0
    Event scheduled: 0
    Total queuing failures: 0
    Maximum length : 102
    Pkts pending processing: 0
    Limit: 5000

  Router Message Queue
    Current instance queue length: 0
    Current redistribution queue length: 0
    Current ex spf queue length: 0
    Current sum spf queue length: 0
    Current intra spf queue length: 0
    Event scheduled: 0
    Maximum length : 101
    Total low queuing failures: 0
```

```

Total medium queuing failures: 0
Total high queuing failures: 0
Total instance events: 919
Processing quantum : 300
Low queuing limit: 8000
Medium queuing limit: 9000
High queuing limit: 9500
Rate-limited LSA processing quantum: 150
Current rate-limited LSA queue length: 0
Rate-limited LSA queue peak len: 517

Rate-limited LSAs processed: 4464
Flush LSA processing quantum: 150
Current flush LSA queue length: 0
Flush LSA queue peak len: 274
Rate-limited flush LSAs processed: 420

SPF-LSA-limit processing quantum: 150
Managed timers processing quantum: 50
Instance message count: 0
Instance pulse send count: 919
Instance pulse received count: 919
Global pulse count: 0
Instance Pulse errors: 0

TE Message Queue
Current queue length: 0
Total queuing failures: 0
Maximum length : 0

Number of Dlink errors: 0

```

This table describes the significant fields shown in the display.

**Table 102: show ospf message-queue Field Descriptions**

| Field                  | Description                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hello Input Queue      | This section provides statistics on the number of events and incoming packets processed in the Hello (incoming packet) thread of the OSPF process.                                                  |
| Router Message Queue   | This section provides statistics on the events and messages processed in the Router (primary) thread of the OSPF process.                                                                           |
| TE Message Queue       | This section provides statistics on traffic-engineering events and messages received by OSPF from TE (the te_control process). These events are processed in the Router thread of the OSPF process. |
| Number of Dlink errors | The number of enqueueing or dequeuing errors seen across all the linked-lists in the OSPF process.                                                                                                  |

**Related Commands**

| Command                                                       | Description                                                                                                                             |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">queue dispatch incoming, on page 1060</a>         | Limits the number of continuous incoming events processed.                                                                              |
| <a href="#">queue dispatch rate-limited-lsa, on page 1062</a> | Sets the maximum number of rate-limited link-state advertisements (LSAs) processed per run.                                             |
| <a href="#">queue dispatch spf-lsa-limit, on page 1064</a>    | Limits the number of summary or external Type 3 to Type 7 link-state advertisements (LSAs) processed per shortest path first (SPF) run. |
| <a href="#">queue limit, on page 1066</a>                     | Sets the high watermark for incoming priority events.                                                                                   |

# show ospf neighbor

To display Open Shortest Path First (OSPF) neighbor information on an individual interface basis, use the **show ospf neighbor** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*|**all**}] [*area-id*] **neighbor** [[*type interface-path-id*] [*neighbor-id*] [**detail**]| **area-sorted**]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed.                                                 |
| <b>vrf</b>               | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                         |
| <i>vrf-name</i>          | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                                                                  |
| <b>all</b>               | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                                                    |
| <i>area-id</i>           | (Optional) Area ID. If you do not specify an area, all areas are displayed.                                                                                                                                                                                                     |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>neighbor-id</i>       | (Optional) Neighbor ID.                                                                                                                                                                                                                                                         |
| <b>detail</b>            | (Optional) Displays all neighbors given in detail (lists all neighbors).                                                                                                                                                                                                        |
| <b>area-sorted</b>       | (Optional) Specifies that all neighbors are grouped by area.                                                                                                                                                                                                                    |

## Command Default

All neighbors

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                              |
|---------------|-------------------------------------------|
| Release 3.5.0 | The <b>area-sorted</b> keyword was added. |
| Release 3.6.0 | The <b>all</b> keyword was added.         |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf neighbor** command showing two lines of summary information for each neighbor:

```
RP/0/0/CPU0:router# show ospf neighbor
```

```
Neighbors for OSPF
```

```
Neighbor ID    Pri   State           Dead Time   Address           Interface
192.168.199.137 1     FULL/DR         0:00:31    172.31.80.37     GigabitEthernet 0/3/0/2
    Neighbor is up for 18:45:22
192.168.48.1   1     FULL/DROTHER    0:00:33    192.168.48.1     GigabitEthernet 0/3/0/3
    Neighbor is up for 18:45:30
192.168.48.200 1     FULL/DROTHER    0:00:33    192.168.48.200   GigabitEthernet 0/3/0/3
    Neighbor is up for 18:45:25
192.168.199.137 5     FULL/DR         0:00:33    192.168.48.189   GigabitEthernet 0/3/0/3
    Neighbor is up for 18:45:27
```

This table describes the significant fields shown in the display.

**Table 103: show ospf neighbor Field Descriptions**

| Field       | Description                                                                 |
|-------------|-----------------------------------------------------------------------------|
| Neighbor ID | Neighbor router ID.                                                         |
| Pri         | Designated router priority.                                                 |
| State       | OSPF state.                                                                 |
| Dead time   | Time (in hh:mm:ss) that must elapse before OSPF declares the neighbor dead. |
| Address     | Address of next hop.                                                        |

| Field          | Description                                                      |
|----------------|------------------------------------------------------------------|
| Interface      | Interface name of next hop.                                      |
| Neighbor is up | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up. |

The following is sample output showing summary information about the neighbor that matches the neighbor ID:

```
RP/0/0/CPU0:router# show ospf neighbor 192.168.199.137

Neighbor 192.168.199.137, interface address 172.31.80.37
  In the area 0.0.0.0 via interface GigabitEthernet 0/3/0/2
  Neighbor priority is 1, State is FULL, 6 state changes
  DR is 0.0.0.0 BDR is 0.0.0.0
  Options is 0x2
  Dead timer due in 0:00:32
  Neighbor is up for 18:45:30
  Number of DBD retrans during last exchange 0
  Index 1/1, retransmission queue length 0, number of retransmission 0
  First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
  Last retransmission scan length is 0, maximum is 0
  Last retransmission scan time is 0 msec, maximum 0 msec
Neighbor 192.168.199.137, interface address 192.168.48.189
  In the area 0.0.0.0 via interface GigabitEthernet 0/3/0/3
  Neighbor priority is 5, State is FULL, 6 state changes
  Options is 0x2
  Dead timer due in 0:00:32
  Neighbor is up for 18:45:30
  Number of DBD retrans during last exchange 0
  Index 1/1, retransmission queue length 0, number of retransmission 0
  First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
  Last retransmission scan length is 0, maximum is 0
  Last retransmission scan time is 0 msec, maximum 0 msec

Total neighbor count: 2
```

This table describes the significant fields shown in the display.

**Table 104: show ospf neighbor 192.168.199.137 Field Descriptions**

| Field             | Description                                                  |
|-------------------|--------------------------------------------------------------|
| Neighbor          | Neighbor router ID.                                          |
| interface address | IP address of the interface.                                 |
| In the area       | Area and interface through which the OSPF neighbor is known. |
| Neighbor priority | Router priority of neighbor and neighbor state.              |
| State             | OSPF state.                                                  |
| state changes     | Number of state changes for this neighbor.                   |

| Field                 | Description                                                                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| DR is                 | Neighbor ID of the designated router.                                                                                                     |
| BDR is                | Neighbor ID of the backup designated router.                                                                                              |
| Options               | Hello packet options field contents(E-bit only; possible values are 0 and 2; 2 indicates area is not a stub; 0 indicates area is a stub). |
| Dead timer            | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                                      |
| Neighbor is up        | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up.                                                                          |
| Number of DBD retrans | Number of re-sent database description packets.                                                                                           |
| Index                 | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor.            |

If you specify the interface along with the neighbor ID, the software displays the neighbors that match the neighbor ID on the interface, as in the following sample display:

```
RP/0/0/CPU0:router# show ospf neighbor GigabitEthernet 0/3/0/2 192.168.199.137

Neighbor 192.168.199.137, interface address 172.31.80.37
  In the area 0.0.0.0 via interface GigabitEthernet 0/3/0/2
  Neighbor priority is 1, State is FULL, 6 state changes
  DR is 0.0.0.0 BDR is 0.0.0.0
  Options is 0x2
  Dead timer due in 0:00:32
  Neighbor is up for 18:45:30
  Number of DBD retrans during last exchange 0
  Index 1/1, retransmission queue length 0, number of retransmission 0
  First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
  Last retransmission scan length is 0, maximum is 0
  Last retransmission scan time is 0 msec, maximum 0 msec

Total neighbor count: 1
```

This table describes the significant fields shown in the display.

**Table 105: show ospf neighbor GigabitEthernet 0/3/0/2 192.168.199.137 Field Descriptions**

| Field             | Description                                                  |
|-------------------|--------------------------------------------------------------|
| Neighbor          | Neighbor router ID.                                          |
| interface address | IP address of the interface.                                 |
| In the area       | Area and interface through which the OSPF neighbor is known. |

| Field                 | Description                                                                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor priority     | Router priority of the neighbor.                                                                                                          |
| State                 | OSPF state.                                                                                                                               |
| state changes         | Number of state changes for this neighbor.                                                                                                |
| DR is                 | Neighbor ID of the designated router.                                                                                                     |
| BDR is                | Neighbor ID of the backup designated router.                                                                                              |
| Options               | Hello packet options field contents (E-bit only; possible values are 0 and 2; 2 indicates area is not a stub; 0 indicates area is a stub) |
| Dead timer            | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                                      |
| Neighbor is up        | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up.                                                                          |
| Number of DBD retrans | Number of re-sent database description packets.                                                                                           |
| Index                 | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor.            |

You can also specify the interface without the neighbor ID to show all neighbors on the specified interface, as in the following sample display:

```
RP/0/0/CPU0:router# show ospf neighbor GigabitEthernet POS 0/3/0/3

Neighbors for OSPF ospf1

   ID            Pri    State           Dead Time      Address          Interface
192.168.48.1      1    FULL/DROTHER   0:00:33      192.168.48.1    GigabitEthernet POS
0/3/0/3
   Neighbor is up for 18:50:52
192.168.48.200    1    FULL/DROTHER   0:00:32      192.168.48.200  GigabitEthernet POS
0/3/0/3
   Neighbor is up for 18:50:52
192.168.199.137  5    FULL/DR        0:00:32      192.168.48.189  GigabitEthernet POS
0/3/0/3
   Neighbor is up for 18:50:52

Total neighbor count: 3
```

This table describes the significant fields shown in the display.

**Table 106: show ospf neighbor GigabitEthernet 0/3/0/3 Field Descriptions**

| Field                 | Description                                                                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| ID                    | Neighbor router ID.                                                                                                                       |
| Pri                   | Route priority of the neighbor.                                                                                                           |
| State                 | OSPF state.                                                                                                                               |
| Dead Time             | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                                      |
| Address               | Address of next hop.                                                                                                                      |
| Interface             | Interface name of next hop.                                                                                                               |
| Neighbor is up        | Time (in hh:mm:ss) that the OSPF neighbor has been up.                                                                                    |
| Options               | Hello packet options field contents (E-bit only; possible values are 0 and 2; 2 indicates area is not a stub; 0 indicates area is a stub) |
| Dead timer            | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                                      |
| Neighbor is up        | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up.                                                                          |
| Number of DBD retrans | Number of re-sent database description packets.                                                                                           |
| Index                 | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor.            |

The following samples are from output from the **show ospf neighbor detail** command:

```
RP/0/0/CPU0:router# show ospf neighbor detail

Neighbor 192.168.199.137, interface address 172.31.80.37
  In the area 0.0.0.0 via interface GigabitEthernet 0/3/0/2
  Neighbor priority is 1, State is FULL, 6 state changes
  DR is 0.0.0.0 BDR is 0.0.0.0
  Options is 0x2
  Dead timer due in 0:00:32
  Neighbor is up for 18:45:30
  Number of DBD retrans during last exchange 0
  Index 1/1, retransmission queue length 0, number of retransmission 0
  First 0x0(0)/0x0(0) Next 0x0(0)/0x0(0)
  Last retransmission scan length is 0, maximum is 0
  Last retransmission scan time is 0 msec, maximum 0 msec

Total neighbor count: 1
```

```

Neighbor 10.1.1.1, interface address 192.168.13.1
  In the area 0 via interface GigabitEthernet0/3/0/1
  Neighbor priority is 1, State is FULL, 10 state changes
  DR is 0.0.0.0 BDR is 0.0.0.0
  Options is 0x52
  LLS Options is 0x1 (LR)
  Dead timer due in 00:00:36
  Neighbor is up for 1w2d
  Number of DBD retrans during last exchange 0
  Index 3/3, retransmission queue length 0, number of retransmission 5
  First 0(0)/0(0) Next 0(0)/0(0)
  Last retransmission scan length is 1, maximum is 1
  Last retransmission scan time is 0 msec, maximum is 0 msec

Neighbor 10.4.4.4, interface address 192.168.34.4
  In the area 0 via interface GigabitEthernet0/3/0/2

```

This table describes the significant fields shown in the display.

**Table 107: show ospf neighbor detail Field Descriptions**

| Field                   | Description                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor                | Neighbor router ID.                                                                                                                                           |
| interface address       | IP address of the interface.                                                                                                                                  |
| In the area             | Area and interface through which the OSPF neighbor is known.                                                                                                  |
| Neighbor priority       | Router priority of neighbor and neighbor state.                                                                                                               |
| State                   | OSPF state.                                                                                                                                                   |
| state changes           | Number of state changes for this neighbor.                                                                                                                    |
| DR is                   | Neighbor ID of the designated router.                                                                                                                         |
| BDR is                  | Neighbor ID of the backup designated router.                                                                                                                  |
| Options                 | Hello packet options field contents. (E-bit only; possible values are 0 and 2; 2 indicates that the area is not a stub; 0 indicates that the area is a stub.) |
| LLS Options is 0x1 (LR) | Neighbor is NFS Cisco capable.                                                                                                                                |

| Field                 | Description                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Dead timer            | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                           |
| Neighbor is up        | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up.                                                               |
| Number of DBD retrans | Number of re-sent database description packets.                                                                                |
| Index                 | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor. |

# show ospf request-list

To display the first ten link-state requests pending that the local router is making to the specified Open Shortest Path First (OSPF) neighbor and interface, use the **show ospf request-list** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*|**all**}] [*area-id*] **request-list** [*type interface-path-id*] [*neighbor-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed.                                         |
| <b>vrf</b>               | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                 |
| <i>vrf-name</i>          | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings "default" and "all" are reserved VRF names.                                                                                                          |
| <b>all</b>               | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                                                            |
| <i>area-id</i>           | (Optional) Area ID. If you do not specify an area, all areas are displayed.                                                                                                                                                                                             |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                   |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br>Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>neighbor-id</i>       | (Optional) IP address of the OSPF neighbor.                                                                                                                                                                                                                             |

## Command Default

All neighbors

## Command Modes

EXEC

## Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.6.0 | The <b>all</b> keyword was added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You might use this command when the databases of two neighboring routers are out of synchronization or if the adjacency does not form between them. Adjacency means that the routers synchronize their databases when they discover each other.

You can look at the list to determine if one router is trying to request a particular database update. Entries that are suspended in the list usually indicate that updates are not being delivered. One possible reason for this behavior is a maximum transmission unit (MTU) mismatch between the routers.

You might also look at this list to make sure it is not corrupted. The list should refer to database entries that actually exist.

Request list information is transient and normally the lists are empty.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf request-list** command:

```
RP/0/0/CPU0:router# show ospf request-list 10.0.124.4 GigabitEthernet3/0/0/0
Request Lists for OSPF pagent
Neighbor 10.0.124.4, interface GigabitEthernet3/0/0/0 address 10.3.1.2
Type   LS ID           ADV RTR           Seq NO           Age    Checksum
  1    192.168.58.17    192.168.58.17    0x80000012      12    0x0036f3
  2    192.168.58.68    192.168.58.17    0x80000012      12    0x00083f
```

This table describes the significant fields shown in the display.

**Table 108: show ospf request-list 10.0.124.4 GigabitEthernet3/0/0/0 Field Descriptions**

| Field     | Description                                                         |
|-----------|---------------------------------------------------------------------|
| Neighbor  | Specific neighbor receiving the request list from the local router. |
| Interface | Specific interface over which the request list is being sent.       |
| Address   | Address of the interface over which the request list is being sent. |
| Type      | Type of link-state advertisement (LSA).                             |

| Field    | Description                           |
|----------|---------------------------------------|
| LS ID    | Link-state ID of the LSA.             |
| ADV RTR  | IP address of the advertising router. |
| Seq NO   | Sequence number of the LSA.           |
| Age      | Age of the LSA (in seconds).          |
| Checksum | Checksum of the LSA.                  |

## Syntax Description

|                         |                                                                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>     | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>              | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>         | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                  |
| <b>all</b>              | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |
| <b>connected</b>        | (Optional) Displays connected routes.                                                                                                                                                                                           |
| <b>external</b>         | (Optional) Displays routes redistributed from other protocols.                                                                                                                                                                  |
| <b>local</b>            | (Optional) Displays the local routes redistributed from the Routing Information Base (RIB).                                                                                                                                     |
| <i>prefix</i>           | (Optional) IP prefix, which limits output to a specific route.<br>If the <i>prefix</i> argument is specified, either the <i>length</i> or <i>mask</i> argument is required.                                                     |
| <i>mask</i>             | (Optional) IP address mask.                                                                                                                                                                                                     |
| <i>/ length</i>         | (Optional) Prefix length, which can be indicated as a slash (/) and number. For example, /8 indicates that the first eight bits in the IP prefix are network bits. If <i>length</i> is used, the slash is required.             |
| <b>multicast-intact</b> | (Optional) Displays multicast intact paths.                                                                                                                                                                                     |
| <b>backup-path</b>      | (Optional) Displays fast-reroute backup path information.                                                                                                                                                                       |

**Command History**

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.3.0 | The command was changed from show ospf route to show ospf routes.                                                                                                                                                                    |
| Release 3.6.0 | The <b>multicast-intact</b> keyword was added.<br>The <b>all</b> keyword was added.                                                                                                                                                  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |
| Release 4.0.1 | The <b>backup-path</b> keyword was added.                                                                                                                                                                                            |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf routes** command to display the OSPF private routing table (which contains only routes calculated by OSPF). If there is something wrong with a route in the RIB, then it is useful to check the OSPF copy of the route to determine if it matches the RIB contents. If it does not match, there is a synchronization problem between OSPF and the RIB. If the routes match and the route is incorrect, OSPF has made an error in its routing calculation.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following is sample output from the **show ospf routes** command:

```
RP/0/0/CPU0:router# show ospf routes

Topology Table for ospf 1 with ID 10.3.4.2

Codes:O - Intra area, O IA - Inter area
       O E1 - External type 1, O E2 - External type 2
       O N1 - NSSA external type 1, O N2 - NSSA external type 2

O E2 10.3.1.0/24, metric 1
    10.3.4.1, from 172.16.10.1, via GigabitEthernet 0/1/0/1
O    10.3.4.0/24, metric 1562
    10.3.4.2, directly connected, via GigabitEthernet 0/1/0/1
O E2 10.1.0.0/16, metric 1
    10.3.4.1, from 172.16.10.1, via GigabitEthernet 0/1/0/1
O IA 10.10.10.0/24, metric 1572
    10.3.4.1, from 172.16.10.1, via GigabitEthernet 0/1/0/1
O E2 130.10.10.0/24, metric 20
```

```
10.3.4.1, from 172.16.10.1, via GigabitEthernet 0/1/0/1
```

This table describes the significant fields shown in the display.

**Table 110: show ospf route Field Descriptions**

| Field            | Description                                                                              |
|------------------|------------------------------------------------------------------------------------------|
| O                | OSPF route.                                                                              |
| E2               | External Type 2 route.                                                                   |
| 10.3.1.0/24      | Network and subnet mask to which the local router has a route.                           |
| metric 1         | Cost to reach network 10.3.1.0.                                                          |
| 10.3.4.1         | Next-hop router on the path to network 10.3.1.0.                                         |
| from 172.16.10.1 | Router ID 172.16.10.1 is the router that advertised this route.                          |
| via POS 0/1/0/1  | Packets destined for the given prefix (10.3.1.0/24) are sent over POS interface 0/1/0/1. |

The following is sample output from the **show ospf routes** command with a process name of 100:

```
RP/0/0/CPU0:router# show ospf 100 routes
Topology Table for ospf 100 with ID 172.23.54.14
Codes:O - Intra area, O IA - Inter area
       O E1 - External type 1, O E2 - External type 2
       O N1 - NSSA external type 1, O N2 - NSSA external type 2
O      10.1.5.0/24, metric 1562
       10.1.5.14, directly connected, via GigabitEthernet 0/3/0/3
O IA   21.0.0.0/24, metric 1572
       10.1.5.12, from 172.23.54.12, via GigabitEthernet 0/3/0/3
O      10.0.0.0/24, metric 10
       10.0.0.12, directly connected, via GigabitEthernet 0/2/0/3
```

This table describes the significant fields shown in the display.

**Table 111: show ospf 100 route Field Descriptions**

| Field | Description      |
|-------|------------------|
| O     | OSPF route.      |
| IA    | Interarea route. |

| Field                       | Description                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| 10.1.5.0/24                 | Network and subnet mask to which the local router has a route.                                       |
| metric 1562                 | Cost to reach network 10.1.5.0.                                                                      |
| 10.1.5.14                   | Next-hop router on the path to network 10.1.5.0.                                                     |
| from 172.23.54.12           | Router ID 172.23.54.12 is the router that advertised this route.                                     |
| via GigabitEthernet 0/3/0/3 | Packets destined for the given prefix (10.3.1.0/24) are sent over GigabitEthernet interface 0/3/0/3. |

The following is sample output from the **show ospf routes** command with a prefix of 10.0.0.0 and a length of 24:

```
RP/0/0/CPU0:router# show ospf routes 10.0.0.0/24
Topology Table for ospf 100 with ID 172.23.54.14
Codes:O - Intra area, O IA - Inter area
       O E1 - External type 1, O E2 - External type 2
       O N1 - NSSA external type 1, O N2 - NSSA external type 2
O IA 10.0.0.0/24, metric 1572
     10.1.5.12, from 172.23.54.12, via GigabitEthernet 0/3/0/3
```

This table describes the significant fields shown in the display.

**Table 112: show ospf route 10.0.0.0/24 Field Descriptions**

| Field                       | Description                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| O                           | Route is an OSPF route.                                                                              |
| IA                          | Route to network 10.0.0.0 is an interarea route.                                                     |
| 10.0.0.0/24                 | Network and subnet mask to which the local router has a route.                                       |
| metric 1572                 | Cost to reach network 10.0.0.0.                                                                      |
| 10.1.5.12                   | IP address of next-hop router on the path to network 10.0.0.0.                                       |
| from 172.23.54.12           | Router ID 172.23.54.12 is the router that advertised this route.                                     |
| via GigabitEthernet 0/3/0/3 | Packets destined for the given prefix (10.0.0.0/24) are sent over GigabitEthernet interface 0/3/0/3. |

This is sample output from the **show ospf routes** command with **backup-path** keyword that displays backup-path information:

```
RP/0/0/CPU0:router#show ospf routes backup-path

Topology Table for ospf 2 with ID 10.1.1.6

Codes: O - Intra area, O IA - Inter area
        O E1 - External type 1, O E2 - External type 2
        O N1 - NSSA external type 1, O N2 - NSSA external type 2

O    2.4.1.0/24, metric 50
      2.4.1.2, directly connected, via TenGigE0/4/0/0
O    10.1.1.3/32, metric 11
      200.40.1.101, from 10.1.1.3, via Bundle-Ether1.1, path-id 1
      Backup path:
        100.100.2.1, from 10.1.1.3, via TenGigE0/2/0/3.1, protected bitmap 0x1
O    10.1.1.6/32, metric 1
      10.1.1.6, directly connected, via Loopback0
O    10.1.1.9/32, metric 22
      200.40.1.101, from 10.1.1.9, via Bundle-Ether1.1, path-id 1
      Backup path:
        100.100.2.1, from 10.1.1.9, via TenGigE0/2/0/3.1, protected bitmap 0x1
O    10.1.1.10/32, metric 111
      200.40.1.101, from 10.1.1.10, via Bundle-Ether1.1, path-id 1
      Backup path:
        100.100.2.1, from 10.1.1.10, via TenGigE0/2/0/3.1, protected bitmap 0x1
```

# show ospf sham-links

To display Open Shortest Path First (OSPF) sham-link information, use the **show ospf sham-links** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*|**all**}] **sham-links**

## Syntax Description

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings "default" and "all" are reserved VRF names.                                                                  |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |

| Release 3.6.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf sham-links** command to display OSPF sham-link information.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

## Examples

The following is sample output from the **show ospf sham-links** command:

```
RP/0/0/CPU0:router# show ospf 1 vrf vrf_1 sham-links
```

```
Sham Links for OSPF 1, VRF vrf_1

Sham Link OSPF_SL0 to address 10.0.0.3 is up
Area 0, source address 10.0.0.1
IfIndex = 185
Run as demand circuit
DoNotAge LSA allowed., Cost of using 1
Transmit Delay is 1 sec, State POINT_TO_POINT,
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 00:00:04
Adjacency State FULL (Hello suppressed)
Number of DBD retrans during last exchange 0
Index 2/2, retransmission queue length 0, number of retransmission 0
First 0(0)/0(0) Next 0(0)/0(0)
Last retransmission scan length is 0, maximum is 0
Last retransmission scan time is 0 msec, maximum is 0 msec
Keychain-based authentication enabled
Key id used is 2
```

This table describes the significant fields shown in the display.

**Table 113: show ospf sham-links Field Descriptions**

| Field                                      | Description                                                                |
|--------------------------------------------|----------------------------------------------------------------------------|
| Sham Link OSPF_SL0 to address              | Address of the destination endpoint of the sham link.                      |
| IfIndex                                    | ifindex associated with the sham link.                                     |
| Run as demand circuit                      | Sham link is treated as a demand circuit.                                  |
| DoNotAge LSA allowed                       | DoNotAge LSAs are allowed to be flooded over the sham link.                |
| Cost of using                              | Sham-link cost.                                                            |
| Transmit Delay                             | Sham-link transmit delay.                                                  |
| State                                      | Sham-link interface state.                                                 |
| Timer intervals configured                 | Various sham-link interface-related timers.                                |
| Hello due in                               | Time before the next Hello is sent over the sham link.                     |
| Adjacency State                            | State of the adjacency with the neighbor over the sham link.               |
| Number of DBD retrans during last exchange | Number of DBD retransmissions during the last exchange over the sham link. |
| Index                                      | Area flood index.                                                          |
| retransmission queue length                | Retransmission queue length on the sham link.                              |

| Field                                 | Description                                                    |
|---------------------------------------|----------------------------------------------------------------|
| number of retransmission              | Number of retransmissions over the sham-link interface.        |
| First                                 | First flood information.                                       |
| Next                                  | Next flood information.                                        |
| Last retransmission scan length is    | Last retransmission scan length on the sham-link interface.    |
| maximum is                            | Maximum retransmission scan length on the sham-link interface. |
| Last retransmission scan time is      | Last retransmission scan time on the sham-link interface.      |
| maximum is 0 msec                     | Maximum retransmission scan time on the sham-link interface.   |
| Keychain-based authentication enabled | Keychain-based authentication is enabled.                      |
| Key id used is                        | Key ID used.                                                   |

# show ospf statistics interface

To display the per interface statistics for OSPFv2, use the **show ospf statistics interface** command in EXEC mode.

**show ospf** [*process name* [*area id*]] [**vrf** {*vrf-name*| **all**}] [*area id*] **statistics interface** [*interface name*] **summary-only**

## Syntax Description

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <i>area id</i>      | (Optional) Area number used to define the particular area.                                                                                                                                                                      |
| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                  |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |
| <b>summary-only</b> | (Optional) Displays only the summary statistics for the given instance or area (if specified).                                                                                                                                  |

| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings "default" and "all" are reserved VRF names.                                                                  |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |

## Command Default

All summary prefixes

## Command Modes

EXEC

## Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.6.0 | The <b>all</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf summary-prefix** command if you configured summarization of external routes with the **summary-prefix** command and you want to display configured summary addresses.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

## Examples

The following is sample output from the **show ospf summary-prefix** command:

```
RP/0/0/CPU0:router# show ospf summary-prefix
OSPF Process 1, summary-prefix
10.1.0.0/255.255.0.0 Metric 20, Type 2, Tag 0
```

This table describes the significant fields shown in the display.

**Table 115: show ospf summary-prefix Field Descriptions**

| Field                | Description                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------|
| 10.1.0.0/255.255.0.0 | Summary address designated for a range of addresses. The IP subnet mask used for the summary route. |
| Metric               | Metric used to advertise the summary routes.                                                        |
| Type                 | External link-state advertisements (LSA) metric type.                                               |
| Tag                  | Tag value that can be used as a “match” value for controlling redistribution through route maps.    |

To display parameters and the current state of Open Shortest Path First (OSPF) virtual links, use the **show ospf virtual-links** command in EXEC mode.

**show ospf** [*process-name*] [**vrf** {*vrf-name*|**all**}] **virtual-links**

## Syntax Description

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPF routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>          | (Optional) Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                         |
| <i>vrf-name</i>     | (Optional) Name of the OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names.                                                                  |
| <b>all</b>          | (Optional) Specifies all OSPF VRF instances.                                                                                                                                                                                    |

## Command Default

All virtual links

## Command Modes

EXEC

## Command History

| Release       | Modification                      |
|---------------|-----------------------------------|
| Release 3.2   | This command was introduced.      |
| Release 3.6.0 | The <b>all</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospf virtual-links** command to display useful information for debugging OSPF routing operations.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

## Examples

The following is sample output from the **show ospf virtual-links** command:

```
RP/0/0/CPU0:router# show ospf virtual-links

Virtual Link to router 172.31.101.2 is up
Transit area 0.0.0.1, via interface GigabitEthernet 0/3/0/0, Cost of using 10
Transmit Delay is 1 sec, State POINT_TO_POINT
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 0:00:08
Adjacency State FULL
```

This table describes the significant fields shown in the display.

**Table 116: show ospf virtual-links Field Descriptions**

| Field                                     | Description                                                              |
|-------------------------------------------|--------------------------------------------------------------------------|
| Virtual Link to router 172.31.101.2 is up | OSPF neighbor and whether the link to that neighbor is up or down.       |
| Transit area 0.0.0.1                      | Transit area through which the virtual link is formed.                   |
| via interface GigabitEthernet 0/3/0/0     | Interface through which the virtual link is formed.                      |
| Cost of usingusing 10                     | Cost of reaching the OSPF neighbor through the virtual link.             |
| Transmit Delay is 1 sec                   | Transmit delay (in seconds) on the virtual link.                         |
| State POINT_TO_POINT                      | State of the OSPF neighbor.                                              |
| Timer intervals                           | Various timer intervals (in seconds) configured for the link.            |
| Hello due in 0:00:08                      | When the next hello message is expected from the neighbor (in hh:mm:ss). |
| Adjacency State FULL                      | Adjacency state between the neighbors.                                   |

## Related Commands

| Command                                    | Description                         |
|--------------------------------------------|-------------------------------------|
| <a href="#">router ospf</a> , on page 1081 | Configures an OSPF routing process. |

# show protocols (OSPF)

To display information about the OSPFv2 processes running on the router, use the **show protocols** command in EXEC mode.

**show protocols** [**afi-all**| **ipv4**| **ipv6**] [**all**| *protocol*]

## Syntax Description

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>afi-all</b>  | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ipv4</b>     | (Optional) Specifies an IPv4 address family.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipv6</b>     | (Optional) Specifies an IPv6 address family.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>all</b>      | (Optional) Specifies all protocols for a given address family.                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>protocol</i> | <p>(Optional) Specifies a routing protocol. For the IPv4 address family, the options are:</p> <ul style="list-style-type: none"> <li>• <b>bgp</b></li> <li>• <b>eigrp</b></li> <li>• <b>isis</b></li> <li>• <b>ospf</b></li> <li>• <b>rip</b></li> </ul> <p>For the IPv6 address family, the options are:</p> <ul style="list-style-type: none"> <li>• <b>bgp</b></li> <li>• <b>eigrp</b></li> <li>• <b>isis</b></li> <li>• <b>ospfv3</b></li> </ul> |

This table describes the significant fields shown in the display.

**Table 117: show protocols ospf Field Descriptions**

| Field               | Description                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Router Id           | ID of the router for this configuration.                                                                                                       |
| Distance            | Administrative distance of OSPF routes relative to routes from other protocols.                                                                |
| Non-Stop Forwarding | Status of nonstop forwarding.                                                                                                                  |
| Redistribution      | Lists the protocols that are being redistributed.                                                                                              |
| Area                | Information about the current area including list of interfaces and the status of Multiprotocol Label Switching traffic engineering (MPLS TE). |

## snmp context (OSPF)

To specify an SNMP context for an OSPF instance, use the **snmp context** command in router configuration mode or in VRF configuration mode. To remove the SNMP context, use the **no** form of this command.

**snmp context** *context\_name*

**no snmp context** *context\_name*

### Syntax Description

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| <i>context_name</i> | Specifies name of the SNMP context for OSPF instance. |
|---------------------|-------------------------------------------------------|

### Command Default

SNMP context is not specified.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **snmp-server** commands need to be configured to perform SNMP request for the OSPF instance. Refer *SNMP Server Commands* module in *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for information on using the **snmp-server** commands.

#### Note

To map an SNMP context with a protocol instance, topology or VRF entity, use the **snmp-server context mapping** command. However, the **feature** option of this command does not work with OSPF protocol.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

## Examples

This example shows how to configure an SNMP context *foo* for OSPF instance *100*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#snmp context foo
```

This example shows how to configure **snmp-server** commands to be used with the **snmp context** command:

```
RP/0/0/CPU0:router(config)#snmp-server host 10.0.0.2 traps version 2c public udp-port 1620
RP/0/0/CPU0:router(config)#snmp-server community public RW
RP/0/0/CPU0:router(config)#snmp-server contact foo
RP/0/0/CPU0:router(config)#snmp-server community-map public context foo
```

This is a sample SNMP context configuration for OSPF instance *100*:

```
snmp-server host 10.0.0.2 traps version 2c public udp-port 1620
snmp-server community public RW
snmp-server contact foo
```

```
snmp-server community-map public context foo
```

```
router ospf 100
router-id 2.2.2.2
bfd fast-detect
nsf cisco
snmp context foo
area 0
interface Loopback1
!
!
area 1
interface GigabitEthernet0/2/0/1
demand-circuit enable
!
interface POS0/3/0/0
!
interface POS0/3/0/1
!
!
!
```

| <b>snmp-server host</b>                                         | Specifies the recipient of an SNMP notification operation.                                                |
| <b>snmp-server community</b>                                    | Configures the community access string to permit access to the Simple Network Management Protocol (SNMP). |
| <b>snmp-server contact</b>                                      | Sets the Simple Network Management Protocol (SNMP) system contact.                                        |

| Command                          | Description                                                                            |
|----------------------------------|----------------------------------------------------------------------------------------|
| <b>snmp-server community-map</b> | Associates a Simple Network Management Protocol (SNMP) community with an SNMP context. |

## snmp trap (OSPF)

To enable SNMP trap for an OSPF instance, use the **snmp trap** command in VRF configuration mode. To disable SNMP trap for the OSPF instance, use the **no** form of this command.

**snmp trap**

**no snmp trap**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Disabled.

**Command Modes** VRF configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.1.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operation   |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** This example shows how to enable SNMP trap for OSPF instance *100* under VRF *vrf-1*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#vrf vrf-1
RP/0/0/CPU0:router(config-ospf-vrf)#snmp trap
```

| Related Commands | Command                                            | Description                                  |
|------------------|----------------------------------------------------|----------------------------------------------|
|                  | <a href="#">snmp context (OSPF)</a> , on page 1153 | Specifies SNMP context for an OSPF instance. |

# snmp trap rate-limit (OSPF)

To control the number of traps that OSPF sends by configuring window size and the maximum number of traps during that window, use the **snmp trap rate-limit** command in router configuration mode. To disable configuring the window size and maximum number of traps during the window, use the **no** form of this command.

**snmp trap rate-limit** *window-size max-num-traps*

**no snmp trap rate-limit** *window-size max-num-traps*

## Syntax Description

|                      |                                                            |
|----------------------|------------------------------------------------------------|
| <i>window-size</i>   | Specifies the trap rate limit sliding window size.         |
| <i>max-num-traps</i> | Specifies the maximum number of traps sent in window time. |

## Command Default

None

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                                                            |
|---------------|---------------------------------------------------------------------------------------------------------|
| Release 3.9.0 | This command was introduced. This command replaces the <b>snmp-server trap ospf rate-limit</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation  |
|---------|------------|
| ospf    | read,write |

## Examples

The following example shows how to set the trap rate limit sliding window size to 30 and the maximum number of traps sent to 100:

```
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#snmp trap rate-limit 30 100
```

## spf prefix-priority (OSPFv2)

To prioritize OSPFv2 prefix installation into the global Routing Information Base (RIB) during Shortest Path First (SPF) run, use the **spf prefix-priority** command in router configuration mode. To return to the system default value, use the **no** form of this command.

**spf prefix-priority route-policy** *policy-name*

**no spf prefix-priority route-policy** *policy-name*

### Syntax Description

**route-policy** *policy-name* Specifies the route policy to apply to OSPFv2 prefix prioritization.

**Note** If SPF prefix prioritization is configured, /32 prefixes are no longer preferred by default. To retain the /32 prefixes in higher-priority queues, define the route-policy accordingly.

### Command Default

SPF prefix prioritization is disabled.

### Command Modes

OSPF router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

SPF prefix prioritization is disabled, by default. In disabled mode, the /32 prefixes are installed into the global RIB before other prefixes.

If SPF prefix prioritization is enabled, routes are matched against the route-policy criteria and are assigned to the appropriate priority queue based on the spf-priority set. Unmatched prefixes, including the /32 prefixes, are placed in the low-priority queue.

If all /32 prefixes are desired in the high-priority queue or medium-priority queue, configure the following single route map:

```
prefix-set ospf-medium-prefixes
  0.0.0.0/0 ge 32
end-set
```

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure OSPFv2 SPF prefix prioritization:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# prefix-set ospf-critical-prefixes
RP/0/0/CPU0:router(config-pfx)# 66.0.0.0/16
RP/0/0/CPU0:router(config-pfx)# end-set
RP/0/0/CPU0:router(config)# route-policy ospf-spf-priority
RP/0/0/CPU0:router(config-rpl)# if destination in ospf-critical-prefixes then set
spf-priority critical
endif
RP/0/0/CPU0:router(config-rpl)# end-policy
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# router-id 66.0.0.1
RP/0/0/CPU0:router(config-ospf)# spf prefix-priority route-policy ospf-spf-priority
```

**Related Commands**

| Command                   | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>prefix-set</b>         | Enters prefix set configuration mode and defines a prefix set.     |
| <b>route-policy (RPL)</b> | Defines a route policy and enters route-policy configuration mode. |

## stub (OSPF)

To define an area as a stub area, use the **stub** command in area configuration mode. To disable this function, use the **no** form of this command.

**stub [no-summary]**

**no stub**

### Syntax Description

|                   |                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------|
| <b>no-summary</b> | (Optional) Prevents an Area Border Router (ABR) from sending summary link advertisements into the stub area. |
|-------------------|--------------------------------------------------------------------------------------------------------------|

### Command Default

No stub area is defined.

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must configure the **stub** command on all routers in the stub area.

Use the **default-cost** command on the ABR of a stub area to specify the cost of the default route advertised into the stub area by the ABR.

To further reduce the number of link-state advertisements (LSAs) sent into a stub area, you can configure the **no-summary** keyword on the ABR to prevent it from sending summary LSAs (LSA Type 3) into the stub area.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to assign a default cost of 20 to stub network 10.0.0.0:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
```

```
RP/0/0/CPU0:router(config-ospf)# area 10.0.0.0
RP/0/0/CPU0:router(config-ospf-ar)# stub
RP/0/0/CPU0:router(config-ospf-ar)# default-cost 20
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/3/0/3
```

**Related Commands**

| Command                                            | Description                                                           |
|----------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">authentication (OSPF), on page 935</a> | Enables authentication for an OSPF area.                              |
| <a href="#">default-cost (OSPF), on page 961</a>   | Specifies a cost for the default summary route sent into a stub area. |

## summary-prefix (OSPF)

To create aggregate addresses for routes being redistributed from another routing protocol into the Open Shortest Path First (OSPF) protocol, use the **summary-prefix** command in the appropriate mode. To stop summarizing redistributed routes, use the **no** form of the command.

**summary-prefix** *address mask* [**not-advertise** | **tag** *tag*]

**no summary-prefix** *address mask*

### Syntax Description

|                       |                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| <i>address</i>        | Summary address designated for a range of addresses.                                                            |
| <i>mask</i>           | IP subnet mask used for the summary route.                                                                      |
| <b>not-advertise</b>  | (Optional) Suppresses summary routes that match the address and mask pair from being advertised.                |
| <b>tag</b> <i>tag</i> | (Optional) Tag value that can be used as a “match” value for controlling redistribution through route policies. |

### Command Default

When this command is not used, specific addresses are created for each route from another route source being distributed into the OSPF protocol.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **summary-prefix** command to cause an OSPF Autonomous System Boundary Router (ASBR) to advertise one external route as an aggregate for all redistributed routes that are covered by the address. This command summarizes only routes from other routing protocols that are being redistributed into OSPF.

You can use this command multiple times to summarize multiple groups of addresses. The metric used to advertise the summary is the lowest metric of all the more specific routes. This command helps reduce the size of the routing table.

If you want to summarize routes between OSPF areas, use the **range** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

In the following example, summary address 10.1.0.0 includes address 10.1.1.0, 10.1.2.0, 10.1.3.0, and so on. Only the address 10.1.0.0 is advertised in an external link-state advertisement.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# summary-prefix 10.1.0.0 255.255.0.0
```

**Related Commands**

| Command                                    | Description                                             |
|--------------------------------------------|---------------------------------------------------------|
| <a href="#">range (OSPF), on page 1068</a> | Consolidates and summarizes routes at an area boundary. |

## timers lsa group-pacing

To change the interval at which Open Shortest Path First (OSPF) link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged, use the **timers lsa group-pacing** command in the appropriate mode. To restore the default value, use the **no** form of this command.

**timers lsa group-pacing** *seconds*

**no timers lsa group-pacing**

### Syntax Description

|                |                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Interval (in seconds) at which LSAs are grouped and refreshed, checksummed, or aged. Range is 10 seconds to 1800 seconds. |
|----------------|---------------------------------------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 240 seconds

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF LSA group pacing is enabled by default. For typical customers, the default group pacing interval for refreshing, checksumming, and aging is appropriate and you need not configure this feature.

The duration of the LSA group pacing is inversely proportional to the number of LSAs the router is handling. For example, if you have approximately 10,000 LSAs, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to change the OSPF pacing between LSA groups to 60 seconds:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# router ospf 1  
RP/0/0/CPU0:router(config-ospf)# timers lsa group-pacing 60
```

# timers lsa min-arrival

To limit the frequency that new instances of any particular Open Shortest Path First (OSPF) link-state advertisements (LSAs) can be accepted during flooding, use the **timers lsa min-arrival** command in the appropriate mode. To restore the default value, use the **no** form of this command.

**timers lsa min-arrival** *milliseconds*

**no timers lsa min-arrival**

## Syntax Description

|                     |                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Minimum interval (in milliseconds) between accepting same LSA.<br>Range is 0 to 600000 milliseconds. |
|---------------------|------------------------------------------------------------------------------------------------------|

## Command Default

*milliseconds* : 100 milliseconds

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                    |
| Release 3.3.0 | This command was added under the VRF configuration mode.                                                                        |
| Release 3.6.0 | The minimum LSA arrival unit was changed to milliseconds. The default minimum LSA arrival interval was set to 100 milliseconds. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to change the minimum interval between accepting the same LSA to 2 seconds:

```
RP/0/0/CPU0:router# configure
```

```
RP/0/0/CPU0:router(config)# router ospf 1  
RP/0/0/CPU0:router(config-ospf)# timers lsa min-arrival 2
```

# timers lsa refresh

To configure the time interval at which Open Shortest Path First (OSPF) self-originated link-state advertisements (LSAs) are refreshed, use the **timers lsa refresh** command in an appropriate configuration mode. To restore the default value, use the **no** form of this command.

**timers lsa refresh** *seconds*

**no timers lsa refresh**

## Syntax Description

|                |                                                                                                |
|----------------|------------------------------------------------------------------------------------------------|
| <i>seconds</i> | How often self-originated LSAs should be refreshed, in seconds. Range is 1800 to 2700 seconds. |
|----------------|------------------------------------------------------------------------------------------------|

## Command Default

*seconds* : 1800 seconds.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**timers lsa refresh** command allows self-originated LSAs to be refreshed at non-standard times, anywhere from 1800 to 2700 seconds. Higher refresh interval value may gradually lead to lower CPU utilization by OSPF process.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure an LSA refresh interval of 1800 seconds:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 100
RP/0/0/CPU0:router(config-ospf)# timers lsa refresh 1800
```

**Related Commands**

| Command                                               | Description                                                                                                                                                   |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">timers lsa group-pacing, on page 1164</a> | Change the interval at which Open Shortest Path First (OSPF) link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged. |
| <a href="#">timers lsa min-arrival, on page 1166</a>  | Limits the frequency that new instances of any particular Open Shortest Path First (OSPF) link-state advertisements (LSAs) can be accepted during flooding.   |

## timers throttle lsa all (OSPF)

To modify the Open Shortest Path First (OSPF) link-state advertisement (LSA) throttling, use the **timers throttle lsa all** command in the appropriate mode. To revert LSA throttling to default settings, use the **no** form of this command

**timers throttle lsa all** *start-interval hold-interval max-interval*

**no timers throttle lsa all**

### Syntax Description

|                       |                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------|
| <i>start-interval</i> | Delay to generate first occurrence of LSA in milliseconds. Range is 0 to 600000 milliseconds.      |
| <i>hold-interval</i>  | Minimum delay between originating the same LSA in milliseconds. Range is 1 to 600000 milliseconds. |
| <i>max-interval</i>   | Maximum delay between originating the same LSA in milliseconds. Range is 1 to 600000 milliseconds. |

### Command Default

*start-interval* : 50 milliseconds  
*hold-interval* : 200 milliseconds  
*max-interval* : 5000 milliseconds

### Command Modes

Router configuration  
 VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The *lsa-start* time is the delay before flooding the first instance of an LSA. The *lsa-hold* interval is the minimum time to elapse before flooding an updated instance of an LSA. The *lsa-max-wait* time is the maximum time that can elapse before flooding an updated instance of an LSA.

For quick convergence, use smaller times for the *lsa-start* time and *lsa-hold* interval. However, in relatively large networks, this may result in a large number of LSAs being flooded in a relatively short time. A balance

with the *lsa-start* time and *lsa-hold* interval can be iteratively arrived at for the size of your network. The *lsa-max-wait* time can be used to ensure that OSPF reconverges within a reasonable amount of time.

**Note**

LSA throttling is always enabled. You can change the timer values with the **timers throttle lsa all** command or specify the **no** keyword to revert back to the default settings.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to change the start, hold, and maximum wait interval values to 500, 1000, and 90,000 milliseconds, respectively:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# timers throttle lsa all 500 1000 90000
```

The following example is output from the show ospf command that displays the modified LSA throttle settings:

```
RP/0/0/CPU0:router# show ospf

Routing Process "ospf 1" with ID 1.1.1.1
  Supports only single TOS(TOS0) routes
  Supports opaque LSA
  It is an area border router

## timers throttle spf (OSPF)

To modify the Open Shortest Path First (OSPF) shortest path first (SPF) throttling, use the **timers throttle spf** command in the appropriate mode. To revert SPF throttling to default settings, use the **no** form of this command.

**timers throttle spf** *spf-start spf-hold spf-max-wait*

**no timers throttle spf**

### Syntax Description

|                     |                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <i>spf-start</i>    | Initial SPF schedule delay (in milliseconds). Range is 1 to 600000 milliseconds.                                 |
| <i>spf-hold</i>     | Minimum hold time (in milliseconds) between two consecutive SPF calculations. Range is 1 to 600000 milliseconds. |
| <i>spf-max-wait</i> | Maximum wait time (in milliseconds) between two consecutive SPF calculations. Range is 1 to 600000 milliseconds. |

### Command Default

spf-start: 50 milliseconds  
spf-hold: 200 milliseconds  
spf-max-wait: 5000 milliseconds

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                             |
|---------------|----------------------------------------------------------|
| Release 3.2   | This command was introduced.                             |
| Release 3.3.0 | This command was added under the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The *spf-start* time is the delay before running SPF for the first time. The *spf-hold* interval is the minimum time to elapse between subsequent SPF runs. The *spf-max-wait* time is the maximum time that can elapse before running SPF again.

**Tip**

Setting a low *spf-start* time and *spf-hold* time causes routing to switch to the alternate path more quickly if there is a failure; however, it consumes more CPU processing time.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to change the start, hold, and maximum wait interval values to 5, 1000, and 90000 milliseconds, respectively:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# timers throttle spf 5 1000 90000
```

# transmit-delay (OSPF)

To set the estimated time required to send a link-state update packet on the interface, use the **transmit-delay** command in the appropriate mode. To return to the default value, use the **no** form of this command.

**transmit-delay** *seconds*

**no transmit-delay** *seconds*

## Syntax Description

|                |                                                                                      |
|----------------|--------------------------------------------------------------------------------------|
| <i>seconds</i> | Time (in seconds) required to send a link-state update. Range is 1 to 65535 seconds. |
|----------------|--------------------------------------------------------------------------------------|

## Command Default

*seconds*: 1 second

## Command Modes

Router configuration  
Area configuration  
Interface configuration  
Virtual-link configuration  
VRF configuration  
Multi-area configuration  
Sham-link configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was added under the VRF configuration mode.                  |
| Release 3.4.1 | This command was added under the multi-area interface configuration mode. |
| Release 3.6.0 | The command was added under sham-link configuration mode.                 |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Link-state advertisements (LSAs) in the update packet must have their ages incremented by the amount specified in the *seconds* argument before transmission. The value assigned should take into account the transmission and propagation delays for the interface.

If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. This setting has significance only on very low-speed networks not supported in Cisco IOS XR software or on networks such as satellite circuits that incur a very long (greater than one second) delay time.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure a transmit delay for interface GigabitEthernet 0/3/0/0:

```
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# area 0
RP/0/0/CPU0:router(config-ospf-ar)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-ospf-ar-if)# transmit-delay 3
```

**Related Commands**

| Command                                                  | Description                                                |
|----------------------------------------------------------|------------------------------------------------------------|
| <a href="#">show ospf</a> , <a href="#">on page 1087</a> | Displays general information about OSPF routing processes. |

# virtual-link (OSPF)

To define an Open Shortest Path First (OSPF) virtual link, use the **virtual-link** command in area configuration mode. To remove a virtual link, use the **no** form of this command.

**virtual-link** *router-id*

**no virtual-link** *router-id*

## Syntax Description

|                  |                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>router-id</i> | Router ID associated with the virtual link neighbor. The router ID appears in the <b>show ospf</b> command display. The router ID can be any 32-bit router ID value specified in four-part, dotted-decimal notation. |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No virtual links are defined.

## Command Modes

Area configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

All areas in an OSPF autonomous system must be physically connected to the backbone area (area 0). In some cases in which this physical connection is not possible, you can use a virtual link to connect to the backbone through a nonbackbone area. You can also use virtual links to connect two parts of a partitioned backbone through a nonbackbone area. The area through which you configure the virtual link, known as a transit area, must have full routing information. The transit area cannot be a stub or not-so-stubby area.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to establish a virtual link with default values for all optional parameters:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# area 10.0.0.0
```

```
RP/0/0/CPU0:router(config-ospf-ar)# virtual-link 10.3.4.5
RP/0/0/CPU0:router(config-ospf-ar-vl)#
```

The following example shows how to establish a virtual link with clear text authentication called mykey:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 201
RP/0/0/CPU0:router(config-ospf)# area 10.0.0.0
RP/0/0/CPU0:router(config-ospf-ar)# virtual-link 10.3.4.5
RP/0/0/CPU0:router(config-ospf-ar-vl)# authentication-key 0 mykey
```

# vrf (OSPF)

To configure an Open Shortest Path First (OSPF) VPN routing and forwarding (VRF) instance, use the **vrf** command in router configuration mode. To terminate an OSPF VRF, use the **no** form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

## Syntax Description

|                 |                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Identifier of an OSPF VRF. The <i>vrf-name</i> argument can be specified as an arbitrary string. The strings “default” and “all” are reserved VRF names. |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No OSPF VRF is defined.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vrf** command to explicitly configure a VRF. Commands configured under the VRF configuration mode (such as the **interface** [OSPF] and **authentication** commands) are automatically bound to that VRF.

To modify or remove the VRF, the *vrf-id* argument format must be the same as the format used when creating the area.

### Note

To remove the specified VRF from the router configuration, use the **no vrf** *vrf-id* command. The **no vrf** *vrf-id* command removes the VRF and all VRF options, such as **authentication** , **default-cost** , **nssa** , **range** , **stub** , **virtual-link** , and **interface**.

To avoid possibly having the router ID change under a VRF, explicitly configure the router ID using the **router-id** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure VRF vrf1 and GigabitEthernet interface 0/2/0/0. GigabitEthernet interface 0/2/0/0 is bound to VRF vrf1 automatically.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# vrf vrf1
RP/0/0/CPU0:router(config-ospf-vrf)# interface GigabitEthernet 0/2/0/0
```

# address-family (OSPFv3)

To enter address family configuration mode for Open Shortest Path First Version 3 (OSPFv3), use the **address-family** command in the router ospfv3 configuration mode. To disable address family configuration mode, use the **no** form of this command.

**address-family ipv6 [unicast]**

**no address-family ipv6 [unicast]**

## Syntax Description

|                |                                                 |
|----------------|-------------------------------------------------|
| <b>ipv6</b>    | Specifies IP Version 6 (IPv6) address prefixes. |
| <b>unicast</b> | (Optional) Specifies unicast address prefixes.  |

## Command Default

An address family is not specified.

## Command Modes

Router ospfv3 configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the OSPFv3 router process with IPv6 unicast address prefixes:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# address-family ipv6 unicast
```

# area (OSPFv3)

To configure an Open Shortest Path First Version 3 (OSPFv3) area, use the **area** command in an appropriate configuration mode. To remove an OSPFv3 area, use the **no** form of this command.

```
area area-id
no area area-id
```

|                    |         |                                                                                                                             |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------------|
| Syntax Description | area-id | Identifier of an OSPFv3 area. The <i>area-id</i> argument can be specified as either a decimal value or as an IPv4 address. |
|--------------------|---------|-----------------------------------------------------------------------------------------------------------------------------|

|                 |                              |
|-----------------|------------------------------|
| Command Default | No OSPFv3 areas are defined. |
|-----------------|------------------------------|

|               |                                                         |
|---------------|---------------------------------------------------------|
| Command Modes | Router OSPFv3 configuration<br>OSPFv3 VRF configuration |
|---------------|---------------------------------------------------------|

|                 |               |                                                                    |
|-----------------|---------------|--------------------------------------------------------------------|
| Command History | Release       | Modification                                                       |
|                 | Release 3.2   | This command was introduced.                                       |
|                 | Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An area must be explicitly configured with the **area** command.

Use the **area** command to place the router in area configuration mode (prompt: config-router-ar), from which you can configure area-specific settings. Commands configured under this mode (such as the **interface** command) are automatically bound to that area.

**Note** To remove the specified OSPFv3 area from the router ospfv3 configuration, use the **no area area-id** command. The **no area area-id** command removes the OSPFv3 area including all OSPFv3 area options, and all the OSPFv3 interfaces and interface options that are configured under the area.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure area 0 for OSPFv3 process 1. The GigabitEthernet 0/1/0/1 interface also is configured:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/1/0/1
```

## authentication (OSPFv3)

To enable plain text, Message Digest 5 (MD5) authentication, or null authentication for an Open Shortest Path First Version 3 (OSPFv3) interface, use the **authentication** command in an appropriate configuration mode. To remove such authentication, use the **no** form of this command.

**authentication** {**ipsec spi** *spi-value* {**md5**|**sha1**} [**clear**|**password**] *password*|**disable**}  
**no authentication**

### Syntax Description

|                             |                                                                            |
|-----------------------------|----------------------------------------------------------------------------|
| <b>ipsec</b>                | Specifies IP Security (IPSec).                                             |
| <b>spi</b> <i>spi-value</i> | Specifies a security policy index (SPI) value. Range is 256 to 4294967295. |
| <b>md5</b>                  | Enables Message Digest 5 (MD5) authentication.                             |
| <b>sha1</b>                 | Enables SHA1 authentication.                                               |
| <b>clear</b>                | (Optional) Specifies that the key be unencrypted.                          |
| <b>password</b>             | (Optional) Specifies that the key be encrypted using a two-way algorithm.  |
| <i>password</i>             | Any contiguous string that can be entered from the keyboard.               |
| <b>disable</b>              | Disables authentication for OSPFv3 packets.                                |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the authentication parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the authentication parameter specified for the process.

If this command is not specified at any level, then the interface does not use authentication.

### Command Modes

Interface configuration  
 Area configuration  
 Router configuration  
 Virtual-link configuration  
 OSPFv3 VRF configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.6.0 | The <b>encryption</b> keyword was changed to <b>password</b> .     |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **authentication** command to specify an authentication type for the interface, which overrides the authentication specified for the area to which this interface belongs. If this command is not included in the configuration file, the authentication configured in the area to which the interface belongs is assumed (as specified by the area **authentication** command).

The authentication type and password must be the same for all OSPFv3 interfaces that are to communicate with each other through OSPFv3.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to enable MD5 authentication:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospfv3 201
RP/0/0/CPU0:router(config-ospfv3)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-ospfv3)# authentication ipsec spi 500 md5
1234567890abcdef1234567890abcdef
```

## auto-cost (OSPFv3)

To control how the Open Shortest Path First Version 3 (OSPFv3) protocol calculates default metrics for an interface, use the **auto-cost** command in an appropriate configuration mode. To set link cost based only on the interface type, use the **disable** form of this command. To re-enable OSPFv3 metric calculation for an interface according to the bandwidth of the interface, use the **no** form of this command.

**auto-cost** [**reference-bandwidth** *mbps*] **disable**

**no auto-cost** [**reference-bandwidth** *mbps*] **disable**

### Syntax Description

|                                        |                                                                      |
|----------------------------------------|----------------------------------------------------------------------|
| <b>reference-bandwidth</b> <i>mbps</i> | (Optional) Sets the rate in Mbps (bandwidth). Range is 1 to 4294967. |
| <b>disable</b>                         | (Optional) Sets the link cost based only on the interface type.      |

### Command Default

*mbps* : 100 Mbps

### Command Modes

Router ospfv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced                                        |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default OSPFv3 calculates the OSPFv3 metric for an interface according to the bandwidth of the interface.

The **no auto-cost disable** form of this command reenables OSPFv3 metric calculation for an interface according to the bandwidth of the interface.

To set link cost based only on the interface type, use the **disable** keyword.

If you have multiple links with high bandwidth, you might want to use a larger number to differentiate the cost on those links.

Recommended usage of cost configuration for all OSPFv3 configured interfaces is to be consistent: Either explicitly configure link costs (by using the **cost** command) or choose an appropriate default (by using the **auto-cost** command).

The value set by the **cost** command overrides the cost resulting from the **auto-cost** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to set the reference value for the auto cost to 64:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# auto-cost reference-bandwidth 64
```

### Related Commands

|---------------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">cost (OSPFv3), on page 1201</a> | Explicitly specifies the cost of the interface (network) for OSPF path calculation. |

## capability vrf-lite (OSPFv3)

To ignore DN bit in LSAs received from peers in the given VRF and to disable automatic ABR status in that VRF, use the **capability vrf-lite** command in OSPFv3 VRF configuration mode. To disable ignoring the DN bit in LSAs and to re-enable automatic ABR status in the VRF, use the **no** form of this command.

**capability vrf-lite**

**no capability vrf-lite**

This command has no keywords or arguments.

### Command Default

Disabled.

### Command Modes

OSPFv3 VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **capability vrf-lite** command when routers (sometimes called multi-vrf CE routers) are directly connected through interfaces associated with a VRF, but without being connected to other PEs through the MPLS/VPN BGP Backbone.

When OSPFv3 is enabled in a VRF, the router is always an ABR. With the capability vrf-lite command enabled, the router becomes an ABR only if it is connected to area 0 (backbone area), and there are other (non-backbone) areas enabled on this router in the given VRF.

#### Note

Routes may be re-introduced to the VPN backbone when this command is used.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

Examples

This example shows how to enable VRF-lite capability for OSPFv3 instance *1* under VRF *vrf1*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)#vrf vrf1
RP/0/0/CPU0:router(config-ospfv3-vrf)#capability vrf-lite
```

|--------------------------------------------|-------------------------------------|
| <a href="#">vrf (OSPFv3), on page 1359</a> | Enters OSPFv3 configuration submode |

# clear ospfv3 process

To reset an Open Shortest Path First Version 3 (OSPFv3) router process without removing and reconfiguring it, use the **clear ospfv3 process** command in EXEC mode.

**clear ospfv3** [*process-name*] [**vrf** *vrf-name*] **process**

## Syntax Description

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only the specified routing process is affected. Otherwise, all OSPFv3 processes are reset. |
| <b>vrf</b>          | (Optional) Specifies VPN routing and forwarding (VRF).                                                                                                                                                                                                        |
| <i>vrf-name</i>     | Name of a VRF.                                                                                                                                                                                                                                                |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                          |
|---------------|---------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                          |
| Release 4.1.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added to support OSPFv3 VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the OSPFv3 router process is reset, OSPFv3 releases all resources allocated, cleans up the internal database, uninstalls routes, and resets all OSPFv3 adjacencies.

### Note

The **clear ospfv3 process** command might clear the router ID configuration if the OSPF router ID is not explicitly configured through the [router-id \(OSPFv3\)](#), [on page 1270](#) command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to reset all OSPFv3 processes:

```
RP/0/0/CPU0:router# clear ospfv3 process
```

The following example shows how to reset the OSPFv3 process 1:

```
RP/0/0/CPU0:router# clear ospfv3 1 process
```

**Related Commands**

# clear ospfv3 redistribution

To flush all the Type 5 and Type 7 link-state advertisements (LSAs) originated by an Open Shortest Path First Version 3 (OSPFv3) process, use the **clear ospfv3 redistribution** command in EXEC mode.

**clear ospfv3** [*process-name*] [**vrf** *vrf-name*] **redistribution**

## Syntax Description

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only the specified routing process is affected. Otherwise, all OSPFv3 processes are reset. |
| <b>vrf</b>          | (Optional) Specifies VPN routing and forwarding (VRF).                                                                                                                                                                                                        |
| <i>vrf-name</i>     | Name of a VRF.                                                                                                                                                                                                                                                |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                          |
|---------------|---------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                          |
| Release 4.1.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added to support OSPFv3 VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear ospfv3 redistribution** command to cause the routing table to be read again. OSPFv3 regenerates and sends Type 5 and Type 7 link-state advertisements (LSAs) to its neighbors. If an unexpected route has appeared in the OSPFv3 redistribution, using this command corrects the issue.

### Note

Use of this command can cause a significant number of LSAs to flood the network. We recommend that you use this command with caution.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to clear all OSPFv3 redistributed routes from other protocols:

```
RP/0/0/CPU0:router# clear ospfv3 redistribution
```

# clear ospfv3 routes

To clear the Open Shortest Path First Version 3 (OSPFv3) internal route table, use the **clear ospfv3 routes** command in EXEC mode.

**clear ospfv3** [*process-name*] [**vrf** *vrf-name*] **routes**

## Syntax Description

|                     |                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only the specified routing process is affected. Otherwise, all OSPFv3 processes are reset. |
| <b>vrf</b>          | (Optional) Specifies VPN routing and forwarding (VRF).                                                                                                                                                                                                        |
| <i>vrf-name</i>     | Name of a VRF.                                                                                                                                                                                                                                                |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                          |
|---------------|---------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                          |
| Release 4.1.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added to support OSPFv3 VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear ospfv3 routes** command to force the internal route table to be repopulated by causing recalculation of the shortest path first (SPF) routing table. When the OSPFv3 routing table is cleared, OSPFv3 routes in the global routing table are also recalculated.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to clear all OSPFv3 routes from the OSPFv3 routing table and recomputes valid routes:

```
RP/0/0/CPU0:router# clear ospfv3 routes
```

# clear ospfv3 statistics

To clear the Open Shortest Path First Version 3 (OSPFv3) statistical counters, use the **clear ospfv3 statistics** command in EXEC mode.

**clear ospfv3** [*process-name*] [**vrf** *vrf-name*] **statistics** [**neighbor** [*type interface-path-id*] [*router-id*]]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only the specified routing process is affected.                                                              |
| <b>neighbor</b>          | (Optional) Clears counters for the specified neighbor only.                                                                                                                                                                                                                     |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>router-id</i>         | (Optional) Specified router ID. This argument must be in 32-bit dotted-decimal notation, similar to an IPv4 address. This argument clears the counters of the specified neighbor only.                                                                                          |
| <b>vrf</b>               | (Optional) Specifies VPN routing and forwarding (VRF).                                                                                                                                                                                                                          |
| <i>vrf-name</i>          | Name of a VRF.                                                                                                                                                                                                                                                                  |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                   |
|---------------|--------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                   |
| Release 4.1.0 | The <b>vrf vrf-name</b> keyword and argument were added to support OSPFv3 VRF. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear ospfv3 statistics** command to reset statistics so that subsequent changes are easily observed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to clear the OSPFv3 statistical counters of all neighbors on GigabitEthernet interface 0/2/0/0:

```
RP/0/0/CPU0:router# clear ospfv3 statistics neighbor GigabitEthernet 0/2/0/0
```

# cost (OSPFv3)

To explicitly specify the cost of the interface (network) for OSPF path calculations, use the **cost** command in an appropriate configuration mode. To remove the cost, use the **no** form of this command.

**cost** *cost*

**no** *cost*

## Syntax Description

|             |                                                                                 |
|-------------|---------------------------------------------------------------------------------|
| <i>cost</i> | Unsigned integer value expressed as the link-state metric. Range is 1 to 65535. |
|-------------|---------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the cost parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the cost parameter specified for the process.

If this command is not specified at any level, then the cost is based on the interface bandwidth, as specified by the **auto-cost** command.

## Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The link-state metric is advertised as the link cost in the router link advertisement.

In general, the path cost is calculated using the following formula:

$10^8 / \text{bandwidth}$

Using this formula, the default path cost is 1 for OC-3 Packet-over-SONET/SDH (POS). If this value does not suit your network, you can use your own method of calculating path costs.

The value set by the **cost** command overrides the cost resulting from the **auto-cost** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to set the cost value to 65 for GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router ospfv3 201
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# cost 65
```

### Related Commands

| <a href="#">auto-cost (OSPFv3), on page 1189</a> | Controls how the OSPFv3 protocol calculates default metrics for an interface. |

# database-filter all out (OSPFv3)

To filter outgoing link-state advertisements (LSAs) to an Open Shortest Path First Version 3 (OSPFv3) interface, use the **database-filter all out** command in an appropriate configuration mode. To restore the forwarding of LSAs to the interface, use the **no** form of this command.

**database-filter all out**

**no database-filter all out**

## Syntax Description

This command has no keywords or arguments.

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the database filter parameter specified for the area.

If this command is not specified in area configuration mode, then the interface adopts the database filter parameter specified for the process.

If this command is not specified in router ospfv3 configuration mode, then the database filter is disabled and all outgoing LSAs are flooded to the interface.

## Command Modes

Interface configuration

Area configuration

Router OSPFv3 configuration

OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **database-filter all out** command to perform the same function that the **neighbor** command (with the **database-filter** keyword) performs on a neighbor basis.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to prevent flooding of OSPFv3 LSAs to neighbors reachable through GigabitEthernet interface 0/2/0/3:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/3
RP/0/0/CPU0:router(config-ospfv3-ar-if)# database-filter all out
```

|                         |                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>Two Open Shortest Path First Version 3 (OSPFv3) routers do not become adjacent if their dead interval values differ.</p> |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If the hello interval is configured, the dead interval value must be larger than the hello interval value. The dead interval value is usually configured four times larger than the hello interval value.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to set the OSPFv3 dead interval on GigabitEthernet interface 0/2/0/3 to 40 seconds:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/3
RP/0/0/CPU0:router(config-ospfv3-ar-if)# dead-interval 40
```

### Related Commands

|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">hello-interval (OSPFv3), on page 1230</a> | Specifies the interval between hello packets that the Cisco IOS XR software sends on the interface. |

## default-cost (OSPFv3)

To specify a cost for the default summary route sent into a stub area or not-so-stubby area (NSSA) for Open Shortest Path First Version 3 (OSPFv3) packets, use the **default-cost** command in area configuration mode. To remove the assigned default route cost, use the **no** form of this command.

**default-cost** *cost*

**no default-cost**

### Syntax Description

|             |                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>cost</i> | Cost for the default summary route used for a stub or NSSA area. The acceptable value is a 24-bit number ranging from 1 to 16777214. |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

*cost* : 1

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-cost** command only on an Area Border Router (ABR) attached to a stub or an NSSA area.

In all routers and access servers attached to the stub area, the area should be configured as a stub area using the **stub (OSPFv3)** command in the area configuration submenu. Use the **default-cost** command only on an ABR attached to the stub area. The **default-cost** command provides the metric for the summary default route generated by the ABR into the stub area.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to assign a cost of 20 to the default route sent into area 10.15.0.0:

```
RP/0/0/CPU0:router(config)# router ospfv3 201
RP/0/0/CPU0:router(config-ospfv3)# area 10.15.0.0
```

```
RP/0/0/CPU0:router(config-ospfv3-ar)# stub
RP/0/0/CPU0:router(config-ospfv3-ar)# default-cost 20
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/1
```

**Related Commands**

| Command                                     | Description                     |
|---------------------------------------------|---------------------------------|
| <a href="#">stub (OSPFv3), on page 1335</a> | Defines an area as a stub area. |

# default-information originate (OSPFv3)

To generate a default external route into an Open Shortest Path First Version 3 (OSPFv3) routing domain, use the **default-information originate** command in router ospfv3 configuration mode. To disable this feature, use the **no** form of this command.

```
default-information originate [route-policy policy-name] [always] [metric metric-value] [metric-type type-value] [tag tag-value]
no default-information originate [route-policy policy-name] [always] [metric metric-value] [metric-type type-value] [tag tag-value]
```

| Syntax Description                     |                                                                                                                                                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>route-policy</b> <i>policy-name</i> | (Optional) Specifies the route policy to apply to default information origination.                                                                                                                                                                                      |
| <b>always</b>                          | (Optional) Always advertises the default route regardless of whether the software has a default route.                                                                                                                                                                  |
| <b>metric</b> <i>metric-value</i>      | (Optional) Specifies a metric used for generating the default route. The default metric value is 1. The value used is specific to the protocol.                                                                                                                         |
| <b>metric-type</b> <i>type-value</i>   | (Optional) Specifies an external link type associated with the default route advertised into the OSPFv3 routing domain. It can be one of the following values:<br><br>1—Type 1 external route<br>2—Type 2 external route                                                |
| <b>tag</b> <i>tag-value</i>            | (Optional) 32-bit dotted-decimal value attached to each external route. This is not used by the OSPFv3 protocol itself. It may be used to communicate information between autonomous system boundary routers (ASBRs). If a tag is not specified, then zero (0) is used. |

|                        |                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|

|---------------|----------------------------------------------------------------|
| Release 3.6.0 | The <b>policy</b> keyword was changed to <b>route-policy</b> . |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Whenever you use the **redistribute** or **default-information** command to redistribute routes into an OSPFv3 routing domain, the software automatically becomes an ASBR. However, an ASBR does not, by default, generate a default route into the OSPFv3 routing domain. The software still must have a default route for itself before it generates one, except when you have specified the **always** keyword.

The **default-information originate** route-policy attach point conditionally injects the default route 0.0.0.0/0 into the OSPF link-state database, and is done by evaluating the attached policy. If any routes specified in the policy exist in the global RIB, then the default route is inserted into the link-state database. If there is no match condition specified in the policy, the policy passes and the default route is generated into the link-state database.

For information about the default-information originate attach point, see the *OSPF v3 Policy Attach Points* section in the *Implementing Routing Policy* chapter in *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

When you use the **default-information originate** command for the OSPFv3 process, the default network must reside in the routing table.

For information about routing policies, see the *Routing Policy Commands* chapter in the *Cisco IOS XR Routing Command Reference for the Cisco XR 12000 Series Router*.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to specify a metric of 100 for the default route redistributed into the OSPFv3 routing domain and an external metric type of Type 1:

```
RP/0/0/CPU0:router(config)#router ospfv3 109
RP/0/0/CPU0:router(config-ospfv3)#default-information originate metric 100 metric-type 1
```

### Related Commands

| Command                                             | Description                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">redistribute (OSPFv3), on page 1263</a> | Redistributes routes from one routing domain into another routing domain. |

# default-metric (OSPFv3)

To set default metric values for routes redistributed from another protocol into Open Shortest Path First Version 3 (OSPFv3), use the **default-metric** command in an appropriate configuration mode. To return to the default state, use the **no** form of this command.

**default-metric** *value*

**no default-metric** *value*

## Syntax Description

|              |                                                                      |
|--------------|----------------------------------------------------------------------|
| <i>value</i> | Default metric value appropriate for the specified routing protocol. |
|--------------|----------------------------------------------------------------------|

## Command Default

Built-in, automatic metric translations, as appropriate for each routing protocol

## Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-metric** command with the **redistribute** command to cause the current routing protocol to use the same metric value for all redistributed routes. A default metric helps solve the problem of redistributing routes with incompatible metrics. Whenever metrics do not convert, use a default metric to provide a reasonable substitute and enable the redistribution to proceed.

The default-metric value configured in OSPF configuration does not apply to connected routes that are redistributed to OSPF using the **redistribute connected** command. To set a non-default metric for connected routes, configure OSPF with the **redistribute connected metric** *metric-value* command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure a router with both the Intermediate System-to-Intermediate System (IS-IS) and the OSPFv3 routing protocols. The OSPFv3 routing protocol advertises IS-IS derived routes and assigns the routes a metric of 10:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# default-metric 10
RP/0/0/CPU0:router(config-ospfv3)# redistribute isis IS-IS_isp
```

## Related Commands

| Command                                             | Description                                                               |
|-----------------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">redistribute (OSPFv3), on page 1263</a> | Redistributes routes from one routing domain into another routing domain. |

# demand-circuit (OSPFv3)

To configure the Open Shortest Path First Version 3 (OSPFv3) router process to treat the interface as an OSPFv3 demand circuit, use the **demand-circuit** command in an appropriate configuration mode. To remove the demand circuit designation from the interface, use the **no** form of this command.

**demand-circuit [disable]**

**no demand-circuit**

## Syntax Description

|                |                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Disables the demand circuit configuration that may have been specified at a higher level in the configuration. |
|----------------|---------------------------------------------------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the demand circuit parameter specified for the area.

If this command is not specified in area configuration mode, then the interface adopts the demand circuit parameter specified for the process.

If this command is not specified at any level, then the interface is not a demand circuit.

## Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
Virtual-link configuration  
OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

On point-to-point interfaces, only one end of the demand circuit must be configured with the **demand-circuit** command. Periodic hello messages are suppressed and periodic refreshes of link-state advertisements (LSAs) do not flood the demand circuit. This command allows the underlying data link layer to be closed when the

topology is stable. In point-to-multipoint topology, only the multipoint end must be configured with this command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to configure GigabitEthernet interface 0/3/0/1 as an on-demand circuit:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3)# interface GigabitEthernet 0/3/0/1
RP/0/0/CPU0:router(config-ospfv3-if)# demand-circuit
```

## distance ospfv3

To define the Open Shortest Path First Version 3 (OSPFv3) route administrative distances based on route type, use the **distance ospfv3** command in router ospfv3 configuration mode. To restore the default value, use the **no** form of this command.

**distance ospfv3** {intra-area| inter-area| external} *distance*

**no distance ospfv3**

### Syntax Description

|                                                         |                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>intra-area</b>   <b>inter-area</b>   <b>external</b> | Type of area. It can be one of the following values:<br><br><b>intra-area</b> —All routes within an area.<br><br><b>inter-area</b> —All routes from one area to another area.<br><br><b>external</b> —All routes from other routing domains, learned by redistribution. |
| <i>distance</i>                                         | The route administrative distance.                                                                                                                                                                                                                                      |

### Command Default

*distance* : 110

### Command Modes

Router ospfv3 configuration

### Command History

| Release     | Modification                |
|-------------|-----------------------------|
| Release 3.2 | This command was introduced |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must specify one of the keywords.

Use the **distance ospfv3** command to perform the same function as the **distance** command used with an access list. However, the **distance ospfv3** command sets a distance for an entire group of routes, rather than a specific route that passes an access list.

A common reason to use the **distance ospfv3** command is when you have multiple OSPFv3 processes with mutual redistribution, and you want to prefer internal routes from one over external routes from the other.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to change the external distance to 200, making it less reliable:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# redistribute ospfv3 2
RP/0/0/CPU0:router(config-ospfv3)# distance ospfv3 external 200
RP/0/0/CPU0:router(config-ospfv3)# exit
RP/0/0/CPU0:router(config)# router ospfv3 2
RP/0/0/CPU0:router(config-ospfv3)# redistribute ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# distance ospfv3 external 200
```

## Related Commands

| Command         | Description                         |
|-----------------|-------------------------------------|
| distance (OSPF) | Defines an administrative distance. |

## distribute-list prefix-list in

To filter the routes that Open Shortest Path First Version 3 (OSPFv3) installs in the Routing Information Base (RIB), use the **distribute-list prefix-list in** command in an appropriate configuration mode. To remove the filter, use the **no** form of this command.

**distribute-list prefix-list** *prefix-list-name* **in**

**no distribute-list prefix-list** *prefix-list-name* **in**

### Syntax Description

|                         |                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i> | IP Version 6 (IPv6) prefix list name. The list defines which IPv6 prefixes are installed in the RIB. |
|-------------------------|------------------------------------------------------------------------------------------------------|

### Command Default

All routes learned by OSPFv3 are installed in the RIB.

### Command Modes

Interface configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode.                                                                                                                                                                   |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **distribute-list prefix-list** command to limit the routes that OSPFv3 installs in the RIB of your router. This command does not affect the information sent to other OSPFv3 routers or the routes that these routers compute and install.

**Note**

Because the other OSPFv3 routers are not aware of any omissions in the RIB, they may send traffic addressed to the missing prefixes. If no other provision has been made for these prefixes, the packets are dropped.

When this command is specified in router ospfv3 configuration mode, the filter applies to all routes computed by OSPFv3.

When this command is specified in interface configuration mode, the filter applies only to routes that forward outgoing traffic over that interface.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to prevent OSPFv3 from installing any routes that have 2001:e624 as the first 32 bits of the address. OSPFv3 is also prevented from installing routes to 2002::/16 that use GigabitEthernet interface 0/2/0/0 as the next-hop interface:

```
RP/0/0/CPU0:router(config)# ipv6 prefix-list preflist1
RP/0/0/CPU0:router(config-ipv6-pfx)# deny 2001:e624::/32 le 128
RP/0/0/CPU0:router(config-ipv6-pfx)# permit ::/0 le 128
!
RP/0/0/CPU0:router(config)# ipv6 prefix-list preflist2
RP/0/0/CPU0:router(config-ipv6-pfx)# deny 2002::/16
RP/0/0/CPU0:router(config-ipv6-pfx)# permit ::/0 le 128
!
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# distribute-list prefix-list preflist1 in
RP/0/0/CPU0:router(config-ospfv3)# area 1
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/0
RP/0/0/CPU0:router(config-ospfv3-ar-if)# distribute-list prefix-list preflist2 in
```

# distribute-list prefix-list out

To filter the routes redistributed into Open Shortest Path First Version 3 (OSPFv3) from other routing protocols, use the **distribute-list prefix-list out** command in an appropriate configuration mode. To remove the filter, use the **no** form of this command.

**distribute-list prefix-list** *prefix-list-name* **out** [*protocol* [*process-id* ]]

**no distribute-list prefix-list** *prefix-list-name* **out** [*protocol* [*process-id* ]]

## Syntax Description

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix-list-name</i> | IP Version 6 (IPv6) prefix list name. The list defines which IPv6 prefixes are installed in the RIB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>protocol</i>         | <p>(Optional) Source protocol from which routes are being redistributed. It can be one of the following keywords: <b>bgp</b>, <b>eigrp</b>, <b>isis</b>, <b>ospfv3</b>, <b>static</b>, and <b>connected</b>.</p> <p>The <b>static</b> keyword is used to redistribute IPv6 static routes.</p> <p>The <b>connected</b> keyword refers to routes that are established automatically because IPv6 is enabled on an interface. For routing protocols such as OSPFv3 and Intermediate System-to-Intermediate System (IS-IS), these routes are redistributed as external to the autonomous system.</p>                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>process-id</i>       | <p>(Optional) For the <b>bgp</b> keyword, an autonomous system number has the following ranges:</p> <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> <p>For the <b>eigrp</b> keyword, an autonomous system number.</p> <p>For the <b>isis</b> keyword, an optional argument that defines a meaningful name for a routing process. You can specify only one IS-IS process for each router. Creating a name for a routing process means that you use names when configuring routing.</p> <p>For the <b>ospfv3</b> keyword, an appropriate OSPFv3 process name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p> |

## Command Default

All routes from protocols specified in the [redistribute \(OSPFv3\)](#), on page 1263 command are redistributed into OSPFv3.

## Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

**Command History**

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.2   | This command was introduced .                                               |
| Release 3.6.0 | The <b>eigrp</b> protocol was supported.                                    |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode.          |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Routes may be redistributed into OSPFv3 from several other routing protocols or from other OSPFv3 processes. These routes are then communicated to other OSPFv3 routes through Type 5 (External) or Type 7 not-so-stubby area (NSSA) link-state advertisements (LSAs). Use the **distribute-list prefix-list out** command to control redistribution by matching redistributed routes against an IPv6 prefix list. Only routes permitted by the prefix list are redistributed into OSPFv3.

Each protocol being redistributed into OSPFv3 can have a separate prefix list. In addition, a prefix list can be defined that applies to all protocols.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to prevent OSPFv3 from redistributing routes that have 2001:e624 as the first 32 bits of the address. In addition, routes with a prefix beginning with 2064 are not redistributed from Border Gateway Protocol (BGP) autonomous system 1, and only those routes are redistributed from BGP autonomous system 5.

```
RP/0/0/CPU0:router(config)# ipv6 prefix-list p1
RP/0/0/CPU0:router(config-ipv6-pfx)# deny 2001:e624::/32 le 128
RP/0/0/CPU0:router(config-ipv6-pfx)# permit ::/0 le 128
!
RP/0/0/CPU0:router(config)# ipv6 prefix-list p2
RP/0/0/CPU0:router(config-ipv6-pfx)# deny 2064::/16 le 128
RP/0/0/CPU0:router(config-ipv6-pfx)# permit ::/0 le 128
!
RP/0/0/CPU0:router(config)# ipv6 prefix-list p3
RP/0/0/CPU0:router(config-ipv6-pfx)# permit 2064::/16 le 128
!
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# redistribute bgp 1
RP/0/0/CPU0:router(config-ospfv3)# redistribute bgp 5
RP/0/0/CPU0:router(config-ospfv3)# distribute-list prefix-list p1 out
```

```
RP/0/0/CPU0:router(config-ospfv3)# distribute-list prefix-list p2 out bgp 1  
RP/0/0/CPU0:router(config-ospfv3)# distribute-list prefix-list p3 out bgp 5
```

|--------------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax Description | secondary       | (Optional) OSPFv3 secondary domain ID.                                                                                                                                   |
|                    | type            | Primary OSPFv3 domain ID in hexadecimal format. <ul style="list-style-type: none"> <li>0005 —Type 0x0005</li> <li>0105 —Type 0x0105</li> <li>0205—Type 0x0205</li> </ul> |
|                    | value           | OSPF domain ID value in hexadecimal format.                                                                                                                              |
|                    | domain-id-value | OSPF domain ID extended community value as a 6 byte hexadecimal number.                                                                                                  |
|                    |                 |                                                                                                                                                                          |

**Command Default** No domain ID is specified.

**Command Modes** VRF configuration

|                 |               |                              |
|-----------------|---------------|------------------------------|
| Command History | Release       | Modification                 |
|                 | Release 4.1.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If no value is specified for the domain ID, the default is Null (all zeros) primary domain ID. One or more secondary domain IDs can be specified.

|         |         |             |
|---------|---------|-------------|
| Task ID | Task ID | Operation   |
|         | ospf    | read, write |

## Examples

This example shows how to specify a domain ID with type *0105* and value *AABBCCDDEEFF*:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router ospf 1
RP/0/0/CPU0:router(config-ospf)# vrf vrf_1
RP/0/0/CPU0:router(config-ospf-vrf)# domain-id type 0105 value AABBCCDDEEFF
```

# encryption

To encrypt and authenticate Open Shortest Path First Version 3 (OSPFv3) packets, use the **encryption** command in an appropriate configuration mode. To remove the encryption, use the **no** form of this command.

**encryption** {**disable**| **ipsec spi** *spi-value* **esp** {**3des**| **aes** [**192**| **256**] | **des**| **null** [**clear**| **password**] *encrypt-password*} [**authentication** {**md5**| **sha1**} [**clear**| **password**] *auth-password*]

**no encryption**

## Syntax Description

|                         |                                                                                                  |
|-------------------------|--------------------------------------------------------------------------------------------------|
| <b>disable</b>          | Disables OSPFv3 packet encryption.                                                               |
| <b>ipsec spi</b>        | Specifies IPSec ESP encryption and authentication with the Security Parameter Index (SPI) value. |
| <i>spi-value</i>        | SPI value. Range is 256 to 4294967295.                                                           |
| <b>esp</b>              | Specifies Encryption Service Payload (ESP) encryption parameters.                                |
| <b>3des</b>             | Specifies the triple DES algorithm.                                                              |
| <b>aes</b>              | Specifies the Advanced Encryption Standard (AES) algorithm.                                      |
| <b>192</b>              | (Optional) Specifies the 192-bit AES algorithm                                                   |
| <b>256</b>              | (Optional) Specifies the 256-bit AES algorithm                                                   |
| <b>des</b>              | Specifies the Data Encryption Standard (DES) algorithm.                                          |
| <b>null</b>             | Specifies no AES algorithm.                                                                      |
| <b>md5</b>              | Enables Message Digest 5 (MD5) authentication.                                                   |
| <b>sha1</b>             | Enables SHA1 authentication.                                                                     |
| <b>clear</b>            | Specifies that the key be unencrypted.                                                           |
| <b>password</b>         | Specifies that the key be encrypted using a two-way algorithm.                                   |
| <i>encrypt-password</i> | Any contiguous string that can be entered from the keyboard as the encryption password.          |
| <i>auth-password</i>    | Any contiguous string that can be entered from the keyboard as the authentication password.      |

## Command Default

No default behavior or values.

**Command Modes**

Interface configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

**Command History**

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.6.0 | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **encryption** command to encrypt and authenticate OSPFv3 packets.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to encrypt and authenticate OSPFv3 packets:

```
RP/0/0/CPU0:router(config)#router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)#encryption ipsec spi 256 esp 3des clear
```

## flood-reduction (OSPFv3)

To suppress the unnecessary flooding of link-state advertisements (LSAs) in stable topologies, use the **flood-reduction** command in an appropriate configuration mode. To disable this feature, use the **no** form of this command.

**flood-reduction [disable]**

**no flood-reduction**

### Syntax Description

|                |                                                                                  |
|----------------|----------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Turns off this functionality at a specific level.                     |
| <b>Note</b>    | The <b>disable</b> keyword is not available in router ospfv3 configuration mode. |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the flood reduction parameter specified by area.

If this command is not specified in area configuration mode, then the interface adopts the flood reduction parameter specified for the process.

If this command is not specified at any level, then flood reduction is disabled.

Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 3.3.0 | Removed the <b>enable</b> keyword.                                 |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

All routers that support Open Shortest Path First Version 3 (OSPFv3) demand circuits are compatible with routers supporting flooding reduction.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to reduce the flooding of unnecessary LSAs for area 0:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/1/0/3  
RP/0/0/CPU0:router(config-ospfv3-ar-if)# flood-reduction
```

**Related Commands**

| Command                                             | Description                                                            |
|-----------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">show ospfv3 interface, on page 1297</a> | Displays OSPFv3-related interface information.                         |
| <a href="#">show ospfv3 neighbor, on page 1302</a>  | Displays OSPFv3 neighbor information on an individual interface basis. |

# graceful-restart (OSPFv3)

To enable graceful restart, use the **graceful-restart** command in an appropriate configuration mode. To disable this feature, use the **no** form of this command.

**graceful-restart** [**helper disable**| **interval** *interval*| **lifetime** *lifetime*]

**no graceful-restart** [**helper disable**| **interval** *interval*| **lifetime** *lifetime*]

## Syntax Description

|                                 |                                                                                                   |
|---------------------------------|---------------------------------------------------------------------------------------------------|
| <b>helper</b> <b>disable</b>    | (Optional) Disables the routers helper support level.                                             |
| <b>interval</b> <i>interval</i> | (Optional) Specifies the minimum interval between graceful restarts. Range is 90 to 3600 seconds. |
| <b>lifetime</b> <i>lifetime</i> | (Optional) Specifies the maximum route lifetime following a restart. Range is 90 to 3600 seconds. |

## Command Default

No default behavior or values.

## Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to enable the Graceful Restart feature with a minimum interval between restarts of 300 seconds:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# graceful-restart interval 300
```

## Related Commands

| Command                                             | Description                                                            |
|-----------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">show ospfv3 interface, on page 1297</a> | Displays OSPFv3-related interface information.                         |
| <a href="#">show ospfv3 neighbor, on page 1302</a>  | Displays OSPFv3 neighbor information on an individual interface basis. |

# hello-interval (OSPFv3)

To specify the interval between hello packets that Open Shortest Path First Version 3 (OSPFv3) sends on an interface, use the **hello-interval** command in an appropriate configuration mode. To return to the default time, use the **no** form of this command.

**hello-interval** *seconds*  
**no hello-interval**

## Syntax Description

|                |                                                                                        |
|----------------|----------------------------------------------------------------------------------------|
| <i>seconds</i> | Interval (in seconds). The value must be the same for all nodes on a specific network. |
|----------------|----------------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the hello interval parameter specified by area.

If this command is not specified in area configuration mode, then the interface adopts the hello interval parameter specified for the process.

If this command is not specified at any level, then the hello interval is 10 seconds (broadcast) or 30 seconds (nonbroadcast).

## Command Modes

Interface configuration  
 Area configuration  
 Router OSPFv3 configuration  
 Virtual-link configuration  
 OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The hello interval value is advertised in the hello packets. The shorter the hello interval, the faster topological changes are detected, but more routing traffic ensues. This value must be the same for all routers and access servers on a specific network.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the interval between hello packets to 15 seconds on GigabitEthernet interface 0/3/0/2:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/2  
RP/0/0/CPU0:router(config-ospfv3-ar-if)# hello-interval 15
```

**Related Commands**

| Command                                              | Description                                                                                   |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <a href="#">dead-interval (OSPFv3), on page 1205</a> | Sets the interval after which a neighbor is declared dead when no hello packets are observed. |

# instance (OSPFv3)

To set the 8-bit instance ID used in Open Shortest Path First Version 3 (OSPFv3) packets sent on an interface, use the **instance** command in an appropriate configuration mode. To remove the instance ID, use the **no** form of this command.

```
instance instance-id
no instance instance-id
```

## Syntax Description

|                    |                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance-id</i> | Instance identifier sent in OSPFv3 packets. Range is 0 to 255. The same value must be used by all the communicating OSPFv3 routers on a link. |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

If this command is not specified in interface configuration mode, then the interface adopts the instance parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the instance parameter specified for the process.

If this command is not specified at any level, then the instance is 0.

## Command Modes

- Interface configuration
- Area configuration
- Router OSPFv3 configuration
- OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The OSPFv3 routing protocol allows multiple unrelated OSPFv3 processes to share a link by using an 8-bit “instance” value to demultiplex the protocol packets. Each OSPFv3 process sets its configured instance value in the OSPFv3 packets that it sends, and ignores received packets with instance values from other OSPFv3 processes.

**Note**

The *instance-id* argument should not be confused with the *process-name* argument that is specified by the **router ospfv3** command. The former is an 8-bit integer that is sent to other routers as part of the OSPFv3 protocol, and the latter is a 1- to 40-character ASCII string that is significant only within a given router. The instance ID value is also unrelated to the router ID that is specified by the **router-id** command, which is a 32-bit integer value that uniquely identifies a router within an OSPFv3 routing domain.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the instance value for GigabitEthernet interface 0/3/0/1 to 42:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# instance 42
```

**Related Commands**

| Command                                          | Description                                            |
|--------------------------------------------------|--------------------------------------------------------|
| <a href="#">router ospfv3, on page 1272</a>      | Configures an OSPFv3 routing process.                  |
| <a href="#">router-id (OSPFv3), on page 1270</a> | Configures a router ID for the OSPFv3 routing process. |

# interface (OSPFv3)

To define the interfaces on which Open Shortest Path First Version 3 (OSPFv3) runs, use the **interface** command in an appropriate configuration mode. To disable OSPFv3 routing for an interface, use the **no** form of this command.

```
interface type interface-path-id
no interface type interface-path-id
```

|                    |                   |                                                                                                                                                                                                                                                                                                |
|--------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax Description | type              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                                          |
|                    | interface-path-id | Physical interface or virtual interface.<br><br><div> <b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br/> For more information about the syntax for the router, use the question mark (?) online help function. </div> |

**Command Default** An interface is not defined.

**Command Modes** Area configuration  
OSPFv3 VRF configuration

| Command History | Release       | Modification                                                       |
|-----------------|---------------|--------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                       |
|                 | Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **interface** command to associate a specific interface with an OSPFv3 area. The interface remains associated with the area even when the IPv6 address of the interface changes.

Similar to IPv4 address behavior for the **interface** command, all configured IPv6 addresses are advertised on an interface after the interface is associated to the OSPF routing process. The only difference is, IPv6 addresses can have multiple primary addresses.

This command places the router in interface configuration mode (prompt: config-router-ar-if), from which you can configure interface-specific settings. Commands configured under this mode (such as the **cost** command) are automatically bound to that interface.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to define two interfaces that belong to area 1. The cost value for packets on GigabitEthernet interface 0/3/0/1 is set at 40; the cost value for GigabitEthernet interface 0/3/0/2 is 65:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 1
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# cost 40
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/2
RP/0/0/CPU0:router(config-ospfv3-ar-if)# cost 65
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
```

# log adjacency changes (OSPFv3)

To change the default syslog messages for Open Shortest Path First Version 3 (OSPFv3) neighbor state changes, use the **log adjacency changes** command in an appropriate configuration mode. To suppress all adjacency change messages, use the **disable** keyword.

**log adjacency changes** [**detail**| **disable**]

## Syntax Description

|                |                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------|
| <b>detail</b>  | (Optional) Provides all (DOWN, INIT, 2WAY, EXSTART, EXCHANGE, LOADING, FULL) adjacency state changes. |
| <b>disable</b> | (Optional) Disables the neighbor state change messages.                                               |

## Command Default

Neighbor state change messages are enabled.

## Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, you are notified of OSPFv3 neighbor changes without explicitly configuring the **log adjacency changes** command. The syslog messages that are sent provide a high-level view of changes to the state of the OSPFv3 peer relationship.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to disable neighbor state change messages:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# log adjacency changes disable
```

The following example shows how to re-enable syslog messages for any OSPFv3 neighbor state changes:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# log adjacency changes
```

## maximum interfaces (OSPFv3)

To control the maximum number of interfaces that can be configured under an Open Shortest Path First Version 3 (OSPFv3) process, use the **maximum interfaces** command in an appropriate configuration mode. To remove the **maximum interfaces** command from the configuration file and restore the system to its default condition with respect to the routing protocol, use the **no** form of this command.

**maximum interfaces** *number-interfaces*

**no maximum interfaces**

### Syntax Description

|                          |                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------|
| <i>number-interfaces</i> | Maximum number of interfaces that can be configured for this OSPFv3 process. Range is 1 to 4294967295. |
|--------------------------|--------------------------------------------------------------------------------------------------------|

### Command Default

If the command is not specified, the default is 1024.

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                     |
| Release 4.1.1 | The range for number of interfaces was changed to 1 to 4294967295 from 1 to 1024. The default number of interfaces was changed to 1024 from 255. |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submodule.                                                                             |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

This example shows how to allow a maximum of 1500 interfaces in an OSPFv3 process:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
```

```
RP/0/0/CPU0:router(config-ospfv3)# maximum interfaces 1500
```

# maximum paths (OSPFv3)

To control the maximum number of parallel routes that the Open Shortest Path First Version 3 (OSPFv3) can support, use the **maximum paths** command in an appropriate configuration mode. To remove the **maximum paths** command from the configuration file and restore the system to its default condition with respect to the routing protocol, use the **no** form of this command.

**maximum paths** *maximum-routes-number*

**no maximum paths**

| Syntax Description | <div> <div><i>maximum-routes-number</i></div> <div>Maximum number of parallel routes that OSPFv3 can install in a routing table. Range is 1 to 32.</div> <div> <b>Note</b> <div>The maximum number of paths that can be configured is 16.</div> </div> </div>                                                                                                                                                                                                                                                       |         |              |             |                              |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|--------------|-------------|------------------------------|
| Command Default    | 16 paths                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |              |             |                              |

| Task ID            | Operations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |         |              |             |                              |
| ospf               | read, write                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |              |             |                              |

## Examples

The following example shows how to allow a maximum of two paths to a destination:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# maximum paths 2
```

## maximum redistributed-prefixes (OSPFv3)

To limit the number of prefixes redistributed into Open Shortest Path First Version 3 (OSPFv3) or to generate a warning when the number of prefixes redistributed into OSPFv3 reaches a maximum, use the **maximum redistributed-prefixes** command in an appropriate configuration mode. To remove the values, use the **no** form of this command.

**maximum redistributed-prefixes** *limit* [*threshold*] [**warning-only**]

**no maximum redistributed-prefixes**

### Syntax Description

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>limit</i>        | Maximum number of IP Version 6 (IPv6) prefixes that are allowed to be redistributed into OSPFv3, or, if the <b>warning-only</b> keyword is present, sets the number of prefixes allowed to be redistributed into OSPFv3 before the system logs a warning message. Range is 1 to 4294967295.<br><br><b>Note</b> If the <b>warning-only</b> keyword is also configured, this value does not limit redistribution; it is simply the number of redistributed prefixes that, when reached, causes a warning message to be logged. |
| <i>threshold</i>    | (Optional) Percentage of the value set for the maximum number of redistributed prefixes that, when reached, causes a warning message to be logged.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>warning-only</b> | (Optional) Causes a warning to be logged when the number of routes defined by the <i>limit</i> argument have been redistributed. Additional redistribution is not prevented.                                                                                                                                                                                                                                                                                                                                                 |

### Command Default

*limit* : 10240  
*threshold* : 75 percent

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If someone mistakenly injects a large number of IPv6 routes into OSPFv3, perhaps by redistributing Border Gateway Protocol (BGP) into OSPFv3, the network can be severely flooded. Limiting the number of redistributed routes prevents this potential problem.

When the **maximum redistributed-prefixes** command is configured, if the number of redistributed routes reaches the maximum value configured, no more routes are redistributed (unless the **warning-only** keyword is configured).

The redistribution limit applies only to external IPv6 prefixes. Default routes and summarized routes are not limited.

The limit is tracked separately for each not-so-stubby-area (NSSA) because redistribution to NSSAs is done independently for each NSSA and independently of all other regular areas.

Select a maximum value based on your knowledge of how many prefixes are redistributed on the router to the OSPFv3 process.

Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

Examples

This example shows how to set a maximum of 2000 prefixes that can be redistributed into OSPFv3 process 1. If the number of prefixes redistributed reaches 75 percent of 2000 (1500 prefixes), a warning message is logged. Another warning is logged if the limit is reached and no more routes are redistributed.

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# redistribute bgp 2406
RP/0/0/CPU0:router(config-ospfv3)# maximum redistributed-prefixes 2000
```

## mtu-ignore (OSPFv3)

To prevent the Open Shortest Path First Version 3 (OSPFv3) router process from checking whether neighbors are using the same maximum transmission unit (MTU) on a common interface when exchanging database descriptor (DBD) packets, use the **mtu-ignore** command in an appropriate configuration mode. To return to the default state, use the **no** form of this command.

**mtu-ignore [disable]**

**no mtu-ignore**

### Syntax Description

|                |                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Disables the attribute in instances in which it is specified at a higher level in the configuration. |
| <b>Note</b>    | The <b>disable</b> keyword is not available in router ospfv3 configuration mode.                                |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the MTU ignore parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the MTU ignore parameter specified for the process.

If this command is not specified at any level, then OSPFv3 checks the MTU received from neighbors when exchanging DBD packets.

### Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 3.3.0 | Removed the <b>enable</b> keyword.                                 |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **mtu-ignore** command to check whether OSPFv3 neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the MTU configured on the incoming interface, OSPF adjacency is not established.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to disable MTU mismatch detection on received DBD packets on GigabitEthernet interface 0/1/0/3:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/1/0/3  
RP/0/0/CPU0:router(config-ospfv3-ar-if)# mtu-ignore
```

## neighbor (OSPFv3)

To configure Open Shortest Path First Version 3 (OSPFv3) routers interconnecting to nonbroadcast networks, use the **neighbor** command in interface configuration mode. To remove a configuration, use the **no** form of this command.

**neighbor** *ipv6-address* [**priority** *number*] [**poll-interval** *seconds*] [**cost** *number*] [**database-filter** **all out**]  
**no neighbor** *ipv6-address* [**priority** *number*] [**poll-interval** *seconds*] [**cost** *number*] [**database-filter** **all out**]

### Syntax Description

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-address</i>                   | Link- local IP Version 6 (IPv6) address of the neighbor. This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons.                                                                                                                                                                                                        |
| <b>priority</b> <i>number</i>         | (Optional) Specifies an 8-bit number indicating the router priority value of the nonbroadcast neighbor associated with the IP address specified. The <b>priority</b> keyword does not apply to point-to-multipoint interfaces.                                                                                                                                                                                 |
| <b>poll-interval</b> <i>seconds</i>   | (Optional) Specifies an unsigned integer value (in seconds) reflecting the poll interval. RFC 1247 recommends that this value be much larger than the hello interval. The <b>poll-interval</b> keyword does not apply to point-to-multipoint interfaces.                                                                                                                                                       |
| <b>cost</b> <i>number</i>             | (Optional) Assigns a cost to the neighbor, in the form of an integer from 1 to 65535. Neighbors with no specific cost configured assume the cost of the interface, based on the <b>cost</b> command. On point-to-multipoint interfaces, <b>cost</b> <i>number</i> is the only keyword and argument combination that works. The <b>cost</b> keyword does not apply to nonbroadcast multiaccess (NBMA) networks. |
| <b>database-filter</b> <b>all out</b> | (Optional) Filters outgoing link-state advertisements (LSAs) to an OSPFv3 neighbor.                                                                                                                                                                                                                                                                                                                            |

### Command Default

No configuration is specified.

**priority** *number* : 0

**poll-interval** *seconds* : 120 seconds (2 minutes)

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

One neighbor entry must be included in the software configuration for each known nonbroadcast network neighbor. The neighbor address must be the IPv6 link-local address of the interface.

If a neighboring router has become inactive (hello packets have not been seen for the router dead interval period), it may still be necessary to send hello packets to the dead neighbor. These hello packets are sent at a reduced rate called the poll interval.

When the router starts up, it sends only hello packets to those routers with nonzero priority; that is, routers that are eligible to become designated routers (DRs) and backup designated routers (BDRs). After the DR and BDR are selected, the DR and BDR then start sending hello packets to all neighbors to form adjacencies.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to declare a router at address fe80::3203:a0ff:fe9d:f3fe on a nonbroadcast network:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/0
RP/0/0/CPU0:router(config-ospfv3-ar)# network non-broadcast
RP/0/0/CPU0:router(config-ospfv3-ar-if)# neighbor fe80::3203:a0ff:fe9d:f3fe
```

**Related Commands**

|-------------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">priority (OSPFv3), on page 1259</a> | Sets the router priority, which helps determine the designated router for this network. |

## network (OSPFv3)

To configure the Open Shortest Path First Version 3 (OSPFv3) network type to a type other than the default for a given medium, use the **network** command in an appropriate configuration mode. To return to the default value, use the **no** form of this command.

**network** {**broadcast**| **non-broadcast**| {**point-to-multipoint** [**non-broadcast**]| **point-to-point**}}  
**no network**

### Syntax Description

|                            |                                                                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>broadcast</b>           | Sets the network type to broadcast.                                                                                                                       |
| <b>non-broadcast</b>       | Sets the network type to nonbroadcast multiaccess (NBMA).                                                                                                 |
| <b>point-to-multipoint</b> | Sets the network type to point-to-multipoint.                                                                                                             |
| [ <b>non-broadcast</b> ]   | (Optional) Sets the point-to-multipoint network to be nonbroadcast. If you use the <b>non-broadcast</b> keyword, the <b>neighbor</b> command is required. |
| <b>point-to-point</b>      | Sets the network type to point-to-point.                                                                                                                  |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the network parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the network parameter specified for the process.

If this command is not specified at any level, then the OSPFv3 network type is the default of the given medium.

### Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **network** command to configure broadcast networks as NBMA networks when, for example, routers in your network do not support multicast addressing.

Most times, it is assumed that when you configure NBMA networks as either broadcast or nonbroadcast, there are virtual circuits from every router to every router or fully meshed network. However, there are other configurations where this assumption is not true; for example, a partially meshed network. In these cases, you can configure the OSPFv3 network type as a point-to-multipoint network. Routing between two routers that are not directly connected goes through the router that has virtual circuits to both routers. You need not configure neighbors when using this command.

If the **network** command is issued on an interface that does not allow it, this command is ignored.

OSPFv3 has two features related to point-to-multipoint networks. One feature applies to broadcast networks and the other feature applies to nonbroadcast networks:

- On point-to-multipoint, broadcast networks, you can use the **neighbor** command, and you must specify a cost to that neighbor.
- On point-to-multipoint, nonbroadcast networks, you must use the **neighbor** command to identify neighbors. Assigning a cost to a neighbor is optional.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

### Examples

The following example shows how to configure an Ethernet interface as point-to-point:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface TenGigE0/1/0/3
RP/0/0/CPU0:router(config-ospfv3-ar-if)# network point-to-point
```

### Related Commands

|-------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">neighbor (OSPFv3), on page 1246</a> | Configures OSPFv3 routers interconnecting to nonbroadcast networks. |

## nssa (OSPFv3)

To configure an area as a not-so-stubby area (NSSA), use the **nssa** command in area configuration mode. To remove the NSSA distinction from the area, use the **no** form of this command.

**nssa** [**no-redistribution**] [**default-information-originate** [**metric** *metric-value*| **metric-type** *type-value*]] [**no-summary**]

**no nssa**

### Syntax Description

|                                      |                                                                                                                                                                                                                                                               |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>no-redistribution</b>             | (Optional) Imports routes into the normal areas, but not into the NSSA area, by the <b>redistribute</b> command when the router is an NSSA area border router (ABR).                                                                                          |
| <b>default-information-originate</b> | (Optional) Generates a Type 7 default into the NSSA area. This keyword takes effect only on an NSSA ABR or NSSA autonomous system boundary router (ASBR).                                                                                                     |
| <b>metric</b> <i>metric-value</i>    | (Optional) Specifies a metric used for generating the default route. If you do not specify a default route metric value using the <b>nssa</b> and <b>defaultmetric</b> commands, the default metric value is 10. The value used is specific to the protocol.  |
| <b>metric-type</b> <i>type-value</i> | (Optional) Specifies an external link type associated with the default route advertised into the Open Shortest Path First Version 3 (OSPFv3) routing domain. It can be one of the following values:<br><br>1—Type 1 external route<br>2—Type 2 external route |
| <b>no-summary</b>                    | (Optional) Prevents an (ABR) from sending summary link advertisements into the NSSA area.                                                                                                                                                                     |

### Command Default

No NSSA area is defined.

If you do not specify a value using the **default-metric** command, the default metric value is 10.

The default *type-value* is Type 2 external route.

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

A default route need not be defined in an NSSA ABR when the **nssa** command is configured. However, if this command is configured on an NSSA ASBR, then a default route must be defined.

Note

NSSA cannot be configured for area 0 (backbone area).

Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

Examples

The following example shows how to configure area 1 as an NSSA area:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# router-id 10.18.1.1
RP/0/0/CPU0:router(config-ospfv3)# area 1
RP/0/0/CPU0:router(config-ospfv3-ar)# nssa
```

## nsr (OSPFv3)

To configure nonstop routing (NSR) for the Open Shortest Path First Version 3 (OSPFv3) protocol, use the **nsr** command in OSPFv3 router configuration mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsr**

**no nsr**

|                           |                                            |

| <b>Task ID</b> | <b>Task ID</b> | <b>Operations</b> |
|----------------|----------------|-------------------|
|                | ospf           | read, write       |

|                 |                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure OSPFv3 to look up DNS names for use in all OSPFv3 <b>show</b> command displays: |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|

```
RP/0/0/CPU0:router(config)# ospfv3 name-lookup
```

## packet-size (OSPFv3)

To configure the size of Open Shortest Path First Version 3 (OSPFv3) packets up to the size specified by the maximum transmission unit (MTU), use the **packet-size** command in an appropriate configuration mode. To disable this function and reestablish the default packet size, use the **no** form of this command.

**packet-size** *bytes*

**no packet-size**

### Syntax Description

|              |                                             |
|--------------|---------------------------------------------|
| <i>bytes</i> | Size in bytes. Range is 256 to 10000 bytes. |
|--------------|---------------------------------------------|

### Command Default

If not specified, the default packet size is 1500 bytes.

### Command Modes

Router OSPFv3 configuration

Area configuration

Interface configuration

OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.6.0 | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **packet-size** command to customize the size of OSPFv3 packets. The OSPFv3 protocol compares the packet size and the MTU size and uses the lower packet size value.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to configure the packet size:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# router ospf osp3  
RP/0/0/CPU0:router(config-ospfv3)# packet-size 3500
```

## passive (OSPFv3)

To suppress the sending of Open Shortest Path First Version 3 (OSPFv3) packets on an interface, use the **passive** command in an appropriate configuration mode. To remove the passive configuration, use the **no** form of this command.

**passive** [**disable**]

**no passive**

### Syntax Description

|                |                                                                                  |
|----------------|----------------------------------------------------------------------------------|
| <b>disable</b> | (Optional) Sends OSPFv3 updates.                                                 |
| <b>Note</b>    | The <b>disable</b> keyword is not available in router ospfv3 configuration mode. |

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the passive parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the passive parameter specified for the process.

If this command is not specified at any level, then the passive parameter is disabled and OSPFv3 updates are sent on the interface.

### Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

OSPF routing information is neither sent nor received through the specified router interface. The specified interface address appears as a stub network in the OSPF domain.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows that OSPFv3 updates run over GigabitEthernet interface 0/3/0/0, 0/2/0/0, and 0/2/0/2. All other interfaces suppress sending OSPFv3 updates because they are in passive mode.

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# router-id 10.0.0.206
RP/0/0/CPU0:router(config-ospfv3)# passive
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-ospfv3-ar-if)# passive disable
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
RP/0/0/CPU0:router(config-ospfv3-ar)# exit
RP/0/0/CPU0:router(config-ospfv3)# area 1
RP/0/0/CPU0:router(config-ospfv3-ar)# passive disable
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/0
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# passive
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/2
RP/0/0/CPU0:router(config-ospfv3-ar-if)# exit
```

## priority (OSPFv3)

To set the router priority for an interface, which helps determine the designated router for an Open Shortest Path First Version 3 (OSPFv3) link, use the **priority** command in an appropriate configuration mode. To return to the default value, use the **no** form of this command.

**priority** *value*

**no priority**

### Syntax Description

|              |                                                                                 |
|--------------|---------------------------------------------------------------------------------|
| <i>value</i> | 8-bit unsigned integer indicating the router priority value. Range is 0 to 255. |
|--------------|---------------------------------------------------------------------------------|

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the priority parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the priority parameter specified by the process.

If this command is not specified at any level, then the default priority is 1.

### Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When two routers attached to a network both attempt to become the designated router, the one with the higher router priority takes precedence. If there is a tie, the router with the higher router ID takes precedence. A router with a router priority set to zero is ineligible to become the designated router or backup designated router. Router priority is configured only for interfaces to broadcast and nonbroadcast multiaccess (NBMA) networks.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the router priority value to 4 on GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-ospfv3-ar-if)# priority 4
```

**Related Commands**

| Command                                         | Description                                                                             |
|-------------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">neighbor (OSPFv3), on page 1246</a> | Configures OSPFv3 routers interconnecting to nonbroadcast networks.                     |
| <a href="#">network (OSPFv3), on page 1248</a>  | Configures the OSPFv3 network type to a type other than the default for a given medium. |

# range (OSPFv3)

To consolidate and summarize routes at an area boundary for Open Shortest Path First Version 3 (OSPFv3), use the **range** command in area configuration mode. To restore the default values, use the **no** form of this command.

```
range ipv6-prefix/prefix-length [advertise|not-advertise] [cost number]
no range ipv6-prefix/prefix-length [advertise|not-advertise] [cost number]
```

| Syntax Description        |                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-prefix</i>        | Summary prefix designated for a range of IP Version 6 (IPv6) prefixes.<br>This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons. |
| <i>/ prefix-length</i>    | Length of the IPv6 prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value.     |
| <b>advertise</b>          | (Optional) Sets the address range status to advertise and generates a Type 3 summary link-state advertisement (LSA).                                                                                                     |
| <b>not-advertise</b>      | (Optional) Sets the address range status to DoNotAdvertise. The Type 3 summary LSA is suppressed and the component networks remain hidden from other networks.                                                           |
| <b>cost</b> <i>number</i> | (Optional) Specifies a cost for the range. Range is 1 to 16777214.                                                                                                                                                       |

**Command Default** Routes are not consolidated and summarized for an area.

**Command Modes** Area configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **range** command only with Area Border Routers (ABRs). It is used to consolidate or summarize routes for an area. The result is that a single summary route is advertised to other areas by the ABR. Routing

information is condensed at area boundaries. External to the area, a single route is advertised for each address range. This process is called *route summarization*.

You can use the **range** command to configure multiple ranges. Thus, OSPFv3 can summarize addresses for many different sets of address ranges.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

The following example shows how to specify one summary route to be advertised by the ABR to other areas for all IPv6 prefixes within the range defined by summary prefix 4004:f000::/32:

```
RP/0/0/CPU0:router(config)# router ospfv3 201  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# range 4004:f000::/32
```

# redistribute (OSPFv3)

To redistribute routes from one routing domain into Open Shortest Path First Version 3 (OSPFv3), use the **redistribute** command in an appropriate configuration mode. To remove the **redistribute** command from the configuration file and restore the system to its default condition in which the software does not redistribute routes, use the **no** form of this command.

## Border Gateway Protocol (BGP)

**redistribute** **bgp** *process-id* [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **bgp** *process-id* [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]

## Local Interface Routes

**redistribute** **connected** [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **connected** [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]

## Enhanced Interior Gateway Routing Protocol (EIGRP)

**redistribute** **eigrp** *process-id* [**match** {**external** [1| 2]| **internal**}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **eigrp** *process-id* [**match** {**external** [1| 2]| **internal**}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**route-policy** *policy-name*] [**tag** *tag-value*]

## Intermediate System-to-Intermediate System (IS-IS)

**redistribute** **isis** *process-id* [**level-1** | **level-2** | **level-1-2**] [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **isis** *process-id* [**level-1** | **level-2** | **level-1-2**] [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]

## Open Shortest Path First Version 3 (OSPFv3)

**redistribute** **ospfv3** *process-id* **match** {**external**| 1| 2| **internal**| **nssa-external**| [1| 2]} [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **ospfv3** *process-id* [**match** {**external**| **internal**| **nssa-external**}] [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]

## Static

**redistribute** **static** [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]  
**no redistribute** **static** [**metric** *metric-value*] [**metric-type** {1| 2}] [**policy** *policy-name*] [**tag** *tag-value*]

### Syntax Description

|            |                                           |
|------------|-------------------------------------------|
| <b>bgp</b> | Distributes routes from the BGP protocol. |
|------------|-------------------------------------------|

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-id</i>                          | <p>For the <b>bgp</b> keyword, an autonomous system number has the following ranges:</p> <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> <p>For the <b>isis</b> keyword, an IS-IS instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p> <p>For the <b>ospf</b> keyword, an OSPF instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p> |
| <b>metric</b> <i>metric-value</i>          | (Optional) Specifies the metric used for the redistributed route. Range is 1 to 16777214. Use a value consistent with the destination protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>metric-type</b> { <b>1</b>   <b>2</b> } | <p>(Optional) Specifies the external link type associated with the route advertised into the OSPF routing domain. It can be one of two values:</p> <ul style="list-style-type: none"> <li>• <b>1</b>—Type 1 external route</li> <li>• <b>2</b>—Type 2 external route</li> </ul> <p>If no <b>metric-type</b> is specified, the default is Type 2 external routes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>tag</b> <i>t ag-value</i>               | (Optional) Specifies the 32-bit dotted-decimal value attached to each external route. This value is not used by the OSPF protocol itself, but is carried in the External LSAs. Range is 0 to 4294967295.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>policy</b> <i>policy-name</i>           | (Optional) Specifies the identifier of a configured policy. A policy is used to filter the importation of routes from this source routing protocol to OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>connected</b>                           | Distributes routes that are established automatically by virtue of having enabled IP on an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>eigrp</b>                               | Distributes routes from the EIGRP protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>isis</b>                                | Distributes routes from the IS-IS protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>level-1</b>                             | (Optional) Redistributes Level 1 routes into other IP routing protocols independently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>level-1-2</b>                           | (Optional) Redistributes both Level 1 and Level 2 routes into other IP routing protocols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>level-2</b>                             | (Optional) Redistributes Level 2 routes into other IP routing protocols independently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ospf</b>                                | Distributes routes from the OSPF protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**match** { **internal** | **external** [ **1** | **2** ] | **nssa-external** [ **1** | **2** ] }

(Optional) Specifies the criteria by which OSPF routes are redistributed into other routing domains. It can be one or more of the following:

- **internal** —Routes that are internal to a specific autonomous system (intra- and inter-area OSPF routes).
- **external** [ **1** | **2** ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 external routes.
- **nssa-external** [ **1** | **2** ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 not-so-stubby area (NSSA) external routes.

For the **external** and **nssa-external** options, if a type is not specified, then both Type 1 and Type 2 are assumed.

If no match is specified, the default is no filtering.

**static** Redistributes IP static routes.

### Command Default

Route redistribution is disabled.

**metric** *metric-value*: Default is 20 for routes from all protocols except BGP routes, in which the default is 1.

**metric-type** *type-value* : Type 2 external route

All routes from the OSPFv3 routing protocol are redistributed.

**tag** *tag-value* : If no value is specified, the remote autonomous system number is used for routes from Border Gateway Protocol (BGP); for other protocols, the default is 0.

### Command Modes

Router OSPFv3 configuration

OSPFv3 VRF configuration

### Command History

|---------------|-----------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                |
| Release 3.6.0 | The <b>eigrp</b> protocol was supported.                                    |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode.          |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

When redistributing routes (into OSPF) using both command keywords for setting or matching of attributes and a route policy, the routes are run through the route policy first, followed by the keyword matching and setting.

Disabling or changing the arguments of any keyword does not affect the state of other keywords.

In general, route redistribution from Level 1 to Level 2 is automatic. You might want to use this command to better control which Level 1 routes can be redistributed into Level 2.

The redistribution of Level 2 routes into Level 1 is called *route leaking*. Route leaking is disabled by default. That is, Level 2 routes are not automatically included in Level 1 link-state protocols. If you want to leak Level 2 routes into Level 1, you must enable that behavior by using this command.

Redistribution from Level 1 into Level 1 and from Level 2 into Level 2 is not allowed.

A router receiving a link-state packet with an internal metric considers the cost of the route from itself to the redistributing router plus the advertised cost to reach the destination. An external metric considers only the advertised metric to reach the destination.

Redistributed routing information should always be filtered by the **distribute-list prefix-list out** command. Use of this command ensures that only those routes intended by the administrator are passed along to the receiving routing protocol.

**OSPFv3 Considerations**

Whenever you use the **redistribute** or the **default-information** command to redistribute routes into an OSPFv3 routing domain, the router automatically becomes an ASBR. However, an ASBR does not, by default, generate a default route into the OSPFv3 routing domain.

When routes are redistributed between OSPFv3 processes, no OSPFv3 metrics are preserved.

When routes are redistributed into OSPF and no metric is specified with the **metric** keyword, OSPF uses 20 as the default metric for routes from all protocols except BGP routes, which get a metric of 1. Furthermore, when the router redistributes from one OSPFv3 process to another OSPFv3 process on the same router, and if no default metric is specified, the metrics in one process are carried to the redistributing process.

**BGP Considerations**

The only connected routes affected by this command are the routes not specified by the **network** (BGP) command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to cause static routes to be redistributed into an OSPFv3 domain:

```
RP/0/0/CPU0:router(config)# router ospfv3 109  
RP/0/0/CPU0:router(config-ospfv3)# redistribute isis level-1
```

## retransmit-interval (OSPFv3)

To specify the time between link-state advertisement (LSA) retransmissions for adjacencies belonging to the Open Shortest Path First Version 3 (OSPFv3) interface, use the **retransmit-interval** command in an appropriate configuration mode. To return to the default value, use the **no** form of this command.

**retransmit-interval** *seconds*

**no retransmit-interval**

### Syntax Description

|                |                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Time (in seconds) between retransmissions. It must be greater than the expected round-trip delay between any two routers on the attached network. Range is 1 to 65535 seconds. |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

If this command is not specified in interface configuration mode, then the interface adopts the retransmit interval parameter specified by the area.

If this command is not specified in area configuration mode, then the interface adopts the retransmit interval parameter specified by the process.

If this command is not specified at any level, then the default retransmit interval is 5 seconds.

### Command Modes

Interface configuration  
Area configuration  
Router OSPFv3 configuration  
Virtual-link configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced                                        |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA.

The setting of this parameter should be conservative, or needless retransmission results. The value should be larger for serial lines and virtual links.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to set the retransmit interval value to 8 seconds while in interface configuration mode:

```
RP/0/0/CPU0:router(config)# router ospfv3 1  
RP/0/0/CPU0:router(config-ospfv3)# area 0  
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/2/0/0  
RP/0/0/CPU0:router(config-ospfv3-ar-if)# retransmit-interval 8
```

# router-id (OSPFv3)

To configure a router ID for the Open Shortest Path First Version 3 (OSPFv3) routing process, use the **router-id** command in an appropriate configuration mode. To cause the software to use the default method of determining the router ID, use the **no** form of this command after clearing or restarting the OSPF process.

**router-id** *router-id*  
**no router-id** *router-id*

|                           |                  |                                                                         |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <b>Usage Guidelines</b> | To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.                                                                                                                                                                                                                 |  |
|                         | We recommend that you use the <b>router-id</b> command to explicitly specify a unique 32-bit numeric value for the router ID. This configuration ensures that OSPFv3 can function regardless of the interface address configuration. Clear the OSPF process using the <b>clear ospf process</b> command or restart the OSPF process for the <b>no router-id</b> command to take effect.                                                               |  |
|                         | In router OSPFv3 configuration mode, OSPF attempts to obtain a router ID in the following ways (in order of preference):                                                                                                                                                                                                                                                                                                                              |  |
|                         | <ol style="list-style-type: none"> <li>1 By default, when the OSPF process initializes, it checks if there is a router-id in the checkpointing database.</li> <li>2 The 32-bit numeric value specified by the OSPF <b>router-id</b> command in router configuration mode. (This value can be any 32-bit value. It is not restricted to the IPv4 addresses assigned to interfaces on this router, and need not be a routable IPv4 address.)</li> </ol> |  |

- 3 A global router ID provided by the system (possibly, the first loopback address found at the boot time).

If the OSPFv3 process cannot obtain a router ID from any of these sources, the router issues the following error message:

```
%OSPFv3-4-NORTRID : OSPFv3 process 1 cannot run - configure a router ID for this process
```

At this point, OSPFv3 is effectively passive on all its interfaces. To run OSPFv3, make a router ID available by one of the methods described.

In VRF configuration mode, it is mandatory to configure a router ID manually. Otherwise, the OSPFv3 process will not become operational in the VRF.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

The following example shows how to assign the IP address of 10.0.0.10 to the OSPFv3 process 109:

```
RP/0/0/CPU0:router(config)# router ospfv3 109
RP/0/0/CPU0:router(config-ospfv3)# router-id 10.0.0.10
```

#### Related Commands

|----------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">clear ospfv3 process, on page 1193</a> | Resets an OSPFv3 router process without stopping and restarting it. |

# router ospfv3

To configure an Open Shortest Path First Version 3 (OSPFv3) routing process, use the **router ospfv3** command in global configuration mode. To terminate an OSPFv3 routing process, use the **no** form of this command.

**router ospfv3** *process-name*

**no router ospfv3** *process-name*

## Syntax Description

|                     |                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | Name that uniquely identifies an OSPFv3 routing process. The process name is any alphanumeric string no longer than 40 characters. |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No OSPFv3 routing process is defined.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can specify multiple OSPFv3 routing processes in each router. Up to 10 processes can be configured. The recommendation is not to exceed 4 OSPFv3 processes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to instantiate an OSPFv3 routing process with a process name of 1:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
```

**Related Commands**

| Command                                          | Description                          |
|--------------------------------------------------|--------------------------------------|
| <a href="#">area (OSPFv3), on page 1185</a>      | Defines an OSPFv3 area.              |
| <a href="#">interface (OSPFv3), on page 1234</a> | Defines an OSPFv3 interface by type. |

# show ospfv3

To display general information about Open Shortest Path First Version 3 (OSPFv3) routing processes, use the **show ospfv3** command in EXEC mode.

```
show ospfv3 [process-name] [vrf {all | vrf-name} ]
```

## Syntax Description

|                     |                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>          | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                        |
| <b>all</b>          | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                    |
| <i>vrf-name</i>     | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                        |

## Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |
| Release 4.1.0 | The <b>vrf <i>vrf_name</i></b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF.                                                  |
| Release 4.2.0 | Non-stop Routing (NSR) information was added in command output.                                                                                                                                                                      |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

## Examples

The following is a sample output from the **show ospfv3** command:

```
RP/0/0/CPU0:router# show ospfv3 1

Routing Process "ospfv3 test" with ID 3.3.3.3
It is an autonomous system boundary router
Redistributing External Routes from,
static
  Maximum number of redistributed prefixes 10240
  Threshold for warning message 75%
Initial SPF schedule delay 5000 msec
Minimum hold time between two consecutive SPF's 10000 msec
Maximum wait time between two consecutive SPF's 10000 msec
Initial LSA throttle delay 0 msec
Minimum hold time for LSA throttle 5000 msec
Maximum wait time for LSA throttle 5000 msec
Minimum LSA arrival 1000 msec
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msec
Retransmission pacing timer 66 msec
Maximum number of configured interfaces 255
Number of external LSA 1. Checksum Sum 0x004468
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
Area BACKBONE(0) (Inactive)
  Number of interfaces in this area is 1
  SPF algorithm executed 1 times
  Number of LSA 3. Checksum Sum 0x018109
  Number of DCbitless LSA 0
  Number of indication LSA 0
  Number of DoNotAge LSA 0
  Flood list length 0
```

This table describes the significant fields shown in the display.

**Table 118: show ospfv3 Field Descriptions**

| Field                                    | Description                                                     |
|------------------------------------------|-----------------------------------------------------------------|
| Routing Process "ospfv3 test" with ID    | OSPFv3 process name.                                            |
| It is                                    | Types are internal, area border, or autonomous system boundary. |
| Redistributing External Routes from      | Lists of redistributed routes, by protocol.                     |
| Maximum number of redistributed prefixes | Number of redistributed prefixes                                |
| Threshold for warning message            | Warning message threshold.                                      |
| Initial SPF schedule delay               | Delay time of SPF calculations.                                 |

| Field                                           | Description                                                                      |
|-------------------------------------------------|----------------------------------------------------------------------------------|
| Minimum hold time between two consecutive SPF's | Minimum hold time between consecutive SPF's.                                     |
| Maximum wait time between two consecutive SPF's | Maximum wait time between consecutive SPF's.                                     |
| Initial LSA throttle delay                      | Delay time of LSA throttle.                                                      |
| Maximum hold time for LSA throttle              | After initial throttle delay, the LSA generation is backed off by hold interval. |
| Maximum wait time for LSA throttle              | Maximum throttle delay for LSA generation.                                       |
| Minimum LSA arrival                             | Minimum LSA arrival.                                                             |
| LSA group pacing timer                          | Configured LSA group pacing timer (in seconds).                                  |
| Interface flood pacing timer                    | Flooding pacing interval.                                                        |
| Retransmission pacing timer                     | Retransmission pacing interval.                                                  |
| Maximum number of configured interfaces         | Maximum number of configured interfaces.                                         |
| Number of external LSA                          | Number of external LSAs.                                                         |
| Number of areas in this router is               | Number of areas configured for the router.                                       |
| Number of interfaces in this area is            | Number of interfaces in the area.                                                |
| SPF algorithm executed <i>n</i> times           | Times SPF algorithm was executed.                                                |
| Number of LSA                                   | Number of LSAs.                                                                  |
| Number of DCbitless LSA                         | Number of DCbitless LSAs.                                                        |
| Number of indication LSA                        | Number of indication LSAs.                                                       |
| Number of DoNotAge LSA                          | Number of do-not-age LSAs.                                                       |
| Flood list length                               | Flood list length.                                                               |

This is sample output from the show ospfv3 vrf command that displays domain -id configuration:

```
RP/0/0/CPU0:router#show ospfv3 0 vrf V1
Mon May 10 14:52:31.332 CEST

Routing Process "ospfv3 0" with ID 100.0.0.2 VRF V1
It is an area border and autonomous system boundary router
Redistributing External Routes from,
    bgp 1
    Maximum number of redistributed prefixes 10240
    Threshold for warning message 75%
Primary Domain ID:
```

```

0x0005:0xcafe00112233
Secondary Domain ID:
0x0105:0xbeef00000001
0x0205:0xbeef00000002
Initial SPF schedule delay 5000 msec
Minimum hold time between two consecutive SPF's 10000 msec
Maximum wait time between two consecutive SPF's 10000 msec
Initial LSA throttle delay 0 msec
Minimum hold time for LSA throttle 5000 msec
Maximum wait time for LSA throttle 5000 msec
Minimum LSA arrival 1000 msec
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msec
Retransmission pacing timer 66 msec
Maximum number of configured interfaces 255
Maximum number of configured paths 16
Number of external LSA 2. Checksum Sum 0x015bb3
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
Auto cost is enabled. Reference bandwidth 100
Area BACKBONE(0)
    Number of interfaces in this area is 1
    SPF algorithm executed 2 times
    Number of LSA 4. Checksum Sum 0x02629d
    Number of DCbitless LSA 0
    Number of indication LSA 0
    Number of DoNotAge LSA 0
    Flood list length 0

```

This is sample output from the **show ospfv3 vrf** command that displays vrf-lite configuration:

```

RP/0/0/CPU0:router#show ospfv3 0 vrf V2
Mon May 10 18:01:38.654 CEST

Routing Process "ospfv3 0" with ID 2.2.2.2 VRF V2
VRF lite capability is enabled
Initial SPF schedule delay 5000 msec
Minimum hold time between two consecutive SPF's 10000 msec
Maximum wait time between two consecutive SPF's 10000 msec
Initial LSA throttle delay 0 msec
Minimum hold time for LSA throttle 5000 msec
Maximum wait time for LSA throttle 5000 msec
Minimum LSA arrival 1000 msec
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msec
Retransmission pacing timer 66 msec
Maximum number of configured interfaces 255
Maximum number of configured paths 16
Number of external LSA 0. Checksum Sum 00000000
Number of areas in this router is 0. 0 normal 0 stub 0 nssa
Auto cost is enabled. Reference bandwidth 100

```

This is sample output from the **show ospfv3** command to verify that (Non-stop routing (NSR) is enabled:

```

RP/0/0/CPU0:router#show ospfv3

Routing Process "ospfv3 100" with ID 3.3.3.3
NSR (Non-stop routing) is Enabled
It is an area border and autonomous system boundary router
Redistributing External Routes from,
    bgp 100
    Maximum number of redistributed prefixes 10240
    Threshold for warning message 75%
Initial SPF schedule delay 5000 msec
Minimum hold time between two consecutive SPF's 10000 msec
Maximum wait time between two consecutive SPF's 10000 msec
Initial LSA throttle delay 0 msec
Minimum hold time for LSA throttle 5000 msec
Maximum wait time for LSA throttle 5000 msec
Minimum LSA arrival 1000 msec
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msec

```

```
Retransmission pacing timer 66 msec
Maximum number of configured interfaces 512
Maximum number of configured paths 16
Number of external LSA 0. Checksum Sum 00000000
Number of areas in this router is 15. 15 normal 0 stub 0 nssa
Auto cost is enabled. Reference bandwidth 100
```

|-----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced                                                                                                                                                         |
|                 | Release 4.1.0 | The <b>vrf</b> <i>vrf_name</i> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | ospf    | read       |

**Examples**

The following is sample output from the **show ospfv3 border-routers** command:

```
RP/0/0/CPU0:router# show ospfv3 border-routers

OSPFv3 1 Internal Routing Table
Codes: i - Intra-area route, I - Inter-area route
i 10.0.0.207 [1] via fe80::3034:30ff:fe33:3742, GigabitEthernet 0/3/0/0, ABR/ASBR, Area
1, SPF 3
i 10.0.0.207 [10] via fe80::204:c0ff:fe22:73fe, Ethernet0/0/0/0, ABR/ASBR, Area 0, SPF 7
```

This table describes the significant fields shown in the display.

**Table 119: show ospf border-routers Field Descriptions**

| Field                     | Description                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| i                         | Type of this route; i indicates an intra-area route, I an inter-area route.                                                   |
| 10.0.0.207                | Router ID of destination.                                                                                                     |
| [1]                       | Cost of using this route.                                                                                                     |
| fe80::3034:30ff:fe33:3742 | Next-hop toward the destination.                                                                                              |
| GigabitEthernet 0/3/0/0   | Packets destined for fe80::3034:30ff:fe33:3742 are sent over GigabitEthernet interface 3/0/0/0.                               |
| ABR/ASBR                  | Router type of the destination; it is either an area border router (ABR) or autonomous system boundary router (ASBR) or both. |
| Area 1                    | Area ID of the area from which this route is learned.                                                                         |
| SPF 3                     | Internal number of the shortest path first (SPF) calculation that installs this route.                                        |

**Related Commands**

## Syntax Description

|                                        |                                                                                                                                                                                                                                     |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>                    | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <i>area-id</i>                         | (Optional) Area number used to define the particular area.                                                                                                                                                                          |
| <b>adv-router</b> [ <i>router-id</i> ] | (Optional) Displays all link-state advertisements (LSAs) of the specified router.                                                                                                                                                   |
| <b>asbr-summary</b>                    | (Optional) Displays information only about the Autonomous System Boundary Router (ASBR) summary LSAs.                                                                                                                               |
| <b>database-summary</b>                | (Optional) Displays how many of each type of LSA are in the database for each area and the total.                                                                                                                                   |
| <b>external</b>                        | (Optional) Displays information only about external LSAs.                                                                                                                                                                           |
| <b>grace</b>                           | (Optional) Displays information about the state for the graceful restart link.                                                                                                                                                      |
| <b>internal</b>                        | (Optional) Displays information only about internal LSAs.                                                                                                                                                                           |
| <b>self-originate</b>                  | (Optional) Displays only self-originated LSAs (from the local router).                                                                                                                                                              |
| <i>link-state-id</i>                   | (Optional) LSA ID that uniquely identifies the LSA. For network LSAs and link LSAs, this ID is the interface ID of the link of the router originating the LSA.                                                                      |
| <b>inter-area prefix</b>               | (Optional) Displays information only about the interarea prefix LSAs.                                                                                                                                                               |
| <b>inter-area router</b>               | (Optional) Displays information only about the interarea router LSAs.                                                                                                                                                               |

|                      |                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------|
| <b>link</b>          | (Optional) Displays information only about the link LSAs.                               |
| <b>network</b>       | (Optional) Displays information only about the network LSAs.                            |
| <b>nssa-external</b> | (Optional) Displays information only about the not-so-stubby area (NSSA) external LSAs. |
| <b>prefix</b>        | (Optional) Displays information only about the prefix LSAs.                             |
| <b>ref-lsa</b>       | (Optional) Displays referenced LSA information.                                         |
| <b>router</b>        | (Optional) Displays information only about the router LSAs.                             |
| <b>unknown</b>       | (Optional) Displays information only about unknown LSAs.                                |
| <b>area</b>          | (Optional) Displays information only about the area LSAs.                               |
| <b>as</b>            | (Optional) Displays information only about the autonomous system LSAs.                  |
| <b>vrf</b>           | Specifies an OSPF VPN routing and forwarding (VRF) instance.                            |
| <b>all</b>           | Display all the VRFs, excluding the default VRF.                                        |
| <i>vrf-name</i>      | Specifies the name of the of the OSPFv3 VRF.                                            |

|-----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Release 3.4.0 | The <b>grace</b> and <b>internal</b> keywords were added.                                                                                                                           |
|                 | Release 3.6.0 | The <b>ref-lsa</b> and <b>internal</b> keywords were added.                                                                                                                         |
|                 | Release 4.1.0 | The <b>vrf</b> <i>vrf_name</i> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |
|                 |               |                                                                                                                                                                                     |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The various forms of this command deliver information about different OSPFv3 link-state advertisements.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

## Examples

The following is sample output from the **show ospfv3 database** command with no arguments or keywords:

RP/0/0/CPU0:router# **show ospfv3 database**

```

OSPFv3 Router with ID (10.0.0.207) (Process ID 1)

Router Link States (Area 0)

ADV Router    Age      Seq#      Fragment ID  Link count  Bits
0.0.0.1       163      0x80000039 0             2           None

This table describes the significant fields shown in the display.

**Table 120: show ospfv3 database Field Descriptions**

| Field      | Description               |
|------------|---------------------------|
| ADV Router | ID of advertising router. |

| Field       | Description                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Age         | Link-state age.                                                                                                                                                                                                                                  |
| Seq#        | Link-state sequence number (detects old or duplicate LSAs).                                                                                                                                                                                      |
| Fragment ID | Router LSA fragment ID.                                                                                                                                                                                                                          |
| Link count  | Number of links described.                                                                                                                                                                                                                       |
| Bits        | B indicates that the router is an area border router. E indicates that the router is an autonomous system boundary router. V indicates that the router is a virtual link endpoint. W indicates that the router is a wildcard multicast receiver. |
| Link ID     | Unique LSA ID.                                                                                                                                                                                                                                   |
| Rtr count   | Number of routers attached to the link.                                                                                                                                                                                                          |
| Prefix      | Prefix of the route being described.                                                                                                                                                                                                             |
| Dest RtrID  | Router ID of the router being described.                                                                                                                                                                                                         |
| Interface   | Link described by the LSA.                                                                                                                                                                                                                       |
| Ref-lstype  | LSA type of the LSA being referenced.                                                                                                                                                                                                            |
| Ref-LSID    | LSA ID of the LSA being referenced.                                                                                                                                                                                                              |

The following is sample output from the **show ospfv3 database** command with the **external** keyword:

```
RP/0/0/CPU0:router# show ospfv3 database external

      OSPFv3 Router with ID (10.0.0.206) (Process ID 1)

      Type-5 AS External Link States

LS age: 189

This table describes the significant fields shown in the display.

**Table 125: show ospfv3 database network Field Descriptions**

| Field                 | Description                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OSPFv3 Router with ID | Router ID number.                                                                                                                                                                                                       |
| Process ID 1          | OSPFv3 process name.                                                                                                                                                                                                    |
| LS age                | Link-state age.                                                                                                                                                                                                         |
| Options               | Type of service options (Type 0 only):<br>DC—Supports demand circuits.E—Capable of processing external LSAs.MC—Forwards IP multicast.N—Supports Type 7 LSAs.R—Router is active.V6—Include in IPv6 routing calculations. |
| LS Type               | Link-state type.                                                                                                                                                                                                        |
| Link State ID         | Link-state ID of the designated router.                                                                                                                                                                                 |
| Advertising Router    | ID of the advertising router.                                                                                                                                                                                           |
| LS Seq Number         | Link-state sequence (detects old or duplicate LSAs).                                                                                                                                                                    |

| Field           | Description                                                                  |
|-----------------|------------------------------------------------------------------------------|
| Checksum        | Link-state checksum (Fletcher checksum of the complete contents of the LSA). |
| Length          | Length (in bytes) of the LSA.                                                |
| Attached Router | List of routers attached to the network, by router ID.                       |

The following is sample output from the **show ospfv3 database** command with the **prefix** keyword:

```
RP/0/0/CPU0:router# show ospfv3 database prefix

      OSPFv3 Router with ID (10.0.0.206) (Process ID 1)

          Intra Area Prefix Link States (Area 1)

Routing Bit Set on this LSA
LS age: 356
LS Type: Intra-Area-Prefix-LSA
Link State ID: 0
Advertising Router: 10.0.0.206
LS Seq Number: 8000001e
Checksum: 0xcdaa
Length: 44
Referenced LSA Type: 2001
Referenced Link State ID: 0
Referenced Advertising Router: 10.0.0.206
Number of Prefixes: 1
Prefix Address: 8006::
Prefix Length: 56, Options: None, Metric: 1
```

This table describes the significant fields shown in the display.

**Table 126: show ospfv3 database prefix Field Descriptions**

| Field                 | Description                                                                  |
|-----------------------|------------------------------------------------------------------------------|
| OSPFv3 Router with ID | Router ID number.                                                            |
| Process ID 1          | OSPFv3 process name.                                                         |
| LS age                | Link-state age.                                                              |
| LS Type               | Link-state type.                                                             |
| Link State ID         | Link-state ID of the designated router.                                      |
| Advertising Router    | ID of the advertising router.                                                |
| LS Seq Number         | Link-state sequence (detects old or duplicate LSAs).                         |
| Checksum              | Link-state checksum (Fletcher checksum of the complete contents of the LSA). |

| Field                         | Description                                                                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Length                        | Length (in bytes) of the LSA.                                                                                                                                                                                                |
| Referenced LSA Type           | Router LSA or network LSA of the prefixes referenced.                                                                                                                                                                        |
| Referenced Link State ID      | Link-state ID of the router or network LSA.                                                                                                                                                                                  |
| Referenced Advertising Router | Advertising router of the referenced LSA.                                                                                                                                                                                    |
| Number of Prefixes            | Number of prefixes listed in the LSA.                                                                                                                                                                                        |
| Prefix Address                | Prefix associated with the router or network.                                                                                                                                                                                |
| Prefix Length                 | Length of the prefix.                                                                                                                                                                                                        |
| Options                       | LA indicates that the prefix is a local address. MC indicates that the prefix is multicast capable. NU indicates that the prefix is not unicast capable. P indicates the prefix should be propagated at an NSSA area border. |
| Metric                        | Cost of the prefix.                                                                                                                                                                                                          |

The following is sample output from the **show ospfv3 database** command with the **router** keyword:

```
RP/0/0/CPU0:router# show ospfv3 database router

# show ospfv3 flood-list

To display a list of Open Shortest Path First Version 3 (OSPFv3) link-state advertisements (LSAs) waiting to be flooded over an interface, use the **show ospfv3 flood-list** command in EXEC mode.

**show ospfv3** [*process-name*] [*area-id*] [**vrf** {**all** | *vrf-name*}] **flood-list** [*type interface-path-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed.                                             |
| <i>area-id</i>           | (Optional) Area number used to define the particular area.                                                                                                                                                                                                                      |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <b>vrf</b>               | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                                    |
| <b>all</b>               | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                                                                |
| <i>vrf-name</i>          | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                                                                    |

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                 |
| Release 3.6.0 | The <i>interface-type interface-path-id</i> arguments were changed from required to optional.                                                                                |
| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospfv3 flood-list** command to display OSPFv3 packet pacing.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following sample output from the **show ospfv3 flood-list** command shows three entries for the OSPFv3 1 process running over GigabitEthernet interface 0/3/0/0:

```
RP/0/0/CPU0:router# show ospfv3 flood-list GigabitEthernet 0/3/0/0
```

```
Flood Lists for OSPFv3 1
```

```
Interface GigabitEthernet 0/3/0/0, Queue length 3
Link state retransmission due in 24 msec
```

```
Displaying 3 entries from flood list:
```

| Type | LS ID      | ADV RTR    | Seq NO     | Age  | Checksum |
|------|------------|------------|------------|------|----------|
| 3    | 0.0.0.199  | 10.0.0.207 | 0x80000002 | 3600 | 0x00c924 |
| 3    | 0.0.0.200  | 10.0.0.207 | 0x80000002 | 3600 | 0x008966 |

| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospfv3 interface** command when the adjacency between two neighboring routers is not forming. Adjacency means that the routers synchronize their databases when they discover each other.

You can look at the output to check the physical link and line protocol status and to confirm that the network type and timer intervals match those of the neighboring routers.

If you have configured BFD interface at the process level, then that applies to both area and interface level, unless area and interface level have different interval configurations specified.

Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

Examples

The following is sample output from the **show ospfv3 interface** command when GigabitEthernet interface 0/ 5/0/0 is specified:

```
RP/0/0/CPU0:router# show ospfv3 interface GigabitEthernet 0/

      5

      /

      0
      /0GigabitEthernet0/5/0/0 is up, line protocol is up
Link Local address fe80::213:1aff:fe14:3faa, Interface ID 2
Area 0, Process ID foo, Instance ID 0, Router ID 1.1.1.1
Network Type BROADCAST, Cost: 1
BFD enabled, interval 300 msec, multiplier 5
Transmit Delay is 1 sec, State BDR, Priority 1
Designated Router (ID) 2.2.2.2, local address fe80::21b:53ff:fe74:eab6
Backup Designated router (ID) 1.1.1.1, local address fe80::213:1aff:fe14:3faa
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
  Hello due in 00:00:06
Index 0/1/1, flood queue length 0
Next 0(0)/0(0)/0(0)
Last flood scan length is 1, maximum is 2
Last flood scan time is 0 msec, maximum is 0 msec
Neighbor Count is 1, Adjacent neighbor count is 1
  Adjacent with neighbor 2.2.2.2 (Designated Router)
Suppress hello for 0 neighbor(s)
```

This table describes the significant fields shown in the display.

Table 129: show ospfv3 interface Field Descriptions

| Field           | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| GigabitEthernet | Status of the physical link and operational status of the protocol. |

| Field                      | Description                                                                        |
|----------------------------|------------------------------------------------------------------------------------|
| Link Local Address         | Interface link local address and interface ID.                                     |
| Area                       | OSPFv3 area ID, process ID, instance ID, and router ID.                            |
| BFD                        | BFD configuration state.                                                           |
| Transmit Delay             | Transmit delay and interface state.                                                |
| Designated Router          | Designated router ID and respective interface IPv6 address.                        |
| Backup Designated router   | Backup designated router ID and respective interface IPv6 address.                 |
| Timer intervals configured | Configuration of timer intervals.                                                  |
| Hello                      | Number of seconds until next hello packet is sent over this interface.             |
| Index 0/2/1                | Link, area and autonomous system flood indexes, and number of flood queue entries. |
| Next 0(0)/0(0)/0(0)        | Next link, area and autonomous system flood information, data pointer, and index.  |
| Last flood scan length     | Length of last flood scan.                                                         |
| Last flood scan time       | Time of last flood scan (in milliseconds).                                         |
| Neighbor Count             | Count of network neighbors and list of adjacent neighbors.                         |
| Suppress hello             | Count of neighbors suppressing hello messages.                                     |

# show ospfv3 message-queue

To display the information about the queue dispatch values, peak lengths, and limits, use the **show ospfv3 message-queue** command in EXEC mode.

**show ospfv3** [*process-name*] [**vrf** {**all** | *vrf-name*} ] **message-queue**

## Syntax Description

|                 |                                                              |
|-----------------|--------------------------------------------------------------|
| <b>vrf</b>      | Specifies an OSPF VPN routing and forwarding (VRF) instance. |
| <b>all</b>      | Display all the VRFs, excluding the default VRF.             |
| <i>vrf-name</i> | Specifies the name of the of the OSPFv3 VRF.                 |

## Command Default

None

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.8.0 | This command was introduced.                                                                                                                                                        |
| Release 4.1.0 | The <b>vrf</b> <i>vrf_name</i> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation |
|---------|-----------|
| ospf    | read      |

## Examples

This is sample output from the **show ospfv3 message-queue** command:

```
RP/0/0/CPU0:router#show ospfv3 message-queue
Mon May 31 16:07:47.143 CEST

OSPFv3 Process 0
```

```
Hello Thread Packet Input Queue:
  Current queue length: 0
  Peak queue length: 2
  Queue limit: 5000
  Packets received: 104091
  Packets processed: 104091

  Pulses received: 1484
```

# show ospfv3 neighbor

To display Open Shortest Path First Version 3 (OSPFv3) neighbor information on an individual interface basis, use the **show ospfv3 neighbor** command in EXEC mode.

**show ospfv3** [*process-name*] [*area-id*] [**vrf** {**all** | *vrf-name*}] **neighbor** [*type interface-path-id*] [*neighbor-id*] [**detail**]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed.                                             |
| <i>area-id</i>           | (Optional) Area ID. If you do not specify an area, all areas are displayed.                                                                                                                                                                                                     |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>neighbor-id</i>       | (Optional) Neighbor router ID.                                                                                                                                                                                                                                                  |
| <b>detail</b>            | (Optional) Displays all neighbors given in detail (lists all neighbors).                                                                                                                                                                                                        |
| <b>vrf</b>               | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                                    |
| <b>all</b>               | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                                                                |
| <i>vrf-name</i>          | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                                                                    |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.8.0 | BFD configuration information was added in the command output. |

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospfv3 neighbor** command when the adjacency between two neighboring routers is not forming. Adjacency means that the routers synchronize their databases when they discover each other.

### Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

### Examples

The following is sample output from the **show ospfv3 neighbor** command showing two lines of summary information for each neighbor:

```
RP/0/0/CPU0:router# show ospfv3 neighbor
```

```
Neighbors for OSPFv3 1
```

```
Neighbor ID      Pri   State           Dead Time   Interface ID  Interface
10.0.0.207       1     FULL/ -         00:00:35    3             GigabitEthernet 0/3/0/0
```

```
Neighbor is up for 01:08:05
10.0.0.207       1     FULL/DR         00:00:35    2             Ethernet0/0/0/0
Neighbor is up for 01:08:05
```

```
Total neighbor count: 2
```

This table describes the significant fields shown in the display.

**Table 130: show ospfv3 neighbor Field Descriptions**

| Field     | Description                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Neighbor router ID.                                                                                                                                  |
| Pri       | Router priority for designated router election. A router with a priority of 0 is never elected as the designated router or backup designated router. |
| State     | OSPFv3 state.                                                                                                                                        |
| Dead Time | Time (in hh:mm:ss) to elapse before OSPFv3 declares the neighbor dead.                                                                               |

| Field          | Description                                               |
|----------------|-----------------------------------------------------------|
| Interface ID   | Number that uniquely identifies an interface on a router. |
| Interface      | Name of the interface that connects to this neighbor.     |
| Neighbor is up | Time (in hh:mm:ss) that the OSPFv3 neighbor has been up.  |

The following is sample output showing summary information about the neighbor that matches the neighbor ID:

```
RP/0/0/CPU0:router# show ospfv3 neighbor 10.0.0.207
```

```
Neighbors for OSPFv3 1
```

```
Neighbor 10.0.0.207
```

```
In the area 0 via interface Ethernet0/0/0/0
Neighbor: interface-id 2, link-local address fe80::204:c0ff:fe22:73fe
Neighbor priority is 1, State is FULL, 6 state changes
DR is 10.0.0.207 BDR is 10.0.0.206
Options is 0x13
Dead timer due in 00:00:38
Neighbor is up for 01:09:21
Index 0/1/2, retransmission queue length 0, number of retransmission 1
First 0(0)/0(0)/0(0) Next 0(0)/0(0)/0(0)
Last retransmission scan length is 1, maximum is 1
Last retransmission scan time is 0 msec, maximum is 0 msec
```

```
Neighbor 10.0.0.207
```

```
In the area 1 via interface GigabitEthernet 0/3/0/0
Neighbor: interface-id 3, link-local address fe80::3034:30ff:fe33:3742
Neighbor priority is 1, State is FULL, 6 state changes
Options is 0x13
Dead timer due in 00:00:38
Neighbor is up for 01:09:21
Index 0/1/1, retransmission queue length 0, number of retransmission 1
First 0(0)/0(0)/0(0) Next 0(0)/0(0)/0(0)
Last retransmission scan length is 1, maximum is 1
Last retransmission scan time is 0 msec, maximum is 0 msec
```

```
Total neighbor count: 2
```

This table describes the significant fields shown in the display.

**Table 131: show ospfv3 neighbor 10.0.0.207 Field Descriptions**

| Field              | Description                                                    |
|--------------------|----------------------------------------------------------------|
| Neighbor           | Neighbor router ID.                                            |
| In the area        | Area and interface through which the OSPFv3 neighbor is known. |
| link-local address | Link local address of the interface.                           |

| Field             | Description                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor priority | Router priority of neighbor and neighbor state.                                                                                                      |
| State             | OSPFv3 state.                                                                                                                                        |
| state changes     | Number of state changes for this neighbor.                                                                                                           |
| DR is             | Neighbor ID of the designated router.                                                                                                                |
| BDR is            | Neighbor ID of the backup designated router.                                                                                                         |
| Options           | Hello packet options field contents (E-bit only; possible values are 0 and 2; 2 indicates that area is not a stub; 0 indicates that area is a stub). |
| Dead timer        | Time (in hh:mm:ss) to elapse before OSPFv3 declares the neighbor dead.                                                                               |
| Neighbor is up    | Time (in hh:mm:ss) that OSPFv3 neighbor has been up.                                                                                                 |
| Index             | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor.                       |

The following sample output shows the neighbors that match the neighbor ID on the interface when the interface along with the neighbor ID is specified:

```
RP/0/0/CPU0:router# show ospfv3 neighbor GigabitEthernet 0/3/0/1 10.0.0.207

Neighbors for OSPFv3 1

Neighbor 10.0.0.207
  In the area 0 via interface GigabitEthernet 0/3/0/1
  Neighbor: interface-id 2, link-local address fe80::204:c0ff:fe22:73fe
  Neighbor priority is 1, State is FULL, 6 state changes
  DR is 10.0.0.207 BDR is 10.0.0.206
  Options is 0x13
  Dead timer due in 00:00:39
  Neighbor is up for 01:11:21
  Index 0/1/2, retransmission queue length 0, number of retransmission 1
  First 0(0)/0(0)/0(0) Next 0(0)/0(0)/0(0)
  Last retransmission scan length is 1, maximum is 1
  Last retransmission scan time is 0 msec, maximum is 0 msec

Total neighbor count: 1
```

This table describes the significant fields shown in the display.

**Table 132: show ospfv3 neighbor GigabitEthernet 0/3/0/1 10.0.0.207 Field Descriptions**

| Field              | Description                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor           | Neighbor router ID.                                                                                                                                  |
| In the area        | Area and interface through which the OSPFv3 neighbor is known.                                                                                       |
| link-local address | Link local address of the interface.                                                                                                                 |
| Neighbor priority  | Router priority of neighbor and neighbor state.                                                                                                      |
| State              | OSPFv3 state.                                                                                                                                        |
| state changes      | Number of state changes for this neighbor.                                                                                                           |
| DR is              | Neighbor ID of the designated router.                                                                                                                |
| BDR is             | Neighbor ID of the backup designated router.                                                                                                         |
| Options            | Hello packet options field contents (E-bit only; possible values are 0 and 2; 2 indicates that area is not a stub; 0 indicates that area is a stub). |
| Dead timer         | Time (in hh:mm:ss) to elapse before OSPFv3 declares the neighbor dead.                                                                               |
| Neighbor is up     | Time (in hh:mm:ss) that OSPFv3 neighbor has been up.                                                                                                 |
| Index              | Index and the remaining lines of this command give detailed information about flooding information received from the neighbor.                       |

The following sample output shows all neighbors on the interface when the interface is specified:

```
RP/0/0/CPU0:router# show ospfv3 neighbor GigabitEthernet 0/3/0/1

Neighbors for OSPFv3 1

Neighbor ID    Pri   State           Dead Time   Interface ID  Interface
10.0.0.207     1     FULL/DR         00:00:37    2             GigabitEthernet 0/3/0/1

Neighbor is up for 01:12:33

Total neighbor count: 1
```

This table describes the significant fields shown in the display.

**Table 133: show ospfv3 neighbor GigabitEthernet 0/3/0/1 Field Descriptions**

| Field          | Description                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor ID    | Neighbor router ID.                                                                                                                                  |
| Pri            | Router priority for designated router election. A router with a priority of 0 is never elected as the designated router or backup designated router. |
| State          | OSPF state.                                                                                                                                          |
| Dead Time      | Time (in hh:mm:ss) to elapse before OSPF declares the neighbor dead.                                                                                 |
| Interface ID   | Number that uniquely identifies an interface on a router.                                                                                            |
| Interface      | Name of the interface that connects to this neighbor.                                                                                                |
| Neighbor is up | Amount of time (in hh:mm:ss) that the OSPF neighbor has been up.                                                                                     |

The following is sample output showing detailed neighbor information for GigabitEthernet interface 0/3/0/1:

```
RP/0/0/CPU0:router# show ospfv3 neighbor GigabitEthernet 0/3/0/1 detail

Neighbors for OSPFv3 1

Neighbor 10.0.0.207
  In the area 0 via interface GigabitEthernet 0/3/0/1
  Neighbor: interface-id 2, link-local address fe80::204:c0ff:fe22:73fe
  Neighbor priority is 1, State is FULL, 6 state changes
  DR is 10.0.0.207 BDR is 10.0.0.206
  Options is 0x13
  Dead timer due in 00:00:39
  Neighbor is up for 01:13:40
  Index 0/1/2, retransmission queue length 0, number of retransmission 1
  First 0(0)/0(0)/0(0) Next 0(0)/0(0)/0(0)

|---------------------------------------------|---------------------------------------|
| <a href="#">router ospfv3, on page 1272</a> | Configures an OSPFv3 routing process. |

# show ospfv3 request-list

To display the first ten link-state requests pending that the local router is making to the specified Open Shortest Path First Version 3 (OSPFv3) neighbor and interface, use the **show ospfv3 request-list** command in EXEC mode.

**show ospfv3** [*process-name*] [*area-id*] [**vrf** {**all** | *vrf-name*} ]**request-list** [*type interface-path-id*] [*neighbor-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed.                                                        |
| <i>area-id</i>           | (Optional) Area ID. If you do not specify an area, all areas are displayed.                                                                                                                                                                                                                |
| <i>type</i>              | (Optional) Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i> | (Optional) Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>neighbor-id</i>       | (Optional) Router ID of the OSPFv3 neighbor. This argument must be in 32-bit dotted-decimal notation, similar to an IPv4 address.                                                                                                                                                          |
| <b>vrf</b>               | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                                               |
| <b>all</b>               | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                                                                           |
| <i>vrf-name</i>          | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                                                                               |

## Command History

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                 |
| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You might use this command when the databases of two neighboring routers are out of synchronization or if the adjacency is not forming between them. Adjacency means that the routers synchronize their databases when they discover each other.

You can look at the list to determine if one router is trying to request a particular database update. Entries that appear to be suspended in the list usually indicate that updates are not being delivered. One possible reason for this behavior is a maximum transmission unit (MTU) mismatch between the routers.

You might also look at this list to make sure it is not corrupted. The list should refer to database entries that actually exist.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following sample output shows request lists for neighbor 10.0.0.207 on the OSPFv3 1 process:

```
RP/0/0/CPU0:router# show ospfv3 1 request-list 10.0.0.207 GigabitEthernet 0/3/0/0
Request Lists for OSPFv3 1
Neighbor 10.0.0.207, interface GigabitEthernet 0/3/0/0 address fe80::3034:30ff:fe33:3742

Type  LS ID          ADV RTR          Seq NO          Age    Checksum
  1    192.168.58.17      192.168.58.17    0x80000012      12    0x0036f3
  2    192.168.58.68      192.168.58.17    0x80000012      12    0x00083f
```

This table describes the significant fields shown in the display.

**Table 135: show ospfv3 request-list Field Descriptions**

| Field     | Description                                           |
|-----------|-------------------------------------------------------|
| Neighbor  | Router ID of the neighboring router.                  |
| interface | Name of the interface that connects to this neighbor. |
| address   | IPv6 address of the neighbor.                         |
| Type      | Type of link-state advertisement (LSA).               |
| LS ID     | Link-state ID of the LSA.                             |
| ADV RTR   | Router ID of the advertising router.                  |

| Field    | Description                  |
|----------|------------------------------|
| Seq NO   | Sequence number of the LSA.  |
| Age      | Age of the LSA (in seconds). |
| Checksum | Checksum of the LSA.         |

To display the first ten link-state entries in the retransmission list that the local router sends to the specified neighbor over the specified interface, use the **show ospfv3 retransmission-list** command in EXEC mode.

**show ospfv3** [*process-name* ] [*area-id*] [**vrf** {**all** | *vrf-name*} ]**retransmission-list** [*type interface-path-id*] [*neighbor-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>      | (Optional) Name that uniquely identifies an Open Shortest Path First Version 3 (OSPFv3) routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed.                |
| <i>area-id</i>           | (Optional) Area ID. If you do not specify an area, all areas are displayed.                                                                                                                                                                                                             |
| <i>type</i>              | (Optional) Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                        |
| <i>interface-path-id</i> | (Optional) Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router. For more information about the syntax for the router, use the question mark (?) online help function. |
| <i>neighbor-id</i>       | (Optional) IP address of the OSPFv3 neighbor.                                                                                                                                                                                                                                           |
| <b>vrf</b>               | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                                                                            |
| <b>all</b>               | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                                                                        |
| <i>vrf-name</i>          | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                                                                            |

## Command History

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                 |
| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You might use this command when the databases of two neighboring routers are out of synchronization or if the adjacency is not forming between them. Adjacency means that the routers synchronize their databases when they discover each other.

You can look at the list to determine if one router is trying to request a particular database update. Entries that appear to be suspended in the list usually indicate that updates are not being delivered. One possible reason for this behavior is a maximum transmission unit (MTU) mismatch between the routers.

You might also look at this list to make sure it is not corrupted. The list should refer to database entries that actually exist.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following sample output shows the retransmission list for neighbor 10.0.124.4 on GigabitEthernet interface 0/3/0/0:

```
RP/0/0/CPU0:router#show ospfv3 retransmission-list 10.0.124.4 GigabitEthernet 0/3/0/0
Neighbor 10.0.124.4, interface GigabitEthernet 0/3/0/0 address fe80::3034:30ff:fe33:3742
```

This table describes the significant fields shown in the display.

**Table 136: show ospfv3 retransmission-list 10.0.124.4 GigabitEthernet 0/3/0/0 Field Descriptions**

| Field     | Description                                           |
|-----------|-------------------------------------------------------|
| Neighbor  | Router ID of the neighboring router.                  |
| interface | Name of the interface that connects to this neighbor. |
| address   | IPv6 address of the neighbor.                         |

# show ospfv3 routes

To display the Open Shortest Path First Version 3 (OSPFv3) route table, use the **show ospfv3 routes** command in EXEC mode.

**show ospfv3** [*process-name*] **vrf** {**all** | *vrf-name*} **routes** [**external**| **connected**] [*ipv6-prefix/prefix-length*]

**show ospfv3** [*process-name*] [**vrf** {**all** | *vrf-name*} ]**routes summary**

## Syntax Description

|                        |                                                                                                                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i>    | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospf</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>external</b>        | (Optional) Displays routes redistributed from other protocols.                                                                                                                                                                    |
| <b>connected</b>       | (Optional) Displays connected routes.                                                                                                                                                                                             |
| <i>ipv6-prefix</i>     | (Optional) IP Version 6 (IPv6) prefix, which limits output to a specific route.<br>This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons. |
| <i>/ prefix-length</i> | (Optional) Length of the IPv6 prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value.   |
| <b>summary</b>         | Displays a summary of the route table.                                                                                                                                                                                            |
| <b>vrf</b>             | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                      |
| <b>all</b>             | Display all the VRFs, excluding the default VRF.                                                                                                                                                                                  |
| <i>vrf-name</i>        | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                      |

| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 4.1.0 | The <b>vrf vrf_name</b> keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospfv3 routes** command to display the OSPFv3 private routing table (which contains only routes calculated by OSPFv3). If there is something wrong with a route in the Routing Information Base (RIB), check the OSPFv3 copy of the route to determine if it matches the RIB contents. If it does not match, there is a synchronization problem between OSPFv3 and the RIB. If the routes match and the route is incorrect, OSPFv3 has made an error in its routing calculation.

### Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

### Examples

The following sample output shows the route table for OSPFv3 process 1:

```
RP/0/0/CPU0:router# show ospfv3 1 routes

Route Table for OSPFv3 1 with ID 10.3.4.2

* 3000:11:22::/64, Inter, cost 21/0, area 1
  GigabitEthernet 0/3/0/0, fe80::3034:30ff:fe33:3742
  10.0.0.207/200
* 3000:11:22:1::/64, Inter, cost 31/0, area 1
  GigabitEthernet 0/3/0/0, fe80::3034:30ff:fe33:3742
  10.0.0.207/1
* 3333::/56, Ext2, cost 20/1, P:0 F:0
  GigabitEthernet 0/3/0/0, fe80::3034:30ff:fe33:3742
  10.0.0.207/0
* 6050::/56, Ext2, cost 20/1, P:0 F:0
  GigabitEthernet 0/3/0/0, fe80::3034:30ff:fe33:3742
  10.0.0.207/1
* 7002::/56, Intra, cost 10/0, area 0
  Ethernet0/0/0/0, connected

* 3000:11:22::/64, Inter, cost 21/0, area 1
  GigabitEthernet 0/3/0/0, fe80::3034:30ff:fe33:3742
  10.0.0.207/200
```

This table describes the significant fields shown in the display.

**Table 137: show ospfv3 1 route Field Descriptions**

| Field           | Description                       |
|-----------------|-----------------------------------|
| 3000:11:22::/64 | Route prefix to the local router. |

| Field                     | Description                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------|
| Inter                     | Prefix 3000:11:22::/64 is interarea.                                                                         |
| cost 21/0                 | Sum of the link costs required to reach prefix 3000:11:22::/64. 0. In this example, 20 is the external cost. |
| GigabitEthernet 0/3/0/0   | Packets destined for prefix 3000:11:22::/64 are sent over the GigabitEthernet 0/3/0/0 interface.             |
| fe80::3034:30ff:fe33:3742 | Next-hop router on the path to prefix 3000:11:22::/64.                                                       |
| 10.0.0.207                | Router 10.0.0.207 is the router that advertised this route.                                                  |

EXEC

## Command History

| Release       | Modification                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                            |
| Release 4.1.0 | The <b>vrf</b> { <i>vrf_name</i> } keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show ospfv3 summary-prefix** command if you configured summarization of external routes with the **summary-prefix** command and you want to display configured summary addresses.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following sample output shows the summary prefix address for the OSPFv3 1 process:

```
RP/0/0/CPU0:router# show ospfv3 1 summary-prefix
OSPFv3 Process 1, Summary-prefix
4004:f000::/32 Metric 20, Type 2, Tag 0
```

This table describes the significant fields shown in the display.

**Table 138: show ospfv3 1 summary-prefix Field Descriptions**

| Field          | Description                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------|
| 4004:f000::/32 | Summary prefix designated for a range of IPv6 prefixes. The length of the IPv6 prefix.           |
| Metric         | Metric used to advertise the summary routes.                                                     |
| Type           | External link-state advertisements (LSAs) metric type.                                           |
| Tag            | Tag value that can be used as a “match” value for controlling redistribution through route maps. |

**Related Commands**

| Command                                               | Description                                                                                           |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">router ospfv3, on page 1272</a>           | Configures an OSPFv3 routing process.                                                                 |
| <a href="#">summary-prefix (OSPFv3), on page 1339</a> | Creates aggregate addresses for routes being redistributed from another routing protocol into OSPFv3. |

# show ospfv3 virtual-links

To display parameters and the current state of Open Shortest Path First Version 3 (OSPFv3) virtual links, use the **show ospfv3 virtual-links** command in EXEC mode.

**show ospfv3** [*process-name*] [**vrf** *vrf-name*] **virtual-links**

## Syntax Description

|                     |                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-name</i> | (Optional) Name that uniquely identifies an OSPFv3 routing process. The process name is defined by the <b>router ospfv3</b> command. If this argument is included, only information for the specified routing process is displayed. |
| <b>vrf</b>          | Specifies an OSPF VPN routing and forwarding (VRF) instance.                                                                                                                                                                        |
| <i>vrf-name</i>     | Specifies the name of the of the OSPFv3 VRF.                                                                                                                                                                                        |

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                            |
| Release 4.1.0 | The <b>vrf</b> { <i>vrf_name</i> } keyword and argument were added to show OSPFv3 VRF configuration information. The output of the command was enhanced to include the name of the VRF. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The information displayed in the **show ospfv3 virtual-links** command is useful in debugging OSPFv3 routing operations.

## Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

**Examples**

The following sample output shows the virtual links for the OSPFv3 1 process:

```
RP/0/0/CPU0:router# show ospfv3 1 virtual-links

Virtual Links for OSPFv3 1
Virtual Link to router 172.31.101.2 is up
Interface ID 16, IPv6 address 3002::206
Transit area 0.0.0.1, via interface GigabitEthernet 0/3/0/0, Cost of using 11
Transmit Delay is 5 sec, State POINT_TO_POINT,
Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
Hello due in 0:00:08
Adjacency State FULL
```

This table describes the significant fields shown in the display.

**Table 139: show ospfv3 virtual-links Field Descriptions**

| Field                        | Description                                                                    |
|------------------------------|--------------------------------------------------------------------------------|
| Virtual Link to router is up | Specifies the OSPFv3 neighbor, and if the link to that neighbor is up or down. |
| Interface ID                 | ID of the virtual link interface.                                              |
| IPv6 address                 | IPv6 address of virtual link endpoint.                                         |
| Transit area                 | Transit area through which the virtual link is formed.                         |
| via interface                | Interface through which the virtual link is formed.                            |
| Cost                         | Cost of reaching the OSPF neighbor through the virtual link.                   |
| Transmit Delay               | Transmit delay on the virtual link.                                            |
| State POINT_TO_POINT         | State of the OSPFv3 neighbor.                                                  |
| Timer intervals              | Various timer intervals configured for the link.                               |
| Hello due in                 | When the next hello message is expected from the neighbor (in hh:mm:ss).       |
| Adjacency State              | Adjacency state between the neighbors.                                         |

**Related Commands**

| Command                                      | Description                           |

## show protocols (OSPFv3)

To display information about the Open Shortest Path First Version 3 (OSPFv3) process running on the router, use the **show protocols** command in EXEC mode.

**show protocols** [**afi-all**| **ipv4**| **ipv6**] [**all**| *protocol*]

### Syntax Description

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>afi-all</b>  | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ipv4</b>     | (Optional) Specifies an IPv4 address family.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ipv6</b>     | (Optional) Specifies an IPv6 address family.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>all</b>      | (Optional) Specifies all protocols for a given address family.                                                                                                                                                                                                                                                                                                                                                              |
| <i>protocol</i> | (Optional) Specifies a routing protocol. For the IPv4 address family, the options are: <ul style="list-style-type: none"><li>• <b>bgp</b></li><li>• <b>eigrp</b></li><li>• <b>isis</b></li><li>• <b>ospf</b></li><li>• <b>rip</b></li></ul> For the IPv6 address family, the options are: <ul style="list-style-type: none"><li>• <b>bgp</b></li><li>• <b>eigrp</b></li><li>• <b>isis</b></li><li>• <b>ospfv3</b></li></ul> |

### Command Default

The default address family is IPv4.

### Command Modes

EXEC

### Command History

| Release       | Modification                                              |
|---------------|-----------------------------------------------------------|
| Release 3.2   | This command was introduced                               |
| Release 3.6.0 | The <b>eigrp</b> and <b>rip</b> protocols were supported. |

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Task ID

| Task ID | Operations |
|---------|------------|
| ospf    | read       |

Examples

The following example is sample output from the `show protocols` command:

```
RP/0/0/CPU0:router# show protocols ipv6 ospfv3

Routing Protocol OSPFv3 1
  Router Id:10.0.0.1
  Distance:110
  Redistribution:
    None
  Area 0
    GigabitEthernet 0/2/0/2
    Loopback1
```

This table describes the significant fields shown in the display.

Table 140: show protocols Field Descriptions

| Field          | Description                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router Id      | Router ID of the OSPFv3 process.                                                                                                                                                           |
| Distance       | Administrative distance for the protocol. This distance determines the priority the Routing Information Base (RIB) gives to the routes, as opposed to other protocols, for example, IS-IS. |
| Redistribution | Protocols from which this OSPFv3 process is redistributing routes.                                                                                                                         |
| Area           | OSPFv3 areas defined in this process, followed by their associated interfaces.                                                                                                             |

# snmp context (OSPFv3)

To specify an SNMP context for an OSPFv3 instance, use the **snmp context** command in router configuration mode or in VRF configuration mode. To remove the SNMP context, use the **no** form of this command.

**snmp context** *context\_name*

**no snmp context** *context\_name*

## Syntax Description

|                     |                                                         |
|---------------------|---------------------------------------------------------|
| <i>context_name</i> | Specifies name of the SNMP context for OSPFv3 instance. |
|---------------------|---------------------------------------------------------|

## Command Default

SNMP context is not specified.

## Command Modes

Router OSPFv3 configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes the proper task IDs. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The snmp-server commands need to be configured to perform SNMP request for the OSPF instance. Refer *SNMP Server Commands* module in *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for information on using the snmp-server commands.

### Note

To map an SNMP context with a protocol instance, topology or VRF entity, use the **snmp-server context mapping** command. However, the **feature** option of this command does not work with OSPFv3 protocol.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

**Examples**

This example shows how to configure an SNMP context *foo* for OSPFv3 instance *100*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospfv3 100
RP/0/0/CPU0:router(config-ospf)#snmp context foo
```

This example shows how to configure **snmp-server** commands to be used with the **snmp context** command:

```
RP/0/0/CPU0:router(config)#snmp-server host 10.0.0.2 traps version 2c public udp-port 1620
RP/0/0/CPU0:router(config)#snmp-server community public RW
RP/0/0/CPU0:router(config)#snmp-server contact foo
RP/0/0/CPU0:router(config)#snmp-server community-map public context foo
```

This is a sample SNMP context configuration for OSPFv3 instance *100*:

```
snmp-server host 10.0.0.2 traps version 2c public udp-port 1620
snmp-server community public RW
snmp-server contact foo
```

```
snmp-server community-map public context foo
```

```
router ospfv3 100
router-id 2.2.2.2
bfd fast-detect
nsf cisco
snmp context foo
area 0
interface Loopback1
!
!
area 1
interface GigabitEthernet0/2/0/1
demand-circuit enable
!
interface POS0/3/0/0
!
interface POS0/3/0/1
!
!
!
```

**Related Commands**

| Command                                          | Description                                                                                               |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <a href="#">snmp trap (OSPFv3), on page 1330</a> | Enables SNMP trap for an OSPFv3 instance.                                                                 |
| <b>snmp-server host</b>                          | Specifies the recipient of an SNMP notification operation.                                                |
| <b>snmp-server community</b>                     | Configures the community access string to permit access to the Simple Network Management Protocol (SNMP). |
| <b>snmp-server contact</b>                       | Sets the Simple Network Management Protocol (SNMP) system contact.                                        |

| Command                          | Description                                                                            |
|----------------------------------|----------------------------------------------------------------------------------------|
| <b>snmp-server community-map</b> | Associates a Simple Network Management Protocol (SNMP) community with an SNMP context. |

## snmp trap (OSPFv3)

To enable SNMP trap for an OSPFv3 instance, use the **snmp trap** command in VRF configuration mode. To disable SNMP trap for the OSPFv3 instance, use the **no** form of this command.

**snmp trap**

**no snmp trap**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Disabled.

**Command Modes** OSPFv3 VRF configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.2.1 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operation   |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** This example shows how to enable SNMP trap for OSPFv3 instance *100* under VRF *vrf-1*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospfv3 100
RP/0/0/CPU0:router(config-ospf)#vrf vrf-1
RP/0/0/CPU0:router(config-ospf-vrf)#snmp trap
```

| Related Commands | Command                                                              | Description                                    |
|------------------|----------------------------------------------------------------------|------------------------------------------------|
|                  | <a href="#">snmp context (OSPFv3)</a> , <a href="#">on page 1327</a> | Specifies SNMP context for an OSPFv3 instance. |

## snmp trap rate-limit (OSPFv3)

To control the number of traps that OSPFv3 sends by configuring window size and the maximum number of traps during that window, use the **snmp trap rate-limit** command in router OSPFv3 configuration mode or OSPFv3 VRF configuration mode. To disable configuring the window size and maximum number of traps during the window, use the **no** form of this command.

**snmp trap rate-limit** *window-size max-num-traps*

**no snmp trap rate-limit** *window-size max-num-traps*

### Syntax Description

|                      |                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------|
| <i>window-size</i>   | Specifies the trap rate limit sliding window size. The range is 2 to 60 windows.        |
| <i>max-num-traps</i> | Specifies the maximum number of traps sent in window time. The range is 0 to 300 traps. |

### Command Default

None

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

### Examples

This example shows how to set the trap rate limit sliding window size to 50 and the maximum number of traps sent to 250 for OSPFv3 instance *100* under vrf *vrf1*:

```
RP/0/0/CPU0:router#configure
```

```
RP/0/0/CPU0:router(config)#router ospfv3 100  
RP/0/0/CPU0:router(config-ospfv3)#vrf vrf1  
RP/0/0/CPU0:router(config-ospfv3-vrf)#snmp trap rate-limit 50 250
```

# spf prefix-priority (OSPFv3)

To prioritize OSPFv3 prefix installation into the global Routing Information Base (RIB) during Shortest Path First (SPF) run, use the **spf prefix-priority** command in router configuration mode or VRF configuration mode. To return to the system default value, use the **no** form of this command.

**spf prefix-priority route-policy** *policy-name* [**disable**]

**spf prefix-priority route-policy** *policy-name*

## Syntax Description

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| <b>route-policy</b> | Specifies the route-policy to prioritize route installation. |
| <i>policy-name</i>  | Name of the route policy.                                    |
| <b>disable</b>      | Disables SPF prefix priority                                 |

## Command Default

SPF prefix prioritization is disabled.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

## Examples

This example shows how to configure OSPFv3 SPF prefix prioritization:

```
RP/0/RP0/CPU0:router# configure
RP/0/RP0/CPU0:router(config)# prefix-set ospf3-critical-prefixes
RP/0/RP0/CPU0:router(config-pfx)# 66.0.0.0/16
RP/0/RP0/CPU0:router(config-pfx)# end-set
```

```

RP/0/RP0/CPU0:router(config)# route-policy ospf3-spf-priority
RP/0/RP0/CPU0:router(config-rpl)# if destination in ospf-critical-prefixes then set
spf-priority critical
endif
RP/0/RP0/CPU0:router(config-rpl)# end-policy
RP/0/RP0/CPU0:router(config-rpl)# commit
RP/0/RP0/CPU0:router(config-rpl)# exit
RP/0/RP0/CPU0:router(config)# router ospfv3 1
RP/0/RP0/CPU0:router(config-ospf)# router-id 66.0.0.1
RP/0/RP0/CPU0:router(config-ospf)# spf prefix-priority route-policy ospf-spf-priority

```

## Related Commands

| Command                   | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>prefix-set</b>         | Enters prefix set configuration mode and defines a prefix set.     |
| <b>route-policy (RPL)</b> | Defines a route policy and enters route-policy configuration mode. |

# stub (OSPFv3)

To define an area as a stub area for Open Shortest Path First Version 3 (OSPFv3), use the **stub** command in area configuration mode. To disable this function, use the **no** form of this command.

**stub [no-summary]**

**no stub**

## Syntax Description

|                   |                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>no-summary</b> | (Optional) Prevents an area border router (ABR) from sending summary link advertisements into the stub area. Areas with this option are known as <i>totally stubby</i> areas. |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No stub area is defined.

## Command Modes

Area configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must configure the **stub** command on all routers in the stub area. Use the **default-cost area** command on the ABR of a stub area to specify the cost of the default route advertised into the stub area by the ABR.

Two stub area router configuration commands exist: the **stub** and **default-cost** commands. In all routers attached to the stub area, the area should be configured as a stub area using the **stub** command. Use the **default-cost** command only on an ABR attached to the stub area. The **default-cost** command provides the metric for the summary default route generated by the ABR into the stub area.

To further reduce the number of link-state advertisements (LSAs) sent into a stub area, you can configure the **no-summary** keyword on the ABR to prevent it from sending summary LSAs (LSA Type 3) into the stub area.

A stub area does not accept information about routes external to the autonomous system.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to create stub area 5 and specifies a cost of 20 for the default summary route sent into this stub area:

```
RP/0/0/CPU0:router(config)# router ospfv3 201  
RP/0/0/CPU0:router(config-ospfv3)# area 5  
RP/0/0/CPU0:router(config-ospfv3-ar)# stub  
RP/0/0/CPU0:router(config-ospfv3-ar)# default-cost 20
```

## Related Commands

| Command                                             | Description                                                           |
|-----------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">default-cost (OSPFv3), on page 1207</a> | Specifies a cost for the default summary route sent into a stub area. |

## stub-router

To modify self originated router LSAs when stub router is active, use the **stub-router** command in an appropriate configuration mode. To disable this function, use the **no** form of this command.

**stub-router router-lsa** [**r-bit**| **v6-bit**| **max-metric**] [**always**] [**on-proc-migration** *interval*] [**on-proc-restart** *interval*] [**on-switchover** *interval*] [**on-startup** [*interval*] **wait-for-bgp**]] [**summary-lsa** [*metric*] ] [**external-lsa** [*metric*] ] [**include-stub**]

**stub-router router-lsa** [**r-bit**| **v6-bit**| **max-metric**]

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>router-lsa</b>        | Specifies that always originate router link-state advertisements (LSAs) with the stub-router.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>r-bit</b>             | Router-LSAs are originated with R-bit clear (v6 bit set), which means the node does not act as a transit router. Directly connected networks (native to OSPF) are still reachable within the OSPF area.                                                                                                                                                                                                                                                                           |
| <b>v6-bit</b>            | Router-LSAs are originated with V6 bit clear (and also r-bit clear). That means the node is not willing to receive any ipv6 traffic. Other ospfv3 routers won't install any route to a node with v6-bit clear.                                                                                                                                                                                                                                                                    |
| <b>max-metric</b>        | Router-LSAs are originated with maximum metric. Unlike the r-bit and v6-bit mode, the router may still act as a transit node, if there is no alternate path.                                                                                                                                                                                                                                                                                                                      |
| <b>always</b>            | Stub-router mode is activated unconditionally.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>on-proc-migration</b> | Stub-router mode is activated for the desired period of time, upon ospfv3 process migration.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>on-proc-restart</b>   | Stub-router mode is activated for the desired period of time, upon ospfv3 process restart.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>on-switchover</b>     | Stub-router mode is activated for the desired period of time, upon RP failover.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>on-startup</b>        | Stub-router mode is activated (for configured time, or until BGP converges) upon router startup (boot).                                                                                                                                                                                                                                                                                                                                                                           |
| <b>wait-for-bgp</b>      | Stub-router mode is terminated upon BGP convergence in ipv6 unicast address family. This option could only be used in the global routing table, not in a non-default VRF. This option is only supported with the on-startup trigger when the router boots.                                                                                                                                                                                                                        |
| <b>summary-lsa</b>       | <p>If enabled, summary LSAs are advertised with modified metric when stub-router is active. This configuration is applicable to max-metric mode.</p> <p>In r-bit mode, ABR/ASBR functionality is implicitly disabled and routers will not use this node as an ABR/ASBR, since it declares no transit capability (r-bit clear).</p> <p>If enabled and metric is not explicitly configured, the default metric for summary LSAs when stub-router active is 16711680 (0xFF0000).</p> |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>external-lsa</b> | <p>If enabled, external LSAs are advertised with modified metric when stub-router is active. This configuration is applicable to max-metric mode.</p> <p>In r-bit mode, ABR/ASBR functionality is implicitly disabled and routers will not use this node as an ABR/ASBR, since it declares no transit capability (r-bit clear).</p> <p>If enabled and metric is not explicitly configured, the default metric for external LSAs when stub-router active is 16711680 (0xFF0000).</p> |
| <b>include-stub</b> | <p>If enabled, intra-area-prefix LSAs that are referencing router LSA are advertised with maximum metric (0xffff) when stub-router is active.</p> <p>Intra-area-prefix LSAs that are referencing network LSA do not change metric</p> <p>Can be used in r-bit and max-metric modes.</p> <p>/128 prefixes that are normally advertised with LA-bit set and 0 metric are also advertised with maximum metric and LA-bit clear when stub-router is active.</p>                         |

**Command Default**

Disabled.

**Command Modes**

Router OSPFv3 configuration  
OSPFv3 VRF configuration

**Command History**

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Only one method (r-bit, v6-bit, max-metric) could be activated at a time. Configuring the methods simultaneously, or different method per trigger, is not supported.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

**Examples**

This example shows how to configure router LSAs are originated with R-bit clear under OSPFv3 VRF, *vrf\_1*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)#vrf vrf_1
RP/0/0/CPU0:router(config-ospfv3-vrf)#stub-router router-lsa r-bit
```

# summary-prefix (OSPFv3)

To create aggregate addresses for routes being redistributed from another routing protocol into Open Shortest Path First Version 3 (OSPFv3) protocol, use the **summary-prefix** command in an appropriate configuration mode. To stop summarizing redistributed routes, use the **no** form of the command.

```
summary-prefix ipv6-prefix/prefix-length [not-advertise] tag tag
no summary-prefix ipv6-prefix/prefix-length
```

| Syntax Description     |                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-prefix</i>     | Summary prefix designated for a range of IP Version 6 (IPv6) prefixes.<br>This argument must be in the form documented in RFC 2373, where the address is specified in hexadecimal using 16-bit values between colons. |
| <i>/ prefix-length</i> | Length of the IPv6 prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value.  |
| <b>not-advertise</b>   | (Optional) Suppresses summary routes that match the address and mask pair from being advertised.                                                                                                                      |
| <b>tag tag</b>         | (Optional) Specifies a tag value that can be used as a “match” value for controlling redistribution.                                                                                                                  |

**Command Default** When this command is not used in router configuration mode, aggregate addresses are not created for routes being redistributed from another routing protocol into the OSPFv3 protocol.

**Command Modes** Router OSPFv3 configuration  
OSPFv3 VRF configuration

| Command History | Release       | Modification                                                       |
|-----------------|---------------|--------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                       |
|                 | Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **summary-prefix** command to cause an OSPFv3 Autonomous System Boundary Router (ASBR) to advertise one external route as an aggregate for all redistributed routes that are covered by the address. This command summarizes only routes from other routing protocols that are being redistributed into OSPFv3.

You can use this command multiple times to summarize multiple groups of addresses. The metric used to advertise the summary is the lowest metric of all the more specific routes. This command helps reduce the size of the routing table.

If you want to summarize routes between OSPFv3 areas, use the **range** command.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

#### Examples

In the following example, if summary prefix 4004:f000:132 is configured and routes 4004:f000:1::/64, 4004:f000:2::/64, and 4004:f000:3::/64 are redistributed into OSPFv3; only route 4004:f000::/32 is advertised in an external link-state advertisement:

```
RP/0/0/CPU0:router(config-ospfv3)# summary-prefix 4004:f000::/32
```

#### Related Commands

| Command                                      | Description                                             |
|----------------------------------------------|---------------------------------------------------------|
| <a href="#">range (OSPFv3), on page 1261</a> | Consolidates and summarizes routes at an area boundary. |

## timers lsa arrival

To set the minimum interval at which the software accepts the same link-state advertisement (LSA) from Open Shortest Path First Version 3 (OSPFv3) neighbors, use the **timers lsa arrival** command in an appropriate configuration mode. To restore the default value, use the **no** form of this command.

**timers lsa arrival** *milliseconds*

**no timers lsa arrival**

### Syntax Description

|                     |                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Minimum delay (in milliseconds) that must pass between acceptance of the same LSA arriving from neighbors. Range is 0 to 60000 milliseconds. |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

1000 milliseconds

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers lsa arrival** command to control the minimum interval for accepting the same LSA. The same LSA is an LSA instance that contains the same LSA ID number, LSA type, and advertising router ID. If an instance of the same LSA arrives sooner than the interval that is set, the LSA is dropped.

We recommend that the *milliseconds* value of the **timers lsa arrival** command be less than or equal to the *hold-interval* value of the **timers throttle lsa all** command for the neighbor.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to set the minimum interval for accepting the same LSA at 2000 milliseconds:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers throttle lsa all 200 10000 45000
RP/0/0/CPU0:router(config-ospfv3)# timers lsa arrival 2000
```

|----------------------------------------------------------------|-----------------------------------------------------|
| <a href="#">timers throttle lsa all (OSPFv3), on page 1349</a> | Sets rate-limiting values for LSAs being generated. |

## timers pacing flood

To configure link-state advertisement (LSA) flood packet pacing, use the **timers pacing flood** command in an appropriate configuration mode. To restore the default flood packet pacing value, use the **no** form of this command.

**timers pacing flood** *milliseconds*

**no timers pacing flood**

### Syntax Description

|                     |                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Time (in milliseconds) at which LSAs in the flooding queue are paced in between updates. Range is 5 milliseconds to 100 milliseconds. |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

*milliseconds: 33*

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Configuring OSPFv3 flood pacing timers allows you to control interpacket spacing between consecutive link-state update packets in the OSPF transmission queue. Use the **timers pacing flood** command to control the rate at which LSA updates occur, thereby preventing high CPU or buffer utilization that can result when an area is flooded with a very large number of LSAs.

The default settings for OSPFv3 packet pacing timers are suitable for the majority of OSPFv3 deployments. Do not change the packet pacing timers unless all other options to meet OSPFv3 packet flooding requirements have been exhausted. Specifically, network operators should prefer summarization, stub area usage, queue tuning, and buffer tuning before changing the default flood timers. Furthermore, no guidelines exist for changing timer values; each OSPFv3 deployment is unique and should be considered on a case-by-case basis. The network operator assumes risks associated with changing the default flood timer values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure LSA flood packet-pacing updates to occur in 55-millisecond intervals for OSPFv3 routing process 1:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers pacing flood 55
```

**Related Commands**

| <a href="#">timers pacing lsa-group, on page 1345</a>       | Changes the interval at which OSPFv3 link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged |
| <a href="#">timers pacing retransmission , on page 1347</a> | Configures LSA retransmission packet pacing.                                                                                         |

## timers pacing lsa-group

To change the interval at which Open Shortest Path First Version 3 (OSPFv3) link-state advertisements (LSAs) are collected into a group and refreshed, checksummed, or aged, use the **timers pacing lsa-group** command in an appropriate configuration mode. To restore the default value, use the **no** form of this command.

**timers pacing lsa-group** *seconds*

**no timers pacing lsa-group**

### Syntax Description

|                |                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Interval (in seconds) at which LSAs are grouped and refreshed, checksummed, or aged. Range is 10 to 1800 seconds. |
|----------------|-------------------------------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 240

OSPFv3 LSA group pacing is enabled by default.

### Command Modes

Router OSPFv3 configuration

OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                       |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers pacing lsa-group** command to control the rate at which LSA updates occur so that high CPU or buffer utilization that can occur when an area is flooded with a very large number of LSAs can be reduced. The default settings for OSPFv3 packet pacing timers are suitable for the majority of deployments. Do not change the packet pacing timers unless all other options to meet OSPFv3 packet flooding requirements have been exhausted. Specifically, network operators should prefer summarization, stub area usage, queue tuning, and buffer tuning before changing the default flooding timers. Furthermore, no guidelines exist for changing timer values; each OSPFv3 deployment is unique and should be considered on a case-by-case basis. The network operator assumes the risks associated with changing the default timer values.

Cisco IOS XR software groups the periodic refresh of LSAs to improve the LSA packing density for the refreshes in large topologies. The group timer controls the interval used for group refreshment of LSAs;

however, this timer does not change the frequency that individual LSAs are refreshed (the default refresh rate is every 30 minutes).

The duration of the LSA group pacing is inversely proportional to the number of LSAs the router is handling. For example, if you have about 10,000 LSAs, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure OSPFv3 group packet-pacing updates between LSA groups to occur in 60-second intervals for OSPFv3 routing process 1:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers pacing lsa-group 60
```

**Related Commands**

| Release 3.6.0 | The high end of the <i>milliseconds</i> range was changed from 200 to 100. |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration submode.         |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers pacing retransmission** command to control interpacket spacing between consecutive link-state update packets in the OSPFv3 retransmission queue. This command controls the rate at which LSA updates occur. When an area is flooded with a very large number of LSAs, the LSA updates can result in high CPU or buffer utilization. Using this command reduces CPU or buffer utilization.

The default settings for OSPFv3 packet retransmission pacing timers are suitable for the majority of deployments. Do not change the packet retransmission pacing timers unless all other options to meet OSPFv3 packet flooding requirements have been exhausted. Specifically, network operators should prefer summarization, stub area usage, queue tuning, and buffer tuning before changing the default flooding timers. Furthermore, no guidelines exist for changing timer values; each OSPFv3 deployment is unique and should be considered on a case-by-case basis. The network operator assumes risks associated with changing the default packet retransmission pacing timer values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure LSA flood pacing updates to occur in 55-millisecond intervals for OSPFv3 routing process 1:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers pacing retransmission 55
```

| <a href="#">timers pacing lsa-group, on page 1345</a> | Changes the interval at which OSPFv3 LSAs are collected into a group and refreshed, checksummed, or aged. |

## timers throttle lsa all (OSPFv3)

To set rate-limiting values for Open Shortest Path First Version 3 (OSPFv3) link-state advertisement (LSA) generation, use the **timers throttle lsa all** command in an appropriate configuration mode. To restore the default values, use the **no** form of this command.

**timers throttle lsa all** *start-interval hold-interval max-interval*

**no timers throttle lsa all**

### Syntax Description

|                       |                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>start-interval</i> | Minimum delay (in milliseconds) for the generation of LSAs. The first instance of LSA is always generated immediately upon a local OSPFv3 topology change. The generation of the next LSA is not before the start interval. Range is 0 to 600000 milliseconds. |
| <i>hold-interval</i>  | Incremental time (in milliseconds). This value is used to calculate the subsequent rate limiting times for LSA generation. Range is 1 to 600000 milliseconds.                                                                                                  |
| <i>max-interval</i>   | Maximum wait time (in milliseconds) between generation of the same LSA. Range is 1 to 600000 milliseconds.                                                                                                                                                     |

### Command Default

*start-interval* : 500 milliseconds  
*hold-interval* : 5000 milliseconds  
*max-interval* : 5000 milliseconds

### Command Modes

Router OSPFv3 configuration  
OSPFv3 VRF configuration

### Command History

| Release       | Modification                                                    |
|---------------|-----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                    |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The “same LSA” is defined as an LSA instance that contains the same LSA ID number, LSA type, and advertising router ID. We recommend that you keep the *milliseconds* value of the **timers lsa arrival** command less than or equal to the *hold-interval* value of the **timers throttle lsa all** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

This example shows how to customize OSPFv3 LSA throttling so that the start interval is 200 milliseconds, the hold interval is 10,000 milliseconds, and the maximum interval is 45,000 milliseconds. The minimum interval between instances of receiving the same LSA is 2000 milliseconds.

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers throttle lsa all 200 10000 45000
RP/0/0/CPU0:router(config-ospfv3)# timers lsa arrival 2000
```

**Related Commands**

| Command                                          | Description                                                                                 |
|--------------------------------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">show ospfv3, on page 1274</a>        | Displays general information about OSPFv3 routing processes.                                |
| <a href="#">timers lsa arrival, on page 1341</a> | Sets the minimum interval at which the software accepts the same LSA from OSPFv3 neighbors. |

# timers throttle spf (OSPFv3)

To turn on Open Shortest Path First Version 3 (OSPFv3) shortest path first (SPF) throttling, use the **timers throttle spf** command in an appropriate configuration mode. To turn off SPF throttling, use the **no** form of this command.

**timers throttle spf** *spf-start spf-hold spf-max-wait*

**no timers throttle spf** *spf-start spf-hold spf-max-wait*

## Syntax Description

|                     |                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <i>spf-start</i>    | Initial SPF schedule delay (in milliseconds). Range is 1 to 600000 milliseconds.                                 |
| <i>spf-hold</i>     | Minimum hold time (in milliseconds) between two consecutive SPF calculations. Range is 1 to 600000 milliseconds. |
| <i>spf-max-wait</i> | Maximum wait time (in milliseconds) between two consecutive SPF calculations. Range is 1 to 600000 milliseconds. |

## Command Default

*spf-start* : 5000 milliseconds  
*spf-hold*: 10000 milliseconds  
*spf-max-wait*: 10000 milliseconds

## Command Modes

Router OSPFv3 configuration  
 OSPFv3 VRF configuration

## Command History

| Release       | Modification                                                    |
|---------------|-----------------------------------------------------------------|
| Release 3.2   | This command was introduced                                     |
| Release 4.1.0 | This command was supported under OSPFv3 VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The first wait interval between SPF calculations is the amount of time (in milliseconds) specified by the *spf-start* argument. Each consecutive wait interval is twice the current hold level (in milliseconds) until the wait time reaches the maximum time (in milliseconds) as specified by the *spf-max-wait* argument. Subsequent wait times remain at the maximum until the values are reset or a link-state advertisement (LSA) is received between SPF calculations.

Tip

Setting a low *spf-start* time and *spf-hold* time causes routing to switch to the alternate path more quickly if a failure occurs. However, it consumes more CPU processing time.

Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

Examples

The following example shows how to change the start, hold, and maximum wait interval values to 5, 1000, and 90,000 milliseconds, respectively:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# timers throttle spf 5 1000 90000
```

## trace (OSPFv3)

To specify the Open Shortest Path First Version 3 (OSPFv3) buffer size, use the **trace** command in router ospfv3 configuration mode. To return to the default value, use the **no** form of this command.

**trace size** *buffer\_name* *size*

**no trace size** *buffer\_name* *size*

### Syntax Description

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>size</b>        | Deletes existing buffer and creates one with <i>N</i> entries.                                                                                       |
| <i>buffer_name</i> | Specifies a buffer from one of the 15 listed buffers. Refer <a href="#">Table 141: Buffer Types, on page 1353</a> table for details on the buffers.  |
| <i>size</i>        | Specifies allowed size for the selected buffer. Options are: 0, 256, 1024, 2048, 4096, 8192, 16384, 32768, and 65536.<br>Select 0 to disable traces. |

### Command Default

No default behavior or values

### Command Modes

Router ospfv3 configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Trace buffers are used to store various traffic and processing events during the runtime. Large buffers can store more events. If the buffer becomes full, old entries are overwritten by the latest entries. In a large network, user may want to increase the trace buffer size to accommodate more events.

**Table 141: Buffer Types**

| Name      | Description           |
|-----------|-----------------------|
| adj       | adjacency             |
| adj_cycle | dbd/flood events/pkts |
| config    | config events         |

| Name      | Description         |
|-----------|---------------------|
| errors    | errors              |
| events    | mda/rtrid/bfd/vrf   |
| ha        | startup/HA/NSF      |
| hello     | hello events/pkts   |
| idb       | interface           |

# transmit-delay (OSPFv3)

To set the estimated time required to send a link-state update packet on the interface, use the **transmit-delay** command in an appropriate configuration mode. To return to the default value, use the **no** form of this command.

**transmit-delay** *seconds*  
**no transmit-delay** *seconds*

|                           |                |                                                                                      |

|                        | Release 4.1.0  | This command was supported under OSPFv3 VRF configuration submode. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>Link-state advertisements (LSAs) in the update packet must have their ages incremented by the amount specified in the <i>seconds</i> argument before transmission. The value assigned should take into account the transmission and propagation delays for the interface.</p> <p>If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. This setting has more significance on very low-speed links.</p> |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

**Examples**

The following example shows how to configure a transmit delay of 3 seconds for GigabitEthernet interface 0/3/0/0:

```
RP/0/0/CPU0:router(config)# router ospfv3 1
RP/0/0/CPU0:router(config-ospfv3)# area 0
RP/0/0/CPU0:router(config-ospfv3-ar)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-ospfv3-ar-if)# transmit-delay 3
```

## virtual-link (OSPFv3)

To define an Open Shortest Path First Version 3 (OSPFv3) virtual link, use the **virtual-link** command in area configuration mode. To remove a virtual link, use the **no** form of this command.

**virtual-link** *router-id*

**no virtual-link**

### Syntax Description

|                  |                                                                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>router-id</i> | Router ID associated with the virtual link neighbor. The router ID appears in the <b>show ospfv3</b> display. This value must be entered in 32-bit dotted-decimal notation, similar to an IP Version 4 (IPv4) address. There is no default. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

No virtual links are defined.

### Command Modes

Area configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

In OSPFv3, when there exists a path through another non-backbone area over which the virtual link can function, all areas must be connected to a backbone area. If the connection to the backbone is lost, it can be repaired by establishing a virtual link.

Virtual links, which are defined in the submode of the area they transit, are in effect virtual point-to-point interfaces belonging to area 0 (the backbone). The virtual links inherit parameter values from the backbone area, rather than the transit area in which they are defined.

Each virtual link neighbor must include the router ID of the virtual link neighbor for the link to be properly established. Use the **show ospfv3** command to display the router ID of an OSPFv3 process.

Use the **virtual-link** command to place the router in virtual-link configuration mode (config-router-ar-vl), from which you can configure virtual-link-specific settings. Commands configured under this mode (such as the **transmit-delay** command) are automatically bound to that virtual link.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| ospf    | read, write |

## Examples

The following example shows how to establish a virtual link with default values for all optional parameters:

```
RP/0/0/CPU0:router(config)# router ospfv3 201  
RP/0/0/CPU0:router(config-ospfv3)# area 1  
RP/0/0/CPU0:router(config-ospfv3-ar)# virtual-link 10.3.4.5
```

## Related Commands

|--------------------------------------------------------|---------------------------------------------------------------------------------------|
| <a href="#">show ospfv3</a> , on page 1274             | Displays general information about OSPF routing processes.                            |
| <a href="#">transmit-delay (OSPFv3)</a> , on page 1355 | Sets the estimated time required to send a link-state update packet on the interface. |

## vrf (OSPFv3)

To configure an Open Shortest Path First Version 3 (OSPFv3) VPN routing and forwarding (VRF) instance and enter OSPFv3 VRF configuration submenu, use the **vrf** command in router configuration mode. To terminate an OSPFv3 VRF, use the **no** form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

### Syntax Description

|                 |                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Specifies a name for the OSPFv3 vrf. If a name is not specified, the default vrf is assumed. |
|-----------------|----------------------------------------------------------------------------------------------|

### Command Default

No OSPFv3 VRF is configured.

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vrf** command to explicitly configure a VRF. This command creates a separate instance of OSPFv3 within the process. Commands configured under the VRF configuration mode (such as the **interface** [OSPFv3] and **authentication** [OSPFv3] commands) are automatically bound to that VRF.

To modify or remove the VRF, the *vrf-name* argument format must be the same as the format used when creating the VRF.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ospf    | read, write |

### Examples

This example shows how to configure VRF *vrf\_1* and enter OSPFv3 VRF configuration submenu:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospfv3 osp3
```

```
RP/0/0/CPU0:router(config-ospfv3)#vrf vrf_1  
RP/0/0/CPU0:router(config-ospfv3-vrf)#
```

# address-family next-hop dampening disable

To disable Routing Information Base (RIB) next-hop dampening, use the **address-family next-hop dampening disable** command in router configuration mode. To enable RIB next-hop dampening, use the **no** form of this command.

**address-family {ipv4|ipv6} next-hop dampening disable**

**no address-family {ipv4|ipv6} next-hop dampening disable**

## Syntax Description

|      |                                                 |
|------|-------------------------------------------------|
| ipv4 | Specifies IP Version 4 (IPv4) address prefixes. |
| ipv6 | Specifies IP Version 6 (IPv6) address prefixes. |

## Command Default

RIB next-hop dampening is enabled.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rib     | read, write |

## Examples

The following example shows how to disable RIB next-hop dampening for IPv6 address families:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router rib
RP/0/0/CPU0:router(config-rib)# address-family ipv6 next-hop dampening disable
```

# clear route

To clear routes from the IP routing table, use the **clear route** command in EXEC mode.

**clear route** [**vrf** {*vrf-name* | **all**}] {**ipv4** | **ipv6** | **safi-all**} {**unicast** | **multicast** | **safi-all**} [**topology** *topo-name*] [*ip-address mask*]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                        |
| <b>ipv4</b>                                 | Specifies IP Version 4 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ipv6</b>                                 | Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>safi-all</b>                             | Specifies IP Version 4 and IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>safiunicast</b>                          | Specifies unicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>multicast</b>                            | Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>safi-all</b>                             | Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                                                                                                                                                                                                                          |
| <i>ip-address node-id</i>                   | (Optional) Clears hardware resource counters from the designated node. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation.                                                                                                                                                                                                                                                                                   |
| <i>ip-address</i>                           | Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                  |
| <i>mask</i>                                 | Network mask specified in either of two ways:<br><br>Network mask can be a four-part, dotted-decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.<br><br>Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address. |

## Command Default

If a **vrf** *vrf-name* is not specified, routes are cleared from the default IPv4 unicast VRF.

## Command Modes

EXEC

**Command History**

| Release       | Modification                                                                                |
|---------------|---------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added. |
| Release 3.3.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                             |
| Release 3.4.0 | The <b>all</b> keyword was added.                                                           |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added.                       |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear route** command to clear routes from an IP routing table to a specific network, a matching subnet address, or all routes.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| rib     | read, write |

**Examples**

The following example shows how to remove all routes matching the subnet address 192.168.2.0 and mask 255.255.255.0 from the IPv4 unicast routing table:

```
RP/0/0/CPU0:router# clear route ipv4 unicast 192.168.2.0 255.255.255.0
```

The following example shows how to remove all routes from the IPv4 unicast routing table:

```
RP/0/0/CPU0:router# clear route ipv4 unicast
```

**Related Commands**

|-------------------------------------------|--------------------------------------------------|
| <a href="#">show route</a> , on page 1428 | Displays the current state of the routing table. |

## maximum prefix (RIB)

To set the prefix limit for the VPN routing and forwarding (VRF) instance, use the **maximum prefix** command in global VRF address family configuration mode. To set the prefix limits to the default values, use the **no** form of this command.

**maximum prefix** *maximum* [ *mid-threshold* ]

**no maximum prefix**

### Syntax Description

|                      |                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>maximum</i>       | Maximum number of prefixes allowed in the VRF instance. Range is 32 to 2000000.                                                                                                            |
| <i>mid-threshold</i> | (Optional) Integer specifying at what percentage of the <i>maximum</i> argument value the software starts to generate a Simple Network Management Protocol (SNMP) trap. Range is 1 to 100. |

### Command Default

No default behavior or values

### Command Modes

Global VRF address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum prefix** command to configure a maximum number of prefixes that a VRF instance is allowed to receive.

A maximum number of routes is applicable to dynamic routing protocols as well as static or connected routes.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rib     | read, write |

## Examples

The following example shows how to set the maximum number of prefixes allowed to 1000:

```
RP/0/0/CPU0:router(config)# vrf vrf-A
RP/0/0/CPU0:router(config-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-vrf-af)# maximum prefix 1000
```

|-----------------------------------------------|---------------------------------------|
| <a href="#">show rib tables, on page 1420</a> | Displays all tables known to the RIB. |

# lcc

To enable Label Consistency Checker (lcc) background scan for IPv6 or IPv4 labels, use the **lcc enable** command in global configuration mode. To disable lcc background scan, use the **no** for of this command.

**lcc {ipv4| ipv6} unicast {enable| period *milliseconds*}**

**no lcc {ipv4| ipv6} unicast {enable| period *milliseconds*}**

## Syntax Description

|                                   |                                                                                          |
|-----------------------------------|------------------------------------------------------------------------------------------|
| <b>ipv4</b>                       | Specifies IP Version 4 address prefixes.                                                 |
| <b>ipv6</b>                       | Specifies IP Version 6 address prefixes.                                                 |
| <b>unicast</b>                    | Specifies unicast address prefixes.                                                      |
| <b>period <i>milliseconds</i></b> | Specifies the period between scans in milliseconds. Range is 100 to 600000 milliseconds. |

## Command Default

Label consistency checker is disabled.

## Command Modes

Global configuration.

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| ipv4    | read, write |
| ipv6    | read, write |

## Examples

This example shows how to enable lcc for IPv6 labels:

```
RP/0/0/CPU0:router#configure
```

```
RP/0/0/CPU0:router(config)#lcc ipv6 unicast enable
```

## rcc

To enable Route Consistency Checker (rcc) background scan for IPv6 or IPv4 routes, use the **rcc enable** command in global configuration mode. To disable rcc background scan, use the **no** form of this command.

**rcc {ipv4| ipv6} unicast {enable| period *milliseconds*}**

**no rcc {ipv4| ipv6} unicast {enable| period *milliseconds*}**

### Syntax Description

|                                   |                                                                                          |
|-----------------------------------|------------------------------------------------------------------------------------------|
| <b>ipv4</b>                       | Specifies IP Version 4 address prefixes.                                                 |
| <b>ipv6</b>                       | Specifies IP Version 6 address prefixes.                                                 |
| <b>unicast</b>                    | Specifies unicast address prefixes.                                                      |
| <b>period <i>milliseconds</i></b> | Specifies the period between scans in milliseconds. Range is 100 to 600000 milliseconds. |

### Command Default

Route consistency checker is disabled.

### Command Modes

Global configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **period** option to control how often the scan be triggered. Each time the scan is triggered, the background scan process resumes verification from where it was left out and sends one buffer's worth of routes to the forwarding information base (FIB).

### Task ID

| Task ID | Operation   |
|---------|-------------|
| ipv4    | read, write |
| ipv6    | read, write |

## Examples

This example shows how to configure rcc for IPv6 unicast:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#rcc ipv6 unicast enable
```

This example shows how to enable rcc with a scan period of 500 milliseconds for IPv6 unicast:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#rcc ipv6 unicast period 500
```

# recursion-depth-max

To set the maximum depth for route recursion checks, use the **recursion-depth-max** command in router configuration mode. To set the recursion checks to the default value, use the **no** form of this command.

**recursion-depth-max** *maximum*

**no recursion-depth-max** *maximum*

## Syntax Description

|                |                                                       |
|----------------|-------------------------------------------------------|
| <i>maximum</i> | Maximum depth for recursion checks. Range is 5 to 16. |
|----------------|-------------------------------------------------------|

## Command Default

The default recursion depth is 128.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **recursion-depth-max** command to configure a specific maximum number of recursion checks in the range of 5 to 16.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rib     | read, write |

## Examples

The following example shows how to set the maximum depth for route recursion checks to 12:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router rib
RP/0/0/CPU0:router(config-rib)# recursion-depth-max 12
```

# router rib

To enter Routing Information Base (RIB) configuration mode, use the **router rib** command in global configuration mode. To remove all RIB configurations and terminate the RIB routing process, use the **no** form of this command.

**router rib**

**no router rib**

**Syntax Description** This command has no arguments or keywords.

**Command Default** Router configuration mode is not enabled.

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.4.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |
|         | ospf    | read, write |
|         | hsrp    | read, write |
|         | isis    | read, write |

**Examples** The following example shows how to enter RIB configuration mode:

```
RP/0/0/CPU0:router(config)# router rib
```

# rump always-replicate

To enable replication from uRIB to muRIB as usual even after features such as MTR are configured, use the **rump always-replicate** command in router configuration mode. To disable replication from uRIB to muRIB, use the **no** form of this command.

**rump always-replicate** [ *access-list* ]

**no rump always-replicate** [ *access-list* ]

## Syntax Description

|                         |                                     |
|-------------------------|-------------------------------------|
| <i>access-list-name</i> | (Optional) Name of the access list. |
|-------------------------|-------------------------------------|

## Command Default

Replication from uRIB to muRIB is enabled.

## Command Modes

Router address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Configuring the **rump always-replicate** command allows routers in a network to be upgraded to multitopology routing gradually without a flag day where all routers need to be configured at the same time without major service disruption. When **rump always-replicate** is configured, replicated routes are added into the muRIB with the lowest admin distance. So if protocols are populating the muRIB, they continue to do so. For the same route, protocol routes win over replicated routes because of higher admin distance.

If an unwanted more specific route comes from the uRIB, optionally provide an access list through which the replicated routes are run. If the route passes the access list, the route is replicated by RUMP.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rib     | read, write |

## Examples

The following example shows how to enable replication from uRIB to muRIB:

```
RP/0/0/CPU0:router(config)# rump rib
```

```
RP/0/0/CPU0:router(config-rib)# address-family ipv4  
RP/0/0/CPU0:router(config-rib-afi)# rump always-replicate
```

# show bcdl statistics

To display queue and Update Group statistics for either producers of data (RIB, LSD etc,.) or consumers of data (FIB etc,.) during system-wide route-prioritization, use the show bcdl statistics command in EXEC mode.

**show bcdl statistics** *statistics\_name*

| Syntax Description | <i>statistics_name</i> | Name of the statistics |
|--------------------|------------------------|------------------------|
|--------------------|------------------------|------------------------|

| Command Default | None |
|-----------------|------|
|-----------------|------|

| Command Modes | EXEC |
|---------------|------|
|---------------|------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.2.0 | This command was introduced. |

| Usage Guidelines | To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Task ID | Task ID | Operation |
|---------|---------|-----------|
|         | bcdl    | read      |

**Examples** This example displays the sample output from **show bcdl statistics** command:

```
RP/0/0/CPU0:router# show bcdl statistics ipv4_lsd
UG 0
  Pri 0 buffers sent = 0
  Pri 1 buffers sent = 2
  Pri 2 buffers sent = 12
  Pri 3 buffers sent = 15
  Pri 4 buffers sent = 16
  Pri 5 buffers sent = 3
UG 1
  Pri 0 buffers sent = 2
  Pri 1 buffers sent = 1
  Pri 2 buffers sent = 120
  Pri 3 buffers sent = 0
  Pri 4 buffers sent = 1
  Pri 5 buffers sent = 0
```

## CBP POOLS STATS:

Transmit: bufs=730: sz=6224: num\_free=730: num\_issued=395: num\_returned=395

Receive: bufs=50: sz=1104: num\_free=50: num\_issued=0: num\_returned=0

Control: bufs=1024: sz=592: num\_free=1024: num\_issued=399: num\_returned=399

## Cumulative Stats

Transmit Queue: buffers in queue=0, buffers enqueued=194, buffers dequeued=194

# show lcc statistics

To view results of a label consistency checker (lcc) background scan, use the **show lcc statistics** command in EXEC mode.

**show lcc {ipv4|ipv6} unicast statistics**

Syntax Description

|         |                                   |
|---------|-----------------------------------|
| ipv4    | IPv4 address prefix.              |
| ipv6    | IPv6 address prefix.              |
| unicast | Specifies unicast address prefix. |

Command Default

None

Command Modes

EXEC

Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Task ID

| Task ID | Operation |
|---------|-----------|
| ipv4    | read      |
| ipv6    | read      |

Examples

This example shows background scan statistics for AFI-SAFI mpls6-unicast:

```
RP/0/0/CPU0:router#show lcc ipv6 unicast statistics
Background Scan Statistics for AFI-SAFI mpls6-unicast:
=====
Scan enabled:                False
Current scan-id:            0
Scan triggered:              False
```

```

Configured period:      60                Current period:      0
Paused by range scan: False
Paused by route churn: False
Paused by error scan: False

Last data sent: 0 entries                Damping percent:      70
Default route churn:   10                Current route churn:   0
Route churn last calculated at            Dec 31 16:00:00.000

| Task ID            | Operation                                                                                                                                                                                                                             |         |              |               |                              |
| mpls               | read                                                                                                                                                                                                                                  |         |              |               |                              |

**Examples** This example shows the output from **show mpls lsd forwarding detail** command:

```
RP/0/0/CPU0:router# show mpls lsd forwarding
In_Label, (ID), Path_Info: <Type>
16002, (IPv4, 'default':4U, 2.1.1.1/32), 1 Paths
  1/1: IPv4, 'default':4U, Gi0/3/0/3, nh=20.1.5.2, lbl=None, tun_id=0 flags=()
    path-id=1, backup-path-id=0
    BCDL priority:3, LSD queue:5, version:7
    Installed Jan 17 14:26:31.140 (05:03:11 ago)
```

This table describes the significant fields shown in the display

| Field          | Description                       |
|----------------|-----------------------------------|
| BCDL priority: | BCDL priority value               |
| LSD queue:     | LSD queue number                  |
| version:       | Version number of the LSD rewrite |

# show rcc

To display route consistency checker (RCC) information, use the **show rcc** command in EXEC mode.

**show rcc** {**ipv4**|**ipv6**} **unicast** [**log**|*prefix netmask vrf vrf-name*]

## Syntax Description

|                            |                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------|
| ipv4                       | Specifies IP Version 4 address prefixes.                                                          |
| ipv6                       | Specifies IP Version 6 address prefixes.                                                          |
| unicast                    | Specifies unicast address prefixes.                                                               |
| log                        | (Optional) Specifies the RCC log.                                                                 |
| prefix                     | (Optional) Starting prefix.                                                                       |
| netmask                    | (Optional) Network mask.                                                                          |
| <b>vrf</b> <i>vrf-name</i> | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |

```

## show rcc statistics

To view results of a route consistency checker (rcc) background scan, use the **show rcc statistics** command in EXEC mode.

**show rcc {ipv4| ipv6} unicast statistics**

### Syntax Description

|                |                                     |
|----------------|-------------------------------------|
| <b>ipv4</b>    | IPv4 address prefix.                |
| <b>ipv6</b>    | IPv6 address prefix.                |
| <b>unicast</b> | Specifies unicast address prefixes. |

### Command Default

None

### Command Modes

EXEC

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation |
|---------|-----------|
| ipv4    | read      |
| ipv6    | read      |

### Examples

This example shows background scan statistics for AFI-SAFI IPv6 unicast:

```
RP/0/0/CPU0:router#show rcc ipv6 unicast statistics
```

```
Background Scan Statistics for AFI-SAFI ipv6-unicast:
=====
```

```
Scan enabled:           False
Current scan-id:        0
Scan triggered:         False
```

```

Configured period:      60          Current period:      0

Paused by range scan: False
Paused by route churn: False
Paused by error scan: False

Last data sent: 0 entries          Damping percent:      70
Default route churn:  10          Current route churn:  0
Route churn last calculated at    Dec 31 16:00:00.000

Logs stored for background scan ids:

Log for AFI-SAFI ipv6-unicast:

End Of Logs

```

# show rcc vrf

To run on-demand route consistency checker (rcc) scan on AFI, SAFI, table, and prefix or the entire set of prefixes in the table, use the **show rcc vrf** command in EXEC mode.

**show rcc {ipv4|ipv6} unicast prefix/mask vrf vrfname**

## Syntax Description

|                     |                                                      |
|---------------------|------------------------------------------------------|
| <b>ipv4</b>         | IPv4 address prefix.                                 |
| <b>ipv6</b>         | IPv6 address prefix.                                 |
| <i>prefix /mask</i> | Specifies unicast address prefix.                    |
| <b>vrf</b>          | Specifies VPN routing and forwarding (VRF) instance. |
| <i>vrfname</i>      | Name of the VRF.                                     |

## Command Default

None.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation |
|---------|-----------|
| ipv4    | read      |
| ipv6    | read      |

## Examples

This example shows how to run on-demand rcc scan for an IPv6 prefix:

```
RP/0/0/CPU0:router#show rcc ipv6 unicast 2001:DB8::/32 vrf vrf_1
```

This example shows how to run on-demand rcc scan for an Ipv4 prefix:

```
RP/0/0/CPU0:router#show rcc ipv4 unicast 10.2.3.4/32 vrf vrf-1
```

# show rib

To display Routing Information Base (RIB) data, use the **show rib** command in EXEC mode.

**show rib** {**ipv4**|**ipv6**} {**unicast**|**multicast**}[**firsthop**| [ *type interface-path-id*]| **next-hop**| [ *type interface-path-id*]| **opaques** | {**attribute** | **ip-nexthop**| **ipfrr**| **safi-tunnel**| **summary** | **tunnel-nexthop**}}| **protocols**| [**standby**]| **statistics**| [*name*]| [**standby**]| **topology**| {*topo-name*| **all**}]

## Syntax Description

|                               |                                                                                                                                                                                                                                                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipv4                          | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                                                                                                              |
| ipv6                          | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                              |
| unicast                       | (Optional) Specifies unicast address prefixes. This is the default.                                                                                                                                                                                                                              |
| multicast                     | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                 |
| firsthop                      | (Optional) Specifies registered first-hop notification addresses                                                                                                                                                                                                                                 |
| type                          | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                                            |
| interface-path-id             | Identifies a physical interface or a virtual interface.<br><br><b>Note</b> Use the show interfaces command to see a list of all possible interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| next-hop                      | (Optional) Specifies registered next-hop notification addresses.                                                                                                                                                                                                                                 |
| opaques                       | (Optional) Specifies opaque data installed in the RIB.                                                                                                                                                                                                                                           |
| <b>attribute</b>              | (Optional) Specifies opaque attributes installed in the RIB.                                                                                                                                                                                                                                     |
| <b>ip-nexthop</b>             | (Optional) Specifies P next-hop data installed in the RIB.                                                                                                                                                                                                                                       |
| <b>ipfrr</b>                  | (Optional) Specifies IP fast reroute (IPFRR) opaque data installed in the RIB.                                                                                                                                                                                                                   |
| <b>safi-tunnel</b>            | (Optional) Specifies subaddress family (SAFI) tunnel opaque data installed in the RIB.                                                                                                                                                                                                           |
| <b>summary</b>                | (Optional) Specifies a summary of opaque data installed in the RIB.                                                                                                                                                                                                                              |
| <b>tunnel-nexthop</b>         | (Optional) Specifies tunnel next-hop opaque data installed in the RIB.                                                                                                                                                                                                                           |
| protocols                     | (Optional) Specifies registered protocols.                                                                                                                                                                                                                                                       |
| <b>statistics</b> <i>name</i> | (Optional) Specifies RIB statistics of a given name.                                                                                                                                                                                                                                             |
| <b>standby</b>                | (Optional) Specifies standby information.                                                                                                                                                                                                                                                        |

|                                  |                                                                                 |
|----------------------------------|---------------------------------------------------------------------------------|
| <b>topology</b> <i>topo-name</i> | (Optional) Specifies topology table information and name of the topology table. |
| all                              | (Optional) Specifies that all topology table information should be displayed.   |

**Command Default** No default behavior or values

**Command Modes** EXEC

| Release       | Modification                                                            |
|---------------|-------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                            |
| Release 3.4.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>standby</b> keywords were added. |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added.   |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Operations |
|---------|------------|
| ipv4    | read       |

**Examples** The following example illustrates the **show rib** command:

```
RP/0/RP0/CPU0:router# show rib
```

```
    ipv4 multicast
```

```
    topology
```

```
    BLUE
```

```
RP/0/RP0/CPU0:router# show rib topology BLUE ipv4 multicast protocols
Protocol  Handle  Instance
isis      0         mt
```

**Related Commands**

|------------------------------------------------|----------------------------------------------|
| <a href="#">show rib afi-all, on page 1391</a> | Displays both IPv4 and IPv6 RIB information. |

# show rib afi-all

To display Routing Information Base (RIB) data for both IPv4 and IPv6 address families, use the **show rib afi-all** command in EXEC mode.

**show rib afi-all** [**attributes**] [**client-id**] [**clients**] [**extcomms**] [**firsthop**] [**history**] [**multicast**] [**next-hop**] [**opaques**] [**protocols**] [**recursion-depth-max**] [**safi-all**] [**statistics**] [**tables**] [**trace**] [**unicast**] [**vpn-attributes**]

## Syntax Description

|                            |                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------|
| <b>attributes</b>          | (Optional) Displays all BGP attributes installed in RIB.                                         |
| <b>client-id</b>           | (Optional) Displays RIB client ID for longer history of redistributed routes sent to the client. |
| <b>clients</b>             | (Optional) Displays RIB clients.                                                                 |
| <b>extcomms</b>            | (Optional) Displays all extended communities installed in RIB.                                   |
| <b>firsthop</b>            | (Optional) Displays registered firsthop notification addresses.                                  |
| <b>history</b>             | (Optional) Displays redistributed routes sent to RIB clients.                                    |
| <b>multicast</b>           | (Optional) Displays multicast commands.                                                          |
| <b>next-hop</b>            | (Optional) Displays registered next-hop notification addresses.                                  |
| <b>opaques</b>             | (Optional) Displays opaque data installed in RIB.                                                |
| <b>protocols</b>           | (Optional) Displays registered protocols.                                                        |
| <b>recursion-depth-max</b> | (Optional) Displays maximum recursion depth in RIB.                                              |
| <b>safi-all</b>            | (Optional) Displays unicast and multicast commands.                                              |
| <b>statistics</b>          | (Optional) Displays RIB statistics.                                                              |
| <b>tables</b>              | (Optional) Displays a list of tables known to RIB.                                               |
| <b>trace</b>               | (Optional) Displays RIB trace entries.                                                           |
| <b>unicast</b>             | (Optional) Displays unicast commands.                                                            |
| <b>vpn-attributes</b>      | (Optional) Displays all VPN attributes installed in RIB.                                         |

## Command Default

No default behavior or values

**Command Modes**

EXEC

**Command History**

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ipv4    | read       |

**Examples**

The following example illustrates the **show rib afi-all attributes** command:

```
RP/0/0/CPU0:router# show rib afi-all attributes
BGP attribute data in IPv4 RIB:
0 Attributes, for a total of 0 bytes.
BGP attribute data in IPv6 RIB:
0 Attributes, for a total of 0 bytes.
```

**Related Commands**

| Command                                | Description               |
|----------------------------------------|---------------------------|
| <a href="#">show rib, on page 1388</a> | Displays RIB information. |

# show rib attributes

To display Border Gateway Protocol (BGP) attributes installed in the Routing Information Base (RIB), use the **show rib attributes** command in EXEC mode.

**show rib attributes [summary] [standby]**

## Syntax Description

|         |                                                                           |
|---------|---------------------------------------------------------------------------|
| summary | (Optional) Displays a summary of BGP attribute data installed in the RIB. |
| standby | (Optional) Displays standby information.                                  |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

## Examples

The following is sample output from the **show rib attributes** command:

```
RP/0/0/CPU0:router# show rib attributes

BGP attribute data in IPv4 RIB:

Attribute ID (0x2):size (68)
Attribute ID (0x3):size (52)
Attribute ID (0x4):size (68)
Attribute ID (0x5):size (52)

4 Attributes, for a total of 240 bytes.

Attribute ID : ID assigned for the attribute by BGP
```

size : size of the attribute data.

# show rib client-id

To display Routing Information Base (RIB) redistribution histories, use the **show rib client-id** command in EXEC mode.

**show rib client-id** *id* **redistribution history** [**standby**]

## Syntax Description

|                        |                                                                      |
|------------------------|----------------------------------------------------------------------|
| <i>id</i>              | ID of the client. Range is 0 to 4294967295.                          |
| redistribution history | Displays longer history of redistributed routes sent to RIB clients. |
| <b>standby</b>         | (Optional) Displays standby information.                             |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                          |
|---------------|---------------------------------------|
| Release 3.3.0 | This command was introduced.          |
| Release 3.4.0 | The <b>standby</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib client-id** command to display a history of the route additions, deletions, and updates sent from RIB to the client across VRFs.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

## Examples

The following is sample output from the **show rib client-id** command:

```
RP/0/0/CPU0:router# show rib client-id 13 redistribution history
```

```
PID      JID      Client      Location
151630   113     bcdl_agent  node0_5_CPU0
```

```

# show rib clients

To display Routing Information Base (RIB) clients, use the **show rib clients** command in EXEC mode.

**show rib** [**afi-all**| **ipv4**| **ipv6**] **clients** [**protocols**| **redistribution** [**history**]] [**standby**]

## Syntax Description

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <b>afi-all</b>        | (Optional) Specifies all address families.                               |
| <b>ipv4</b>           | (Optional) Specifies IP Version 4 address prefixes. This is the default. |
| <b>ipv6</b>           | (Optional) Specifies IP Version 6 address prefixes.                      |
| <b>protocols</b>      | (Optional) Specifies client protocols.                                   |
| <b>redistribution</b> | (Optional) Specifies protocols redistributed by clients                  |
| <b>history</b>        | (Optional) Specifies redistributed routes sent to RIB clients.           |
| <b>standby</b>        | (Optional) Displays standby information.                                 |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                                                            |
|---------------|-------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                            |
| Release 3.4.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>standby</b> keywords were added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib clients** command to display the list of clients who have registered with RIB, what protocol routes they are redistributing, and a history of the routes sent to the client.

The maximum number of redistribution entries is 5000 for Bulk Content Downloader (BCDL) and 500 for other protocols.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

## Examples

The following is sample output from the **show rib clients** command:

```
RP/0/0/CPU0:router# show rib clients

Process           Location           Client ID  Redist  Proto
isis              node0_5_CPU0      0          insync  insync
ospf              node0_5_CPU0      2          insync  insync

RP/0/0/CPU0:router# show rib clients redistribution

isis node0_5_CPU0
  ipv4 uni         vrf default      insync          route
  static           insync
ospf node0_5_CPU0
  ipv4 uni         vrf default      insync          route

  ipv4 uni         vrf default      insync          rib_fib
  ipv4 uni         vrf bar          insync          rib_fib
  ipv4 uni         vrf abc          insync          rib_fib
  ipv4 uni         vrf test         insync          rib_fib
```

This table describes the significant fields shown in the display.

**Table 143: show rib clients Field Descriptions**

| Field     | Description                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process   | Client process name.                                                                                                                                                                                   |
| Location  | Location where the client process is running.                                                                                                                                                          |
| Client ID | ID assigned to the client by RIB.                                                                                                                                                                      |
| Redist    | Whether the client is redistributing any protocols or not and whether it has read all routes from RIB or not. <ul style="list-style-type: none"> <li>insync—read</li> <li>outsync—not read.</li> </ul> |

| Field | Description                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Proto | Whether the protocol has sent all its routes to RIB and signaled update complete or not. <ul style="list-style-type: none"><li>• insync—read</li><li>• outsync—not read.</li></ul> |

# show rib extcomms

To display all extended communities installed in the Routing Information Base (RIB), use the **show rib extcomms** command in EXEC mode.

**show rib [afi-all| ipv4| ipv6] extcomms [summary] [standby]**

Syntax Description

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <b>afi-all</b> | (Optional) Specifies all address families.                               |
| <b>ipv4</b>    | (Optional) Specifies IP Version 4 address prefixes. This is the default. |
| <b>ipv6</b>    | (Optional) Specifies IP Version 6 address prefixes.                      |
| <b>summary</b> | (Optional) Specifies a summary of all extended communities in the RIB.   |
| <b>standby</b> | (Optional) Displays standby information.                                 |

Command Default

No default behavior or values

Command Modes

| Release 3.4.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>standby</b> keywords were added. |

Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

Examples

The following is sample output from the **show rib extcomms** command:

```
RP/0/0/CPU0:router# show rib extcomms
```

Extended community data in RIB:

| Extended community        | Ref count |
|---------------------------|-----------|
| COST:128:128:41984        | 1         |
| EIGRP route-info:0x8000:0 | 1         |
| EIGRP AD:1:25600          | 1         |
| EIGRP RHB:255:0:16384     | 1         |
| EIGRP LM:0x0:1:4470       | 1         |

This table describes the significant fields shown in the display.

**Table 144: show rib extcomms Field Descriptions**

| Field              | Description                                                                               |
|--------------------|-------------------------------------------------------------------------------------------|
| Extended Community | Type of extended communities. Different protocols can add different extended communities. |
| Ref Count          | Number of routes referring to the Extended community.                                     |

# show rib firsthop

To display registered first-hop notification addresses, use the **show rib firsthop** command in EXEC mode.

**show rib** [**vrf** {*vrf-name* | **all**}] [**afi-all** **ipv4** | **ipv6**] [**unicast** | **multicast** | **safi-all**] **firsthop** [*client-name*] [*type* | *interface-path-id* | *ip-address* /*prefix-length* | *ip-address mask*] **resolved** | **unresolved** | **damped**] [**summary**] [**standby**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                             |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                                                                                                                                                                                                    |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. This is the default.                                                                                                                                                                                                      |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                           |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes. This is the default.                                                                                                                                                                                                           |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                              |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                  |
| <i>client-name</i>                          | (Optional) Name of the RIB client.                                                                                                                                                                                                                                            |
| <i>type</i>                                 | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i>                    | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <i>ip-address</i>                           | (Optional) Network that BGP advertises.                                                                                                                                                                                                                                       |
| / <i>prefix-length</i>                      | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value.                                     |
| <i>ip-address mask</i>                      | (Optional) Network mask applied to the <i>ip-address</i> argument.                                                                                                                                                                                                            |
| <b>resolved</b>                             | (Optional) Specifies resolved next-hops.                                                                                                                                                                                                                                      |
| <b>unresolved</b>                           | (Optional) Specifies unresolved next-hops.                                                                                                                                                                                                                                    |
| <b>damped</b>                               | (Optional) Specifies next-hops that are damped.                                                                                                                                                                                                                               |

|                |                                                             |
|----------------|-------------------------------------------------------------|
| <b>summary</b> | (Optional) Specifies a summary of the next-hop information. |
| <b>standby</b> | (Optional) Displays standby information.                    |

**Command Default** If a **vrf** *vrf-name* is not specified, the registered first-hop notifications addresses are displayed for the default IPv4 unicast VRF.

**Command Modes** EXEC

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>                                                                                                                                                           |
|------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | Release 3.3.0  | This command was introduced.                                                                                                                                                  |
|                        | Release 3.4.0  | The following keywords were added: <ul style="list-style-type: none"> <li>• <b>all</b></li> <li>• <b>looped</b></li> <li>• <b>damped</b></li> <li>• <b>standby</b></li> </ul> |
|                        | Release 3.6.0  | The <b>looped</b> keyword was removed.                                                                                                                                        |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib firsthop** command to display the list of first hops registered by various clients with RIB and the address and interface through which they are resolved.

| <b>Task ID</b> | <b>Task ID</b> | <b>Operations</b> |
|----------------|----------------|-------------------|
|                | rib            | read              |

**Examples** The following is sample output from the **show rib firsthop** command:

```
RP/0/0/CPU0:router# show rib firsthop

Registered firsthop notifications:
0.0.0.0/0 via 1.1.0.1 - MgmtEth0/5/CPU0/0, ospf/node0_5_CPU0
1.1.0.1/32 via 1.1.0.1 - MgmtEth0/5/CPU0/0, ipv4_static/node0_5_CPU0
1.1.1.1/32 via 1.1.1.1 - MgmtEth0/5/CPU0/0, ipv4_static/node0_5_CPU0
```

```
10.10.10.1/32 via 10.10.10.1 - Loopback0, ipv4_static/node0_5_CPU0
10.10.10.3/32 via 10.10.10.3 - Loopback0, ipv4_static/node0_5_CPU0
15.15.15.1/32 via 10.10.10.1 - Loopback0, ipv4_static/node0_5_CPU0
20.20.20.1/32 via 1.1.1.1 - MgmtEth0/5/CPU0/0, ipv4_static/node0_5_CPU0
30.30.30.1/32 via 1.1.1.2 - MgmtEth0/5/CPU0/0, ipv4_static/node0_5_CPU0
```

# show rib history

To display history information for Routing Information Base (RIB) clients, use the **show rib history** command in EXEC mode.

**show rib** [**afi-all**| **ipv4**| **ipv6**] **history** [**client-id** *client-id*] [**standby**]

## Syntax Description

|                                   |                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------|
| <b>afi-all</b>                    | (Optional) Specifies all address families.                                                         |
| <b>ipv4</b>                       | (Optional) Specifies IP Version 4 address prefixes. This is the default.                           |
| <b>ipv6</b>                       | (Optional) Specifies IP Version 6 address prefixes.                                                |
| <b>client-id</b> <i>client-id</i> | (Optional) Specifies the ID of the client. Range for <i>client-id</i> argument is 0 to 4294967295. |
| <b>standby</b>                    | (Optional) Displays standby information.                                                           |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                          |
|---------------|---------------------------------------|
| Release 3.3.0 | This command was introduced.          |
| Release 3.4.0 | The <b>standby</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib history** command to display the list of routes that RIB has sent to various clients.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show rib history** command:

```
RP/0/0/CPU0:router# show rib history

JID   Client           Location
229   isis             node0_5_CPU0
      Table ID: 0xe0000000
        S 80.80.80.0/24[1/0]      update, 6 path(s),    04:32:09
        S 100.100.100.0/24[1/0]   update, 1 path(s),    04:32:09
        S 40.40.40.0/24[1/0]     update, 1 path(s),    04:32:09
        S 15.15.15.0/24[1/0]     update, 1 path(s),    04:32:09
JID   Client           Location
260   ospf             node0_5_CPU0
      Table ID: 0xe0000000
        S 80.80.80.0/24[1/0]      update, 6 path(s),    04:32:09
        S 100.100.100.0/24[1/0]   update, 1 path(s),    04:32:09
        S 40.40.40.0/24[1/0]     update, 1 path(s),    04:32:09
        S 15.15.15.0/24[1/0]     update, 1 path(s),    04:32:09
```

This table describes the significant fields shown in the display.

**Table 145: show rib history Field Descriptions**

| Field    | Description                                            |
|----------|--------------------------------------------------------|
| JID      | Job ID of the client process.                          |
| Client   | Name of the client process.                            |
| Location | Information about where the client process is running. |

# show rib next-hop

To display registered next-hop notification addresses, use the **show rib next-hop** command in EXEC mode.

```
show rib [vrf {vrf-name| all}] [afi-all| ipv4| ipv6] [unicast| multicast| safi-all] next-hop [client-name]
[type interface-path-id ip-address /prefix-length ip-address mask] resolved| unresolved| damped] [summary]
[standby]
```

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. This is the default.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes. This is the default.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>client-name</i>                          | (Optional) Name of the RIB client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>type</i>                                 | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>interface-path-id</i>                    | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function.                                                                                                                                                                                                                        |
| <i>ip-address</i>                           | (Optional) Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>mask</i>                                 | (Optional) Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted-decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address.</li> </ul> |

|                        |                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ prefix-length</i> | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value. |
| <b>resolved</b>        | (Optional) Specifies resolved next-hops.                                                                                                                                                                                                  |
| <b>unresolved</b>      | (Optional) Specifies unresolved next-hops.                                                                                                                                                                                                |
| <b>damped</b>          | (Optional) Specifies next-hops that are damped.                                                                                                                                                                                           |
| <b>summary</b>         | (Optional) Specifies a summary of the next-hop information.                                                                                                                                                                               |
| <b>standby</b>         | (Optional) Displays standby information.                                                                                                                                                                                                  |

**Command Default**

No default behavior or values

**Command Modes**

**Command History**

| Release       | Modification                           |
|---------------|----------------------------------------|
| Release 3.5.0 | This command was introduced.           |
| Release 3.6.0 | The <b>looped</b> keyword was removed. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib next-hop** command to display the list of next-hops registered by various clients with the RIB and the address and interface through which they are resolved.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show rib next-hop** command:

```
RP/0/0/CPU0:router# show rib next-hop
Registered nexthop notifications:
0.0.0.0/0 via 172.29.52.1 - MgmtEth0/RP1/CPU0/0, ospf/node0_RP0_CPU0
```

```
172.29.52.1/32 via 172.29.52.1 - MgmtEth0/RP1/CPU0/0, ipv4_static/node0_RP0_CPU0
```

# show rib opaques

To display opaque data installed in the Routing Information Base (RIB), use the **show rib opaques** command in EXEC mode.

**show rib** [**vrf** {*vrf-name*| **all**}] [**afi-all**| **ipv4**| **ipv6**] [**unicast**| **multicast**| **safi-all**] **opaques** {**attribute**| **ip-nexthop**| **ipfrr**| **safi-tunnel**| **summary**| **tunnel-nexthop**} [*rib-client-name*] [**standby**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. | <b>standby</b>                              | (Optional) Displays standby information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Command Default** No default behavior or values

**Command Modes** EXEC

| Command History | Release       | Modification                             |
|-----------------|---------------|------------------------------------------|
|                 | Release 3.5.0 | This command was introduced.             |
|                 | Release 4.0.1 | The <b>ipfrr</b> keyword was deprecated. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If information is not used by the RIB server process, it is viewed as opaque data. Use the **show rib opaques** command to display opaque data installed in the RIB.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | rib     | read       |

**Examples** The following is sample output from the **show rib opaques** command:

```
RP/0/0/CPU0:router# show rib opaques safi-tunnel

Summary of safi tunnel opaque data in IPv4 RIB:

Opaque key: 1:10.1.0.2
Opaque data:
Tunnel Encap - ifhandle=0x1000180, type=L2TPv3, Params=[Session-id=0x1EB1127C, `
CookieIen=8, Cookie=0xA73A3E0AFCD419A6] Opaque key: 65535:10.0.101.1 Opaque data:

RP/0/0/CPU0:router# show rib ipv6 opaques tunnel-nexthop

Summary of 6PE/6VPE IP over tunnel nexthop opaque data in IPv6 RIB:

Opaque key: 1::ffff:10.1.0.2
Opaque key: 65535::ffff:10.0.101.1
Opaque key: 65535::ffff:10.0.101.2
Opaque key: 65535::ffff:10.0.101.3
Opaque key: 65535::ffff:10.0.101.4
Opaque key: 65535::ffff:10.0.101.5
```

This table describes the significant fields shown in the display.

**Table 146: show rib opaques Field Descriptions**

| Field       | Description                                                         |
|-------------|---------------------------------------------------------------------|
| Opaque key  | Unique key for the opaque data as populated by the protocol client. |
| Opaque data | Data for the given key.                                             |

**Related Commands**

# show rib protocols

To display protocols registered for route addition, use the **show rib protocols** command in EXEC mode.

**show rib** [**vrf** {*vrf-name*| **all**}] [**afi-all**| **ipv4**| **ipv6**] [**unicast**| **multicast**| **safi-all**] **protocols** [**standby**]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                        |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. This is the default.                          |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes. This is the default.                               |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If a **vrf** *vrf-name* is not specified, the registered first-hop notification addresses are displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                         |
| Release 3.4.0 | The <b>all</b> and <b>standby</b> keywords were added.                                                                                                                                                                               |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show rib protocols** command:

```
RP/0/0/CPU0:router# show rib protocols
```

```

Protocol  Handle  Instance
isis      0        rib
connected 1
static    2
local     3
bgp       4        102
ospf      5        1

```

This table describes the significant fields shown in the display.

**Table 147: show rib protocols Field Descriptions**

| Field    | Description                               |
|----------|-------------------------------------------|
| Protocol | Name of the protocol.                     |
| Handle   | Handle assigned to the protocol instance. |
| Instance | Protocol instance.                        |

# show rib recursion-depth-max

To display the maximum recursion depth in the Routing Information Base (RIB), use the **show rib recursion-depth-max** command in EXEC mode.

**show rib** [**afi-all**| **ipv4**| **ipv6**] **recursion-depth-max** [**standby**]

## Syntax Description

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <b>afi-all</b> | (Optional) Specifies all address families.                               |
| <b>ipv4</b>    | (Optional) Specifies IP Version 4 address prefixes. This is the default. |
| <b>ipv6</b>    | (Optional) Specifies IP Version 6 address prefixes.                      |
| <b>standby</b> | (Optional) Displays standby information.                                 |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib recursion-depth-max** command to display the maximum recursion depth for RIB. Recursion depth is the number of next-hops that can be specified.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

## Examples

The following is sample output from the **show rib recursion-depth-max** command:

```
RP/0/0/CPU0:router# show rib recursion-depth-max
IPv4:
-----
```

```
Maximum recursion depth in RIB:
```

```
    Configured: 12  
      In Use: 128
```

```
IPv6:
```

```
-----  
Maximum recursion depth in RIB:
```

```
    Configured: 12  
      In Use: 128
```

This table describes the significant fields shown in the display.

**Table 148: show rib recursion-depth-max Field Descriptions**

| Field      | Description                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configured | Value of maximum recursion depth currently configured.                                                                                                                                                             |
| In Use     | Value of maximum recursion depth RIB is using. This value can be different from the configured value because RIB has to be restarted after the configuration is changed for the new configuration to be effective. |

# show rib statistics

To display Routing Information Base (RIB) statistics, use the **show rib statistics** command in EXEC mode.

```
show rib [vrf {vrf-name| all}] [afi-all| ipv4| ipv6] [unicast| multicast| safi-all] statistics [ client-name ]
[standby]
```

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                        |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. This is the default.                          |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes. This is the default.                               |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <i>client-name</i>                          | (Optional) Name of the RIB client.                                                                |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If **vrf** *vrf-name* is not specified, the registered first-hop notification addresses are displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib statistics** command to display RIB statistics. The statistics include requests sent from the clients to the RIB and the information redistributed to the client.

RIB maintains counters for all requests sent from a client including:

- Route operations
- Table registrations
- Next-hop registrations
- Redistribution registrations
- Attribute registrations
- Synchronization completion

RIB also maintains the results of the requests.

Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

Examples

The following is sample output from the `show rib statistics` command:

```
RP/0/0/CPU0:router# show rib statistics

RIB Statistics:
  Received 142 batch messages
    137 route operations, 0 attribute operations
    0 opaque operations
    11 complete operations, 0 convergent operations
  Results of the batch message received:
    142 successes
    0 forward references, 0 invalid client id, 0 unknown errors
    0 memory allocation errors, 0 client lookup errors, table lookup errors 0
    0 proto lookup errors, 0 client proto lookup errors
    ipv4_connected/node0_RP0_CPU0 last performed route operation
      with status BATCH_SUCCESS at Jun 26 21:43:33.601

  Received 217422 light weight messages
    4 route add requests, 2 route delete requests
    10 protocol registered, 1 protocol unregistered
    0 protocol modify, 0 protocol purged
    14 protocol redistributions, 0 unregistered protocol redistributions
    0 reset protocol redistributions
    3 first hop registered, 1 first hop unregistered
    3 advertisements, 0 unregistered advertisement
    57 bind data, 97 update completes, 217230 other requests
    udp/node0_RP0_CPU0 last performed firsthop lookup operation
      with status success at Jun 27 10:09:59.990

  Received 0 nexthop batch messages
    0 successes
    0 inits
    0 registers, 0 unregisters
    0 register complete, 0 sync unregistered, 0 batch finished
```

This table describes the significant fields shown in the display.

**Table 149: show rib statistics Field Descriptions**

| Field                                    | Description                                                                                             |
|------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Received                                 | Statistics received including batch messages and route, attribute, complete, and convergent operations. |
| Results of the batch message received    | Batch message results.                                                                                  |
| Received <i>n</i> light weight messages  | Number of lightweight API messages sent from RIB clients.                                               |
| Received <i>n</i> nexthop batch messages | Number of batch API messages sent from RIB clients received by the RIB.                                 |

# show rib tables

To display all tables known to the Routing Information Base (RIB), use the **show rib tables** command in EXEC mode.

**show rib [afi-all| ipv4| ipv6] tables [summary] [standby]**

## Syntax Description

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <b>afi-all</b> | (Optional) Specifies all address families.                               |
| <b>ipv4</b>    | (Optional) Specifies IP Version 4 address prefixes. This is the default. |
| <b>ipv6</b>    | (Optional) Specifies IP Version 6 address prefixes.                      |
| <b>summary</b> | (Optional) Displays summary table information.                           |
| <b>standby</b> | (Optional) Displays standby information.                                 |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                                                            |
|---------------|-------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                            |
| Release 3.4.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>standby</b> keywords were added. |
| Release 3.5.0 | The <b>summary</b> keyword was added.                                   |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rib tables** command to display all tables known to the RIB, including table attributes. Attributes include VPN routing and forwarding (VRF) instance, address family, and maximum prefix information.

## Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show rib tables** command when entered without an address:

```
RP/0/0/CPU0:router# show rib tables

Codes: N - Prefix Limit Notified, F - Forward Referenced
       D - Table Deleted, C - Table Reached Convergence

VRF          SAFI  Table ID      PrfxLmt   PrfxCnt  TblVersion  N F D C
default      uni   0xe0000000    2000000    72       137        N N N Y
default      multi 0xe0100000    2000000    0        0         N N N Y
```

This table describes the significant fields shown in the display.

**Table 150: show rib tables Field Descriptions**

| Field      | Description                                                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VRF        | Name of the VRF instance.                                                                                                                                                                                                       |
| SAFI       | Subaddress family instance.                                                                                                                                                                                                     |
| Table ID   | ID of the RIB table.                                                                                                                                                                                                            |
| PrfxLmt    | Configured prefix limit for the RIB table.                                                                                                                                                                                      |
| PrfxCnt    | Number of configured prefixes in the RIB table.                                                                                                                                                                                 |
| TblVersion | Tables version number.                                                                                                                                                                                                          |
| N          | Message sent when prefix limit is exceeded.                                                                                                                                                                                     |
| F          | Forward referenced. If Y is indicated, a table has been created by RIB because a client has registered for the table, but RIB has not heard from the router space infrastructure (RSI) about the table. RSI manages the tables. |
| D          | If Y is indicated, the table has been deleted in the RSI but RIB has not cleared the information.                                                                                                                               |
| C          | Table reached convergence.                                                                                                                                                                                                      |

# show rib trace

To display all Routing Information Base (RIB) library call tracer (ltrace) entries, use the **show rib trace** command in EXEC mode.

**show rib** [**afi-all**| **ipv4**| **ipv6**] **trace** [**clear**| **counts**| **event-manager**| **startup**| **sync**| **timing**] [**unique**| **wrapping**] [**last entries**] [**hexdump**] [**reverse**] [**tailif**] [**stats**] [**verbose**] [**file name original location node-id**] **location** {**all**| **node-id**}

## Syntax Description

|                                            |                                                                                                                                                                |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>afi-all</b>                             | (Optional) Specifies all address families.                                                                                                                     |
| <b>ipv4</b>                                | (Optional) Specifies IP Version 4 address prefixes. This is the default.                                                                                       |
| <b>ipv6</b>                                | (Optional) Specifies IP Version 6 address prefixes.                                                                                                            |
| <b>counts clear</b>                        | (Optional) Displays route clear trace entries.                                                                                                                 |
| <b>counts</b>                              | (Optional) Displays counts trace entries.                                                                                                                      |
| <b>event-manager</b>                       | (Optional) Displays RIB event manager trace entries.                                                                                                           |
| <b>startup</b>                             | (Optional) Displays RIB startup trace entries.                                                                                                                 |
| <b>sync</b>                                | (Optional) Displays client synchronization trace entries.                                                                                                      |
| <b>timing</b>                              | (Optional) Displays timing trace entries.                                                                                                                      |
| <b>unique</b>                              | (Optional) Displays unique entries with counts.                                                                                                                |
| <b>wrapping</b>                            | (Optional) Displays wrapping entries.                                                                                                                          |
| <b>last entries</b>                        | (Optional) Displays a specified number of the last entries. Range is 1 to 4294967295.                                                                          |
| <b>hexdump</b>                             | (Optional) Displays traces in hexadecimal format.                                                                                                              |
| <b>reverse</b>                             | (Optional) Displays the latest traces first.                                                                                                                   |
| <b>tailif</b>                              | (Optional) Displays new traces as they are added.                                                                                                              |
| <b>stats</b>                               | (Optional) Displays statistics.                                                                                                                                |
| <b>verbose</b>                             | (Optional) Displays internal debugging information.                                                                                                            |
| <b>file name original location node-id</b> | (Optional) Displays trace entries for a specific file for the designated node. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. |

|                                                 |                                                                                                                                                                                                           |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>location</b> { <b>all</b>   <i>node-id</i> } | (Optional) Displays ltrace entries for the designated node. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. The <b>all</b> keyword displays ltrace entries for all nodes. |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# show rib vpn-attributes

To display all VPN attributes installed in the Routing Information Base (RIB), use the **show rib vpn-attributes** command in EXEC mode.

**show rib [afi-all| ipv4| ipv6] vpn-attributes [summary] [standby]**

## Syntax Description

|                |                                                     |
|----------------|-----------------------------------------------------|
| <b>afi-all</b> | (Optional) Specifies all address families.          |
| <b>ipv4</b>    | (Optional) Specifies IP Version 4 address prefixes. |
| <b>ipv6</b>    | (Optional) Specifies IP Version 6 address prefixes. |
| <b>summary</b> | (Optional) Displays VPN attribute information.      |
| <b>standby</b> | (Optional) Displays standby information.            |

## Command Default

The default is IPv4 address prefixes.

## Command Modes

EXEC

This table describes the significant fields shown in the display.

**Table 151: show rib vpn-attributes Field Descriptions**

| Field              | Description                                                |
|--------------------|------------------------------------------------------------|
| Extended Community | Extended community added by the protocol clients           |
| Ref Count          | Number of routes referring to the same extended community. |
| MVPN Attribute     | Connector attribute added by BGP to support MVPNs.         |
| Ref Count          | Number of routes referring to the same extended community. |

# show rib vrf

To display all VRF table information in the Routing Information Base (RIB), use the **show rib vrf** command in EXEC mode.

**show rib vrf** {*vrf-name* | **all**} [**ipv4**] [**ipv6**] [**afi-all**] [**firsthop**] [**next-hop**] [**opaques**] [**protocols**] [**statistics** *name*]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                               |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                        |
| <b>firsthop</b>                             | (Optional) Specifies registered first-hop notification addresses                                  |
| <b>next-hop</b>                             | (Optional) Specifies registered next-hop notification addresses.                                  |
| <b>opaques</b>                              | (Optional) Specifies opaque data installed in the RIB.                                            |
| <b>protocols</b>                            | (Optional) Specifies registered protocols.                                                        |
| <b>statistics</b> <i>name</i>               | (Optional) Specifies RIB statistics for the given name.                                           |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| ipv4    | read       |

**Examples**

The following example shows output from the **show rib vrf all statistics** command:

```
RP/0/0/CPU0:router# show rib vrf all statistics
RP/0/0/CPU0:router#
```

**Related Commands**

| Command                                | Description               |
|----------------------------------------|---------------------------|
| <a href="#">show rib, on page 1388</a> | Displays RIB information. |

# show route

To display the current routes in the Routing Information Base (RIB), use the **show route** command in EXEC mode.

**show route** [**vrf** { *vrf-name* | **all** } ] [**afi-all** | **ipv4** | **ipv6** ] [**unicast** | **multicast** **topology** *topo-name* | **safi-all** ] [**protocol** [ *instance* ] | *ip-address* [ *mask* ] | *ip-address/prefix-length* ] [**standby**] [**detail**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                    |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                           |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes. This is the default.                                                                                                                                                                                                                                                                             |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                  |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes. This is the default.                                                                                                                                                                                                                                                                                  |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                     |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                                                                                                                                      |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                                                                                         |
| <i>protocol</i>                             | (Optional) Name of a routing protocol. If you specify a routing protocol, use one of the following keywords: <ul style="list-style-type: none"> <li>• <b>bgp</b></li> <li>• <b>eigrp</b></li> <li>• <b>isis</b></li> <li>• <b>ospf</b></li> <li>• <b>rip</b></li> <li>• <b>static</b></li> <li>• <b>local</b></li> <li>• <b>connected</b></li> </ul> |
| <b>instance</b>                             | (Optional) Number or name used to identify an instance of the specified protocol.                                                                                                                                                                                                                                                                    |
| <i>ip-address</i>                           | (Optional) Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                   |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mask</i>           | (Optional) Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted-decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address.</li> </ul> |
| <i>/prefix-length</i> | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value.                                                                                                                                                                                                                                                            |
| <b>standby</b>        | (Optional) Displays standby information.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>detail</b>         | (Optional) Displays detailed information for the specified prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Command Default**

If a **vrf** *vrf-name* is not specified, routes are displayed for the default IPv4 unicast VRF.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added.                                                                                                                                              |
| Release 3.3.0 | The <b>egrp</b> and <b>rip</b> keywords and <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                                                                                                                              |
| Release 3.4.0 | The <b>all</b> , <b>detail</b> , and <b>standby</b> keywords were added.                                                                                                                                                             |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword.                                                                                                                   |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |
| Release 4.0.1 | Fast re-route (FRR) backup-path information was added.                                                                                                                                                                               |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the **afi-all** keyword is used, the *ip-address* and *mask* arguments are not available.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route** command when entered without an address:

```
RP/0/0/CPU0:router# show route

Codes: C - connected, S - static, R - RIP, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local, G - DAGR
       A - access/subscriber, (!) - FRR Backup path

Gateway of last resort is 1.0.0.1 to network 0.0.0.0

S*   0.0.0.0/0 [1/0] via 1.0.0.1, 13:14:59
C    1.0.0.0/16 is directly connected, 13:14:59, MgmtEth0/5/CPU0/0
L    1.0.14.15/32 is directly connected, 13:14:59, MgmtEth0/5/CPU0/0
C    3.2.3.0/24 is directly connected, 00:04:39, GigabitEthernet0/3/0/0
L    3.2.3.2/32 is directly connected, 00:04:39, GigabitEthernet0/3/0/0
O E2 5.2.5.0/24 [110/20] via 3.3.3.1, 00:04:20, GigabitEthernet0/3/0/0
O E2 6.2.6.0/24 [110/20] via 3.3.3.1, 00:04:20, GigabitEthernet0/3/0/0
C    7.2.7.0/24 is directly connected, 00:04:20, GigabitEthernet0/3/0/7
L    7.2.7.2/32 is directly connected, 00:04:20, GigabitEthernet0/3/0/7
O E2 8.2.8.0/24 [110/20] via 3.3.3.1, 00:04:20, GigabitEthernet0/3/0/0

C    10.3.0.0/16 is directly connected, 13:14:59, GigabitEthernet0/0/0/0
L    10.3.0.2/32 is directly connected, 13:14:59, GigabitEthernet0/0/0/0
```

This table describes the significant fields shown in the display.

**Table 152: show route Field Descriptions**

| Field | Description                                                                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S*    | Code indicating how the route was derived. See the code legend preceding the output. In this case, the route was derived from a static (candidate default). |

| Field                   | Description                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| [1/0]                   | First number in the brackets is the administrative distance of the information source; the second number is the metric for the route.     |
| 1.0.0.0/16              | Address and prefix length of the remote network.                                                                                          |
| MgmtEthernet 0/5/CPU0/0 | Specifies the interface through which the specified network can be reached.                                                               |
| C                       | Code indicating how the route was derived. See the code legend preceding the output. In this case, the route was connected.               |
| L                       | Code indicating how the route was derived. See the code legend preceding the output. In this case, the route was local.                   |
| O                       | Code indicating how the route was derived. See the code legend preceding the output. In this case, the route was on-demand routing (ODR). |
| E2                      | Code indicating how the route was derived. See the code legend preceding the output. In this case, the route was OSPF external type 2.    |
| 8.2.8.0/24              | Address and prefix length of the remote network connected to the static route.                                                            |
| via 3.3.3.1             | Specifies the address of the next router to the remote network.                                                                           |
| 13:14:59                | Specifies the last time the route was updated.                                                                                            |
| (!)                     | Code indicating fast re-route (FRR) backup path information.                                                                              |

When you specify that you want information about a particular network, more detailed statistics are displayed. The following is sample output from the **show route** command when entered with an IP address:

```
RP/0/0/CPU0:router# show route 10.0.0.0

Routing entry for 10.0.0.0/16
  Known via "connected", distance 0, metric 0 (connected)
  Installed Mar 22 22:10:20.906
  Routing Descriptor Blocks
    directly connected, via GigabitEthernet0/0/0/0
      Route metric is 0
  No advertising protos.
```

Intermediate System-to-Intermediate System (IS-IS) includes an IP address typed length value (TLV) in its link-state packet (LSP) that helps identify the node injecting the route into the network. The IS-IS node uses one of its own interface addresses in this TLV. A loopback address is preferred among interfaces configured under IS-IS. When other networking devices calculate IP routes, they can store the IP address as the originator address with each route in the routing table.

The following example shows the output from the **show route** command for a specific IP address on a router configured with IS-IS. Each path that is shown under the Routing Descriptor Blocks report displays two IP addresses. The first address (10.0.0.9) is the next-hop address; the second is the originator IP address from the advertising IS-IS router.

```
RP/0/0/CPU0:router# show route 10.0.0.1

Routing entry for 10.0.0.0/8
  Known via "isis", distance 115, metric 10, type level-2
    Installed Jan 22 09:26:56.210
    Routing Descriptor Blocks:
      * 10.0.0.9, from 10.0.0.9, via GigabitEthernet2/1
        Route metric is 10
    No advertising protos.
```

This table describes the significant fields shown in the display.

**Table 153: show route with IP Address Field Descriptions**

| Field                      | Description                                                                                                                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing entry for          | Network address and mask.                                                                                                                                                                                                      |
| Known via                  | Indicates how the route was derived.                                                                                                                                                                                           |
| distance                   | Administrative distance of the information source.                                                                                                                                                                             |
| metric                     | Route value assigned by the routing protocol.                                                                                                                                                                                  |
| type                       | IS-IS type level.                                                                                                                                                                                                              |
| Routing Descriptor Blocks: | Displays the next-hop IP address followed by the information source.                                                                                                                                                           |
| from ... via ...           | First address is the next-hop IP address, and the other is the information source. This report is followed by the interface for this route.                                                                                    |
| Route metric               | Best metric for this Routing Descriptor Block.                                                                                                                                                                                 |
| No advertising protos.     | Indicates that no other protocols are advertising the route to their redistribution consumers. If the route is being advertised, protocols are listed in the following manner:<br><br>Redist Advertisers:<br>isis p<br>ospf 43 |

The following example illustrates the **show route** command with the **topology topo-name** keyword and argument specified:

```
RP/0/0/CPU0:router# show route ipv4 multicast topology green

Codes: C - connected, S - static, R - RIP, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local, G - DAGR
       A - access/subscriber, (!) - FRR Backup path

Gateway of last resort is not set

i L1 10.1.102.0/24 [115/20] via 10.1.102.41, 1w4d, GigabitEthernet0/1/0/0.1
i L1 10.3.3.0/24 [115/20] via 10.1.102.41, 1w4d, GigabitEthernet0/1/0/0.1
i L1 192.168.0.40/32 [115/20] via 10.1.102.41, 1w4d, GigabitEthernet0/1/0/0.1
```

This example is a sample **show route summary** command output that displays fast-reroute (FRR) Backup path information. The FRR Backup paths are indicated with a (!).

```
RP/0/0/CPU0:router#show route summary

Codes: C - connected, S - static, R - RIP, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local, G - DAGR
       A - access/subscriber, (!) - FRR Backup path

Gateway of last resort is not set

B 1.2.3.4/32 [200/0] via 10.10.1.3, 00:01:40

This example is a sample **show route detail** command output that displays path ID and backup-path ID information:

```

RP/0/0/CPU0:router#show route 10.1.1.3 detail
Routing entry for 10.1.1.16/32
  Known via "ospf 2", distance 110, metric 21, type intra area
  Installed Oct 28 16:07:05.752 for 00:01:56
  Routing Descriptor Blocks
    40.1.10.1, from 10.1.1.16, via Bundle-Ether10, Protected
      Route metric is 21
      Label: None
      Tunnel ID: None
      Extended communities count: 0
      Path id:2          Path ref count:0
      Backup path id:33
    200.40.1.101, from 10.1.1.16, via Bundle-Ether1.1, Protected
      Route metric is 21
      Label: None
      Tunnel ID: None
      Extended communities count: 0
      Path id:1          Path ref count:0
      Backup path id:33
    100.100.2.1, from 10.1.1.16, via TenGigE0/2/0/3.1, Backup
      Route metric is 0
      Label: None
      Tunnel ID: None
      Extended communities count: 0
      Path id:33          Path ref count:2
  Route version is 0xe (14)
  No local label
  IP Precedence: Not Set
  QoS Group ID: Not Set
  Route Priority: RIB_PRIORITY_NON_RECURSIVE_LOW (6) SVD Type RIB_SVD_TYPE_LOCAL
  No advertising protos.

# show route backup

To display backup routes from the Routing Information Base (RIB), use the **show route backup** command in EXEC mode.

**show route** [**vrf** {*vrf-name* | **all**}] [**afi-all** **ipv4** | **ipv6**] [**unicast** | **multicast**] {**topology** *topo-name*} [**safi-all**] **backup** [*ip-address* [*mask*] | *ip-address* / *prefix-length*] ][**standby**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>safi-all</b> safi-all                    | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>ip-address</i>                           | (Optional) Network IP address about which backup routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>mask</i>                                 | (Optional) Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are ones, and the corresponding bits of the address are the network address.</li> </ul> |
| <i>/prefix-length</i>                       | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value.                                                                                                                                                                                                                                                              |
| <b>standby</b>                              | (Optional) Displays standby information.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Command Default

If a **vrf** *vrf-name* is not specified, the backup routes from the RIB are displayed for the default IPv4 unicast VRF.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added.                        |
| Release 3.3.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                                                    |
| Release 3.4.0 | The <b>all</b> and <b>standby</b> keywords were added.                                                             |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route backup** command to display information about routes that have been installed into the RIB as backup routes. This command also displays information about the currently selected active route for which there is a backup.

When the **afi-all** keyword is used, the *ip-address* and *mask* arguments are not available.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route backup** command:

```
RP/0/0/CPU0:router# show route backup

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local
S      172.73.51.0/24 is directly connected, 2d20h, GigabitEthernet 4/0/0/1
      Backup O E2 [110/1] via 10.12.12.2, GigabitEthernet 3/0/0/1
```

This table describes the significant fields shown in the display.

**Table 154: show route backup Field Descriptions**

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |

# show route best-local

To display the best local address to use for return packets from the given destination, use the **show route best-local** command in EXEC mode.

**show route** [**vrf** {*vrf-name* | **all**}] [**ipv4**| **ipv6**] [**unicast**| **multicast**| {**topology** *topo-name*}| **safi-all**] **best-local** *ip-address* [ **standby**]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                               |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                    |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                   |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <i>ip-address</i>                           | IP address about which best local information should be displayed.                                |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If a **vrf** *vrf-name* is not specified, the best local address is displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route best-local** command to display information about the best local routes in the routing table.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

### Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

### Examples

The following is sample output from the **show route best-local** command:

```
RP/0/0/CPU0:router# show route best-local 10.12.12.1/32

Routing entry for 10.12.12.1/32
  Known via "local", distance 0, metric 0 (connected)
  Routing Descriptor Blocks
    10.12.12.1 directly connected, via GigabitEthernet3/0/0/1
    Route metric is 0
```

This table describes the significant fields shown in the display.

**Table 155: show route best-local Field Descriptions**

| Field                      | Description                                                          |
|----------------------------|----------------------------------------------------------------------|
| Routing entry for          | Identifies the requested IP address.                                 |

# show route connected

To display the current connected routes of the routing table, use the **show route connected** command in EXEC mode.

**show route** [**vrf** {*vrf-name*| **all**}] [**afi-all**| **ipv4**| **ipv6**] [**unicast**| **multicast**| {*topology topo-name*}| **safi-all**] **connected** [**standby**]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                        |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                               |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                    |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                   |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If a **vrf** *vrf-name* is not specified, the current connected routes of the routing table are displayed for the default IPv4 unicast VRF.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

## Command Modes

EXEC

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route connected** command to display information about connected routes in the routing table.

### Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

### Examples

The following is sample output from the **show route connected** command:

```
RP/0/0/CPU0:router# show route connected
C    1.68.0.0/16 is directly connected, 13:43:40, MgmtEth0/5/CPU0/0
C    3.3.3.0/24 is directly connected, 00:23:23, GigabitEthernet0/3/0/0
C    7.7.7.0/24 is directly connected, 00:33:00, GigabitEthernet0/3/0/7
C    10.0.0.0/16 is directly connected, 13:43:40, GigabitEthernet0/0/0/0
C    10.10.10.0/30 is directly connected, 13:43:40, Loopback0
C    11.11.11.0/24 is directly connected, 13:43:40, Loopback11
```

This table describes the significant fields shown in the display.

|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added.                        |
| Release 3.3.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                                                    |
| Release 3.4.0 | The <b>all</b> and <b>standby</b> keywords were added.                                                             |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route local** command to display information about local routes in the routing table.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route local** command:

```
RP/0/0/CPU0:router# show route local

L   10.10.10.1/32 is directly connected, 00:14:36, Loopback0
L   10.91.36.98/32 is directly connected, 00:14:32, GigabitEthernet6/0/0/1
L   172.22.12.1/32 is directly connected, 00:13:35, GigabitEthernet3/0/0/1
L   192.168.20.2/32 is directly connected, 00:13:27, GigabitEthernet4/0/0/1
L   10.254.254.1/32 is directly connected, 00:13:26, GigabitEthernet5/0/0/1
```

This table describes the significant fields shown in the display.

# show route longer-prefixes

To display the current routes in the Routing Information Base (RIB) that share a given number of bits with a given network, use the **show route longer-prefixes** command in EXEC mode.

**show route** [**vrf** {*vrf-name*| **all**}] [**ipv4**| **ipv6**] [**unicast**| **multicast**] {**topology** *topo-name*} [**safi-all**]  
**longer-prefixes** {*ip-address mask* | *ip-address/prefix-length*} [**standby**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>ip-address</i>                           | Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>mask</i>                                 | Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted-decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address.</li> </ul> |
| <i>/ prefix-length</i>                      | Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value.                                                                                                                                                                                                                                                            |
| <b>standby</b>                              | (Optional) Displays standby information.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Command Default

If a **vrf** *vrf-name* is not specified, the current routes in the RIB sharing a specified number of bits with a network are displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

**Command History**

| Release       | Modification                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added.                        |
| Release 3.3.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                                                    |
| Release 3.4.0 | The <b>all</b> and <b>standby</b> keywords were added.<br>The <b>afi-all</b> keyword was removed.                  |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route longer-prefixes** command to troubleshoot forwarding problems whose cause may be a long prefix.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route longer-prefixes** command:

```
RP/0/0/CPU0:router# show route longer-prefixes 172.16.0.0/8

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local

L   172.29.52.70/32 is directly connected, 4d15h, MgmtEth0/RP0/CPU0/0
L   172.29.52.71/32 is directly connected, 4d15h, MgmtEth0/RP1/CPU0/0
L   172.29.52.72/32 [0/0] via 172.29.52.72, 4d15h, MgmtEth0/RP0/CPU0/0
```

This table describes the significant fields shown in the display.

**Table 158: show route longer-prefixes Field Descriptions**

| Field                | Description                                                                  |
|----------------------|------------------------------------------------------------------------------|
| 172.29.52.70/32      | IP address and length of the route.                                          |
| 4d15h                | Time (in hh:mm:ss or <i>ndnh</i> ) since the route was installed in the RIB. |
| MgmtEth0/ RP0/CPU0/0 | Outbound interface for the route.                                            |

**Related Commands**

|--------------------------------------------------|-----------------------------------------------------------------------|
| router static                                    | Establishes a static route.                                           |
| show interfaces                                  | Lists interface information.                                          |
| <a href="#">show route summary, on page 1461</a> | Displays the current contents of the routing table in summary format. |

# show route next-hop

To filter routes by the next-hop address or interface, use the **show route next-hop** command in EXEC mode.

**show route** [**vrf** {*vrf-name*| **all**}] [**ipv4**| **ipv6**] [**unicast**| **multicast**| {**topology** *topo-name*}| **safi-all**] **next-hop** [*ip-address*][**[standby]**]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                               |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                    |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                   |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <i>ip-address</i>                           | (Optional) IP address about which next-hop information is to be displayed.                        |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If a **vrf** *vrf-name* is not specified, the next-hop gateway or host is displayed for the default IPv4 unicast VRF.

|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.4.0 | Function of this command was changed. See the <b>show route resolving-next-hop</b> command.                        |
| Release 3.5.0 | The <i>ip-address</i> argument was changed from required to optional.                                              |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route next-hop** command to find all routes going through a next-hop address or interface.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route next-hop** command filtering routes on the next-hop address:

```
RP/0/0/CPU0:router# show route next-hop 1.68.0.1

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
U - per-user static route, o - ODR, L - local

Gateway of last resort is 1.68.0.1 to network 0.0.0.0

S* 0.0.0.0/0 [1/0] via 1.68.0.1, 15:01:49
S 223.255.254.254/32 [1/0] via 1.68.0.1, 15:01:49
```

The following is sample output from the **show route next-hop** command filtering routes on the next-hop interface:

```
RP/0/0/CPU0:router# show route next-hop GigabitEthernet 0/1/0/2

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
U - per-user static route, o - ODR, L - local

Gateway of last resort is 1.68.0.1 to network 0.0.0.0

C 11.1.1.0/24 is directly connected, 15:01:46, GigabitEthernet0/1/0/2
L 11.1.1.2/32 is directly connected, 15:01:46, GigabitEthernet0/1/0/2
```

This table describes the significant fields shown in the display.

**Table 159: show route next-hop Field Descriptions**

| Field                  | Description                                                                  |
|------------------------|------------------------------------------------------------------------------|
| 11.1.1.0/24            | IP address and length of the route.                                          |
| 15:01:46               | Time (in hh:mm:ss or <i>ndnh</i> ) since the route was installed in the RIB. |
| GigabitEthernet0/1/0/2 | Outbound interface for the route.                                            |

# show route quarantined

To display mutually recursive (looping) routes, use the **show route quarantined** command in EXEC mode.

**show route** [**vrf** {*vrf-name* | **all**}] [**ipv4** | **ipv6**] [**unicast** | **multicast**] {**topology** *topo-name*} [**safi-all**] **quarantined** [*ip-address/prefix-length*] *ip-address mask* [**standby**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                         |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                                                                                                                                                                       |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                                                                                                                                                                       |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                                                                                                                                                            |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                                                                                                                                                          |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                                                                                                                                                           |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                                                                                                                                                              |
| <i>ip-address</i>                           | (Optional) IP address about which looping routes information is to be displayed.                                                                                                                                                          |
| <i>/ prefix-length</i>                      | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value. |
| <i>ip-address mask</i>                      | (Optional) Network mask applied to the <i>ip-address</i> argument.                                                                                                                                                                        |
| <b>standby</b>                              | (Optional) Displays standby information.                                                                                                                                                                                                  |

## Command Default

If a **vrf** *vrf-name* is not specified, the next-hop gateway or host is displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

| Release       | Modification                                                                                                |

| Release 3.6.0 | The <i>ip-address</i> argument was changed to <i>ip-address /prefix-length   ip-address mask</i> .          |
| Release 3.7.0 | The <b>topology topo-name</b> keyword and argument were added as options from the <b>multicast</b> keyword. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

RIB quarantining detects mutually recursive routes and quarantines the last route that actually completes the mutual recursion. The quarantined route is periodically evaluated to see if the mutual recursion has gone away. If the recursion still exists, the route remains quarantined. If the recursion has gone away, the route is released from quarantine.

Use the **show route quarantined** command to display mutually recursive (looping) routes.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

### Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

### Examples

The following is sample output from the **show route quarantined** command:

```
RP/0/0/CPU0:routerr# show route quarantined

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - ISIS, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, su - IS-IS summary null, * - candidate default
       U - per-user static route, o - ODR, L - local

S    10.10.109.1/32 [1/0] via 10.10.34.1, 00:00:01 (quarantined)
                        [1/0] via 10.10.37.1, 00:00:01 (quarantined)
                        [1/0] via 10.10.60.1, 00:00:01 (quarantined)

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route resolving-next-hop** command to perform a recursive route lookup on the supplied destination address and return information on the next immediate router (next hop) to the destination.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

### Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

### Examples

The following is sample output from the **show route resolving-next-hop** command:

```
RP/0/0/CPU0:router# show route resolving-next-hop 10.1.1.1
Nexthop matches 10.1.1.1/32
  Known via "local", distance 0, metric 0 (connected)
  Installed Aug 22 01:57:08.514
  Directly connected nexthops
    10.1.1.1 directly connected, via Loopback0
    Route metric is 0
```

This table describes the significant fields shown in the display.

**Table 161: show route resolving-next-hop Field Descriptions**

| Field           | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| Known via       | Name of the routing protocol that installed the matching route. |
| Route metric is | Metric of the route.                                            |

**Related Commands**

| Command                                  | Description                                         |
|------------------------------------------|-----------------------------------------------------|
| <a href="#">show route, on page 1428</a> | Displays the current contents of the routing table. |

# show route static

To display the current static routes of the Routing Information Base (RIB), use the **show route static** command in EXEC mode.

**show route** [**vrf** {*vrf-name* | **all**}] [**afi-all** | **ipv4** | **ipv6**] [**unicast** | **multicast** | {**topology** *topo-name*}] **safi-all** **static** [**standby**]

## Syntax Description

|                                             |                                                                                                   |
|---------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
| <b>afi-all</b>                              | (Optional) Specifies all address families.                                                        |
| <b>ipv4</b>                                 | (Optional) Specifies IP Version 4 address prefixes.                                               |
| <b>ipv6</b>                                 | (Optional) Specifies IP Version 6 address prefixes.                                               |
| <b>unicast</b>                              | (Optional) Specifies unicast address prefixes.                                                    |
| <b>multicast</b>                            | (Optional) Specifies multicast address prefixes.                                                  |
| <b>topology</b> <i>topo-name</i>            | (Optional) Specifies topology table information and name of the topology table.                   |
| <b>safi-all</b>                             | (Optional) Specifies unicast and multicast address prefixes.                                      |
| <b>standby</b>                              | (Optional) Displays standby information.                                                          |

## Command Default

If a **vrf** *vrf-name* is not specified, the current static routes of the RIB are displayed for the default IPv4 unicast VRF.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>afi-all</b> and <b>safi-all</b> keywords were added.                        |
| Release 3.3.0 | The <b>vrf</b> <i>vrf-name</i> keyword and argument were added.                                                    |
| Release 3.4.0 | The <b>all</b> and <b>standby</b> keywords were added.                                                             |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route static** command to display information about static routes in the routing table.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

**Task ID**

| Task ID | Operations |
|---------|------------|
| rib     | read       |

**Examples**

The following is sample output from the **show route static** command:

```
RP/0/0/CPU0:router# show route static

S    10.1.1.0/24 is directly connected, 00:54:05, GigabitEthernet3/0/0/1
S    192.168.99.99/32 [1/0] via 10.12.12.2, 00:54:04
```

This table describes the significant fields shown in the display.

**Table 162: show route static Field Descriptions**

| Field                  | Description                                                  |
|------------------------|--------------------------------------------------------------|
| S                      | Code to indicate the route is static.                        |
| 10.1.1.0/24            | IP address and distance for the route.                       |
| 00:54:05               | Time (in hh:mm:ss) since the route was installed in the RIB. |
| GigabitEthernet3/0/0/1 | Outbound interface for the route.                            |
| [1/0]                  | Distance and metric for the route.                           |

|---------------|--------------------------------------------------------------------------------------------------------------------|
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added as options from the <b>multicast</b> keyword. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show route summary** command to display information about routes in the routing information base.

When a route summary is needed frequently—for instance, in a polling situation—use the **show route summary** command without the **detail** keyword. The **detail** keyword is used less frequently for verification purposes, because it is much more expensive (in bandwidth), requiring a scan of the entire routing database.

The **topology** keyword must be accompanied by the **ipv4 multicast** keywords, except when the **afi-all** keyword or the **safi-all** keyword is specified.

### Task ID

| Task ID | Operations |
|---------|------------|
| rib     | read       |

### Examples

The following is sample output from the **show route summary** command:

```
RP/0/0/CPU0:router# show route summary

Route Source    Routes    Backup    Deleted    Memory (bytes)
static          1         0         0          136
connected       2         1         0          408
local           3         0         0          408
ospf            1673      2         0          272
isis            2         0         0          272
Total           10        1         0          1496
```

This table explains fields in the output of the **show route summary** command.

**Table 163: show route summary Field Descriptions**

| Field        | Description                                                                            |
|--------------|----------------------------------------------------------------------------------------|
| Route Source | Routing protocol name.                                                                 |
| Routes       | Number of selected routes that are present in the routing table for each route source. |
| Backup       | Number of routes that are not selected (are backup to a selected route).               |

| Field   | Description                                                                                   |
|---------|-----------------------------------------------------------------------------------------------|
| Deleted | Number of routes that have been marked for deletion in the RIB, but have not yet been purged. |
| Memory  | Number of bytes allocated to maintain all routes for the particular route source.             |

The following is sample output from the **show route summary** command with the **detail** keyword:

```
RP/0/0/CPU0:router# show route summary detail
```

| Route Source | Active Route | Active Path | Backup Route | Backup Path |
|--------------|--------------|-------------|--------------|-------------|
| static       | 1            | 1           | 0            | 0           |
| connected    | 2            | 2           | 1            | 1           |
| local        | 3            | 3           | 0            | 0           |
| isis         | 1            | 1           | 1            | 1           |
| Level 1:     | 0            | 0           | 1            | 1           |
| Level 2:     | 1            | 1           | 0            | 0           |
| ospf 1673    | 6            | 12          | 0            | 0           |
| Intra-Area:  | 3            | 6           | 0            | 0           |
| Inter-Area:  | 3            | 6           | 0            | 0           |
| External-1:  | 0            | 0           | 0            | 0           |
| External-2:  | 0            | 0           | 0            | 0           |
| bgp 100      | 10           | 20          | 4            | 8           |
| External:    | 5            | 10          | 4            | 8           |
| Internal:    | 5            | 10          | 0            | 0           |
| local:       | 0            | 0           | 0            | 0           |
| Total        | 7            | 7           | 2            | 2           |

This table explains fields in the output of the **show route summary detail** command.

**Table 164: show route summary detail Field Descriptions**

| Field        | Description                                                                 |
|--------------|-----------------------------------------------------------------------------|
| Route Source | Source of the route. Routing protocol name and type.                        |
| Active Route | Number of active routes present in the routing table for each route source. |
| Active Path  | Number of active paths present in the routing table for each route source.  |
| Backup Route | Number of routes that are backup to a selected route for each route source. |
| Backup Path  | Number of paths that are backup to a selected path for each route source.   |

## authentication keychain mode (RIP)

To enable an authentication keychain mechanism on RIP interfaces, use the **authentication keychain mode** command in interface configuration mode or VRF-interface configuration mode. To disable authentication keychain configuration on RIP interfaces, use the **no** form of this command.

**authentication keychain keychain\_name mode {md5| text}**

**no authentication keychain keychain\_name mode {md5| text}**

### Syntax Description

|                      |                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>keychain-name</i> | Specifies the name of the keychain configured using the keychain command.<br><b>Note</b> All keychains need to be configured in Cisco IOS XR keychain database using the keychain configuration commands described in <i>Implementing Keychain Management</i> module of <i>Cisco IOS XR System Security Configuration Guide for the Cisco XR 12000 Series Router</i> |
| <b>md5</b>           | Specifies that the authentication keychain mode is keyed message digest (md5).                                                                                                                                                                                                                                                                                       |
| <b>text</b>          | Specifies that the authentication keychain mode is clear text.                                                                                                                                                                                                                                                                                                       |

### Command Default

Keychain authentication is disabled.

### Command Modes

Interface configuration  
VRF-interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

All keychains need to be configured in Cisco IOS XR keychain database using the keychain configuration commands described in *Implementing Keychain Management* module of *Cisco IOS XR System Security Configuration Guide for the Cisco XR 12000 Series Router*

### Task ID

| Task ID | Operation   |
|---------|-------------|
| rip     | read, write |

## Examples

This example shows how to configure an authentication keychain in md5 mode on a RIP VRF interface:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router rip
RP/0/0/CPU0:router(config-rip)#vrf vrf_rip_auth
RP/0/0/CPU0:router(config-rip-vrf)#interface POS 0/6/0/0
RP/0/0/CPU0:router(config-rip-vrf-if)#authentication keychain key1 mode md5
```

This example shows how to configure an authentication keychain in clear text mode on a RIP interface:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router rip
RP/0/0/CPU0:router(config-rip)#interface POS 0/6/0/1
RP/0/0/CPU0:router(config-rip-if)#authentication keychain key2 mode text
```

## auto-summary (RIP)

To enable the automatic summarization of subnet routes into network-level routes, use the **auto-summary** command in the appropriate configuration mode. To disable this function and send subprefix routing information across classful network boundaries, use the **no** form of this command.

**auto-summary**

**no auto-summary**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                        |          |
|------------------------|----------|
| <b>Command Default</b> | Disabled |
|------------------------|----------|

|                      |                                           |
|----------------------|-------------------------------------------|
| <b>Command Modes</b> | Router configuration<br>VRF configuration |
|----------------------|-------------------------------------------|

| <b>Command History</b> | Release       | Modification                 |
|------------------------|---------------|------------------------------|
|                        | Release 3.3.0 | This command was introduced. |

|                         |                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Use the **auto-summary** command to turn on route summarization. Route summarization reduces the amount of routing information in the routing tables.

Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is off, subnets are advertised. Automatic summarization is disabled by default.

| <b>Task ID</b> | Task ID | Operations  |
|----------------|---------|-------------|
|                | rip     | read, write |

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to turn on RIP auto-summarization: |
|-----------------|--------------------------------------------------------------------|

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip)# auto-summary
```

**Related Commands**

| Command                                                  | Description                                               |
|----------------------------------------------------------|-----------------------------------------------------------|
| <a href="#">vrf (RIP)</a> , <a href="#">on page 1535</a> | Defines a VRF instance and enters VRF configuration mode. |

# broadcast-for-v2

To send Routing Information Protocol (RIP) Version 2 output packets to a broadcast address, use the **broadcast-for-v2** command in the appropriate configuration mode. To disable this feature, use the **no** form of this command.

**broadcast-for-v2**

**no broadcast-for-v2**

**Syntax Description** This command has no arguments or keywords.

**Command Default** RIPv2 output packets are not broadcasted.

**Command Modes**

- Router configuration
- VRF configuration
- Interface configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **broadcast-for-v2** command to broadcast RIP Version 2 broadcast updates to hosts that do not listen to multicasts. Version 2 updates (requests and responses) will be sent to the IP broadcast address 255.255.255.255 instead of the IP multicast address 244.0.0.9.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rip     | read, write |

**Examples** The following example shows how to send RIP v2 output messages to a broadcast address for all RIP interfaces:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# broadcast-for-v2
```

# clear rip

To clear VRF and interface-related information for Routing Information Protocol (RIP) such as database entries and statistics, use the **clear rip** command in EXEC mode.

**clear rip** [**vrf** {*vrf* | **all**}]

## Syntax Description

|                                        |                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
|----------------------------------------|---------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

RIP VRFs and interfaces that are forcibly deactivated by the software because of a severe memory state are not activated again until the out-of-memory state is cleared by using the **clear rip** , **clear rip interface** , or **clear rip out-of-memory** command.

## Task ID

| Task ID | Operations |
|---------|------------|
| rip     | read       |

## Examples

The following example shows how to clear all database, interface, and VRF entries in RIP:

```
RP/0/0/CPU0:routerr# clear rip vrf all
```

**Related Commands**

# clear rip database

To clear only database entries from the Routing Information Protocol (RIP) topology table, use the **clear rip database** command in EXEC mode.

**clear rip** [*vrf {vrf | all}*] **database** [*interface type interface-path-id*]

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                 |
| <b>interface</b>                       | (Optional) Specifies the interface to clear topology entries.                                                                                                                                                                                                                     |

| <i>interface-path-id</i>               | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

RIP VRFs and interfaces that are forcibly deactivated by the software because of a severe memory state are not activated again until after out-of-memory state is cleared by using the **clear rip** , **clear rip interface** or **clear rip out-of-memory** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to clear all interface-related data such as routes and statistics from the GigabitEthernet 0/1/0/0 interface:

```
RP/0/0/CPU0:router# clear rip vrf vpn-1 interface GigabitEthernet 0/1/0/0
```

# clear rip out-of-memory

To clear the out-of-memory state for Routing Information Protocol (RIP), use the **clear rip out-of-memory** command in EXEC mode.

**clear rip** [*vrf {vrf | all}*] **out-of-memory** [*interface type interface-path-id*]

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                 |
| <b>interface</b>                       | (Optional) Specifies the interface to clear topology entries.                                                                                                                                                                                                                     |

|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear rip out-of-memory** command, to clear the out-of-memory state completely and allow the RIP process to force the VRF or interface to shut down.

When the router begins to run out of memory, the RIP process can transition through different memory states defined as Normal, Minor, Severe, and Critical:

- In Normal state, RIP VRFs and interfaces function normally.

- In Minor state, RIP VRFs and interfaces that are currently active are allowed to remain active. VRFs and interfaces that are not currently active are not allowed to become active until the RIP process transitions to Normal state.
- In Severe state, a few VRFs and interfaces are forcibly brought down periodically until the RIP process transitions to another state.
- In Critical state, the RIP process is forcibly shut down.

VRFs and interfaces that are forcibly shut down in Severe state are not automatically activated when the RIP process transitions to Minor or Normal state. When a VRF or interface is forcibly brought down while in Severe state, the **clear rip**, **clear rip interface** or **clear rip out-of-memory** command clears the Forced Down state and reactivates the VRF or interface.

The **show rip** and **show rip interface** commands allow you to view the current out-of-memory state.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to clear the out-of-memory state for a RIP process:

```
RP/0/0/CPU0:router# clear rip out-of-memory
```

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to originate a default route in RIP updates based on the result of running the route policy on the routing table:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# default-information originate route-policy policy1
```

**Related Commands**

| Command                                           | Description                                                                        |
|---------------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">route-policy (RIP)</a> , on page 1509 | Applies a routing policy to updates advertised to or received from a RIP neighbor. |

## default-metric (RIP)

To set default metric values for routes redistributed from other protocols into Routing Information Protocol (RIP), use the **default-metric** command in the appropriate configuration mode. To return to the default state, use the **no** form of this command.

**default-metric** *number-value*

**no default-metric**

| Syntax Description | <i>number-value</i> | Default metric value. Range is 1 to 15. |
|--------------------|---------------------|-----------------------------------------|
|--------------------|---------------------|-----------------------------------------|

| Command Default | Default metrics are not set. |
|-----------------|------------------------------|
|-----------------|------------------------------|

| Command Modes | Router configuration<br>VRF configuration |
|---------------|-------------------------------------------|
|---------------|-------------------------------------------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

| Usage Guidelines | To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Use the **default-metric** command with the **redistribute** command to cause RIP to use the same metric value for all redistributed routes. A default metric helps solve the problem of redistributing routes with incompatible metrics by providing a reasonable substitute and enables redistribution to proceed. If you want to set different metrics for other redistributed protocols, use the **route-policy** option in the **redistribute** command.

The RIP metric used for redistributed routes is determined by the route policy. If a route policy is not configured or the route policy does not set the RIP metric, the metric is determined based on the redistributed protocol. For VPNv4 routes redistributed by BGP, the RIP metric set at the remote PE router is used, if valid.

In all other cases (BGP, IS-IS, OSPF, EIGRP, connected, static), the metric set by the **default-metric** command is used. If a valid metric cannot be determined, then redistribution does not happen.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rip     | read, write |

## Examples

The following example shows how a router in autonomous system 109 uses both the RIP and the Open Shortest Path First (OSPF) routing protocols. The example advertises OSPF-derived routes using RIP and assigns the OSPF-derived routes a RIP metric of 10:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# vrf vpn-1
RP/0/0/CPU0:router(config-rip-vrf)# default-metric 10
RP/0/0/CPU0:router(config-rip-vrf)# redistribute ospf 109
```

## Related Commands

| Command                                          | Description                                            |
|--------------------------------------------------|--------------------------------------------------------|
| <a href="#">redistribute (RIP), on page 1503</a> | Redistributes routes from one routing domain into RIP. |

## distance (RIP)

To define the administrative distance assigned to routes discovered by the Routing Information Protocol (RIP), use the **distance admin-distance** command in the appropriate configuration mode. To remove the distance definition from the configuration file and restore the system to its default condition, use the **no** form of this command.

**distance** *admin-distance* [*prefix prefix-length* | *prefix mask*]

**no distance** *admin-distance*

### Syntax Description

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>admin-distance</i> | Administrative distance to be assigned to RIP routes. Range is 0 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>prefix</i>         | (Optional) Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>prefix-length</i>  | (Optional) The <i>prefix-length</i> argument specifies the length of the IP prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value. Range is 0 to 32 for IPv4 addresses.                                                                                                                                                                                 |
| <i>mask</i>           | (Optional) Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 shows that the first 8 bits of the mask are ones, and the corresponding bits of the address are the network address.</li> </ul> |

### Command Default

| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **distance** command to change the preference of RIP routes over other protocol routes. When administrative distance and redistribution features are used together, routing behavior may be affected for routes accepted from and advertised to RIP neighbors.

Numerically, an administrative distance is an integer from 0 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means that the routing information source cannot be trusted at all and should be ignored.

The order in which you enter distance commands can affect the assigned administrative distances in unexpected ways.

This table lists default administrative distances.

**Table 165: Default Administrative Distances of Routing Protocols**

| Routing Protocol              | Administrative Distance Value |
|-------------------------------|-------------------------------|
| Connected interface           | 0                             |
| Static route out an interface | 0                             |
| Static route to next-hop      | 1                             |
| EIGRP Summary Route           | 5                             |
| External BGP                  | 20                            |

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to set the administrative distance for a particular prefix:

```
RP/0/0/CPU0:router(config)# router rip
```

```
RP/0/0/CPU0:router(config-rip)# distance 85 192.168.10.0/24
```

**Related Commands**

| Command                                           | Description                                            |

# interface (RIP)

To define the interfaces on which the Routing Information Protocol (RIP) runs and enter interface configuration mode, use the **interface** command in router configuration mode. To disable RIP routing for interfaces, use the **no** form of this command.

**interface** *type interface-path-id*

**no interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>              | Interface type. | <i>interface-path-id</i> | Physical interface or a virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

## Command Default

When you do not specify this command in configuration mode, RIP routing for interfaces is not enabled.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **interface** command to associate a specific interface with a RIP process. The interface remains associated with the process even when the IPv4 address of the interface changes.

This command places the router in interface configuration mode, from which you can configure interface-specific settings. Commands configured under this mode (such as the [broadcast-for-v2](#), on page 1471 command) are automatically bound to that interface.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

**Examples**

The following example shows how to enter interface configuration mode for a RIP process, and send RIP Version 2 messages to the broadcast address on the GigabitEthernet interface 0/1/0/0:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# ?

broadcast-for-v2    Specify broadcast address for RIP v2 output packet
commit             Commit the configuration changes to running
describe           Describe a command without taking real actions
do                 Run an exec command
exit               Exit from this submode
metric-zero-accept Accept rip update with metric 0 to compensate a common bug
no                 Negate a command or set its defaults
passive-interface  Suppress routing updates on this interface
poison-reverse     Enable poison reverse
receive            Advertisement reception
route-policy       Apply route policy to routing updates
send               Advertisement transmission
show               Show contents of configuration
site-of-origin     SOO community for prefixes learned over this interface
split-horizon      Disable split horizon
RP/0/0/CPU0:router(config-rip-if)# broadcast-for-v2
```

**Related Commands**

| Command                                        | Description                                                |
|------------------------------------------------|------------------------------------------------------------|
| <a href="#">broadcast-for-v2, on page 1471</a> | Sends RIP Version 2 output packets to a broadcast address. |

## maximum-paths (RIP)

To configure the maximum number of equal cost parallel routes that the Routing Information Protocol (RIP) will install into the routing table, use the **maximum-paths** command in the appropriate configuration mode. To remove the **maximum-paths** command from the configuration file and restore the system to its default condition with respect to RIP, use the **no** form of this command.

**maximum-paths** *maximum*

**no maximum-paths**

### Syntax Description

|         |                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------|
| maximum | Maximum number of parallel routes that RIP can install in a routing table. Range is . Range is 1 to 16. |
|---------|---------------------------------------------------------------------------------------------------------|

### Command Default

4 paths

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to allow a maximum of 16 equal cost paths to a destination:

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip)# maximum-paths 16
```

# metric-zero-accept

To allow RIP to accept routing entries from RIP updates with a metric set to zero (0), use the **metric-zero-accept** command in interface configuration mode. To remove the **metric-zero-accept** command from the configuration file and restore the system to its default condition with respect to RIP, use the **no** form of this command.

**metric-zero-accept**

**no metric-zero-accept**

## Syntax Description

This command has no arguments or keywords.

## Command Default

RIP routes received with a metric of zero (0) are ignored.

## Command Modes

Interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

After the **metric-zero-accept** command is configured on routing entries from RIP updates, RIP accepts these routes and then sets the metric to one (1).

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to set the RIP interface to accept metric zero on routing entries:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# metric-zero-accept
```

## neighbor (RIP)

To define a neighboring router with which to exchange Routing Information Protocol (RIP) information, use the **neighbor** command in the appropriate configuration mode. To remove an entry, use the **no** form of this command.

**neighbor** *ip-address*

**no neighbor** *ip-address*

### Syntax Description

|            |                                                                          |
|------------|--------------------------------------------------------------------------|
| ip-address | IP address of a peer router with which routing information is exchanged. |
|------------|--------------------------------------------------------------------------|

### Command Default

No neighboring routers are defined.

### Command Modes

Router configuration

VRF configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **neighbor** command to permit the point-to-point (nonbroadcast) exchange of routing information. When the **neighbor** command is used in combination with the **passive-interface** command in router configuration mode, routing information can be exchanged between a subset of routers and access servers on a LAN.

Multiple **neighbor** commands can be used to specify additional neighbors or peers.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to permit the sending of RIP updates to specific neighbors. One copy of the update is generated per neighbor:

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip)# vrf vpn-1  
RP/0/0/CPU0:router(config-rip-vrf)# neighbor 172.16.1.2
```

## Related Commands

| Command                                                | Description                                            |
|--------------------------------------------------------|--------------------------------------------------------|

## nsf (RIP)

To configure nonstop forwarding (NSF) on Routing Information Protocol (RIP) routes after a RIP process shutdown or restart, use the **nsf** command in the appropriate configuration mode. To remove this command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**nsf**

**no nsf**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                        |                  |
|------------------------|------------------|
| <b>Command Default</b> | NSF is disabled. |
|------------------------|------------------|

|                      |                                           |
|----------------------|-------------------------------------------|
| <b>Command Modes</b> | Router configuration<br>VRF configuration |
|----------------------|-------------------------------------------|

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | Release 3.3.0  | This command was introduced. |

|                         |                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

When you use the **nsf** command, NSF lifetime is automatically set to two times the update time (with a minimum value of 60 seconds). The RIP process must reconverge within this time. If the convergence exceeds the NSF lifetime, routes are purged from the Routing Information Base (RIB) and NSF may fail.

| <b>Task ID</b> | <b>Task ID</b> | <b>Operations</b> |
|----------------|----------------|-------------------|
|                | rip            | read, write       |

|                 |                                                       |
|-----------------|-------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure RIP NSF: |
|-----------------|-------------------------------------------------------|

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# vrf vpn-1
RP/0/0/CPU0:router(config-rip-vrf)# nsf
```

# output-delay

To change the interpacket delay for Routing Information Protocol (RIP) updates sent, use the **output-delay** command in the appropriate configuration mode. To remove the delay, use the **no** form of this command.

**output-delay** *delay*

**no output-delay** *delay*

## Syntax Description

|       |                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------|
| delay | Delay (in milliseconds) between consecutive packets in a multiple-packet RIP update. The range is from 8 to 50. |
|-------|-----------------------------------------------------------------------------------------------------------------|

## Command Default

The default is no delay.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **output-delay** command if you are sending at high speed to a low-speed router that might not be able to receive at the high speed. Configuring this command helps prevent the routing table from losing information.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to set the interpacket delay to 10 milliseconds:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# vrf vpn-1
RP/0/0/CPU0:router(config-rip-vrf)# output-delay 10
```

# passive-interface (RIP)

To suppress the sending of Routing Information Protocol (RIP) updates on an interface, use the **passive-interface** command in interface configuration mode. To unsuppress updates, use the **no** form of this command.

**passive-interface**  
**no passive-interface**

**Syntax Description** This command has no arguments or keywords.

**Command Default** RIP updates are sent on the interface.

**Command Modes** Interface configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

While RIP stops sending routing updates to the multicast (or broadcast) address on a passive interface, RIP continues to receive and process routing updates from its neighbors on that interface.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rip     | read, write |

**Examples** The following example shows that GigabitEthernet interface 0/1/0/0 stops multicasting (or broadcasting) RIP updates while continuing to receive RIP updates normally. GigabitEthernet interface 0/1/0/3 sends and receives updates normally. Also RIP updates are unicast to neighbor 172.168.1.2 over the appropriate interface:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# neighbor 172.16.1.2
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# passive-interface
RP/0/0/CPU0:router(config-rip-if)# exit
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/3
RP/0/0/CPU0:router(config-rip-if)# exit
```

**Related Commands**

| Command                                       | Description                                                                   |
|-----------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">neighbor (RIP)</a> , on page 1493 | Defines a neighboring router with which to exchange RIP protocol information. |

# poison-reverse

To enable poison reverse processing of Routing Information Protocol (RIP) router updates, use the **poison-reverse** command in interface configuration mode. To disable poison reverse processing of RIP updates, use the **no** form of this command.

**poison-reverse**

**no poison-reverse**

## Syntax Description

This command has no arguments or keywords.

## Command Default

Poison reverse processing is disabled.

## Command Modes

Interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Route poisoning prevents routing loops by communicating to other routers that a route is no longer reachable, effectively removing these routes from other router's routing tables. The system default, **split horizon**, provides that routes learned through RIP are not advertised from the interface over which they were learned.

The **poison-reverse** command enables poison reverse processing of RIP router updates. A router that receives route poisoning information sends the poisoning information back to the sending router, a process called poison reverse. This process ensures that all routers on the same interface have received the poisoned route information.

If both **poison-**reverse and split horizon are configured, then simple split horizon behavior (suppression of routes from the interface over which they were learned) is replaced by poison reverse behavior. If split horizon is disabled, the poison reverse configuration is ignored.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to enable poison reverse processing for an interface running RIP:

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0  
RP/0/0/CPU0:router(config-rip-if)# poison-reverse
```

## Related Commands

| Command                                                    | Description                           |
|------------------------------------------------------------|---------------------------------------|
| <a href="#">split-horizon disable (RIP)</a> , on page 1530 | Disables the split horizon mechanism. |

## receive version

To configure the Routing Information Protocol (RIP) interface to accept version-specific packets, use the **receive version** command in interface configuration mode. To revert to the default setting, use the **no** form of this command.

**receive version** {1| 2| 1 2}

**no receive version** {1| 2| 1 2}

### Syntax Description

|     |                                |
|-----|--------------------------------|
| 1   | Version 1 packets.             |
| 2   | Version 2 packets.             |
| 1 2 | Both versions 1 and 2 packets. |

### Command Default

Version 2

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **receive version** command to override the default behavior of RIP. This command applies only to the interface being configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to configure an interface to accept both RIP Version 1 and 2 packets:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# receive version 1 2
```

**Related Commands**

| <a href="#">send version, on page 1511</a> | Configures the RIP interface to send version specific packets. |

# redistribute (RIP)

To redistribute routes from another routing domain into Routing Information Protocol (RIP), use the **redistribute** command in the appropriate configuration mode. To remove the **redistribute** command from the configuration file and restore the system to its default condition in which the software does not redistribute routes, use the **no** form of this command.

## Border Gateway Protocol (BGP)

**redistribute** *bgp process-id* [*route-policy name*] [*external*| *internal*| *local*]

**no redistribute** *bgp process-id*

## Connected Interface Routes

**redistribute** *connected* [*route-policy name*]

**no redistribute** *connected*

## Enhanced Interior Gateway Routing Protocol (EIGRP)

**redistribute** *eigrp process-id* [*route-policy name*]

**no redistribute** *eigrp process-id*

## Intermediate System-to-Intermediate System (ISIS)

**redistribute** *isis process-id* [*route-policy name*] [*level-1*| *level-1-2*| *level-2*]

**no redistribute** *isis process-id*

## Open Shortest Path First (OSPF)

**redistribute** *ospf process-id* [*route-policy name*] [*match* {*external* [*1*| *2*]| *internal*| *nssa-external* [*1*| *2*]}]

**no redistribute** *ospf process-id*

## IP Static Routes

**redistribute** *static* [*route-policy name*]

**no redistribute** *static*

### Syntax Description

|            |                                           |
|------------|-------------------------------------------|
| <i>bgp</i> | Distributes routes from the BGP protocol. |
|------------|-------------------------------------------|

---

process-id

- For the **bgp** keyword:
  - Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.
  - Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.
  - Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.
- For the **eigrp** keyword, an EIGRP instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.
- For the **isis** keyword, an IS-IS instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.
- For the **ospf** keyword, an OSPF instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.

---

|                                 |                                                                                                                                                            |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| external                        | (Optional) Specifies BGP external routes only.                                                                                                             |
| internal                        | (Optional) Specifies BGP internal routes only.                                                                                                             |
| local                           | (Optional) Specifies BGP local routes only.                                                                                                                |
| <b>route-policy</b> <i>name</i> | (Optional) Specifies the identifier of a configured policy. A policy is used to filter the importation of routes from this source routing protocol to RIP. |
| level-1                         | (Optional) Redistributes Level 1 IS-IS routes into other routing protocols independently.                                                                  |
| level-1-2                       | (Optional) Distributes both Level 1 and Level 2 IS-IS routes into other routing protocols.                                                                 |
| level-2                         | (Optional) Distributes Level 2 IS-IS routes into other routing protocols independently.                                                                    |

---

[ **match** { **external** [ **1** | **2** ] | **internal** | **nssa-external** [ **1** | **2** ] } [ **route-policy** *name* ]

(Optional) Specifies the criteria by which OSPF routes are redistributed into other routing domains. It can be one or more of the following:

- **internal** —Routes that are internal to a specific autonomous system (intra- and inter-area OSPF routes).
- **external** [ **1** | **2** ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 external routes.
- **nssa-external** [ **1** | **2** ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 not-so-stubby area (NSSA) external routes.

For the external and nssa-external options, if a type is not specified, then both Type 1 and Type 2 are assumed.

If no match is specified, the default is no filtering.

|        |                                 |
|--------|---------------------------------|
| static | Redistributes IP static routes. |
|--------|---------------------------------|

#### Command Default

Route redistribution is disabled.

#### Command Modes

Router configuration  
VRF configuration

#### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.5.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

#### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

When you are redistributing routes (into RIP) using both command keywords for setting or matching of attributes and a route policy, the routes are run through the route policy first, followed by the keyword matching and setting.

Redistributed routing information may be filtered by the **route-policy** *name* keyword and argument. This filtering ensures that only those routes intended by the administrator are redistributed by RIP.

The RIP metric used for redistributed routes is determined by the route policy. If a route policy is not configured or the route policy does not set the RIP metric, the metric is determined based on the redistributed protocol. For VPNv4 routes redistributed by BGP, the RIP metric set at the remote PE router is used, if valid.

In all other cases (BGP, IS-IS, OSPF, EIGRP, connected, static), the metric set by the **default-metric** command is used. If a valid metric cannot be determined, then redistribution does not happen.

For information about routing policies, see the *Routing Policy Commands on Cisco IOS XR Software* module of the *Cisco IOS XR Routing Command Reference*.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to cause BGP routes to be redistributed into a RIP process:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# redistribute bgp 100
```

# router rip

To configure a routing process and enter router configuration mode for a Routing Information Protocol (RIP) process, use the **router rip** command in global configuration mode. To turn off the RIP routing process, use the **no** form of this command.

**router rip**

**no router rip**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No router process is defined.

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rip     | read, write |

**Examples** The following example shows how to configure a router process for RIP:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)#
```

The following example shows how to enter router configuration mode for RIP and identify commands that can be issued from that mode.

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# ?

auto-summary          Enable automatic network number summarization
broadcast-for-v2       Send RIP v2 output packets to broadcast address
commit                Commit the configuration changes to running
```

|                        |                                                        |
|------------------------|--------------------------------------------------------|
| default-information    | Control distribution of default information            |
| default-metric         | Set metric of redistributed routes                     |
| describe               | Describe a command without taking real actions         |

| timers                 | Adjust routing timers                                  |
| validate-update-source | Validate source address of routing updates             |
| vrf                    | Enter the RIP vrf configuration submode                |

RP/0/0/CPU0:router(config-rip)#

## route-policy (RIP)

To apply a routing policy to updates advertised to or received from a Routing Information Protocol (RIP) neighbor, use the **route-policy** command in the appropriate configuration mode. To disable applying routing policy to updates, use the **no** form of this command.

**route-policy** *name* {**in**|**out**}

**no route-policy** *name* {**in**|**out**}

### Syntax Description

|      |                                    |
|------|------------------------------------|
| name | Name of route policy.              |
| in   | Applies policy to inbound routes.  |
| out  | Applies policy to outbound routes. |

### Command Default

No policy is applied.

### Command Modes

Router configuration  
VRF configuration  
Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-policy** command to specify a routing policy for an inbound or outbound route. The policy can be used to filter routes or modify route attributes.

#### Note

If a route policy is configured both on the interface and on the VRF, the interface route policy is applied.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to filter routing updates received on an interface:

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0  
RP/0/0/CPU0:router(config-rip-if)# route-policy updpol-1 in
```

## send version

To configure the Routing Information Protocol (RIP) interface to send version specific packets, use the **send version** command in interface configuration mode. To revert to the default setting, use the **no** form of this command.

**send version** {1| 2| 1 2}

**no send version** {1| 2| 1 2}

### Syntax Description

|     |                                       |
|-----|---------------------------------------|
| 1   | Version 1 packets.                    |
| 2   | Version 2 packets.                    |
| 1 2 | Both Version 1 and Version 2 packets. |

### Command Default

Version 2

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **send version** command to override the default behavior of RIP. This command applies only to the interface being configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to configure an interface to send only RIP Version 2 packets:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# send version 2
```

**Related Commands**

| Command                                       | Description                                                      |
|-----------------------------------------------|------------------------------------------------------------------|
| <a href="#">receive version, on page 1501</a> | Configures the RIP interface to accept version-specific packets. |

## show protocols (RIP)

To display information about the Routing Information Protocol (RIP) process configuration, use the **show protocols** command in EXEC mode.

**show protocols** [**ipv4**| **afi-all**] [**all**| *protocol*] [**default-context**| **vrf** *vrf-name*] [**private**]

### Syntax Description

|                            |                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                | (Optional) Specifies an IPv4 address family.                                                                                                                                                                        |
| <b>afi-all</b>             | (Optional) Specifies all address families.                                                                                                                                                                          |
| <b>all</b>                 | (Optional) Specifies all protocols for a given address family.                                                                                                                                                      |
| <i>protocol</i>            | (Optional) Specifies a routing protocol.<br><ul style="list-style-type: none"> <li>For the IPv4 address family, the options are <b>eigrp</b> , <b>bgp</b> , <b>isis</b> , <b>ospf</b> , and <b>rip</b> .</li> </ul> |
| <b>default-context</b>     | (Optional) Displays default context information. This keyword is available when the <b>eigrp</b> or <b>rip</b> protocol is specified.                                                                               |
| <b>vrf</b> <i>vrf-name</i> | (Optional) Displays VPN routing and forwarding (VRF) information for the specified process. This keyword is available when the <b>eigrp</b> or <b>rip</b> protocol is specified.                                    |
| <b>private</b>             | (Optional) Displays private EIGRP data. This keyword is available when the <b>eigrp</b> protocol is specified.                                                                                                      |

### Command Modes

EXEC

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show protocols** command to get information about the protocols running on the router and to quickly determine which protocols are active. The command summarizes the important characteristics of the running protocol, and command output varies depending on the specific protocol selected.

For RIP, the command output lists the instance number, default AS context, router ID, default networks, distance, maximum paths, and so on.

## Task ID

| Task ID | Operations |
|---------|------------|
| RIP     | read       |

## Examples

The following is sample output from the **show protocols rip** command:

```
RP/0/0/CPU0:router# show protocols rip
Routing Protocol RIP
  2 VRFs (including default) configured, 2 active
  25 routes, 16 paths have been allocated
  Current OOM state is "Normal"
  UDP socket descriptor is 37
    VRF      Active  If-config If-active Routes  Paths  Updates
    default  Active   3         3        11      7      30s
```

This table describes the significant fields shown in the display.

**Table 166: show protocols Field Descriptions**

| Field           | Description                                 |
|-----------------|---------------------------------------------|
| VRFs configured | Number of VRFs configured.                  |
| VRFs active     | Number of active VRFs.                      |
| Routes          | Number of allocated routes.                 |
| Paths           | Number of allocated paths.                  |
| OOM state       | Current out-of-memory state of RIP process. |
| UDP socket      | Current UDP socket descriptor value.        |

# show rip

To display configuration and status of Routing Information Protocol (RIP), use the **show rip** command in EXEC mode.

**show rip** [*vrf {vrf|all}*]

## Syntax Description

|                                        |                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
|----------------------------------------|---------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |

| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| rip     | read       |

## Examples

The following example shows sample output from the **show rip** command:

```
RP/0/0/CPU0:router# show rip

RIP config:
Active?:                Yes
Added to socket?:       Yes
Out-of-memory state:    Normal
Version:                2
Default metric:         Not set
Maximum paths:          4
Auto summarize?:        No
Broadcast for V2?:      No
Packet source validation?: Yes
NSF:                    Disabled
Timers: Update:         30 seconds (25 seconds until next update)
```

```

Invalid:          180 seconds
Holddown:         180 seconds
Flush:           240 seconds

```

This table describes the significant fields shown in the display.

**Table 167: show rip Field Descriptions**

| Field                     | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| Active?                   | Active state setting.                                                                                   |
| Added to socket?          | Multicast group setting on RIP configured interfaces. If yes, updates are received on these interfaces. |
| Out-of-memory state       | Out-of-memory state for RIP can be one of the following: Normal, Minor, Severe, or Critical.            |
| Version                   | Version number is 2.                                                                                    |
| Default metric            | Default metric value, if configured. Otherwise Not set.                                                 |
| Maximum paths             | Number of maximum paths allowed per RIP route.                                                          |
| Auto summarize?           | Auto-summarize state setting.                                                                           |
| Broadcast for V2?         | RIP Version 2 broadcast setting.                                                                        |
| Packet source validation? | Validation setting for the source IP address of incoming routing updates to RIP.                        |
| Timers                    | RIP network timer settings.                                                                             |

# show rip database

To display database entry information from the Routing Information Protocol (RIP) topology table, use the **show rip database** command in EXEC mode.

**show rip** [**vrf** {*vrf* | **all**}] **database** [*prefix prefix-length*] *prefix mask*]

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>prefix</i>                          | (Optional) Network IP address about which routing information should be displayed.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>prefix-length</i>                   | (Optional) The <i>prefix-length</i> argument specifies the length of the IP prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash between must precede the decimal value. Range is 0 to 32 for IPv4 addresses.                                                                                                                                                                         |
| <i>prefix-mask</i>                     | (Optional) Network mask specified in either of two ways: <ul style="list-style-type: none"> <li>• Network mask can be a four-part, dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• Network mask can be indicated as a slash (/) and number. For example, /8 shows that the first 8 bits of the mask are ones, and the corresponding bits of the address are the network address.</li> </ul> |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Summary address entries appear in the database only if relevant child routes are summarized. When the last child route for a summary address becomes invalid, the summary address is also removed from the routing table.

## Task ID

| Task ID | Operations |
|---------|------------|
| rip     | read       |

## Examples

The following is sample output from the **show rip database** command:

```
RP/0/0/CPU0:router# show rip database

Routes held in RIP's topology database:
 10.0.0.0/24
   [0] directly connected, GigabitEthernet0/6/0/0
 10.0.0.0/8 auto-summary
 12.0.0.0/24
   [5] distance: 20 redistributed
 12.0.0.0/8 auto-summary
 50.50.0.0/24
   [1] via 10.0.0.20, next-hop 10.0.0.20, Uptime: 1s, GigabitEthernet0/6/0/0
 50.50.1.0/24 (inactive)
   [1] via 10.0.0.20, next-hop 10.0.0.20, Uptime: 1s, GigabitEthernet0/6/0/0
 50.0.0.0/8 auto-summary
 90.90.0.0/24
   [5] distance: 20 redistributed
 90.90.1.0/24
   [5] distance: 20 redistributed
```

This table describes the significant fields shown in the display.

**Table 168: show rip database Field Descriptions**

| Field                                                                                                | Description                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10.0.0.0/24<br>[0] directly connected, GigabitEthernet0/6/0/0                                        | Prefix and prefix length for a RIP connected route.<br>10.0.0.0/24 is directly connected to GigabitEthernet 0/6/0/0. The [0] represents the metric.                        |
| 10.0.0.0/8 auto-summary                                                                              | 10.0.0.0/8 is a summary route entry.                                                                                                                                       |
| 12.0.0.0/24<br>[5] distance: 20 redistributed                                                        | 12.0.0.0/24 is a redistributed route. The metric is 5, and the distance is 20.                                                                                             |
| 50.50.0.0/24<br>[1] via 10.0.0.20, next-hop 10.0.0.20, Uptime: 1s, GigabitEthernet0/6/0/0            | The destination route 50.50.0.0/24 is learned through RIP, and the source 10.0.0.20 advertised it from GigabitEthernet 0/6/0/0. The route was last updated one second ago. |
| 50.50.1.0/24 (inactive)<br>[1] via 10.0.0.20, next hop 10.0.0.20, Uptime: 1s, GigabitEthernet0/6/0/0 | The destination route 50.50.1.0/24 is not active in the routing table.                                                                                                     |

# show rip interface

To display interface entry information from the Routing Information Protocol (RIP) topology table, use the **show rip interface** command in EXEC mode.

**show rip** [**vrf** {*vrf* | **all**}] **interface** [*type interface-path-id*]

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                                |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances.                                                                                                                                                                              |
| <b>interface</b>                       | (Optional) Specifies the interface from which to clear topology entries.                                                                                                                                                                                                       |
| <i>type</i>                            | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                        |
| <i>interface-path-id</i>               | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router. For more information about the syntax for the router, use the question mark ( ? ) online help function. |

| Release 4.0.0 | The command output was modified to include authentication keychain configuration information. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| rip     | read       |

**Examples**

This example is sample output from the **show rip interface** command:

```
RP/0/0/CPU0:router# show rip interface

GigabitEthernet0_6_0_0
Rip enabled?:                Yes
Out-of-memory state:         Normal
Broadcast for V2:            No
Accept Metric 0?:            No
Send versions:                2
Receive versions:            2
Interface state:              Up
IP address:                   10.0.0.12/24
Metric Cost:                  0
Split horizon:                Enabled
Poison Reverse:               Disabled
Joined multicast group?:      Yes

GigabitEthernet0_6_0_2
Out-of-memory state:         Normal
Rip enabled?:                Yes
Broadcast for V2:            No
Accept Metric 0?:            No
Send versions:                2
Receive versions:            2
Interface state:              Up
IP address:                   12.0.0.12/24
Metric Cost:                  0
Split horizon:                Enabled
Poison Reverse:               Disabled
Joined multicast group?:      Yes

RIP peers attached to this interface:
 12.0.0.13
   uptime: 3    version: 2
   packets discarded: 0    routes discarded: 402
```

This table describes the significant fields shown in the display.

**Table 169: show rip interface Field Descriptions**

| Field               | Description                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------|
| Rip enabled?        | Specifies whether the RIP routing protocol is enabled on the interface.                                  |
| Out-of-memory state | Specifies the current out-of-memory state on the interface.                                              |
| Broadcast for V2    | Specifies whether RIP Version 2 output packets are sent to a broadcast address on the interface.         |
| Accept Metric 0?    | Specifies whether this interface accepts routing entries from RIP updates with a metric set to zero (0). |
| Send versions:      | Specifies which version RIP uses to send out packets on this interface.                                  |

| Field                                             | Description                                                                   |
|---------------------------------------------------|-------------------------------------------------------------------------------|
| Receive versions:                                 | Specifies which version packets RIP accepts on this interface.                |
| Interface state:                                  | Specifies whether the interface is in an up or a down state.                  |
| IP address:                                       | IP address of the interface.                                                  |
| Metric Cost:                                      | Specifies metric cost value.                                                  |
| Split horizon:                                    | Specifies whether split horizon is enabled on this interface.                 |
| Poison Reverse:                                   | Specifies whether poison reverse is enabled on this interface.                |
| Joined multicast group?:                          | Specifies whether the interface has joined the RIP multicast group 224.0.0.9. |
| RIP peers attached to this interface<br>12.0.0.13 | List of RIP neighbors on this interface.                                      |
| uptime: 3                                         | Specifies how long this neighbor is up.                                       |
| version: 2                                        | Specifies which version packets are received from this neighbor.              |
| packets discarded: 0                              | Specifies the number of packets discarded from this neighbor.                 |
| routes discarded: 402                             | Specifies the number of routes discarded from this neighbor.                  |

### Authentication Keychain Configuration for RIP Interface on Default VRF

These examples are output of the **show rip interface *interface-path-id*** command to display authentication keychain configuration for RIP interface on default VRF.

When an existing keychain with MD5 cryptographic algorithm was configured on the RIP interface:

```
GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?: No
Out-of-memory state: Normal
Broadcast for V2: No
Accept Metric 0?: No
Send versions: 2
Receive versions: 2
Interface state: Unknown State
IP address: 0.0.0.0/0
Metric Cost: 0
Split horizon: Enabled
```

```

Poison Reverse:           Disabled
Socket set options:
Joined multicast group?:   No
LPTS filter set?:         No
Authentication mode: MD5   Key chain: <key-chain-name>
Current active send key id: <send key id>
Current active receive key id: <recv key id>
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>

```

When the keychain configured on the RIP interface does not exists or does not have any active keys:

```

GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?:             No
Out-of-memory state:      Normal
Broadcast for V2:         No
Accept Metric 0?:        No
Send versions:            2
Receive versions:         2
Interface state:          Unknown State
IP address:               0.0.0.0/0
Metric Cost:              0
Split horizon:            Enabled
Poison Reverse:           Disabled
Socket set options:
Joined multicast group?:   No
LPTS filter set?:         No

Authentication mode: MD5   Key chain: <key-chain-name>
No active key found in keychain database.
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>

```

When an active key exists in the keychain configured on the RIP interface, but not configured with MD5 cryptographic algorithm:

```

GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?:             No
Out-of-memory state:      Normal
Broadcast for V2:         No
Accept Metric 0?:        No
Send versions:            2
Receive versions:         2
Interface state:          Unknown State
IP address:               0.0.0.0/0
Metric Cost:              0
Split horizon:            Enabled
Poison Reverse:           Disabled
Socket set options:
Joined multicast group?:   No
LPTS filter set?:         No

Authentication mode: MD5   Key chain: <key-chain-name>
Key(s) not configured with MD5 cryptographic algorithm.
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>

```

When no authentication keychain was configured on the RIP interface:

```
GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?: No
Out-of-memory state: Normal
Broadcast for V2: No
Accept Metric 0?: No
Send versions: 2
Receive versions: 2
Interface state: Unknown State
IP address: 0.0.0.0/0
Metric Cost: 0
Split horizon: Enabled
Poison Reverse: Disabled
Socket set options:
Joined multicast group?: No
LPTS filter set?: No
```

```
Authentication mode is not set.
Packets received: <num-rx-packets>
```

### Authentication keychain Configuration for RIP Interface on Non-default VRF

These examples are output of the **show rip vrf vrf-name interface interface-path-id** command to display authentication keychain configuration for RIP interface on a non- default VRF.

When an existing keychain with MD5 cryptographic algorithm has been configured on the RIP interface:

```
GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?: No
Out-of-memory state: Normal
Broadcast for V2: No
Accept Metric 0?: No
Send versions: 2
Receive versions: 2
Interface state: Unknown State
IP address: 0.0.0.0/0
Metric Cost: 0
Split horizon: Enabled
Poison Reverse: Disabled
Socket set options:
Joined multicast group?: No
LPTS filter set?: No

Authentication mode: MD5 Key chain: <key-chain-name>
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>
```

When the keychain configured on the RIP interface does not exist or does not have any active keys:

```
GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?: No
Out-of-memory state: Normal
Broadcast for V2: No
Accept Metric 0?: No
Send versions: 2
Receive versions: 2
Interface state: Unknown State
IP address: 0.0.0.0/0
Metric Cost: 0
Split horizon: Enabled
Poison Reverse: Disabled
Socket set options:
Joined multicast group?: No
```

```

LPTS filter set?:          No

Authentication mode: MD5  Key chain: <key-chain-name>
No active key found  in keychain database.
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>

```

When an active key exists in the keychain configured on the RIP interface, but not configured with MD5 cryptographic algorithm:

```

GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?:              No
Out-of-memory state:       Normal
Broadcast for V2:          No
Accept Metric 0?:         No
Send versions:             2
Receive versions:          2
Interface state:           Unknown State
IP address:                0.0.0.0/0
Metric Cost:               0
Split horizon:             Enabled
Poison Reverse:            Disabled
Socket set options:
Joined multicast group?:    No
LPTS filter set?:          No

Authentication mode: MD5  Key chain: <key-chain-name>
Key(s) not configured with MD5 cryptographic algorithm.
Packets received: <num-rx-packets>
Authenticated packets received: <num-auth-rx-packets>
Packets dropped due to wrong keychain config: <num-rx-wrong-auth-cfg-pkts>
Packets received without authentication data: <num-rx-auth-missing-pkt>
Packets received with invalid authentication: <num-rx-invalid-auth-pkt>

```

When no authentication keychain has been configured on the RIP interface:

```

GigabitEthernet0/3/0/3 (Forward Reference)
Rip enabled?:              No
Out-of-memory state:       Normal
Broadcast for V2:          No
Accept Metric 0?:         No
Send versions:             2
Receive versions:          2
Interface state:           Unknown State
IP address:                0.0.0.0/0
Metric Cost:               0
Split horizon:             Enabled
Poison Reverse:            Disabled
Socket set options:
Joined multicast group?:    No
LPTS filter set?:          No

Authentication mode is not set.
Packets received: <num-rx-packets>

```

This table describes the significant fields shown in the display.

**Table 170: show rip [vrf <vrf-name>] interface Field Descriptions**

|                                    |                                     |
|------------------------------------|-------------------------------------|
| Authentication mode: MD5 Key chain | MD5 authentication mode is enabled. |
| Current active send key id         | Active send key ID.                 |
| Current active receive key id      | Active receive key ID.              |

|                                                        |                                                                |
|--------------------------------------------------------|----------------------------------------------------------------|
| Packets received                                       | Number of packets received on the interface.                   |
| Authenticated packets received                         | Number packets received with valid authentication.             |
| Packets dropped due to wrong keychain config           | Number of packets dropped due to wrong keychain configuration. |
| Packets received without authentication data           | Number packets received without authentication data .          |
| Packets received with invalid authentication           | Number of packets received with invalid authentication.        |
| No active key found in keychain database               | No active keys are available in IOS XR keychain database.      |
| Key(s) not configured with MD5 cryptographic algorithm | Keys are not configured with MD5 cryptographic algorithm.      |
| Authentication mode is not set                         | Authentication mode is not set.                                |

# show rip statistics

To display statistical entry information from the Routing Information Protocol (RIP) topology table, use the **show rip statistics** command in EXEC mode.

**show rip** [**vrf** {*vrf* | **all**}] **statistics**

## Syntax Description

|                                        |                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding (VRF) instance or all VRF instances. |
|----------------------------------------|---------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| rip     | read       |

## Examples

The following example is sample output from the **show rip statistics** command:

```
RP/0/0/CPU0:router# show rip statistics

RIP statistics:
  Total messages sent:      5597
  Message send failures:    0
  Regular updates sent:    5566
  Queries responded to:    0
  RIB updates:             6
  Total packets received:  5743
  Discarded packets:       0
  Discarded routes:        0
  Number of routes allocated: 18
  Number of paths allocated: 14
```

```

Route malloc failures:      0
Path malloc failures:      0

```

This table describes the significant fields shown in the display.

**Table 171: show rip statistics Field Descriptions**

| Field                       | Description                                                           |
|-----------------------------|-----------------------------------------------------------------------|
| Total messages sent:        | Number of RIP packets sent.                                           |
| Message send failures:      | Number of times that the packet send operation failed.                |
| Queries responded to:       | Number of times RIP updates are sent in response to a RIP query.      |
| RIB updates:                | Number of route addition and deletion messages sent to RIB.           |
| Total packets received:     | Number of RIP packets received.                                       |
| Discarded packets:          | Number of received RIP packets that are discarded.                    |
| Discarded routes:           | Number of routes (in received RIP update packets) that are discarded. |
| Number of routes allocated: | Number of routes allocated for the RIP internal topology database.    |
| Number of paths allocated:  | Number of paths allocated for the RIP internal topology database.     |
| Route malloc failures:      | Number of failures during route allocation.                           |
| Path malloc failures:       | Number of failures during route allocation.                           |

**Note**

The number of routes found in the allocated field might not be the same number of routes present in the RIP database.

## site-of-origin (RIP)

To configure the Site of Origin (SoO) filtering on a Routing Information Protocol (RIP) interface, use the **site-of-origin** command in interface configuration mode. To disable SoO filtering on an interface, use the **no** form of this command.

**site-of-origin** {*as-number* : *number*| *ip-address* : *number*}

**no site-of-origin** {*as-number* : *number*| *ip-address* : *number*}

### Syntax Description

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> :  | Autonomous system number. <ul style="list-style-type: none"> <li>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> <p>A colon is used to separate the autonomous system number and network number.</p> |
| <i>number</i>       | Network number. Range is from 0 to 4294967295 when a 2-byte AS number is used. Range is from 0 to 65535 when a 4-byte AS number is used.                                                                                                                                                                                                                                                                                            |
| <i>ip-address</i> : | The IP address argument specifies the IP address in four-part, dotted-decimal notation. A colon is used to separate the IP address and network number.                                                                                                                                                                                                                                                                              |

### Command Default

No default behavior or values

### Command Modes

Interface configuration

### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.5.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

A RIP process must be capable of retrieving the SoO attribute on routes redistributed from the Border Gateway Protocol (BGP) when required to support complex topologies that include MPLS VPN links between sites with backdoor links.

Use the **site-of-origin** command to set an SoO BGP extended community attribute that is used to identify routes that have originated from a site so that the readvertisement of that prefix back to the source site can be prevented. The SoO extended community uniquely identifies the site from which a provider edge (PE) router has learned a route.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to configure SoO filtering on a RIP interface:

```
RP/0/0/CPU0:router(config)# router rip  
RP/0/0/CPU0:router(config-rip) interface GigabitEthernet 0/1/0/0  
RP/0/0/CPU0:router(config-rip-if) site-of-origin 10.0.0.1:20
```

# split-horizon disable (RIP)

To disable split horizon for a Routing Information Protocol (RIP) process, use the **split-horizon disable** command in interface configuration mode. To enable split horizon, use the **no** form of this command.

**split-horizon disable**

**no split-horizon disable**

## Syntax Description

This command has no arguments or keywords.

## Command Default

Split horizon is enabled for a RIP process.

## Command Modes

Interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can explicitly specify the **split-horizon disable** command in your configuration.

If split horizon is disabled, the poison reverse configuration is ignored.

### Note

In general, we recommend that you do not change the default state of split horizon unless you are certain that your application requires the change to properly advertise routes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

## Examples

The following example shows how to disable split horizon on a Packet-over-SONET/SDH link:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-rip-if)# split-horizon disable
```

**Related Commands**

|-----------------------------------------------|----------------------------------------------------------|
| <a href="#">poison-reverse</a> , on page 1499 | Enables poison reverse processing of RIP router updates. |

## timers basic

To adjust Routing Information Protocol (RIP) network timers, use the **timers basic** command in router configuration mode. To restore the timers default values, use the **no** form of this command.

**timers basic** *update invalid holddown flush*

**no timers basic**

### Syntax Description

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>update</i>   | Rate, in seconds, at which updates are sent. This is the fundamental timing parameter of the routing protocol. Range is 5 to 50000.                                                                                                                                                                                                                                                                                                                                                              |
| <i>invalid</i>  | Interval, in seconds, after which a route is declared invalid; it should be at least three times the value of the update argument. A route becomes invalid when there is an absence of updates that refresh the route. The route then enters into a holddown state. The route is marked inaccessible and is advertised as unreachable. Range is 15 to 200000.                                                                                                                                    |
| <i>holddown</i> | Interval, in seconds, during which routing information regarding better paths is suppressed. It should be at least three times the value of the update argument. A route enters into a holddown state when an update packet is received that indicates that the route is unreachable. The route is marked inaccessible and is advertised as unreachable. When holddown expires, routes advertised by other sources are accepted, and the route is no longer inaccessible. Range is 15 to 200000. |
| <i>flush</i>    | Amount of time, in seconds, that must pass before the route is removed from the routing table; the interval specified should be greater than the value of the <i>invalid</i> argument. If it is less than the invalid timer value, the proper holddown interval cannot elapse, which results in a new route being accepted before the holddown interval expires. Range is 16 to 250000.                                                                                                          |

### Command Default

*update* : 30  
*invalid* : 180  
*holddown* : 180  
*flush* : 240

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The basic timing parameters for RIP are adjustable. Because RIP is running a distributed, asynchronous routing algorithm, these timers must be the same for all routers in the network.

**Note**

Use the **show rip** command to display the current and default timer values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

**Examples**

The following example shows how to set updates to be broadcast every 5 seconds. If a router is not heard from in 15 seconds, the route is declared unusable. Further information is suppressed for an additional 15 seconds. At the end of the flush period, the route is flushed from the routing table.

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip) timers basic 5 15 15 30
```

**Related Commands**

| Command                                 | Description                               |
|-----------------------------------------|-------------------------------------------|
| <a href="#">show rip</a> , on page 1515 | Displays configuration and status of RIP. |

# validate-update-source disable

To stop the Cisco IOS XR software from validating the source IP address of incoming routing updates for Routing Information Protocol (RIP), use the **validate-update-source disable** command in router configuration mode. To reenale this function, use the **no** form of this command.

**validate-update-source disable**

**no validate-update-source disable**

**Syntax Description** This command has no arguments or keywords.

**Command Default** The source IP address of incoming updates for RIP is always validated.

**Command Modes** Router configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the **validate-update-source disable** command is used, validation is not performed.

By default, the software ensures that the source IP address of incoming routing updates is on the same IP network as one of the addresses defined for the receiving interface.

For unnumbered IP interfaces (interfaces configured as IP unnumbered), no checking is performed.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rip     | read, write |

**Examples** The following example shows how to disable source validation:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip) validate-update-source disable
```

## vrf (RIP)

To define a VPN routing and forwarding (VRF) instance and to enter VRF configuration mode, use the **vrf** command in router configuration mode. To remove a VRF instance use the no form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

### Syntax Description

|          |                                                             |
|----------|-------------------------------------------------------------|
| vrf-name | Specifies a particular VPN routing and forwarding instance. |
|----------|-------------------------------------------------------------|

### Command Default

No VRFs are defined.

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the vrf command to configure a VRF instance. A VRF instance is a collection of VPN routing and forwarding tables maintained at the provider edge (PE) router.

From VRF configuration mode, you can issue all commands available in router configuration mode such as the **auto-summary** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rip     | read, write |

### Examples

The following example shows how to enter VRF configuration mode and identify RIP commands that can be issued from that mode:

```
RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# vrf vpn-1
RP/0/0/CPU0:router(config-rip-vrf)# ?

    auto-summary          Enable automatic network number summarization
```

|                        |                                                        |
|------------------------|--------------------------------------------------------|
| broadcast-for-v2       | Send RIP v2 output packets to broadcast address        |
| commit                 | Commit the configuration changes to running            |
| default-information    | Control distribution of default information            |
| default-metric         | Set metric of redistributed routes                     |
| describe               | Describe a command without taking real actions         |
| distance               | Define an administrative distance                      |
| do                     | Run an exec command                                    |
| exit                   | Exit from this submode                                 |
| interface              | Enter the RIP interface configuration submode          |
| maximum-paths          | Maximum number of paths allowed per route              |
| neighbor               | Specify a neighbor router                              |
| no                     | Negate a command or set its defaults                   |
| nsf                    | Enable Cisco Non Stop Forwarding                       |
| output-delay           | Interpacket delay for RIP updates                      |
| redistribute           | Redistribute information from another routing protocol |
| route-policy           | Apply route policy to routing updates                  |
| show                   | Show contents of configuration                         |
| timers                 | Adjust routing timers                                  |
| validate-update-source | Validate source address of routing updates             |

RP/0/0/CPU0:router(config-rip-vrf)#

## Routing Policy Language Commands

---

This module describes the Cisco IOS XR software routing policy language (RPL) commands used to create, modify, monitor, and maintain routing policies.

For detailed information about RPL concepts, configuration tasks, and examples, see the *Implementing Routing Policy on Cisco IOS XR Software* module in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

## abort (RPL)

To discard a route policy or set definition and return to global configuration mode, use the **abort** command in the appropriate configuration mode.

**abort**

### Syntax Description

This command has no arguments or keywords.

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration  
Prefix set configuration  
Route distinguisher set configuration  
AS path set configuration  
Community set configuration  
Extended community set configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

### Examples

The following example shows how to discard a route policy definition that was started and return to global configuration mode:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# if as-path is-local then
RP/0/0/CPU0:router(config-rpl-if)# abort
RP/0/0/CPU0:router(config)#
```

The following example shows how to discard a prefix set definition that was started and return to global configuration mode:

```
RP/0/0/CPU0:router(config)# prefix-set legal-ipv4-prefix-examples  
RP/0/0/CPU0:router(config-pfx)# 10.0.1.1,  
RP/0/0/CPU0:router(config-pfx)# 10.0.2.0/24,  
RP/0/0/CPU0:router(config-pfx)# abort  
RP/0/0/CPU0:router(config)#
```

# add

To add a value to an Routing Information Protocol (RIP) or Enhanced Interior Gateway Protocol (EIGRP) existing metric, use the **add** command in route-policy configuration mode.

**add** {**eigrp-metric** *bandwidth delay reliability loading max-transmission*| **rip-metric** {*number*| *parameter*}}

## Syntax Description

|                         |                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------|
| <b>eigrp-metric</b>     | Specifies an EIGRP metric attribute.                                              |
| <i>bandwidth</i>        | Bandwidth in kilobits per second. Range is from 0 to 4294967295.                  |
| <i>delay</i>            | Delay in 10-microsecond units. Range is from 0 to 4294967295.                     |
| <i>reliability</i>      | Reliability metric. 255 is 100-percent reliable. Range is from 0 to 255.          |
| <i>loading</i>          | Effective bandwidth (loading). 255 is 100-percent loaded. Range is from 0 to 255. |
| <i>max-transmission</i> | Maximum transmission of the path. Range is from 0 to 65535.                       |
| <b>rip-metric</b>       | Specifies an RIP metric attribute.                                                |
| <i>number</i>           | Value assigned to a four-bit unsigned integer. Range is from 0 to 16.             |
| <i>parameter</i>        | Parameter name. The parameter name must be preceded with a "\$."                  |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If the add value is greater than the maximum allowed value, the metric is added. If the resulting metric exceeds the maximum for the routing protocol, then the route is dropped (by the client routing protocol).

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows how to offset the RIP metric value:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# add rip-metric 4
RP/0/0/CPU0:router(config-rpl)# end-policy
```

The following example shows how to set the EIGRP metric value:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# add eigrp-metric 50000 24000 230 14000
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# apply

To execute a parameterized or unparameterized policy from within another policy, use the **apply** command in route-policy configuration mode.

**apply** *policy\_name* [*argument1*, *argument2*, . . . , *argumentN*]

## Syntax Description

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>policy_name</i> | Name of a route policy.                                                                                                         |
| <i>argument</i>    | (Optional) Parameter name. The <i>argument</i> can be a value (for example, '100' ) or a parameter (for example, '\$parameter') |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                       |
|---------------|----------------------------------------------------|
| Release 3.2   | This command was introduced.                       |
| Release 4.2.1 | Wildcard support was added for apply policy-names. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **apply** command to execute a policy (either parameterized or unparameterized) from within another policy, which allows for the reuse of common blocks of policy.

Wildcards can be used in apply policy names. This supports the nested wildcard apply scenario. A wildcard is specified by inserting an asterisk (\*) in place of one of the portions of the apply policy name; the wildcard indicates that any value for that portion of the apply policy name matches. The nested wildcard apply policy allows wildcard (\*) based apply nesting. The wildcard operation permits declaration of a generic apply statement that calls all policies that contain a specific defined set of alphanumeric characters, defined on the router.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the policy CustomerIn applies the route-policy SetLocalPref to conditionally set the local preference on a route. The parameters 20, 30, 40, and 50 are passed to the parameterized policy SetLocalPref, where the local preference is set to:

- 20, if the community 217:20 is present in the route
- 30, if the community 217:30 is present in the route
- 40, if the community 217:40 is present in the route
- 50, if the community 217:50 is present in the route

```
RP/0/0/CPU0:router(config)# route-policy SetLocalPref ($lp0, $lp1, $lp2, $lp3, $lp4)
RP/0/0/CPU0:router(config-rpl)# if community matches-any ($lp0:$lp1) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference $lp1
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-any ($lp0:$lp2) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference $lp2
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-any ($lp0:$lp3) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference $lp3
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-any ($lp0:$lp4) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference $lp4
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy

RP/0/0/CPU0:router(config)# route-policy CustomerIn($cust)
RP/0/0/CPU0:router(config-rpl)# apply SetLocalPref ($cust, 20, 30, 40, 50)
RP/0/0/CPU0:router(config-rpl)# end-policy

RP/0/0/CPU0:router(config)# route-policy Cust_217
RP/0/0/CPU0:router(config-rpl)# apply CustomerIn(217)
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# as-path in

To match the AS path of a route to an AS path set, use the **as-path in** command in route-policy configuration mode.

**as-path in** {*as-path-set-name*|*inline-as-path-set*|*parameter*}

## Syntax Description

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <i>as-path-set-name</i>   | Name of an AS path set.                                                     |
| <i>inline-as-path-set</i> | Inline AS path set. The inline AS path set must be enclosed in parentheses. |
| <i>parameter</i>          | Parameter name. The parameter name must be preceded with a "\$."            |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.2   | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path in** command as a conditional expression within an **if** statement to match the AS path of a route to an AS path set. The AS path is a sequence of autonomous system numbers traversed by a route.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **as-path in** command evaluates to true if at least one of the regular expressions defined in the associated AS path set matches the AS path attribute of the route.

In the case where the AS path set is defined but contains no elements in it, the **as-path in** conditional expression command returns false.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

For example, assume we have an AS path set named my-as-set defined as follows:

```
RP/0/0/CPU0:router(config)# as-path-set my-as-set
RP/0/0/CPU0:router(config-as)# ios-regex '_12$',
RP/0/0/CPU0:router(config-as)# ios-regex '_13$'
RP/0/0/CPU0:router(config-as)# end-set
```

and the following policy excerpt using an *as-path-set-name* argument:

```
RP/0/0/CPU0:router(config-rpl)# if as-path in my-as-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

The AS path in condition evaluates to true if one or more of the regular expression matches in the set my-as-set match the AS path associated with the route. In the case of a defined but empty AS path set, this operator returns false.

The preceding policy excerpt is equivalent to the following version, which uses an *inline-as-path* set variable:

```
RP/0/0/CPU0:router(config-rpl)# if as-path in (ios-regex '_12$',ios-regex '_13$') then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

# as-path is-local

To determine if this router or another router within this autonomous system or confederation originated a Border Gateway Protocol (BGP) route, use the **as-path is-local** command in route-policy configuration mode.

**as-path is-local**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                |
|-------------|-----------------------------|
| Release 3.2 | This command was supported. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path is-local** command as a conditional expression within an **if** statement to determine if this router (or another router within this autonomous system or confederation) originated the route.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

Routes that are locally originated within the autonomous system or confederation carry an empty AS path. For the Border Gateway Protocol (BGP) specification, when a route is advertised across the autonomous system boundary or a confederation boundary, the local autonomous system number or confederation ID is appended to the autonomous system path. The AS path of a locally originated aggregate is also empty unless it has been modified by policy.

The **is-local** operator evaluates to true for autonomous system paths that are empty. An empty AS path is how an AS path that is local to our autonomous system is represented in BGP.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, if the AS path is local, then the local preference is set to 100:

```
RP/0/0/CPU0:router(config-rpl)# if as-path is-local then  
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)#
```

## as-path length

To compare the number of ASN in the AS path of a Border Gateway Protocol (BGP) route, use the **as-path length** command in route-policy configuration mode.

**as-path length** {eq| is| ge| le} {*number*| *parameter*}

### Syntax Description

|                          |                                                                        |
|--------------------------|------------------------------------------------------------------------|
| <b>eq   is   ge   le</b> | Equal to; greater than or equal to; less than or equal to.             |
| <i>number</i>            | Value assigned to an 11-bit unsigned integer. Range is from 0 to 2047. |
| <i>parameter</i>         | Parameter name. The parameter name must be preceded with a "\$."       |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path length** command as a conditional expression within an **if** statement to perform a conditional check based on the length of the AS path.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command takes either a specific integer value or a range of integer values specified with the **ge** and **le** operators. Any or all these integers can be parameterized. The operator counts one for each autonomous system in the path. In the case where the route may be aggregated and contain one or more AS sets, the length operator adds one for each set present, the occurrence of an AS set typically indicates that this route is an aggregated route, and the aggregated route had a component route that contained one of the autonomous systems in the set. Likewise, in the case of confederations, a count of one is added for each confederation in the path or each confederation set in the path. A null AS path has a length of zero.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, if the AS path length equals 10, then the local preference is set to 100:

```
RP/0/0/CPU0:router(config-rpl)# if as-path length eq 10 then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

**Related Commands**

| Command                                               | Description                                                                                                                                                                               |

## as-path neighbor-is

To test autonomous system numbers at the head of the AS path against a sequence of one or more values or parameters, use the **as-path neighbor-is** command in route-policy configuration mode.

**as-path neighbor-is** *as-number-list* [**exact**]

### Syntax Description

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number-list</i> | Numbers or parameters, enclosed in single quotation marks, that represent a sequence of autonomous system numbers. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| <b>exact</b>          | (Optional) Specifies that with the <b>exact</b> keyword, the <i>as-number-list</i> value must identically match the AS path for the route; without the <b>exact</b> keyword, any element in the <i>as-number-list</i> argument matches one or more occurrences of that element in the AS path for the route.                                                                                                                                   |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                                    |
|---------------|---------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                    |

| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.     |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path neighbor-is** command as a conditional expression within an **if** statement to test the autonomous system number or numbers at the head of the AS path against a sequence of one or more integral

values or parameters. In other words, to test to learn if the sequence of autonomous system numbers matches the path beginning with the neighboring autonomous system from which this route was heard.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command has an equivalent regular expression (ios-regex). For example, AS path neighbor-is '1' would be '^1\_'.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following are incomplete configuration examples:

```
RP/0/0/CPU0:router(config-rpl)# if as-path neighbor-is '10' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path neighbor-is '$asnum' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path neighbor-is '10 20' then
```

These statements evaluate to true when the first autonomous system numbers on the AS path match, in the same order, the supplied parameters or integer values in the **neighbor-is** statement. If the neighboring autonomous system location happens to be an AS-set, the operator evaluates to true if the corresponding argument to the **neighbor-is** operator is an element of the AS-set.

Without the **exact** keyword, repeated autonomous system numbers in the AS path are ignored. For example,

```
RP/0/0/CPU0:router(config-rpl)# if as-path neighbor-is '10 20' then
```

matches an AS path beginning

```
10 10 10 20 ...
```

and an AS path beginning:

```
10 20 ....
```

With the **exact** keyword, repetitions are not ignored, therefore

```
RP/0/0/CPU0:router(config-rpl)# if as-path neighbor-is '10 20' exact then
```

matches the second of these AS paths but not the first.

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path originates-from** command as a conditional expression within an **if** statement to compare an AS path to the autonomous system sequence.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **originates-from** operator is similar to the **neighbor-is** operator, except that it looks at the autonomous system number at the opposite end of the AS path. In other words, it is comparing to the autonomous system that originated the route. It can take numbers or parameters, enclosed in single quotation marks, that represent a sequence of autonomous system numbers. When more than one number is specified in the list, the sequence of autonomous system numbers listed must appear as a subsequence in the AS path, with the last number corresponding to the autonomous system that originated the route.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following are incomplete configuration examples:

```
RP/0/0/CPU0:router(config-rpl)# if as-path originates-from '10 11' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path originates-from '$asnum 11' then
```

The first line of the preceding example evaluates to true if autonomous system 11 originated the route and then advertised it to autonomous system 10, from which the route was eventually propagated to us. In the case where the route has been aggregated, and the location of the originating autonomous system contains an AS-set, the **originates-from** operator evaluates to true if the argument to the **originates-from** operator is contained in the AS-set.

Without the **exact** keyword, repeated autonomous system numbers in the AS path are ignored. For example,

```
RP/0/0/CPU0:router(config-rpl)# if as-path originates-from '10 11' then
```

matches an autonomous system path ending

```
...10 10 10 11
```

and an autonomous system path ending

```
...10 11
```

With the **exact** keyword, repetitions are not ignored, therefore

```
RP/0/0/CPU0:router(config-rpl)# if as-path originates-from '10 11' exact then
```

matches the second of these autonomous system paths but not the first.

## as-path passes-through

To verify if the supplied integer or parameter appears anywhere in the AS path or if the supplied sequence of integers and parameters appears, in the same order, anywhere in the AS path, use the **as-path passes-through** command in route-policy configuration mode.

**as-path passes-through** *as-number-list* [**exact**]

### Syntax Description

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number-list</i> | Numbers or parameters, enclosed in single quotation marks, that represent a sequence of autonomous system numbers. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| <b>exact</b>          | (Optional) Specifies that with the <b>exact</b> keyword, the <i>as-number-list</i> value must identically match the AS path for the route; without the <b>exact</b> keyword, any element in the <i>as-number-list</i> argument matches one or more occurrences of that element in the AS path for the route.                                                                                                                                   |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                                    |
|---------------|---------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                    |
| Release 3.4.0 | The <i>as-number-list</i> 4-byte number range 1.0 to 65535.65535 was supported. |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.     |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path passes-through** command as a conditional expression within an **if** statement to verify if the specified integer or parameter appears anywhere in the AS path or if the sequence of integers and parameters appears.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **passes-through** operator takes a sequence of integers or parameters, enclosed in single quotation marks, as an argument. It can also take a single integer or parameter as an argument. It evaluates to true if the supplied integer or parameter appears anywhere in the AS path, or if the supplied sequence of integers and parameters appears, in the same order, anywhere in the AS path. This includes the **originates-from** or **neighbor-is** location in the AS path.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following are incomplete configuration examples:

```
RP/0/0/CPU0:router(config-rpl)# if as-path passes-through '10' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path passes-through '$asnum' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path passes-through '10 11' then
RP/0/0/CPU0:router(config-rpl-if)# if as-path passes-through '10 $asnum 12' then
```

Without the **exact** keyword, repeated autonomous system numbers in the AS path are ignored. For example:

```
RP/0/0/CPU0:router(config-rpl)# if as-path passes-through '9 10 11' then
```

matches an AS path containing

```
...9 10 10 10 11 ....
```

and an AS path containing:

```
...9 10 11...
```

With the **exact** keyword, repetitions are not ignored. Therefore:

```
RP/0/0/CPU0:router(config-rpl)# if as-path passes-through '9 10 11' exact then
```

matches the second of these AS paths but not the first.

# as-path-set

To create a named AS path set, use the **as-path-set** command in global configuration mode. To remove the named AS path set, use the **no** form of this command.

**as-path-set** *name*

**no as-path-set** *name*

## Syntax Description

|             |                          |
|-------------|--------------------------|
| <i>name</i> | Name of the AS path set. |
|-------------|--------------------------|

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path-set** command to create a named AS path set.

An AS path set comprises operations for matching an AS path attribute.

This command enters AS path set configuration mode, in which you can use the **ios-regex** keyword to indicate the type of regular expression. Single quotation marks are required around the regular expression.

The inline set form is a parenthesized list of comma-separated expressions.

See the “Understanding Regular Expressions, Special Characters and Patterns” appendix in the *Cisco IOS XR Getting Started Guide for the Cisco XR 12000 Series Router* for information about forming regular expressions.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following is a sample definition of an AS path set named aset1:

```
RP/0/0/CPU0:router(config)# as-path-set aset1  
RP/0/0/CPU0:router(config-as)# ios-regex '_42$',  
RP/0/0/CPU0:router(config-as)# ios-regex '_127$'  
RP/0/0/CPU0:router(config-as)# end-set
```

This AS path set is composed of two elements. When used in a matching operation, this AS path set matches any route whose AS path ends with either the autonomous system number 42 or 127.

The following is a sample of an inline set:

```
RP/0/0/CPU0:router(config-rpl)# if as-path in (ios-regex '_42$', ios-regex$ '_127$')  
RP/0/0/CPU0:router(config-rpl-if)# pass  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)#
```

## as-path unique-length

To perform specific checks based on the length of the AS path (match against the number of unique ASNs in the AS path), use the **as-path unique-length** command in route-policy configuration mode.

**as-path unique-length** {eq| is| ge| le} {number| parameter}

### Syntax Description

|                          |                                                                        |
|--------------------------|------------------------------------------------------------------------|
| <b>eq   is   ge   le</b> | Equal to; greater than or equal to; less than or equal to.             |
| <i>number</i>            | Value assigned to an 11-bit unsigned integer. Range is from 0 to 2047. |
| <i>parameter</i>         | Parameter name. The parameter name must be preceded with a "\$."       |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-path unique-length** command as a conditional expression within an **if** statement to perform a match based on the length of the AS path.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **unique-length** operator is similar to the length operator, except that when an AS path has been padded with the same autonomous system number multiple times, the operator counts only one when the route is padded. Therefore, given an AS path of 333 333 111 222 123 444 444 444, the **unique-length** operator would return a value of 5, whereas the length operator would return a value of 8.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows how to perform checks based on the AS path length. If the AS path matches the specified values, the local preference is set to 100:

```
RP/0/0/CPU0:router(config-rpl)# if as-path unique-length eq 10 then
RP/0/0/CPU0:router(config-rpl-if)# if as-path unique-length ge 10 then
RP/0/0/CPU0:router(config-rpl-if)# if as-path unique-length le 10 then

RP/0/0/CPU0:router(config-rpl)# if as-path unique-length eq $integerparam then
RP/0/0/CPU0:router(config-rpl-if)# if as-path unique-length ge $geparam then
RP/0/0/CPU0:router(config-rpl-if)# if as-path unique-length le $leparam then

RP/0/0/CPU0:router(config-rpl)# set local-preference 100
RP/0/0/CPU0:router(config-rpl)# endif
```

## Related Commands

# community is-empty

To check if a route has no community attributes associated with it, use the **community is-empty** command in route-policy configuration mode.

**community is-empty**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **community is-empty** command as a conditional expression within an **if** statement to check if a route has community attributes associated with it.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command takes no arguments and evaluates to true only if the route has no community attributes associated with it.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** In the following example, if the route has no community attributes associated with it, then the local preference is set to 100:

```
RP/0/0/CPU0:router(config-rpl)# if community is-empty then
RP/0/0/CPU0:router(config-rpl-if) # set local-preference 100
RP/0/0/CPU0:router(config-rpl-if) # endif
```

# community matches-any

To match any elements of a community set, use the **community matches-any** command in route-policy configuration mode.

**community matches-any** {*community-set-name*| *inline-community-set*| *parameter*}

## Syntax Description

|                             |                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------|
| <i>community-set-name</i>   | Name of a community set.                                                        |
| <i>inline-community-set</i> | Inline community set. The inline community set must be enclosed in parentheses. |
| <i>parameter</i>            | Parameter name. The parameter name must be preceded with a "\$."                |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The BGP community matching operators were enhanced to allow comparisons on ranges and regular expressions. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                                                                                       |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **community matches-any** command as a conditional expression within an **if** statement to match any element of a community set.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-any** operator evaluates as true if at least one community element of the community attribute for the route matches an element in the community set operand. If no community in the route matches any of the specifications in the named or inline set, then the condition evaluates to false. Likewise, when there is no community at all in the route, the condition evaluates to false.

Matching of a community in the route to a specification in a named or an inline set is intuitive. If the community specification in a set is the familiar colon-separated decimal 16-bit numbers specification, or one of the well-known communities, the community matches the specification if the specification denotes the same 32-bit number as that in the route. If the community specification uses a wildcard, then the community in the route matches if it is one of the many communities denoted by the wildcard specification. In inline sets, community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

Communities may also be matched using range and regular expression operators. Range specifications are entered as follows: [ *low-value* .. *high-value* ]. Either or both colon-separated halves of a community value may contain a range. The following are valid range specifications:

```
10:[100..1000]
[10..100]:80
[10..100]:[100..2000]
```

In addition, the **private-as** keyword may be used to specify the range from 64512 to 65534. Regular expressions are specified as the **ios-regex** keyword followed by a valid regular expression string.

Community values from the route are matched one at a time to the match specifications. Therefore, regex match specifications are expected to represent one individual community value and not a sequence of community values.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, a named community set called my-community-set and a route policy called community-matches-any-example are created. The policy sets the local-preference to 100 for any route that has one or more of the communities in the my-community-set community set. If the route does not have any of these communities, the policy checks whether it has any communities whose first half is in the range from 10 to 25 and whose second half is the value 35, in which case it sets the local-preference to 200. Otherwise, it checks for a community value in the range of 30:100 to 30:500, in which case it sets the local-preference to 300.

```
RP/0/0/CPU0:router(config)# community-set my-community-set
RP/0/0/CPU0:router(config-comm)# 10:20,
RP/0/0/CPU0:router(config-comm)# 10:30,
RP/0/0/CPU0:router(config-comm)# 10:40
RP/0/0/CPU0:router(config-comm)# end-set

RP/0/0/CPU0:router(config)# route-policy community-matches-any-example
RP/0/0/CPU0:router(config-rpl)# if community matches-any my-community-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# elseif community matches-any ([10..25]:35) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-any (30:[100..500]) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 300
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

| Release 3.2   | This command was introduced.<br><br>The BGP community matching operators were enhanced to allow comparisons on ranges and regular expressions. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                                                                                       |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **community matches-every** command as a conditional expression within an **if** statement to match every element of a community set.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-every** operator evaluates as true if every specification in the named set or inline set specified matches at least one community value in the route. If any community specification in the named or inline set is not matched, then the operation evaluates to false.

Matching of a community in the route to a specification in a named or an inline set is intuitive. If the community-specification in a set is the familiar colon-separated decimal 16-bit numbers specification, or one

of the well-known communities, the community matches the specification if the specification denotes the same 32-bit number as that in the route. If the community specification uses a wildcard, then the community in the route matches if it is one of the many communities denoted by the wildcard specification. In inline sets, community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

Communities may also be matched using range and regular expression operators. Range specifications are entered as follows: [ *low-value* .. *high-value* ]. Either or both colon-separated halves of a community value may contain a range. The following are valid range specifications:

```
10:[100..1000]
[10..100]:80
[10..100]:[100..2000]
```

Therefore, a **matches-every** operation with two community range specifications means that a community must be present in the route that corresponds to each range. For example, in the following statement:

```
if community matches-every (10:[100..200],20:[100..200]) then
```

the statement evaluates as true if one or more communities in the route lie in the range 10:[100..200] and one or more communities in the route lie in the range 20:[100..200].

In addition, the **private-as** keyword may be used to specify the range from 64512 to 65534.

Regular expressions are specified as the **ios-regex** keyword followed by a valid single-quoted regular expression string. Community values from the route are matched one at a time against the match specifications. Therefore, regex match specifications are expected to represent one individual community value and not a sequence of community values.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the route policy named community-matches-every-example sets the local-preference value to 100 for all routes that have all three communities in the my-community-set community set. Routes that do not have all three communities but have a community that matches the first regular expression match have the local-preference value set to 200. Finally, any remaining routes that match the last regular expression have the local-preference values set to 300.

```
RP/0/0/CPU0:router(config)# community-set my-community-set
RP/0/0/CPU0:router(config-comm)# 10:20,
RP/0/0/CPU0:router(config-comm)# 10:30,
RP/0/0/CPU0:router(config-comm)# 10:40
RP/0/0/CPU0:router(config-comm)# end-set

RP/0/0/CPU0:router(config)# route-policy community-matches-every-example
RP/0/0/CPU0:router(config-rpl)# if community matches-every my-community-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-every (ios-regex
'10:[0-9]0_') then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# elseif community matches-every
(ios-regex'20:[0-9]0_') then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 300
```

```
RP/0/0/CPU0:router(config-rpl-elseif)# endif  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# community-set

To define a community set, use the **community-set** command in global configuration mode. To remove the community set, use the **no** form of this command.

**community-set** *name*

**no community-set** *name*

## Syntax Description

|             |                            |
|-------------|----------------------------|
| <i>name</i> | Name of the community set. |
|-------------|----------------------------|

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Regular expressions and ranges can be specified to match the communities. An attempt to use a community set that contains a range or regular expression to set a community value is rejected when an attempt to attach such a policy is made.

A community set holds community values for matching against the Border Gateway Protocol (BGP) community attribute. A community is a 32-bit quantity. For notational convenience, each community value must be split in half and expressed as two unsigned decimal integers in the range from 0 to 65535, separated by a colon.

The inline form of a community set also supports parameterization. Each 16-bit portion of the community may be parameterized.

The routing policy language (RPL) provides symbolic names for the standard well-known community values: **accept-own** is 0xFFFF0001, **internet** is 0:0, **no-export** is 65535:65281, **no-advertise** is 65535:65282, and **local-as** is 65535:65283.

RPL also provides a facility for using wildcards in community specifications. A wildcard is specified by inserting an asterisk (\*) in place of one of the 16-bit portions of the community specification, which indicates that any value for that portion of the community matches.

Every community set must contain at least one community value. An empty community set is invalid and the policy configuration system rejects it.

Community sets can be entered in these formats:

| Format              | Description                                                  |
|---------------------|--------------------------------------------------------------|
| <i>#-remark</i>     | Remark beginning with '#'                                    |
| <i>*</i>            | Wildcard (any community or part thereof)                     |
| <i>0-65535</i>      | 16-bit half-community number                                 |
| <i>[</i>            | Left bracket to begin range                                  |
| <b>accept-own</b>   | Accept-Own (BGP well-known community)                        |
| <b>dfa-regex</b>    | DFA (deterministic finite automata) style regular expression |
| <b>internet</b>     | Internet (BGP well-known community)                          |
| <b>ios-regex</b>    | Traditional IOS style regular expression                     |
| <b>local-AS</b>     | Do not send outside local AS (BGP well-known community)      |
| <b>no-advertise</b> | Do not advertise to any peer (BGP well-known community)      |
| <b>no-export</b>    | Do not export to next AS (BGP well-known community)          |
| <b>private-as</b>   | Match within BGP private AS range [64512..65534]             |

**Note**

The dfa-regex and ios-regex syntax for community set is `"[/][^':&<>]*:[^':&<>]*[/]"`. This means that regex starts with a single-quote (") followed by a string of any character (that does not include single-quote, colon, ampersand, less-than, greater-than, or space) followed by a colon, and a string of any characters (that does not include single-quote, colon, ampersand, less-than, greater-than, or space) followed by single-quote.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, a community set named `cset_accept_own` is created:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#community-set cset_accept_own
RP/0/0/CPU0:router(config-comm)#accept-own
RP/0/0/CPU0:router(config-comm)#end-set
```

In the following example, a community set named `cset1` is created:

```
RP/0/0/CPU0:router(config)# community-set cset1
```

```
RP/0/0/CPU0:router(config-comm)# 12:34,  
RP/0/0/CPU0:router(config-comm)# 12:56,  
RP/0/0/CPU0:router(config-comm)# 12:78,  
RP/0/0/CPU0:router(config-comm)# internet  
RP/0/0/CPU0:router(config-comm)# end-set
```

In the following example, a community set named cset2 is created:

```
RP/0/0/CPU0:router(config)# community-set cset2  
RP/0/0/CPU0:router(config-comm)# 123:456,  
RP/0/0/CPU0:router(config-comm)# no-advertise,  
RP/0/0/CPU0:router(config-comm)# end-set
```

In the following example, a community set named cset3 is created. This policy uses wildcards and matches all communities where the autonomous system part of the community is 123.

```
RP/0/0/CPU0:router(config)# community-set cset3  
RP/0/0/CPU0:router(config-comm)# 123:*  
RP/0/0/CPU0:router(config-comm)# end-set
```

# delete community

To delete community attributes associated with a Border Gateway Protocol (BGP) route, use the **delete community** command in route-policy configuration mode.

**delete community** {**all** | **in** {*community-set-name* | *inline-community-set* | *parameter*} | **not in** {*community-set-name* | *inline-community-set* | *parameter*}}

## Syntax Description

|                             |                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>                  | Removes all communities except the well-known communities.                                                                                     |
| <b>in</b>                   | Removes any communities associated with the route that are listed in either the named community set or the inline community set.               |
| <i>community-set-name</i>   | Name of a community set.                                                                                                                       |
| <i>inline-community-set</i> | Inline community set. The inline community set must be enclosed in parentheses.                                                                |
| <i>parameter</i>            | Parameter name. The parameter name must be preceded with a "\$."                                                                               |
| <b>not in</b>               | Removes all communities that are not listed in either the named community set or the inline community set, and are not well-known communities. |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The BGP community deletion operations were extended to allow communities that match a range specification or a regular expression to be deleted. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                                                                                                                             |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **delete community** command to delete community attributes associated with a BGP route.

**Note**

The **delete community** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Communities are 32-bit values carried in Border Gateway Protocol (BGP) routes. Each route may have zero or more communities in an unordered list.

You can remove a well-known community (internet, no-export, no-advertise, or local-as) from a route, but this removal must be done explicitly. This command should be used with a degree of caution. In general, few circumstances exist in which you would need to remove a well-known community.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows how to delete any communities associated with the routes that are listed in either the named community set or inline community set, respectively.

```
RP/0/0/CPU0:router(config-rpl)# delete community in my_community_set
RP/0/0/CPU0:router(config-rpl)# delete community in (10:[0..50],20:[60..80])
```

The following example shows how to remove all communities including well-known communities.

```
RP/0/0/CPU0:router(config-rpl)# delete community in (internet, no-export, no-advertise,
local-as, *:*)
```

The following example shows how to remove all communities except for the well-known communities.

```
RP/0/0/CPU0:router(config-rpl)# delete community all
```

The following example shows how to delete the well-known community value internet from a route:

```
RP/0/0/CPU0:router(config-rpl)# delete community in (internet)
```

# delete extcommunity rt

To delete route target (RT) extended community attributes associated with a Border Gateway Protocol (route), use the **delete extcommunity rt** command in route-policy configuration mode.

**delete extcommunity rt** {**all**| **in** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}| **not in** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}}

## Syntax Description

|                                |                                                                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>                     | Removes all extended communities.                                                                                                                                                  |
| <b>in</b>                      | Removes any extended communities associated with the routes that are listed in either the named extended community set or the inline extended community set.                       |
| <i>extcommunity-set-name</i>   | Name of an extended community set.                                                                                                                                                 |
| <i>inline-extcommunity-set</i> | Inline extended community set. The inline extended community set must be enclosed in parentheses.                                                                                  |
| <i>parameter</i>               | Parameter name. The parameter name must be preceded with a "\$."                                                                                                                   |
| <b>not in</b>                  | Removes all extended communities that are not listed in either the named extended community set or the inline extended community set, and are not well-known extended communities. |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                                                                  |
|---------------|---------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                  |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                                                      |
| Release 3.5.0 | Support was added for the usage of Wildcards (*) and regular expressions for extended community set elements. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **delete extcommunity rt** command to delete extended community values from a BGP route target extended community list in a route.

**Note**

The **delete extcommunity rt** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Extended communities are similar to regular Border Gateway Protocol (BGP) communities but contain more data and have a richer structure for encoding information in them.

Extended communities can be in the following forms: SoO:AS:tag, SoO:IP:tag, RT:AS:tag, or RT:IP:tag.

Wildcards (\*) and regular expressions are allowed for extended community set elements.

The forms of this command that take a named extended community set or an inline extended community set value as arguments are equivalent. They delete any extended communities that are listed in either the named set or the inline set, respectively.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, all extended communities are deleted:

```
RP/0/0/CPU0:router(config-rpl)# delete extcommunity rt all
```

In this example, any extended communities that are listed in my-extcommunity-set are deleted:

```
RP/0/0/CPU0:router(config-rpl)# delete extcommunity rt in my-extcommunity-set
```

In this example, extended communities associated with the route listed in the named inline extended community sets are deleted:

```
RP/0/0/CPU0:router(config-rpl)# delete extcommunity rt in (67:29, 67:55)
```

# destination in

To match a destination entry in a named prefix set or inline prefix set, use the **destination in** command in route-policy configuration mode.

**destination in** {*prefix-set-name*| *inline-prefix-set*| *parameter*}

## Syntax Description

|                               |                                                                           |
|-------------------------------|---------------------------------------------------------------------------|
| <i>prefix-set-name</i>        | Name of a prefix set.                                                     |
| <i>inline-prefix-set</i>      | Inline prefix set. The inline prefix set must be enclosed in parentheses. |
| <i>parameter</i><br>parameter | Parameter name. The parameter name must be preceded with a "\$."          |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.2   | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **destination in** command as a conditional expression within an **if** statement to match a destination entry in a named prefix set or inline prefix set.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command takes either a named prefix set or an inline prefix set value as an argument. The condition returns true if the destination entry matches any entry in the prefix set or inline prefix set. An attempt to match a destination using a prefix set that is defined but contains no elements returns false.

The routing policy language (RPL) provides the ability to test destinations for a match to a list of prefix match specifications using the **in** operator. The **destination in** command is protocol-independent.

In Border Gateway Protocol (BGP), the destination of a route is also known as its network-layer reachability information (NLRI). It comprises a prefix value and a mask length.

RPL supports both 32-bit IPv4 prefixes, specified in dotted-decimal format, and 128-bit IPv6 prefixes, specified in colon-separated hexadecimal format.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, a prefix set named my-prefix-set is defined and a route policy named use-destination-in is created. Within the use-destination-in route policy, the **destination in** command is used within an **if** statement to learn if the destination is in the prefix-set named my-prefix-set. If it is, then local preference is set to 100. If it is not in my-prefix-set but does match the next prefix specifications, then local preference is set to 200.

```
RP/0/0/CPU0:router(config)# prefix-set my-prefix-set
RP/0/0/CPU0:router(config-pfx)# 10.0.0.1/32,
RP/0/0/CPU0:router(config-pfx)# fe80::203:0:0:0/64,
RP/0/0/CPU0:router(config-pfx)# 10.0.0.2/24 le 32
RP/0/0/CPU0:router(config-pfx)# end-set

RP/0/0/CPU0:router(config)# route-policy use-destination-in
RP/0/0/CPU0:router(config-rpl)# if destination in my-prefix-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# elseif destination in (10.0.0.1/32, 10.0.0.2/24 le 32)
then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

In the following example, a prefix set named ipv6-prefix-set is defined and a route policy named ipv6-destination-in is created. Within the ipv6-destination-in route policy, the **destination in** command is used within an **if** statement to learn if the destination is in the prefix-set named ipv6-prefix-set. If it is, then the next-hop is set to 2001:abcd:fedc::1. If it is not in ipv6-prefix-set but does match the next prefix specifications, then the next-hop is set to 1111:2222:3333:4444:5555:6666:7777:8888.

```
RP/0/0/CPU0:router(config)# prefix-set ipv6-prefix-set
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:1::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:2::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:3::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:4::/64
RP/0/0/CPU0:router(config-pfx)# end-set

RP/0/0/CPU0:router(config)# route-policy ipv6-destination-in
RP/0/0/CPU0:router(config-rpl)# if destination in ipv6-prefix-set then
RP/0/0/CPU0:router(config-rpl-if)# set next-hop 2001:abcd:fedc::1
RP/0/0/CPU0:router(config-rpl-if)# elseif destination in (2001::1, 2002:1:2:3::/64) then
RP/0/0/CPU0:router(config-rpl-elseif)# set next-hop 1111:2222:3333:4444:5555:6666:7777:8888

RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# done

To stop executing a policy and accept the route, use the **done** command in route-policy configuration mode.

**done**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **done** command to stop executing the policy and accept the route.

**Note** The **done** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

When encountering a **done** statement the route is passed and no further policy statements are executed. All modifications made to the route prior to the **done** statement are still valid.

**Note** The default action of a route policy is to drop or discard any routes that have not been either explicitly passed or for which no attempt has been made to modify with an action. The routing policy language (RPL) does not have specific “match clauses,” which means the default drop behavior is controlled by whether a route has been explicitly passed or an attempt has been to modify the route using an action statement.

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, if the destination match succeeds for 29.0.0.0/8 le 32, the execution continues past set community 102:12 and onto the next statement. If the destination match succeeds for 39.0.0.0/8 le 32 execution, then the policy execution stops when it encounters the *done* statement.

```
RP/0/0/CPU0:router(config)# route-policy done_st_example
RP/0/0/CPU0:router(config-rpl)# if destination in (29.0.0.0/8 le 32) then
RP/0/0/CPU0:router(config-rpl-if)# set community 102:12
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# if destination in (39.0.0.0/8 le 32) then
RP/0/0/CPU0:router(config-rpl-if)# set community 102:39
RP/0/0/CPU0:router(config-rpl-if)# done
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# if destination in (49.0.0.0/8 le 32) then
RP/0/0/CPU0:router(config-rpl-if)# set community 102:49
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# if destination in (59.0.0.0/8 le 32) then
RP/0/0/CPU0:router(config-rpl-if)# set community 102:59
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# drop

To discard a route, use the **drop** command in route-policy configuration mode.

## drop

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **drop** command within a route policy to drop a route.

**Note** The **drop** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

This command causes the route to be dropped. After a route is dropped, no further execution of policy occurs. Therefore, if after executing the first two statements of a policy the **drop** statement is encountered, the route is discarded and execution stops immediately even when the policy contains further statements.

**Note** The default action of a route policy is to drop or discard any routes that have not been either explicitly passed or attempted to be modified with an action. The routing policy language (RPL) does not have specific “match clauses,” which means the default drop behavior is controlled by whether a route has been explicitly passed or an attempt has been to modify the route using an action statement.

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, any route with a destination address contained within the prefix set pset1 is dropped:

```
RP/0/0/CPU0:router(config-rpl)# if destination in pset1 then  
RP/0/0/CPU0:router(config-rpl-if)# drop  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)#
```

# edit

To edit the contents of a route policy, a prefix set, an AS path set, a community set, or an extended community set, use the **edit** command in EXEC mode.

**edit** {**route-policy**|**prefix-set**|**as-path-set**|**community-set**|**extcommunity-set** {**rt**|**soo**}|**policy-global**|**rd-set**} *name* [**nano**|**emacs**|**vim**|**inline** {**add**|**prepend**|**remove**} *set-element*]

## Syntax Description

| Command History | Release       | Modification                                                                                                                                                                                                              |
|-----------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                                                                                                                                                                              |
|                 | Release 3.3.0 | Added <b>vim</b> keyword.                                                                                                                                                                                                 |
|                 | Release 3.4.0 | The <b>policy-global</b> keyword was added.                                                                                                                                                                               |
|                 | Release 3.5.0 | The <b>nano</b> keyword was added and GNU nano text editor became the default editor type.                                                                                                                                |
|                 | Release 3.6.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>inline</b></li> <li>• <b>add</b></li> <li>• <b>prepend</b></li> <li>• <b>remove</b></li> <li>• <i>set-element</i></li> </ul> |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **edit** command to edit the contents of a route policy, a prefix set, an AS path set, a community set, an extended community set, a global policy, or a route destination set.

After editing with Nano, save the edit buffer and exit the editor using the Ctrl-X keystroke.

After editing with Emacs, save the editor buffer by using the Ctrl-X and Ctrl-S keystrokes. To save and exit the editor, use the Ctrl-X and Ctrl-C keystrokes.

After editing with VIM, to write to a current file and exit use the :wq or :x or ZZ keystrokes. To quit and confirm, use the :q keystrokes. To quit and discard changes, use the :q! keystrokes.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples**

In the following example, the policy\_A policy is opened in the editor:

```
RP/0/0/CPU0:router# edit route-policy policy_A
```

```
-----
== MicroEMACS 3.8b () == rpl_edit.139281 ==
  if destination in (2001::/8) then
    drop
  endif
end-policy
!

== MicroEMACS 3.8b () == rpl_edit.139281 ==
Parsing.
83 bytes parsed in 1 sec (82)bytes/sec
Committing.
1 items committed in 1 sec (0)items/sec
Updating.
Updated Commit database in 1 sec
```

If there are parse errors, you are asked whether editing should continue:

```
RP/0/0/CPU0:router#edit route-policy policy_B
== MicroEMACS 3.8b () == rpl_edit.141738
route-policy policy_B
  set metric-type type_1
  if destination in (2001::/8) then
    drop
  endif
end-policy
!
== MicroEMACS 3.8b () == rpl_edit.141738 ==
Parsing.
105 bytes parsed in 1 sec (103)bytes/sec

% Syntax/Authorization errors in one or more commands.!! CONFIGURATION
FAILED DUE TO SYNTAX/AUTHORIZATION ERRORS
  set metric-type type_1
  if destination in (2001::/8) then
    drop
  endif
end-policy
!

Continue editing? [no]:
```

If you answer **yes**, the editor continues on the text buffer from where you left off. If you answer **no**, the running configuration is not changed and the editing session is ended.

After the policy is opened, it may be manipulated using normal editor commands, then saved and committed to the running configuration.

# end-global

To end the definition of global parameters and exit global parameter configuration mode, use the **end-global** command in global parameter configuration mode.

**end-global**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or values

## Command Modes

Global parameter configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **end-global** command to end the definition of global parameters and exit global parameter configuration mode.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the **end-global** command ends the definition of global parameters:

```
RP/0/0/CPU0:router(config)#policy-global
RP/0/0/CPU0:router(config-rp-gl)# glbpathtype 'ebgp'
RP/0/0/CPU0:router(config-rp-gl)# glbtag '100'
RP/0/0/CPU0:router(config-rp-gl)# end-global
```

## Related Commands

|---------------------------------------------|---------------------------------------------|
| <a href="#">policy-global, on page 1636</a> | Enters global parameter configuration mode. |

# end-policy

To end the definition of a route policy and exit route-policy configuration mode, use the **end-policy** command in route-policy configuration mode.

**end-policy**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **end-policy** command to end the definition of a route policy and exit route-policy configuration mode.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** In the following example, the **end-policy** command ends the definition of a route policy:

```
RP/0/0/CPU0:router(config)#route-policy med-to-local-pref
RP/0/0/CPU0:router(config-rpl)#if med eq 150 then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 10
RP/0/0/CPU0:router(config-rpl-if)# elseif med eq 200 then
RP/0/0/CPU0:router(config-elseif)# set local-preference 60
RP/0/0/CPU0:router(config-elseif)# elseif med eq 250 then
RP/0/0/CPU0:router(config-elseif)# set local-preference 0

RP/0/0/CPU0:router(config-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

|---------------------------------------------------|--------------------------------------------------------------------|
| <a href="#">route-policy (RPL)</a> , on page 1653 | Defines a route policy and enters route-policy configuration mode. |

# end-set

To end the definition of an AS path set, a prefix set, a community set, an extended community set, or an RD set and return to global configuration mode, use the **end-set** command in route-policy configuration mode.

**end-set**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or values

## Command Modes

AS path set configuration  
Prefix set configuration  
Community set configuration  
Extended community set configuration  
Route distinguisher set configuration

## Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.2   | This command was introduced.                               |
| Release 3.3.0 | Added support functionality for the <b>rd-set</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **end-set** command to end the definition of an AS path set, a prefix set, a community set, or an extended community set.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the **end-set** command ends the definition of an AS path set named aset1:

```
RP/0/0/CPU0:router(config)# as-path-set aset1
RP/0/0/CPU0:router(config-as)# ios-regex '_42$',
RP/0/0/CPU0:router(config-as)# ios-regex '_127$'
```

```
RP/0/0/CPU0:router(config-as)# end-set
RP/0/0/CPU0:router(config)#
```

The following example shows how to create an RD set called `my_rd_set` and use the `end-set` command to end the definition:

```
RP/0/0/CPU0:router(config)# rd-set my_rd_set
RP/0/0/CPU0:router(config-rd)# 172.16.0.0/16:*,
RP/0/0/CPU0:router(config-rd)# 172.17.0.0/16:100,
RP/0/0/CPU0:router(config-rd)# 192:*,
RP/0/0/CPU0:router(config-rd)# 192:100
RP/0/0/CPU0:router(config-rd)# end-set
```

# extcommunity rt is-empty

To check if a Border Gateway Protocol (BGP) route has route target (RT) extended community attributes associated with it, use the **extcommunity rt is-empty** command in route-policy configuration mode.

**extcommunity rt is-empty**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or value

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                    |
|---------------|-----------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                    |
|               | This command replaced the <b>extcommunity is-empty</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity rt is-empty** command as a conditional expression within an **if** statement to check if a BGP route has extended community attributes associated with it.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **is-empty** operator takes no arguments and evaluates to true if the route has no extended community attributes associated with it.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, if the extended community is empty, then the local preference is set to 100:

```
RP/0/0/CPU0:router(config)# route-policy extcommunity-is-empty-example
RP/0/0/CPU0:router(config-rpl)# if extcommunity rt is-empty then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
```

 **extcommunity rt is-empty**

```
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## extcommunity rt matches-any

To match any element of a Border Gateway Protocol (BGP) route target (RT) extended community set, use the **extcommunity rt matches-any** command in route-policy configuration mode.

**extcommunity rt matches-any** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}

### Syntax Description

|                                |                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------|
| <i>extcommunity-set-name</i>   | Name of an RT extended community set.                                                                |
| <i>inline-extcommunity-set</i> | Inline RT extended community set. The inline extended community set must be enclosed in parentheses. |
| <i>parameter</i>               | Parameter name. The parameter name must be preceded with a "\$."                                     |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                                           |
|---------------|----------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                           |
|               | This command replaced the <b>extcommunity matches-any</b> command.                     |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                               |
| Release 3.5.0 | Wildcards (*) and regular expressions are allowed for extended community set elements. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity rt matches-any** command as a conditional expression within an **if** statement to match elements of an extended community set.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-any** operator evaluates as true if at least one extended community in the route matches an extended community specification in the named or inline set. If no extended community

in the route matches any of the specifications in the named or inline set, then this simple condition evaluates to false. Likewise, when there is no extended community at all in the route, the condition evaluates to false.

Matching an extended community in the route to a specification in a named or an inline set is intuitive. In inline sets, extended community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, an extended community set named my-extcommunity-set and a parameterized route-policy named my-extcommunity-set-example(\$tag,\$ip) are defined. The **extcommunity rt matches-any** command is used in an if statement such that if at least one extended community in the route matches an extended community specification in the named set, then the local preference is set to 100. If there is no extended community in the route that matches any of the specifications in the named set, then the condition evaluates as false and the extended community is compared to the inline extended sets.

```
RP/0/0/CPU0:router(config)# extcommunity-set rt my-extcommunity-set
RP/0/0/CPU0:router(config-ext)# 10:615,
RP/0/0/CPU0:router(config-ext)# 10:6150,
RP/0/0/CPU0:router(config-ext)# 15.15.15.15:15
RP/0/0/CPU0:router(config-ext)# end-set

RP/0/0/CPU0:router(config)# route-policy my-extcommunity-set-example($tag,$ip)
RP/0/0/CPU0:router(config-rpl)# if extcommunity rt matches-any my-extcommunity-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# elseif extcommunity rt matches-any (10:20, 10:$tag) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# elseif extcommunity rt matches-any ($ip:$tag) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 300
RP/0/0/CPU0:router(config-rpl-elseif)# elseif extcommunity rt matches-any (2.3.4.5:$tag)
then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 400
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## Related Commands

| <a href="#">extcommunity rt matches-every</a> , on page 1599 | Matches every element of a BGP RT extended community set. |

## extcommunity rt matches-every

To match every element of a Border Gateway Protocol (BGP) route target (RT) extended community set, use the **extcommunity rt matches-every** command in route-policy configuration mode.

**extcommunity rt matches-every** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}

### Syntax Description

|                                |                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------|
| <i>extcommunity-set-name</i>   | Name of an RT extended community set.                                                                |
| <i>inline-extcommunity-set</i> | Inline RT extended community set. The inline extended community set must be enclosed in parentheses. |
| <i>parameter</i>               | Parameter name. The parameter name must be preceded with a "\$."                                     |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                                                                  |
|---------------|---------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                  |
|               | This command replaced the <b>extcommunity matches-every</b> command.                                          |
| Release 3.4.0 | The <i>parameter</i> argument was added.                                                                      |
| Release 3.5.0 | Support was added for the usage of Wildcards (*) and regular expressions for extended community set elements. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity rt matches-every** command as a conditional expression within an **if** statement to match every element of an RT extended community set.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-every** operator evaluates as true if every extended community value in the extended community attribute for the route matches at least one element of the extended community set or inline set. If no extended community in the route matches any of the specifications in the named or

inline set, then this simple condition evaluates to false. Likewise, when there is no extended community at all in the route, the condition evaluates to false.

Matching an extended community in the route to a specification in a named or an inline set is intuitive. In inline sets, extended community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, an extended community set named my-extcommunity-set and a parameterized route policy named extcommunity-matches-every-example (\$as, \$tag) are defined. The condition extcommunity rt matches-every is used in an if statement in this policy. If it evaluates to true, the local-preference value is set to 100. If it evaluates to false, the extended community is evaluated using an inline set. If that condition evaluates to true, the local-preference value is set to 200. If it evaluates to false, the local-preference value is set to 300.

```
RP/0/0/CPU0:router(config)# extcommunity-set rt my-extcommunity-set
RP/0/0/CPU0:router(config-ext)# 10:20,
RP/0/0/CPU0:router(config-ext)# 10:30,
RP/0/0/CPU0:router(config-ext)# 10:40
RP/0/0/CPU0:router(config-ext)# end-set
RP/0/0/CPU0:router(config)# route-policy extcommunity-matches-every-example($as,$tag)
RP/0/0/CPU0:router(config-rpl)# if extcommunity rt matches-every my-extcommunity-set then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# elseif extcommunity rt matches-every (10:20, 10:$tag,
$as:30) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# elseif
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 300
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

| Command                                                   | Description                                             |
|-----------------------------------------------------------|---------------------------------------------------------|
| <a href="#">extcommunity rt matches-any, on page 1597</a> | Matches any element of a BGP RT extended community set. |

## extcommunity rt matches-within

To match at least one element of an extended community set of a Border Gateway Protocol (BGP) route target (RT), use the **extcommunity rt matches-within** command in route-policy configuration mode.

**extcommunity rt matches-within** {*rt-type-extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}

### Syntax Description

|                                      |                                                            |
|--------------------------------------|------------------------------------------------------------|
| <i>rt-type-extcommunity-set-name</i> | Name of an RT extended community set.                      |
| <i>inline-extcommunity-set</i>       | Inline RT extended community set, enclosed in parentheses. |
| <i>parameter</i>                     | Parameter name preceded with a "\$" symbol.                |

### Command Default

None

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity rt matches-within** command as a conditional expression within an if statement to match elements of an extended community set.

#### Note

For a list of all conditional expressions available within an if statement, see the if command.

A simple condition using the matches-within operator evaluates as true if all the elements in extended community from the route match any element in the extended community set. For example, let 'c' be the RTs from the route and 'm' be the RT set from the policy. With the **extcommunity rt matches-within** configuration, each value in 'c' must match any (or at least one) value in 'm'.

Matching an extended community in the route to a specification in a named or an inline set is intuitive. In inline sets, extended community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

**Task ID**

| Task ID      | Operation   |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, an extended community set named *my-extcommunity-set* and a parameterized route-policy named *my-extcommunity-set-example(\$tag,\$ip)* are defined. The **extcommunity rt matches-within** command is used in an if statement such that if all extended community values in the route match any element of the extended community specification in the named set, then the local preference is set to 100.

```
RP/0/0/CPU0:router(config)#extcommunity-set rt my-extcommunity-set
RP/0/0/CPU0:router(config-ext)#10:615,
RP/0/0/CPU0:router(config-ext)#10:6150,
RP/0/0/CPU0:router(config-ext)#15.15.15.15:15
RP/0/0/CPU0:router(config-ext)#end-set
RP/0/0/CPU0:router(config)#route-policy my-extcommunity-set-example($tag,$ip)
RP/0/0/CPU0:router(config-rpl)#if extcommunity rt matches-within my-extcommunity-set then
RP/0/0/CPU0:router(config-rpl-if)#set local-preference 100
```

# extcommunity-set cost

To define a cost extended community set, use the **extcommunity-set cost** command in global configuration mode. To remove the cost extended community set, use the **no** form of this command.

**extcommunity-set cost** *name*

**no extcommunity-set cost** *name*

## Syntax Description

|             |                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i> | Name of a cost extended community set. The <i>name</i> argument is case sensitive, can contain any alphanumeric characters, and can be up to 63 characters in length. |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release       | Modification                                                                                                  |
|---------------|---------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                  |
| Release 3.5.0 | Support was added for the usage of Wildcards (*) and regular expressions for extended community set elements. |
| Release 3.9.0 | Support was added for more cost extended community formats.                                                   |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity-set cost** command to define a cost extended community set.

An extended community set is analogous to a community set except that it contains extended community values instead of regular community values. Extended community values are 64-bit structured values. An extended community set also supports named forms and inline forms.

Cost extended communities can be entered in these formats:

- **#-remark** ---Remark beginning with '#'
- **0-255**---Decimal number
- **abort** ---Discard RPL definition and return to top level config
- **end-set** ---End of set definition
- **exit** ---Exit from the submode

- **igp**:---Cost Community with IGP as point of insertion
- **pre-bestpath**: ---Cost Community with Pre-Bestpath as point of insertion
- **show** ---Show partial RPL configuration

Multiple cost community set clauses can be configured in each route policy block or sequence. Each cost community set clause must have a different ID (0-255). The cost community set clause with the lowest cost-value is preferred by the best path selection process when all other attributes are equal.

As with community sets, the inline form supports parameterization within parameterized policies. Either portion of the extended community value can be parameterized.

Every extended community set must contain at least one extended community value. Empty extended community sets are invalid and the policy configuration system rejects them.

Wildcards (\*) and regular expressions are allowed for extended community set elements.

## Examples

In the following example, a cost extended community set named extcomm-cost is defined:

```
RP/0/0/CPU0:router(config)# extcommunity-set cost extcomm-cost  
RP/0/0/CPU0:router(config-ext)# IGP:90:914,  
RP/0/0/CPU0:router(config-ext)# Pre-Bestpath:91:915  
RP/0/0/CPU0:router(config-ext)# end-set
```

## extcommunity-set rt

To define a Border Gateway Protocol (BGP) route target (RT) extended community set, use the **extcommunity-set rt** command in global configuration mode. To remove the RT community set, use the **no** form of this command.

**extcommunity-set rt** *name*

**no extcommunity-set rt** *name*

### Syntax Description

|             |                                       |
|-------------|---------------------------------------|
| <i>name</i> | Name of an RT extended community set. |
|-------------|---------------------------------------|

### Command Default

No default behavior or values

### Command Modes

Global configuration

### Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
|               | This command replaced the <b>extcommunity-set</b> command. |
| Release 3.9.0 | Support was added for more rt extended community formats.  |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity-set rt** command to define an RT extended community set for BGP.

Regular expressions and ranges can be specified to match the extended communities. Regular expressions and ranges can be specified in an extended community set to support the matching of communities. An attempt to use an extended community set that contains a range or regular expression to set an extended community set value is rejected when an attempt to attach such a policy is made.

An extcommunity set RT holds RT extended community values to match against the Border Gateway Protocol (BGP) RT extended community attribute. RT extended communities can be entered in these formats:

- *#-remark* ---Remark beginning with '#'
- *\*---* Wildcard (any community or part thereof)
- *1-4294967295---* 32-bit decimal number
- *1-65535 ---* 16-bit decimal number

- *A.B.C.D/M:N* ---Extended community - IPv4 prefix format
- *A.B.C.D:N*---Extended community - IPv4 format
- *ASN:N* ---Extended community - ASPLAIN format
- *X.Y:N* ---Extended community - ASDOT format
- **dfa-regex** ---DFA (deterministic finite automata) style regular expression
- **ios-regex** ---Traditional IOS style regular expression

**Note**

The dfa-regex and ios-regex syntax for community set is "[^<>]\*:[^<>]\*[ ]". This means that regex starts with a single-quote (") followed by a string of any character (that does not include single-quote, colon, ampersand, less-than, greater-than, or space) followed by a colon, and a string of any characters (that does not include single-quote, colon, ampersand, less-than, greater-than, or space) followed by single-quote.

*N* is a number within the range of 1 to 65535.

**Examples**

In the following example, an RT extended community set named extcomm-rt is defined:

```
RP/0/0/CPU0:router(config)# extcommunity-set rt extcomm-rt
RP/0/0/CPU0:router(config-ext)# 10002:666
RP/0/0/CPU0:router(config-ext)# 10.0.0.2:666
RP/0/0/CPU0:router(config-ext)# end-set
```

## extcommunity-set soo

To define a Border Gateway Protocol (BGP) Site-of-Origin (SoO) extended community set, use the **extcommunity-set soo** command in global configuration mode. To remove the SoO extended community set, use the **no** form of this command.

**extcommunity-set soo** *name*

**no extcommunity-set soo** *name*

### Syntax Description

|             |                                        |
|-------------|----------------------------------------|
| <i>name</i> | Name of an SoO extended community set. |
|-------------|----------------------------------------|

### Command Default

No default behavior or values

### Command Modes

Global configuration

### Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
|               | This command replaced the <b>extcommunity-set</b> command. |
| Release 3.9.0 | Support was added for more soo extended community formats. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity-set soo** command to define an SoO extended community set.

An extcommunity set soo holds SoO extended community values to match against the Border Gateway Protocol (BGP) SoO extended community attribute. SoO extended communities can be entered in these formats:

- *#-remark* ---Remark beginning with '#'
- *\*---* Wildcard (any community or part thereof)
- *1-4294967295---*32-bit decimal number
- *1-65535 ---*16-bit decimal number
- *A.B.C.D/M:N* ---Extended community - IPv4 prefix format
- *A.B.C.D:N* ---Extended community - IPv4 format
- *ASN:N* ---Extended community - ASPLAIN format

- *X.Y:N* ---Extended community - ASDOT format
- **abort** ---Discard RPL definition and return to top level config
- **dfa-regex** ---DFA style regular expression
- **end-set** ---End of set definition
- **exit** ---Exit from the submode
- **ios-regex** ---Traditional IOS style regular expression
- **show** ---Show partial RPL configuration

*N* is a site-specific number.

## Examples

In the following example, a SoO extended community set named extcomm-soo is defined:

```
RP/0/0/CPU0:router(config)# extcommunity-set soo extcomm-soo
RP/0/0/CPU0:router(config-ext)# 66:60001,
RP/0/0/CPU0:router(config-ext)# 77:70001,
RP/0/0/CPU0:router(config-ext)# 88:80001,
RP/0/0/CPU0:router(config-ext)# 99:90001,

RP/0/0/CPU0:router(config-ext)# 100.100.100.1:153
RP/0/0/CPU0:router(config-ext)# end-set
```

# extcommunity soo is-empty

To determine if a Border Gateway Protocol (BGP) route has any Site-of-Origin (SoO) extended communities associated with it, use the **extcommunity soo is-empty** command in route-policy configuration mode.

**extcommunity soo is-empty**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Command History | Release       | Modification                                                    |
|-----------------|---------------|-----------------------------------------------------------------|
|                 | Release 3.3.0 | This command was introduced.                                    |
|                 |               | This command replaced the <b>extcommunity is-empty</b> command. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity soo is-empty** command as a conditional expression within an **if** statement to check if a BGP SoO route has extended community attributes associated with it.

**Note** For a list of all conditional expressions available within an **if** statement, see the **if** command.

The **is-empty** operator takes no arguments and evaluates to true if the route has no SoO extended community attributes associated with it.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** In the following example, if a route has no SoO extended communities associated with it, the local preference is set to 100:

```
RP/0/0/CPU0:router(config)# route-policy extcommunity-is-empty-example
```

```
RP/0/0/CPU0:router(config-rpl)# if extcommunity soo is-empty then  
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## extcommunity soo matches-any

To match any element of a Border Gateway Protocol (BGP) Site-of-Origin (SoO) extended community set, use the **extcommunity soo matches-any** command in route-policy configuration mode.

**extcommunity soo matches-any** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}

### Syntax Description

|                                |                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------|
| <i>extcommunity-set-name</i>   | Name of a SoO extended community set.                                                                 |
| <i>inline-extcommunity-set</i> | Inline SoO extended community set. The inline extended community set must be enclosed in parentheses. |
| <i>parameter</i>               | Parameter name. The parameter name must be preceded with a "\$."                                      |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                       |
|---------------|--------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                       |
|               | This command replaced the <b>extcommunity matches-any</b> command. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                           |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity soo matches-any** command as a conditional expression within an **if** statement to match elements of an extended community set.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-any** operator evaluates as true if at least one extended community in the route matches an extended community specification in the named or inline set. If no extended community in the route matches any of the specifications in the named or inline set, then this simple condition evaluates to false. Likewise, when there is no extended community at all in the route, the condition evaluates to false.

Matching an extended community in the route to a specification in a named or an inline set is intuitive. In inline sets, extended community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, an SoO extended community set named extcomm-soo and a parameterized route policy named my-extcommunity-set-example(\$tag,\$ip) are defined.

The condition route policy named extcommunity soo matches-any is used in an if statement in this policy. If it evaluates to true, the local preference value is set to 100.

If it evaluates to false, the SoO extended community is evaluated using an inline set. If it evaluates to true, the local preference value is set to 200.

If it evaluates to false, the SoO extended community is evaluated using a different inline set. If it evaluates to true, the local preference value is set to 300.

If it evaluates to false, the SoO extended community is evaluated using a different inline set. If it evaluates to true, the local preference value is set to 400.

```
RP/0/0/CPU0:router(config)# extcommunity-set soo extcomm-soo
RP/0/0/CPU0:router(config-ext)# 66:60001,
RP/0/0/CPU0:router(config-ext)# 77:70001,
RP/0/0/CPU0:router(config-ext)# 88:80001,
RP/0/0/CPU0:router(config-ext)# 99:90001,
RP/0/0/CPU0:router(config-ext)# 100.100.100.1:153
RP/0/0/CPU0:router(config-ext)# end-set

RP/0/0/CPU0:router(config)# route-policy my-extcommunity-set-example($tag,$ip)
RP/0/0/CPU0:router(config-rpl)# if extcommunity soo matches-any extcomm-soo then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# elseif extcommunity soo matches-any (10:20, 10:$tag)
then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 200
RP/0/0/CPU0:router(config-rpl-elseif)# elseif extcommunity soo matches-any ($ip:$tag) then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 300
RP/0/0/CPU0:router(config-rpl-elseif)# elseif extcommunity soo matches-any (2.3.4.5:$tag)
then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 400
RP/0/0/CPU0:router(config-rpl-elseif)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## extcommunity soo matches-every

To match every element of a Border Gateway Protocol (BGP) Site-of-Origin (SoO) extended community set, use the **extcommunity soo matches-every** command in route-policy configuration mode.

**extcommunity soo matches-every** {*extcommunity-set-name*| *inline-extcommunity-set*| *parameter*}

### Syntax Description

|                                |                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------|
| <i>extcommunity-set-name</i>   | Name of a SoO extended community set.                                                                 |
| <i>inline-extcommunity-set</i> | Inline SoO extended community set. The inline extended community set must be enclosed in parentheses. |
| <i>parameter</i>               | Parameter name. The parameter name must be preceded with a "\$."                                      |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                         |
|---------------|----------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                         |
|               | This command replaced the <b>extcommunity matches-every</b> command. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                             |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **extcommunity soo matches-every** command as a conditional expression within an **if** statement to match every element of a SoO extended community set.

#### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A simple condition using the **matches-every** operator evaluates as true if every extended community value in the extended community attribute for the route matches at least one element of the extended community set or inline set. If no extended community in the route matches any of the specifications in the named or inline set, then this simple condition evaluates to false. Likewise, when there is no extended community at all in the route, the condition evaluates to false.

Matching an extended community in the route to a specification in a named or an inline set is intuitive. In inline sets, extended community specifications may be parameterized, in which case the relevant matching is done when the value of the parameter has been supplied.

## Examples

In the following example, an extended community set named my-extcomm-rt-set and a parameterized route policy named extcommunity-matches-every-example(\$as, \$tag) are defined. The condition extcommunity soo matches-every is used in an if statement in this policy and if it evaluates to true, the local-preference value is set to 100. If it evaluates to false, the extended community is evaluated using an inline set. If that condition evaluates to true, the local-preference value is set to 200. If it evaluates to false, the local-preference value is set to 300.

```
RP/0/0/CPU0:router(config)# extcommunity-set soo my-extcomm-rt-set
RP/0/0/CPU0:router(config-ext)# 10:20,
RP/0/0/CPU0:router(config-ext)# 10:30,
RP/0/0/CPU0:router(config-ext)# 10:40
RP/0/0/CPU0:router(config-ext)# end-set

RP/0/0/CPU0:router(config)# route-policy extcommunity-matches-every-example($as, $tag)

# if

To decide which actions or dispositions should be taken for a given route, use the **if** command in route-policy configuration mode.

**if** *conditional-expression* **then** *action-statement* [ *action-statement* ] [**elseif** *conditional-expression* **then** *action-statement* [ *action-statement* ] ] [**else** *action-statement* [ *action-statement* ] ] **endif**

## Syntax Description

|                               |                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------|
| <i>conditional-expression</i> | Expression to decide which actions or dispositions should be taken for the given route. |
| <b>then</b>                   | Executes an action statement if the <b>if</b> condition is true.                        |
| <b>elseif</b>                 | Strings together a sequence of tests.                                                   |
| <b>else</b>                   | Executes an action statement if the <b>if</b> condition is false.                       |
| <b>endif</b>                  | Ends the <b>if</b> statement.                                                           |
| <i>action-statement</i>       | Sequence of operations that modify a route.                                             |

| Release 3.2   | This command was introduced.                                                                                                        |
| Release 4.2.0 | Support was added for Apply Condition Policies that allow the usage of a route-policy in an "if" statement of another route-policy. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **if** command uses a conditional expression to decide which actions or dispositions should be taken for a given route. [Table 172: Conditional Expressions, on page 1616](#) lists the conditional expressions.

An action statement is a sequence of operations that modify a route, most of which are distinguished by the **set** keyword. In a route policy, these operations can be grouped. [Table 173: Action Statements, on page 1618](#) lists the action statements.

Apply Condition policies allow usage of a route-policy in an "if" statement of another route-policy.

```
Route-policy policy_name
If apply policyA and apply policyB then
Set med 100
Else if not apply policyD then
Set med 200
Else
Set med 300
Endif
End-policy
```

**Table 172: Conditional Expressions**

| Command                                                   | Description                                                                                                                                 |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">as-path in, on page 1548</a>                  | Matches the AS path of a route to an AS path set. The AS path is a sequence of autonomous system numbers traversed by a route.              |
| <a href="#">as-path is-local, on page 1550</a>            | Determines if the router (or another router within this autonomous system or confederation) originated the route.                           |
| <a href="#">as-path length, on page 1552</a>              | Performs a conditional check based on the length of the AS path.                                                                            |
| <a href="#">as-path neighbor-is, on page 1554</a>         | Tests the autonomous system number or numbers at the head of the AS path against a sequence of one or more integral values or parameters.   |
| <a href="#">as-path originates-from, on page 1557</a>     | Tests an AS path against the AS sequence beginning with the AS number that originated a route.                                              |
| <a href="#">as-path passes-through, on page 1560</a>      | Tests to learn if the specified integer or parameter appears anywhere in the AS path or if the sequence of integers and parameters appears. |
| <a href="#">as-path unique-length, on page 1565</a>       | Performs specific checks based on the length of the AS path.                                                                                |
| <a href="#">community is-empty, on page 1567</a>          | Learns if a route has community attributes associated with it.                                                                              |
| <a href="#">community matches-any, on page 1568</a>       | Matches any element of a community set.                                                                                                     |
| <a href="#">community matches-every, on page 1571</a>     | Matches every element of a community set.                                                                                                   |
| <a href="#">destination in, on page 1581</a>              | Matches a destination entry in a named prefix set or inline prefix set.                                                                     |
| <a href="#">extcommunity rt is-empty, on page 1595</a>    | Learns if a route has RT extended community attributes associated with it.                                                                  |
| <a href="#">extcommunity rt matches-any, on page 1597</a> | Matches elements of an RT extended community set.                                                                                           |

| Command                                                      | Description                                                                                                  |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <a href="#">extcommunity rt matches-every, on page 1599</a>  | Matches every element of an RT extended community set.                                                       |
| <a href="#">extcommunity rt matches-within, on page 1601</a> | Matches at least one element of a Border Gateway Protocol (BGP) route target (RT) extended community set.    |
| <a href="#">extcommunity soo is-empty, on page 1609</a>      | Learns if a route has SoO extended community attributes associated with it.                                  |
| <a href="#">extcommunity soo matches-any, on page 1611</a>   | Matches elements of an SoO extended community set.                                                           |
| <a href="#">extcommunity soo matches-every, on page 1613</a> | Matches every element of an SoO extended community set.                                                      |
| <a href="#">local-preference, on page 1622</a>               | Specifies BGP local-preference attribute                                                                     |
| <a href="#">med, on page 1624</a>                            | Compares the MED to an integer value or a parameterized value.                                               |
| <a href="#">next-hop in, on page 1626</a>                    | Compares the next-hop associated with the route to data contained in either a named or an inline prefix set. |
| <a href="#">orf prefix in, on page 1628</a>                  | Matches a prefix in a prefix set or an inline prefix set.                                                    |
| <a href="#">origin is, on page 1630</a>                      | Tests the value of the origin attribute.                                                                     |
| <a href="#">path-type is, on page 1634</a>                   | Tests the path type.                                                                                         |
| <a href="#">protocol, on page 1642</a>                       | Checks if a protocol is installing the route.                                                                |
| <a href="#">rd in, on page 1644</a>                          | Compares the RD associated with the route to data contained in either a named or an inline RD set.           |
| <a href="#">rib-has-route, on page 1650</a>                  | Checks if a route is in the RIB.                                                                             |
| <a href="#">route-has-label, on page 1652</a>                | Checks if a route has a Multiprotocol Label Switching (MPLS) label.                                          |
| <a href="#">route-type is, on page 1655</a>                  | Compares route types when redistribution is being performed into BGP, OSPF, or IS-IS.                        |
| <a href="#">source in, on page 1817</a>                      | Tests the source of the route against the data in either a named or an inline prefix set.                    |
| <a href="#">tag, on page 1821</a>                            | Matches a specific tag value.                                                                                |

| Command                                             | Description                                               |
|-----------------------------------------------------|-----------------------------------------------------------|
| <a href="#">vpn-distinguisher is</a> , on page 1825 | Compares the VPN distinguisher against a specified value. |

**Table 173: Action Statements**

| Command                                               | Description                                                                                                           |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">abort (RPL)</a> , on page 1542            | Discards a route policy definition and returns to global configuration mode.                                          |
| <a href="#">add</a> , on page 1544                    | Adds an offset to an existing value.                                                                                  |
| <a href="#">apply</a> , on page 1546                  | Executes a parameterized or an unparameterized policy from within another policy.                                     |
| <a href="#">delete community</a> , on page 1577       | Deletes community values from a community list in a route.                                                            |
| <a href="#">delete extcommunity rt</a> , on page 1579 | Deletes extended community values from an extended community list in a route.                                         |
| <a href="#">done</a> , on page 1583                   | Accepts this route with no further processing                                                                         |
| <a href="#">drop</a> , on page 1585                   | Drops a route.                                                                                                        |
| <a href="#">end-policy</a> , on page 1591             | Ends the definition of a route policy and exits route-policy configuration mode.                                      |
| <a href="#">pass</a> , on page 1632                   | Signifies that even though the route has not been modified, the user wants to continue executing in the policy block. |
| <a href="#">prepend as-path</a> , on page 1640        | Prepends the AS path with additional autonomous system numbers.                                                       |
| <a href="#">replace as-path</a> , on page 1648        | Replaces a sequence of AS numbers or private AS numbers in the AS path with the configured local AS.                  |
| <a href="#">set community</a> , on page 1661          | Sets the BGP community attribute.                                                                                     |
| <a href="#">set dampening</a> , on page 1665          | Configures BGP route dampening.                                                                                       |
| <a href="#">set eigrp-metric</a> , on page 1667       | Sets the Enhanced Interior Gateway Routing Protocol (EIGRP) metric value.                                             |
| <a href="#">set extcommunity cost</a> , on page 1669  | Replaces or adds the extended communities for a cost on the route.                                                    |

| Command                                               | Description                                                                                     |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">set extcommunity rt, on page 1671</a>     | Replaces or adds the extended communities for an RT on the route.                               |
| <a href="#">set ip-precedence, on page 1673</a>       | Sets the IP precedence to classify packets.                                                     |
| <a href="#">set isis-metric, on page 1675</a>         | Sets the IS-IS metric attribute value.                                                          |
| <a href="#">set label, on page 1676</a>               | Sets the BGP label attribute value.                                                             |
| <a href="#">set level, on page 1677</a>               | Configures the IS-IS level in which redistributed routes should be sent.                        |
| <a href="#">set local-preference, on page 1679</a>    | Specifies a preference value for the autonomous system path.                                    |
| <a href="#">set med, on page 1681</a>                 | Sets the MED value.                                                                             |
| <a href="#">set metric-type (IS-IS), on page 1683</a> | Controls whether IS-IS treats the metric as an internal or external metric.                     |
| <a href="#">set metric-type (OSPF), on page 1685</a>  | Controls whether OSPF treats the cost as a Type 1 or Type 2 metric.                             |
| <a href="#">set next-hop, on page 1687</a>            | Replaces the next-hop associated with a given route.                                            |
| <a href="#">set origin, on page 1689</a>              | Changes the origin attribute.                                                                   |
| <a href="#">set ospf-metric, on page 1691</a>         | Sets an OSPF protocol metric attribute value.                                                   |
| <a href="#">set qos-group (RPL), on page 1694</a>     | Sets the QoS group to classify packets.                                                         |
| <a href="#">set rib-metric, on page 1696</a>          | Sets a RIB metric attribute value for a table policy.                                           |

| Command                                              | Description                       |
|------------------------------------------------------|-----------------------------------|
| <a href="#">set vpn-distinguisher</a> , on page 1708 | Sets the VPN distinguisher value. |

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, any route whose AS path is in the set as-path-set-1 is dropped:

```
RP/0/0/CPU0:router(config-rpl)# if as-path in as-path-set-1 then
RP/0/0/CPU0:router(config-rpl-if)# drop
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

The contents of the **then** clause may be an arbitrary sequence of action statements.

The following example shows an **if** statement with two action statements:

```
RP/0/0/CPU0:router(config-rpl)# if origin is igp then
RP/0/0/CPU0:router(config-rpl-if)# set med 42
RP/0/0/CPU0:router(config-rpl-if)# prepend as-path 73 5
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

The **if** command also permits an **else** clause to be executed if the expression is false, as follows:

```
RP/0/0/CPU0:router(config-rpl)# if med eq 200 then
RP/0/0/CPU0:router(config-rpl-if)# set community (12:34) additive
RP/0/0/CPU0:router(config-rpl-if)# else
RP/0/0/CPU0:router(config-rpl-else)# set community (12:56) additive
RP/0/0/CPU0:router(config-rpl-else)# endif
RP/0/0/CPU0:router(config-rpl)#
```

The routing policy language (RPL) also provides syntax using the **elseif** command to string together a sequence of tests, as shown in the following example:

```
RP/0/0/CPU0:router(config-rpl)# if med eq 150 then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 10
RP/0/0/CPU0:router(config-rpl-if)# elseif med eq 200 then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 60
RP/0/0/CPU0:router(config-rpl-elseif)# elseif med eq 250 then
RP/0/0/CPU0:router(config-rpl-elseif)# set local-preference 110
RP/0/0/CPU0:router(config-rpl-elseif)# else
RP/0/0/CPU0:router(config-rpl-else)# set local-preference 0
RP/0/0/CPU0:router(config-rpl-else)# endif
RP/0/0/CPU0:router(config-rpl)#
```

The statements within an **if** statement may themselves be **if** statements, as shown in this example:

```
RP/0/0/CPU0:router(config-rpl)# if community matches-any (12:34, 56:78) then
RP/0/0/CPU0:router(config-rpl-if)# if med eq 150 then
RP/0/0/CPU0:router(config-rpl-if)# drop
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# endif
```

```
RP/0/0/CPU0:router(config-rpl)#
```

The policy configuration shown sets the value of the local preference attribute to 100 on any route that has a community value of 12:34 or 56:78 associated with it. However, if any of these routes has a Multi Exit Discriminator (MED) value of 150, then each route with both the community value of 12:34 or 56:78 and a MED of 150 is dropped.

# local-preference

To compare the local-preference attribute of a BGP route to an integer value or a parameterized value, use the local-preference command in route-policy configuration mode.

**local-preference** {**eq**|**is**|**ge**|**le**} {*number*|*parameter*}

## Syntax Description

|                                               |                                                                         |
|-----------------------------------------------|-------------------------------------------------------------------------|
| <b>eq</b>   <b>is</b>   <b>ge</b>   <b>le</b> | Equal to; exact match; greater than or equal to; less than or equal to. |
| <i>number</i>                                 | Value assigned to a 32-bit unsigned integer. Range is 0 to 4294967295.  |
| <i>parameter</i>                              | Parameter name. The parameter name must be preceded with a "\$."        |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **local-preference** command as a conditional expression within an **if** statement to compare the local-preference attribute to an integer value or a parameterized value.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The MED is a 32-bit unsigned integer. The **eq** operation compares the local-preference to either a static value or a parameterized value passed to a parameterized policy for equality with that value. A greater than or equal to comparison can also be done with the **ge** operator, and a less than or equal to comparison can be performed using the **le** operator.

## Examples

The following example shows that if the **local-preference** is 10, local-preference is set to 100:

```
RP/0/RSP0RP0/CPU0:router(config-rpl)# if local-preference eq 10 then
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# set weight 100
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# endif
```

```
RP/0/RSP0RP0/CPU0:router(config-rpl)#
```

# med

To compare the Multi Exit Discriminator (MED) to an integer value or a parameterized value or compare the MED attribute of a BGP route to an integer value, use the **med** command in route-policy configuration mode.

**med** {**eq**|**is**|**ge**|**le**} {*number*|*parameter*}

## Syntax Description

|                                               |                                                                         |
|-----------------------------------------------|-------------------------------------------------------------------------|
| <b>eq</b>   <b>is</b>   <b>ge</b>   <b>le</b> | Equal to; exact match; greater than or equal to; less than or equal to. |
| <i>number</i>                                 | Value assigned to a 32-bit unsigned integer. Range is 0 to 4294967295.  |
| <i>parameter</i>                              | Parameter name. The parameter name must be preceded with a "\$."        |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **med** command as a conditional expression within an **if** statement to compare the MED to an integer value or a parameterized value.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The MED is a 32-bit unsigned integer. The **eq** operation compares the MED to either a static value or a parameterized value passed to a parameterized policy for equality with that value. A greater than or equal to comparison can also be done with the **ge** operator, and a less than or equal to comparison can be performed using the **le** operator.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows that if the **med** commands match, the local preference is set to 100:

```
RP/0/0/CPU0:router(config-rpl)# if med eq 10 then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 100
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

# next-hop in

To compare the next-hop associated with the route to data contained in either an inline or a named prefix set, use the **next-hop in** command in route-policy configuration mode.

**next-hop in** {*prefix-set-name*| *inline-prefix-set*| *parameter*}

## Syntax Description

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <i>prefix-set-name</i>   | Name of a prefix set.                                                     |
| <i>inline-prefix-set</i> | Inline prefix set. The inline prefix set must be enclosed in parentheses. |
| <i>parameter</i>         | Parameter name. The parameter name must be preceded with a "\$."          |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.2   | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **next-hop in** command as a conditional expression within an **if** statement to compare the next-hop associated with the route to data contained in either an inline or a named prefix set. The result is true if any value in the prefix set matches the next-hop of the route. A comparison that refers to a named prefix set that has no elements in it returns false.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The next-hop is an IPv4 address entered as a dotted-decimal or an IPv6 address entered as a colon-separated hexadecimal.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows that if the **next-hop in** commands match, the local preference is set to 100

```
RP/0/0/CPU0:router(config-rpl)# if next-hop in some-prefix-set then
RP/0/0/CPU0:router(config-rpl-if)# if next-hop in (10.0.0.5, fe80::230/64) then
RP/0/0/CPU0:router(config-rpl-if)# set local-preference 0
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

# orf prefix in

To configure an outbound route filter (ORF), use the **orf prefix in** command in route-policy configuration mode.

**orf prefix in** {*prefix-set-name*| *inline-prefix-set*}

## Syntax Description

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <i>prefix-set-name</i>   | Name of a prefix set.                                                     |
| <i>inline-prefix-set</i> | Inline prefix set. The inline prefix set must be enclosed in parentheses. |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **orf prefix in** command to match a prefix in a prefix set or an inline prefix set.

This command takes either a named prefix set or an inline prefix set value as an argument. It returns true if the destination NLRI matches any entry in the prefix set. An attempt to match destination using a prefix set that is defined but contains no elements returns false.

This command is used in the context of the orf route-policy attach point in BGP. The destination of a route is also known in Border Gateway Protocol (BGP) as its network-layer reachability information (NLRI). It comprises a prefix value and a mask length. The routing policy language (RPL) provides one operation on prefixes, testing them for matching against a list of prefix-match specifications using the **in** operator.

## Examples

In the following example, the prefix set orfpreset1 and the route policy named orfpolicy are defined. Next, the orfpolicy is applied to the neighbor orf attach point.

If the prefix of the route matches any of the prefixes specified in orfpreset1 (211.105.1.0/24, 211.105.5.0/24, 211.105.11.0/24), then the prefix is dropped. If the prefix matches in(211.105.3.0/24, 211.105.7.0/24, 211.105.13.0/24), then the prefix is accepted. In addition to this inbound filtering, BGP sends these prefix

entries to the upstream neighbor indicating a permit or deny so that the neighbor can make the same filter updates.

```
RP/0/0/CPU0:router(config)# prefix-set orfpreset1
RP/0/0/CPU0:router(config-pfx)# 211.105.1.0/24,
RP/0/0/CPU0:router(config-pfx)# 211.105.5.0/24,
RP/0/0/CPU0:router(config-pfx)# 211.105.11.0/24
RP/0/0/CPU0:router(config-pfx)# end-set
!
!
RP/0/0/CPU0:router(config)# route-policy orfpolicy
RP/0/0/CPU0:router(config-rpl)# if orf prefix in orfpreset1 then
RP/0/0/CPU0:router(config-rpl-if)# drop
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# if orf prefix in (211.105.3.0/24, 211.105.7.0/24,
211.105.13.0/24) then
RP/0/0/CPU0:router(config-rpl-if)# pass
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
!
!
RP/0/0/CPU0:router(config)# router bgp 2
RP/0/0/CPU0:router(config-bgp)# neighbor 1.1.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 3
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# orf route-policy orfpolicy
```

#### Related Commands

| Command    | Description                                       |
|------------|---------------------------------------------------|
| <b>orf</b> | Specifies BGP ORF and inbound filtering criteria. |

# origin is

To match a specific origin type, use the **origin is** command in route-policy configuration mode.

**origin is** {*igp*|*egp*|*incomplete*|*parameter*}

## Syntax Description

|                   |                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>igp</b>        | Specifies Interior Gateway Protocol.                                                                                                                                                      |
| <b>egp</b>        | Specifies Exterior Gateway Protocol.                                                                                                                                                      |
| <b>incomplete</b> | Specifies that Border Gateway Protocol (BGP) first learned the route by means other than BGP or Interior Gateway Protocol (IGP); for example, the route is learned through configuration. |
| <i>parameter</i>  | Parameter name. The parameter name must be preceded with a "\$."                                                                                                                          |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **origin is** command as a conditional expression within an **if** statement to test the value of the origin attribute.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The origin of a BGP route is an enumeration; it is **igp** , **egp** , or **incomplete** .

This command can be parameterized.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the origin is tested within an **if** statement to learn if it is either **igp** or **egp** :

```
RP/0/0/CPU0:router(config-rpl)# if origin is igp or origin is egp then
```

In the following example, a parameter is used to match a specific origin type:

```
RP/0/0/CPU0:router(config)# route-policy bar($origin)
RP/0/0/CPU0:router(config-rpl)# if origin is $origin then
RP/0/0/CPU0:router(config-rpl-if)# set med 20
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

# pass

To pass a route for further processing, use the **pass** command in route-policy configuration mode.

**pass**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **pass** command to signify that even though this route has not been modified, the user wants to continue executing in this policy block.

### Note

The **pass** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

When a policy block has finished executing, any route that has been modified in this policy block or has received a pass disposition in this policy block passes the policy and execution finishes for that policy. If this policy block is applied from within another policy block and the route is either passed or modified, then execution continues in the policy block that applied this policy block.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows how to accept the route unconditionally without modifying it:

```
RP/0/0/CPU0:router(config-rpl)# pass
```

This example accepts the route unconditionally, without modifying it, if the destination is in prefix-set permitted:

```
RP/0/0/CPU0:router(config-rpl)# if destination in permitted then  
RP/0/0/CPU0:router(config-rpl-if)# pass  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)#
```

# path-type is

To match path types, use the **path-type is** command in route-policy configuration mode.

**path-type is** {**ibgp**|**ebgp**|*parameter*}

## Syntax Description

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <b>ibgp</b>      | Specifies an internal BGP path.                                  |
| <b>ebgp</b>      | Specifies an external BGP path.                                  |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$." |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **path-type is** command as a conditional expression within an **if** statement to match path types.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, if the path is an external BGP path the route is accepted:

```
RP/0/0/CPU0:router(config)# route-policy policy_A
RP/0/0/CPU0:router(config-rpl)# if path-type is ebgp then
RP/0/0/CPU0:router(config-rpl-if)# pass
```

```
RP/0/0/CPU0:router(config-rpl-if)# else  
RP/0/0/CPU0:router(config-rpl-else)# drop  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# policy-global

To define global parameters and enter global parameter configuration mode, use the **policy-global** command in global configuration mode. To remove global parameters, use the **no** form of this command.

**policy-global**

**no policy-global**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.4.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **policy-global** command to define global parameters and enter global parameter configuration mode.

RPL supports the definition of systemwide global parameters that can be used inside a policy definition. The global parameter values can be used directly inside a policy definition similar to the local parameters of parameterized policy. When a parameterized policy has a parameter name “collision” with a global parameter name, parameters local to policy definition take precedence, effectively ‘masking off’ global parameters. In addition, a validation mechanism is in place to prevent the deletion of a particular global parameter if it is referred by any policy. For more information on global parameters and parameterization, see the *Implementing Routing Policy on Cisco ASR 9000 Series Router Cisco IOS XR Software* module of the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** The following example shows how to configure global parameters:

```
RP/0/0/CPU0:router(config)# policy-global
RP/0/0/CPU0:router(config-rp-gl)# glbpathtype 'ebgp'
```

```
RP/0/0/CPU0:router(config-rp-gl)# glbtag '100'  
RP/0/0/CPU0:router(config-rp-gl)# end-global
```

In the following example, the *globalparam* argument makes use of the global parameters *gbpathtype* and *glbtag* defined above and is defined for a nonparameterized policy:

```
RP/0/0/CPU0:router(config)# route-policy globalparam  
RP/0/0/CPU0:router(config-rpl)# if path-type is $glbpathtype then  
RP/0/0/CPU0:router(config-rpl)# set tag $glbtag  
RP/0/0/CPU0:router(config-rpl)# endif  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## Related Commands

# prefix-set

To enter prefix set configuration mode and define a prefix set, use the **prefix-set** command in global configuration mode. To remove a named prefix set, use the **no** form of this command.

**prefix-set** *name*

**no prefix-set** *name*

## Syntax Description

|             |                       |
|-------------|-----------------------|
| <i>name</i> | Name of a prefix set. |
|-------------|-----------------------|

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **prefix-set** command to enter prefix set configuration mode and define a prefix set.

A prefix set is a comma-separated list of prefix match specifications. It holds IPv4 or IPv6 prefix match specifications, each of which has four parts: an address, a mask length, a minimum matching length, and a maximum matching length. The address is required, but the other three parts are optional. The address is a standard four-part, dotted-decimal numeric IPv4 address or a colon-separated hexadecimal IPv6 address. The mask length, if present, is a nonnegative decimal integer in the range from 0 to 32 for IPv4 prefixes or 0 to 128 for IPv6 prefixes following the address and separated from it by a slash. The optional minimum matching length follows the address and optional mask length and is expressed as the keyword **ge** (mnemonic for **greater than or equal to**), followed by a nonnegative decimal integer in the range from 0 to 32 for IPv4 or 0 to 128 for IPv6. The optional maximum matching length follows the rest and is expressed by the keyword **le** (mnemonic for **less than or equal to**), followed by yet another nonnegative decimal integer in the range from 0 to 32 for IPv4 or 0 to 128 for IPv6. A syntactic shortcut for specifying an exact length for prefixes to match is the **eq** keyword, mnemonic for **equal to**.

If a prefix match specification has no mask length, then the default mask length is 32 for IPv4 or 128 for IPv6. The default minimum matching length is the mask length. If a minimum matching length is specified, then the default maximum matching length must be less than 32 for IPv4 prefixes or 128 for IPv6 prefixes. Otherwise, if neither a minimum nor maximum length is specified, the default maximum length is the mask length.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows a prefix set named legal-ipv4-prefix-examples:

```
RP/0/0/CPU0:router(config)# prefix-set legal-ipv4-prefix-examples
RP/0/0/CPU0:router(config-pfx)# 10.0.1.1,
RP/0/0/CPU0:router(config-pfx)# 10.0.2.0/24,
RP/0/0/CPU0:router(config-pfx)# 10.0.3.0/24 ge 28,
RP/0/0/CPU0:router(config-pfx)# 10.0.4.0/24 le 28,
RP/0/0/CPU0:router(config-pfx)# 10.0.5.0/24 ge 26 le 30,
RP/0/0/CPU0:router(config-pfx)# 10.0.6.0/24 eq 28
RP/0/0/CPU0:router(config-pfx)# end-set
```

The first element of the prefix set matches only one possible value, 10.0.1.1/32 or the host address 10.0.1.1. The second element matches only one possible value, 10.0.2.0/24. The third element matches a range of prefix values, from 10.0.3.0/28 to 10.0.3.255/32. The fourth element matches a range of values, from 10.0.4.0/24 to 10.0.4.240/28. The fifth element matches prefixes in the range from 10.0.5.0/26 to 10.0.5.252/30. The sixth element matches any prefix of length 28 in the range from 10.0.6.0/28 through 10.0.6.240/28.

The following prefix set consists entirely of invalid prefix match specifications:

```
RP/0/0/CPU0:router(config)# prefix-set INVALID-PREFIX-EXAMPLES
RP/0/0/CPU0:router(config-pfx)# 10.1.1.1 ge 16,
RP/0/0/CPU0:router(config-pfx)# 10.1.2.1 le 16,
RP/0/0/CPU0:router(config-pfx)# 10.1.3.0/24 le 23,
RP/0/0/CPU0:router(config-pfx)# 10.1.4.0/24 ge 33,
RP/0/0/CPU0:router(config-pfx)# 10.1.5.0/25 ge 29 le 28
RP/0/0/CPU0:router(config-pfx)# end-set
```

Neither the minimum length nor the maximum length is legal without a mask length. The maximum length must be at least the mask length. The minimum length must be less than 32, the maximum length of an IPv4 prefix. The maximum length must be equal to or greater than the minimum length.

The following example shows a valid IPv6 prefix set named legal-ipv6-prefix-examples:

```
RP/0/0/CPU0:router(config)# prefix-set legal-ipv6-prefix-examples
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:1::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:2::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:3::/64,
RP/0/0/CPU0:router(config-pfx)# 2001:0:0:4::/64
RP/0/0/CPU0:router(config-pfx)# end-set
```

# prepend as-path

To prepend the AS path with additional autonomous system numbers, use the **prepend as-path** command in route-policy configuration mode.

**prepend as-path** {*as-number*| *parameter*| **most-recent**} [*number*| *parameter*]

## Syntax Description

|                    |                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>   | Autonomous system number to prepend to the path. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| <i>parameter</i>   | Parameter name. The parameter name must be preceded with a "\$."                                                                                                                                                                                                                                                                                                             |
| <b>most-recent</b> | Specifies that the most recent autonomous system number should be prepended.                                                                                                                                                                                                                                                                                                 |
| <i>number</i>      | (Optional) Number of times the autonomous system number should be prepended. Range is 1 to 63.                                                                                                                                                                                                                                                                               |

## Command Default

The default *number* is 1.

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                                                                            |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                            |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.<br>The <b>most-recent</b> keyword was added. |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.                                             |

## Usage Guidelines

Use the **prepend as-path** command to prepend the AS path with additional autonomous system numbers.

**Note**

The **prepend as-path** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

This command can take one or two arguments. The first argument (either a number or parameter) is the autonomous system number to prepend to the path. The optional second argument (either a number or parameter) is the number of times the autonomous system number should be prepended.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows how to prepend the autonomous system number 666.1 to the AS path three times:

```
RP/0/0/CPU0:router(config-rpl)# prepend as-path 666.1 3
```

The following example shows how to prepend the autonomous system number 666.0 to the AS path one time:

```
RP/0/0/CPU0:router(config-rpl)# prepend as-path 666.0 1
```

# protocol

To check the protocol that installs the route, use the **protocol** command in route-policy configuration mode.

**protocol** {**in** | (*protocol-set*) | **is** | *protocol-name*}

## Syntax Description

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>in</b> ( <i>protocol-set</i> ) | <p>Specifies a member of a set. The <i>protocol-set</i> argument accepts the following keywords within parentheses:</p> <ul style="list-style-type: none"> <li>• <b>bgp</b> —Border Gateway Protocol (BGP)</li> <li>• <b>connected</b> —Connected routes</li> <li>• <b>eigrp</b> —Enhanced Interior Gateway Routing Protocol (EIGRP)</li> <li>• <b>isis</b> —ISO Intermediate System-to-Intermediate System (IS-IS)</li> <li>• <b>ospf</b> —Open Shortest Path First (OSPF)</li> <li>• <b>ospfv3</b> —Open Shortest Path First version 3 (OSPFv3)</li> <li>• <b>rip</b> —Routing Information Protocol (RIP)</li> <li>• <b>static</b> —Static routes</li> </ul> <p>Keywords must be separated by a comma.</p> |
| <b>is</b> <i>protocol-name</i>    | Specifies a single protocol name, and accepted keywords are similar to the <i>protocol-set</i> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                         |
| Release 3.6.0 | Support for the <b>ospfv3</b> keyword was added to the <i>protocol-set</i> argument. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **protocol** command as a conditional expression within an if statement to specify a protocol to install a route.

Use the **in** keyword to determine if a protocol listed in the *protocol-set* is the originator of the route being filtered.

Use the **is** keyword to determine if *protocol-name* is an exact match.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows how to use the **protocol** command as a conditional expression within if statements:

```
RP/0/0/CPU0:router(config)# route-policy rip1
RP/0/0/CPU0:router(config-rpl)# if protocol in (connected, static) then
RP/0/0/CPU0:router(config-rpl-if)# add rip-metric 2
RP/0/0/CPU0:router(config-rpl-if)# elseif protocol is bgp 1 then
RP/0/0/CPU0:router(config-rpl-elseif)# add rip-metric 3
RP/0/0/CPU0:router(config-rpl-elseif)# elseif protocol is ospf 2 then
RP/0/0/CPU0:router(config-rpl-elseif)# add rip-metric 4
RP/0/0/CPU0:router(config-rpl-elseif)# else
RP/0/0/CPU0:router(config-rpl-else)# add rip-metric 5
RP/0/0/CPU0:router(config-rpl-else)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy

RP/0/0/CPU0:router(config)# router rip
RP/0/0/CPU0:router(config-rip)# interface GigabitEthernet0/1/0/1
RP/0/0/CPU0:router(config-rip-if)# route-policy rip1 out
```

# rd in

To compare the route distinguisher (RD) associated with the route to RDs contained in either a named or an inline RD set, use the **rd in** command in route-policy configuration mode.

**rd in** {*rd-set-name*| *inline-rd-set*| *parameter*}

## Syntax Description

|                      |                                                                   |
|----------------------|-------------------------------------------------------------------|
| <i>rd-set-name</i>   | Name of an RD set.                                                |
| <i>inline-rd-set</i> | Inline RD set. The inline RD set must be enclosed in parentheses. |
| <i>parameter</i>     | Parameter name. The parameter name must be preceded with a "\$."  |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.3.0 | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **rd in** command as a conditional expression within an **if** statement to match a destination entry in a named prefix set or inline prefix set.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command takes either a named RD set or an inline RD set value as an argument. The condition returns true if the destination entry matches any entry in the RD set or inline RD set. An attempt to match an RD using an RD set that is defined but contains no elements returns false.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows the **rd in** command with an inline RD set value as an argument:

```
RP/0/0/CPU0:router(config)# route-policy
RP/0/0/CPU0:router(config-rpl)# if rd in (128.1.0.0/16:100) then
RP/0/0/CPU0:router(config-rpl-if)# pass
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# rd-set

To define a route distinguisher (RD) set and enter RD configuration mode, use the **rd-set** command in global configuration mode.

**rd-set** *name*

**no rd-set** *name*

## Syntax Description

|      |                              |
|------|------------------------------|
| name | Name of an RD community set. |
|------|------------------------------|

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **rd-set** command to create a set with RD elements and enter RD configuration mode. An RD set is a 64-bit value prepended to an IPv4 address to create a globally unique Border Gateway Protocol (BGP) VPN IPv4 address.

### Note

For *m*, the mask length is supported.

You can define RD values with the following commands:

- *a.b.c.d/m:\**—BGP VPN RD in IPv4 format with a wildcard character. For example, 10.0.0.2/24.0:\*
- *a.b.c.d/m:n*—BGP VPN RD in IPv4 format with a mask. For example, 10.0.0.2/24:666.
- *a.b.c.d:\** —BGP VPN RD in IPv4 format with a wildcard character. For example, 10.0.0.2:\*
- *a.b.c.d:n*—BGP VPN RD in IPv4 format. For example, 10.0.0.2:666.
- *asn:\**—BGP VPN RD in ASN format with a wildcard character. For example, 10002:\*
- *asn:n*—BGP VPN RD in ASN format. For example, 10002:666.
- *x.y:\**—BGP VPN RD in 4-byte ASN format with a wildcard character. For example, 10002.101:\*

- *x.y:n*—BGP VPN RD in 4-byte ASN format. For example, 10002.101:666.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following example shows how to create an RD set called my\_rd\_set:

```
RP/0/0/CPU0:router(config)# rd-set my_rd_set  
RP/0/0/CPU0:router(config-rd)# 172.16.0.0/16:*,  
RP/0/0/CPU0:router(config-rd)# 172.17.0.0/16:100,  
RP/0/0/CPU0:router(config-rd)# 192:*,  
RP/0/0/CPU0:router(config-rd)# 192:100  
RP/0/0/CPU0:router(config-rd)# end-set
```

# replace as-path

To replace a sequence of AS numbers or private AS numbers in the AS path with the configured local AS number, use the **replace as-path** command in route-policy configuration mode.

**replace as-path** *{[as-number-list parameter]| private-as}*

## Syntax Description

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number-list</i> | (Optional) Sequence of AS numbers to replace. The sequence must be enclosed in single quotes ( ' '). You can use 2-byte or 4-byte AS numbers. <ul style="list-style-type: none"> <li>• The 2-byte value is entered as a 16-bit unsigned decimal value. The range is 0 to 65535.</li> <li>• The 4-byte value is entered as two 16-bit unsigned decimal values separated by a period. The range is 1.0 to 65535.65535.</li> </ul> |
| <i>parameter</i>      | (Optional) Parameter name. The parameter name must be preceded with a "\$."                                                                                                                                                                                                                                                                                                                                                     |
| <b>private-as</b>     | Matches within the BGP private AS range. Range is from 64512 to 65534.                                                                                                                                                                                                                                                                                                                                                          |

## Command Default

None.

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **replace as-path** command to replace a sequence of AS numbers or private AS numbers in the AS path with the local AS numbers. For example, if the AS path is '67 65534 100 65533 5 78 89 90' and the local AS number is 900, then:

```
replace as-path '5 78'
```

replaces '5 78' in the AS path with 900 (from the local AS), and the new path would be '67 65534 100 65533 900 89 90'.

Consider following statement:

```
replace as-path private-as
```

Because 65534 and 65533 are within the private AS range, they are replaced with 900. The path is '67 900 100 900 5 78 89 90'. The length of the path remains the same.

The **replace as-path** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

#### Caution

The **replace as-path** command changes the AS path content which can lead to routing loops.

#### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

#### Examples

The following example shows how to use the **replace as-path** command to replace AS numbers in the AS path:

```
RP/0/0/CPU0:router(config)# route-policy drop-as-1234
RP/0/0/CPU0:router(config-rpl)# replace as-path '90 78 45 $asnum'
RP/0/0/CPU0:router(config-rpl)# replace as-path private-as
RP/0/0/CPU0:router(config-rpl)# replace as-path '9.9 7.89 14.15 $asnum'
RP/0/0/CPU0:router(config-rpl)# replace as-path '9 89 14.15 $asnum'
```

# rib-has-route

To check if a route listed in the prefix set exists in the Routing Information Base (RIB), use the **rib-has-route** command in route-policy configuration mode.

**rib-has-route in** {*prefix-set-name*| *inline-prefix-set*| *parameter*}

## Syntax Description

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <i>prefix-set-name</i>   | Name of a prefix set.                                                     |
| <i>inline-prefix-set</i> | Inline prefix set. The inline prefix set must be enclosed in parentheses. |
| <i>parameter</i>         | Parameter name. The parameter name must be preceded with a "\$."          |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                                                                                                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                         |
| Release 3.4.0 | The <i>name</i> argument was removed. The following arguments were added: <ul style="list-style-type: none"> <li>• <i>prefix-set-name</i></li> <li>• <i>inline-prefix-set</i></li> <li>• <i>parameter</i></li> </ul> |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If routes are active, then they are advertised. Routes are considered active if they are already installed in the Routing Information Base (RIB).

The prefix sets used in the **rib-has-route** command contain two match specifications. The first is where an exact route match is requested (for example, 10.10.0.0/16 will match exactly one route) and the second is where a route match or any more-specific route match is allowed (for example, 10.10.0.0/16 le 32 will match the 10.10.0.0/16 route and any longer prefix).

Use the **rib-has-route** command as a conditional expression within an **if** statement to check if there is an active route with a specific prefix contained in the RIB. If the statement reveals an active route that meets that criteria, additional actions are executed.

For a list of all conditional expressions available within an **if** statement, see the **if** command.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

### Examples

In the following example, an **if** statement is used to learn if a route contained in a prefix set 10.10.0.0/16 is in the RIB:

```
RP/0/0/CPU0:router(config-rpl)# if rib-has-route in (10.10.0.0/16 ge 16) then  
RP/0/0/CPU0:router(config-rpl-if)# pass  
RP/0/0/CPU0:router(config-rpl-if)# endif  
RP/0/0/CPU0:router(config-rpl)#
```

# route-has-label

To check if there is a Multiprotocol Label Switching (MPLS) label in a route during redistribution, use the **route-has-label** command in route-policy configuration mode.

**route-has-label**

## Syntax Description

This command has no arguments or keywords.

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-has-label** command as a conditional expression within an **if** statement to check if there is an MPLS label in a route during redistribution.

For a list of all conditional expressions available within an **if** statement, see the **if** command.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, an **if** statement learns if an MPLS label is present in a route:

```
RP/0/0/CPU0:router(config-rpl)# if route-has-label then
RP/0/0/CPU0:router(config-rpl-if)# pass
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

# route-policy (RPL)

To define a route policy and enter route-policy configuration mode, use the **route-policy** command in global configuration mode. To remove a policy definition, use the **no** form of this command.

**route-policy** *name* [(*parameter1*, *parameter2*, . . . , *parameterN*)]

**no route-policy** *name* (*parameter1*, *parameter2*, . . . , *parameterN*)

## Syntax Description

|                  |                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>      | Name of a route policy.                                                                                                                 |
| <i>parameter</i> | (Optional) Parameter name. The parameter name must be preceded with a "\$." The <i>parameters</i> must be enclosed in parenthesis "()". |

## Command Default

No default behavior or values

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-policy** command to define a route policy and enter route-policy configuration mode.

Policy definitions create named bundles of policy statements. A policy definition consists of the **route-policy** command followed by a name, a group of policy statements, and the **end-policy** command.

The policy name serves as a handle for binding the policy to protocols.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows a simple policy named drop-everything that drops any route it encounters:

```
RP/0/0/CPU0:router(config)# route-policy drop-everything
RP/0/0/CPU0:router(config-rpl)# drop
```

```
RP/0/0/CPU0:router(config-rpl)# end-policy
```

Policies may also refer to other policies such that common blocks of policy can be reused. This reference to other policies is accomplished by using the **apply** command. The following is a simple example:

```
RP/0/0/CPU0:router(config)# route-policy drop-as-1234
RP/0/0/CPU0:router(config-rpl)# if as-path passes-through '1234' then
RP/0/0/CPU0:router(config-rpl-if)# apply check-communities
RP/0/0/CPU0:router(config-rpl-if)# else
RP/0/0/CPU0:router(config-rpl-else)# pass
RP/0/0/CPU0:router(config-rpl-else)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

The **apply** command indicates that the policy check-communities should be executed if the route under consideration passed through autonomous system 1234 before it was received. If so, the communities of the route are checked, and based on the findings the route may be accepted unmodified, accepted with changes, or dropped.

| Command                                   | Description                            |
|-------------------------------------------|----------------------------------------|
| <a href="#">end-policy</a> , on page 1591 | Ends the definition of a route policy. |

## route-type is

To match route types when redistribution is being performed into Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), or Integrated Intermediate System-to-Intermediate System (IS-IS), use the **route-type is** command in route-policy configuration mode.

**route-type is** {**local**|**interarea**|**internal**|**type-1**|**type-2**|**level-1**|**level-2**|*parameter*}

### Syntax Description

|                  |                                                                   |
|------------------|-------------------------------------------------------------------|
| <b>local</b>     | Uses a local value to match locally generated BGP routes.         |
| <b>interarea</b> | Uses an interarea value to match IS-IS interarea routes.          |
| <b>internal</b>  | Uses an internal value to match OSPF intra- and interarea routes. |
| <b>type-1</b>    | Uses a Type 1 value to match Type 1 OSPF routes.                  |
| <b>type-2</b>    | Uses a Type 2 value to match Type 2 OSPF routes.                  |
| <b>level-1</b>   | Uses a Level 1 value to match Level 1 IS-IS routes.               |
| <b>level-2</b>   | Uses a Level 2 value to match Level 2 IS-IS routes.               |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."  |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release     | Modification                                                                 |
|-------------|------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.                                                 |
|             | The <b>level-1-2</b> keyword was replaced with the <b>interarea</b> keyword. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-type is** command as a conditional expression within an **if** statement to compare route types when redistribution is being performed into BGP, OSPF, or IS-IS.

**Note**

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The valid keywords are **local**, **internal**, **interarea**, **type-1**, **type-2**, **level-1**, and **level-2**. A parameterized value that fills in one of these values may also be used. The **local** value is used to match locally generated BGP routes. The **internal** value is used to match OSPF intra- and interarea routes. The **type-1** and **type-2** values are used to match Type 1 and Type 2 OSPF external routes. The **level-1**, **level-2**, and **interarea** values are used to match IS-IS routes of those respective types.

Because the route type is a matching operator, it appears in conditional clauses of **if** and **then** statements.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, non-local routes are dropped:

```
RP/0/0/CPU0:router(config)# route-policy policy_A
RP/0/0/CPU0:router(config-rpl)# if route-type is local then
RP/0/0/CPU0:router(config-rpl-if)# pass
RP/0/0/CPU0:router(config-rpl-if)# else
RP/0/0/CPU0:router(config-rpl-else)# drop
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# rpl editor

To set the default routing policy language (RPL) editor, use the **rpl editor** command in global configuration mode.

**rpl editor** {**nano**|**emacs**|**vim**}

## Syntax Description

|              |                                          |
|--------------|------------------------------------------|
| <b>nano</b>  | Sets the default RPL editor to GNU nano. |
| <b>emacs</b> | Sets the default RPL editor to EMACS.    |
| <b>vim</b>   | Sets the default RPL editor to VIM.      |

## Command Default

The Nano editor is the default.

## Command Modes

Global configuration

## Command History

| Release       | Modification                                                                                   |
|---------------|------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                   |
| Release 3.5.0 | The <b>nano</b> keyword was added and the GNU nano text editor became the default editor type. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the default RPL editor is set to Nano:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# rpl editor nano
```

In the following example, the default RPL editor is set to EMACS:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# rpl editor emacs
```

In the following example, the default RPL editor is set to VIM:

```
RP/0/0/CPU0:router# configure  
RP/0/0/CPU0:router(config)# rpl editor vim
```

# rpl maximum

To configure system limits on the routing policy subsystem, use the **rpl maximum** command in global configuration mode.

**rpl maximum** {*lines*|*policies*} *number*

## Syntax Description

|                               |                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------|
| <b>lines</b> <i>number</i>    | Configures the number of lines of configuration limit. Range is from 1 to 131072. |
| <b>policies</b> <i>number</i> | Configures the number of policies limit. Range is from 1 to 5000.                 |

## Command Default

**lines** *number* : 65536  
**policies** *numbers* : 3500

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **rpl maximum** command to configure system limits on the routing policy subsystem. As such, **rpl maximum** configuration lines do not appear as statements within a routing policy. This command places resource limits on the routing policy subsystem. Use the **rpl maximum** command to configure the maximum number of lines of configuration and number of policies.

The number of lines of configuration includes the beginning and ending statements, for example, **route-policy** and **end-policy**. Each line of configuration for sets is also counted.

A line of configuration is counted only once; it is not counted each time it is used. Similarly, any multiple use of policy in an apply statement counts only as one policy.

A user can change the default values for lines and policies but cannot exceed the maximum value, nor can the value for lines and policies be configured lower than the number of lines or policies that are currently configured.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the maximum number of RPL system limits are modified:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# rpl maximum lines 50
RP/0/0/CPU0:router(config)# rpl maximum policies 6
```

**Related Commands**

| <a href="#">show rpl maximum, on page 1768</a> | Displays the maximum limits for lines of configuration and number of policies. |

# set community

To set the Border Gateway Protocol (BGP) community attributes in a route, use the **set community** command in route-policy configuration mode.

**set community** {*community-set-name*| *inline-community-set*| *parameter*} [**additive**]

## Syntax Description

|                             |                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------|
| <i>community-set-name</i>   | Community set name.                                                             |
| <i>inline-community-set</i> | Inline community set. The inline community set must be enclosed in parentheses. |
| <i>parameter</i>            | Parameter name. The parameter name must be preceded with a "\$."                |
| <b>additive</b>             | (Optional) Adds communities to communities in the route.                        |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.2   | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set community** command to set the BGP community attribute.

### Note

The **set community** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Communities are 32-bit values carried in BGP routes. Each route may have zero or more communities in an unordered list.

Use this command to replace the communities in a route or add to them using the optional **additive** keyword.

As with the other community forms that support inline sets, either or both 16-bit portions of the community can be parameterized. Likewise, the names of the well-known communities **internet** (0:0), **no-advertise**

(65535:65281), **no-export** (65535:65282), and **local-AS** (65535:65283) can also be used. In an inline community set, each 16-bit portion can also be specified as the **peer-as** to express the AS number of the neighbor from which the route was received. If the neighbor AS employs a 4-byte ASN, the IANA-assigned 16-bit value 23456 (AS\_TRANS) is used as **peer-as** instead.

Without the **additive** keyword, any existing communities (other than the well-known communities) are removed and replaced with the given communities. The **additive** keyword specifies that all communities already present in the route be maintained and the list of communities be added to them.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following are incomplete configuration examples using the **set community** command:

```
RP/0/0/CPU0:router(config-rpl)# set community (10:24)
RP/0/0/CPU0:router(config-rpl)# set community (10:24, $as:24, $as:$tag)
RP/0/0/CPU0:router(config-rpl)# set community (10:24, internet) additive
RP/0/0/CPU0:router(config-rpl)# set community (10:24, $as:24) additive
RP/0/0/CPU0:router(config-rpl)# set community (10:24, peer-as:24) additive
```

## set core-tree

To set a Multicast Distribution Tree (MDT) type, use the **set core-tree** command in route-policy configuration mode.

**set core-tree** {gre-rosten| mldp-inband| mldp-partitioned-mp2mp| mldp-partitioned-p2mp| mldp-rosten| rsvp-te-partitioned-p2mp| *parameter*}

### Syntax Description

|                                 |                                                                  |
|---------------------------------|------------------------------------------------------------------|
| <b>gre-rosten</b>               | Specifies the IP GRE Rosen core MDT type                         |
| <b>mldp-inband</b>              | Specifies the MLDP InBand core MDT type                          |
| <b>mldp-partitioned-mp2mp</b>   | Specifies theMLDP Partitioned MP2MP core MDT type                |
| <b>mldp-partitioned-p2mp</b>    | Specifies the MLDP Partitioned P2MP core MDT type                |
| <b>mldp-rosten</b>              | Specifies the MLDP Rosen core MDT type                           |
| <b>rsvp-te-partitioned-p2mp</b> | Specifies the RSVP TE core core MDT type                         |
| <i>parameter</i>                | Parameter name. The parameter name must be preceded with a "\$." |

### Command Default

None

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID      | Operation   |
|--------------|-------------|
| route-policy | read, write |

## Examples

In this example, the Multicast Distribution Tree type is set to IP GRE Rosen core:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#route-policy policy_mdt_type
RP/0/0/CPU0:router(config-rpl)#set core-tree gre-rosen
```

# set dampening

To configure Border Gateway Protocol (BGP) route dampening, use the **set dampening** command in route-policy configuration mode.

**set dampening** {**halflife** {*minutes*| *parameter*}| **max-suppress** {*minutes*| *parameter*}| **reuse** {*seconds*| *parameter*}| **suppress** {*penalty-units*| *parameter*}| **others default**}

## Syntax Description

|                                      |                                                                                                                                                                                                                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>halflife</b> <i>minutes</i>       | Specifies the time (in minutes) after which a penalty is decreased. After the route has been assigned a penalty, the penalty is decreased by half after the half-life period. The process of reducing the penalty happens every 5 seconds. Range is 1 to 45 minutes. |
| <i>parameter</i>                     | Parameter name. The parameter name must be preceded with a "\$."                                                                                                                                                                                                     |
| <b>max-suppress</b> <i>minutes</i>   | Specifies the maximum time (in minutes) a route can be suppressed. Range is 1 to 20000. If the half-life value is allowed to default, the maximum suppress time defaults to 60 minutes.                                                                              |
| <b>reuse</b> <i>seconds</i>          | Unsuppresses a route if the penalty for flapping the route decreases enough to fall below the configured value (in seconds). The process of unsuppressing routes occurs at 10-second increments. Range is 1 to 20000.                                                |
| <b>suppress</b> <i>penalty-units</i> | Specifies a penalty of 1000 each time a route flaps. When a route penalty exceeds the configured limit, it is suppressed. Range is 1 to 20000.                                                                                                                       |
| <b>others default</b>                | If all four keyword values are not specified in the command, then the command <i>must</i> end with <b>others default</b> . This designation indicates that any keyword not defined is set to its default.                                                            |

## Command Default

**half-life** : 15 minutes  
**max-suppress** : 60 minutes (four times the half-life)  
**reuse** : 750 seconds  
**suppress** : 2000 penalty units

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                 |
|---------------|----------------------------------------------|
| Release 3.2   | This command was introduced.                 |
| Release 3.4.0 | The <i>parameter</i> argument was supported. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The BGP protocol supports route dampening using an exponential backoff algorithm. The algorithm is controlled by setting the four supported BGP values: half-life, max-suppress, reuse, and suppress. Use the **set dampening** command to configure BGP route dampening.

**Note**

The **set dampening** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

A value for at least one of the four keywords must be set. If the **set dampening** command defines values for three or fewer of the supported keywords, then the configuration must end with the **others default**, which indicates that any keyword value not defined in the command is set to its default value.

The keywords may appear in the command in any order.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following examples, the half-life is set to 20 minutes and the maximum suppress time is set to 90 minutes. Each command must end with **others default** because three or fewer keywords are defined.

```
RP/0/0/CPU0:router(config-rpl)# set dampening halflife 20 others default
RP/0/0/CPU0:router(config-rpl)# set dampening max-suppress 90 others default
```

In this example, all four keywords are defined, which means the command does not use **others default**.

```
RP/0/0/CPU0:router(config-rpl)# set dampening halflife 15 max-suppress 60 reuse 750 suppress 2000
```

The following command is invalid because it is missing **others default**.

```
RP/0/0/CPU0:router(config-rpl)# set dampening reuse 700
```

In the following example, the parameters are used.

```
RP/0/0/CPU0:router(config-rpl)# set dampening halflife $p1 suppress $p4 reuse $p3 max-suppress $p2
```

# set eigrp-metric

To set Enhanced Interior Gateway Routing Protocol (EIGRP) route metrics, use the **set eigrp-metric** command in route-policy configuration mode.

**set eigrp-metric** *bandwidth delay reliability loading mtu*

## Syntax Description

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bandwidth</i>   | Minimum bandwidth of the route in kilobits per second. Range is 1 to 4294967295.                                                                           |
| <i>delay</i>       | Route delay in tens of microseconds. Delay is 1 or any positive number that is a multiple of 39.1 nanoseconds. Range is 1 to 4294967295.                   |
| <i>reliability</i> | Likelihood of successful packet transmission expressed as a number between 0 and 255. The value 255 means 100 percent reliability; 0 means no reliability. |
| <i>loading</i>     | Effective bandwidth of the route expressed as a number from 1 to 255 (255 is 100 percent loading).                                                         |
| <i>mtu</i>         | Minimum maximum transmission unit (MTU) size of the route in bytes. Range is from 1 to 65535.                                                              |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can use the **add** command to further offset an existing EIGRP metric value.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the EIGRP metrics are adjusted for route policy policy\_1:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set eigrp-metric 1400 120 250 100 1500
RP/0/0/CPU0:router(config-rpl)# end-policy
```

## Related Commands

| Command                                            | Description                          |
|----------------------------------------------------|--------------------------------------|
| <a href="#">add</a> , <a href="#">on page 1544</a> | Adds an offset to an existing value. |

## set extcommunity cost

To set the Border Gateway Protocol (BGP) cost extended community attributes, use the **set extcommunity cost** command in route-policy configuration mode.

**set extcommunity cost** {*cost-extcommunity-set-name*|*cost-inline-extcommunity-set*|*parameter*} [**additive**]

### Syntax Description

|                                     |                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <i>cost-extcommunity-set-name</i>   | Cost extended community set name.                                                                           |
| <i>cost-inline-extcommunity-set</i> | Inline cost extended community set. The inline cost extended community set must be enclosed in parentheses. |
| <i>parameter</i>                    | Parameter name. The parameter name must be preceded with a "\$."                                            |
| <b>additive</b>                     | (Optional) Adds extended communities for cost to extended communities in the route.                         |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
|               | This command replaced the <b>set extcommunity</b> command. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                   |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set extcommunity cost** command to either replace the extended communities on the route or add to them using the optional **additive** keyword. Cost community is an extended community used to tie break the best path selection process in BGP so as to have a localized custom decision for packet forwarding. The extended community format defines generic points of insertion (POI) that influence the decision at different points of the bestpath algorithm.

**Note**

The **set extcommunity cost** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

As with the other extended community forms that support inline sets, either or both portions of the community can be parameterized. Similarly to regular communities, the **additive** keyword can be used to signify adding these extended communities to those that are already present, as opposed to replacing them. Without the **additive** keyword, any existing extended communities for cost (other than the well-known communities) are removed and replaced with the given communities. The **additive** keyword specifies that all extended communities for cost already present in the route be maintained and the set of extended communities be added to them. Well-known communities include internet, local-AS, no-advertise, and no-export.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

The following are incomplete configuration examples using the **set extcommunity cost** command:

```
RP/0/0/CPU0:router(config-rpl)# set extcommunity cost (IGP:10:20)
RP/0/0/CPU0:router(config-rpl)# set extcommunity cost (Pre-Bestpath:33:44)
RP/0/0/CPU0:router(config-rpl)# set extcommunity cost (IGP:11:21)
```

## set extcommunity rt

To set the Border Gateway Protocol (BGP) route target (RT) extended community attributes, use the **set extcommunity rt** command in route-policy configuration mode.

**set extcommunity rt** {*rt-extcommunity-set-name*|*rt-inline-extcommunity-set*|*parameter*} **additive**

### Syntax Description

|                                   |                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>rt-extcommunity-set-name</i>   | Route target extended community set name.                                                                                   |
| <i>rt-inline-extcommunity-set</i> | Inline route target extended community set. The inline route target extended community set must be enclosed in parentheses. |
| <i>parameter</i>                  | Parameter name. The parameter name must be preceded with a "\$."                                                            |
| <b>additive</b>                   | (Optional) Adds extended communities for an RT to extended communities in the route.                                        |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
|               | This command replaced the <b>set extcommunity</b> command. |
| Release 3.4.0 | The <i>parameter</i> argument was added.                   |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set extcommunity rt** command to either replace the extended communities on the route or add to them using the optional **additive** keyword.

#### Note

The **set extcommunity rt** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

As with the other extended community forms that support inline sets, either or both portions of the community can be parameterized. Similarly to regular communities, the **additive** keyword can be used to signify adding these extended communities to those that are already present, as opposed to replacing them.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following are incomplete configuration examples using the **set extcommunity rt** command:

```
RP/0/0/CPU0:router(config-rpl)# set extcommunity rt (10:24)
RP/0/0/CPU0:router(config-rpl)# set extcommunity rt (10:24, $as:24, $as:$tag)
RP/0/0/CPU0:router(config-rpl)# set extcommunity rt (10:24, internet) additive
RP/0/0/CPU0:router(config-rpl)# set extcommunity rt (10:24, $as:24) additive
```

Without the **additive** keyword, any existing extended communities for cost (other than the well-known communities) are removed and replaced with the given communities. The **additive** keyword specifies that all extended communities for cost already present in the route be maintained and the list of extended communities be added to them.

# set ip-precedence

To set the IP precedence, use the **set ip-precedence** command in route-policy configuration mode.

**set ip-precedence** {*number*|*parameter*}

## Syntax Description

*number* Value of the precedence. The precedence value can be a number from 0 to 7:

- 7 —network (set packets with network control precedence)
- 6 —internet (set packets with internetwork control precedence)
- 5 —critical (set packets with critical precedence)
- 4 —flash-override (set packets with flash override precedence)
- 3 —flash (set packets with flash precedence)
- 2 —immediate (set packets with immediate precedence)
- 1 —priority (set packets with priority precedence)
- 0 —routine (set packets with routine precedence)

*parameter* Parameter name. The parameter name must be preceded with a "\$."

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set ip-precedence** command to set the IP precedence to classify packets. This command is supported at the BGP table-policy attachpoint. Prefixes are marked for subsequent processing in the forwarding plane. After QoS Policy Propagation through Border Gateway Protocol (BGP) (QPPB) is enabled on an interface, corresponding traffic shaping and policing is completed using packet classification based on the IP precedence or QoS group ID. See *Cisco IOS XR Modular Quality of Service Configuration Guide for the Cisco XR 12000 Series Router* for information on QPPB.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

This example shows how use **set ip-precedence** command:

```
RP/0/0/CPU0:router(config)# route-policy policy_1  
RP/0/0/CPU0:router(config-rpl)# set ip-precedence 3  
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set isis-metric

To set the Intermediate System-to-Intermediate System (IS-IS) metric attribute value, use the **set is-is metric** command in route-policy configuration mode.

**set isis-metric** {*number*|*parameter*}

## Syntax Description

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <i>number</i>    | 24-bit integer number. Range is from 0 to 16777215.              |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$." |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set isis-metric** command to set the IS-IS metric attribute value for routes that are redistributed into IS-IS.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the IS-IS metric attribute value is set to 1000:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set isis-metric 1000
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set label

To set the Border Gateway Protocol (BGP) label attribute value, use the **set label** command in route-policy configuration mode.

**set label** {**explicit-null**|**implicit-null**| *parameter*}

## Syntax Description

|                      |                                                                  |
|----------------------|------------------------------------------------------------------|
| <b>explicit-null</b> | Sets the label to the well-known explicit value of 0.            |
| <b>implicit-null</b> | Sets the label to the well-known implicit value of 3.            |
| <i>parameter</i>     | Parameter name. The parameter name must be preceded with a "\$." |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set label** command in a route policy at the allocate label attachpoint to set the label to explicit-null or implicit-null based on deployment preference. During inter-AS operation, the ASBR sends some of its own loopbacks to other its peers and labels them either implicit null or explicit null.

## Examples

The following example shows how to set the labels:

```
RP/0/0/CPU0:router(config)# route-policy labelpolicy
RP/0/0/CPU0:router(config-rpl)# if destination in (206.141.1.0/24) then
RP/0/0/CPU0:router(config-rpl)# set label explicit-null
RP/0/0/CPU0:router(config-rpl)# elseif destination in (206.141.3.0/24) then
RP/0/0/CPU0:router(config-rpl)# drop
RP/0/0/CPU0:router(config-rpl)# elseif destination in (206.141.4.0/24) then
RP/0/0/CPU0:router(config-rpl)# set label explicit-null
RP/0/0/CPU0:router(config-rpl)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set level

To configure the Intermediate System-to-Intermediate System (IS-IS) link-state packet (LSP) level advertised to redistributed routes, use the **set level** command in route-policy configuration mode.

**set level** {**level-1**| **level-2**| **level-1-2**| *parameter*}

## Syntax Description

|                  |                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------|
| <b>level-1</b>   | Specifies that redistributed routes are advertised in the Level 1 LSP of the router.          |
| <b>level-2</b>   | Specifies that redistributed routes are advertised in the Level 2 LSP of the router.          |
| <b>level-1-2</b> | Specifies that redistributed routes are advertised in Level 1 and Level 2 LSPs of the router. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."                              |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the IS-IS **set level** command to configure the LSP level advertised to redistributed routes.

### Note

The **set level** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

This command supports parameterization of the **level** keyword.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the level is set to Level 2:

```
RP/0/0/CPU0:router(config)# route-policy bgp_isis_redist
RP/0/0/CPU0:router(config-rpl)# if destination in (172.2.0.0/16 ge 16) then
RP/0/0/CPU0:router(config-rpl)# set level level-2
RP/0/0/CPU0:router(config-rpl)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set local-preference

To set the Border Gateway Protocol (BGP) local preference attribute in a route, use the **set local-preference** command in route-policy configuration mode.

**set local-preference** *{number|parameter}*

## Syntax Description

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 32-bit unsigned integer. Range is 0 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."       |

## Command Default

Default value is 100.

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set local-preference** command to specify a preference value for the autonomous system path. Local preference is a nontransitive (does not cross autonomous system boundaries) attribute and is the second metric considered in the BGP best path calculation (the highest local preference is chosen). Weight is the first metric evaluated for best path, but it is local to the router and propagates only to iBGP peers. See the *Implementing BGP on Cisco ASR 9000 Series Router Cisco IOS XR Software* module of the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router* for information on the BGP best path calculation.

### Note

The **set local-preference** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

The local preference is a 32-bit unsigned integer.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the local preference value is set to 10:

```
RP/0/0/CPU0:router(config-rpl)# set local-preference 10
```

# set med

To set the Border Gateway Protocol (BGP) Multi Exit Discriminator (MED) attribute, use the **set med** command in route-policy configuration mode.

**set med** {*number*|*parameter*} **igp-cost** {+| {*number*|*parameter*}} -| {*number*|*parameter*}} | **max-reachable**}

## Syntax Description

|                      |                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>number</i>        | Value assigned to a 32-bit unsigned integer. Range is 0 to 4294967295.                                                 |
| <i>parameter</i>     | Parameter name. The parameter name must be preceded with a "\$."                                                       |
| <b>igp-cost</b>      | Sets the MED value to the cost for the Interior Gateway Protocol (IGP) route to resolve the next-hop of the BGP route. |
| +   -                | Sets the MED to the MED plus or minus a static offset. An integer or parameter must follow the plus or minus.          |
| <b>max-reachable</b> | Sets the MED value to the maximum possible value of 4294967295.                                                        |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set med** command to set the MED value, which is a 32-bit unsigned integer.

### Note

The **set med** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

This command can take the following as argument values: an integer, a parameter, the **igp-cost** keyword, or a mathematical operator (either plus or minus) followed by an integer or a parameter. Setting the MED to the IGP cost is supported on outbound BGP policies only. The MED cannot be set to the IGP cost in policies applied to other BGP attach points.

The **max-reachable** keyword sets the MED to the maximum value while leaving the route reachable.

The plus or minus variants allow the user to set the MED to the MED plus or minus a static offset. The variants that allow a user to add or subtract offsets to the MED value are also range checked for underflow or overflow. If the value underflows as a result of subtraction, then the MED value is set to zero. If the value overflows, the value is set to 4294967295, which is the maximum value for MED. when MED is set to 4294967295, the route is unreachable.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following two examples show how to set the MED to a value that is either specified directly (using the integer 156) or passed to the policy as a parameter:

```
RP/0/0/CPU0:router(config-rpl)# set med 156
RP/0/0/CPU0:router(config-rpl)# set med $med_param
```

The following example shows how to instruct BGP to automatically set the MED value to the cost of the IGP route that resolves the next-hop of the BGP route:

```
RP/0/0/CPU0:router(config-rpl)# set med igp-cost
```

## set metric-type (IS-IS)

To configure the integrated Intermediate System-to-Intermediate System (IS-IS) metric type, use the **set metric-type** command in route-policy configuration mode.

```
set metric-type {internal| external| rib-metric-as-internal| rib-metric-as-external| parameter}
```

### Syntax Description

|                               |                                                                  |
|-------------------------------|------------------------------------------------------------------|
| <b>internal</b>               | Sets metric type to internal.                                    |
| <b>external</b>               | Sets the metric type to external.                                |
| <b>rib-metric-as-internal</b> | Uses RIB metric and sets IS-IS internal metric type.             |
| <b>rib-metric-as-external</b> | Uses RIB metric and sets IS-IS external metric type.             |
| <i>parameter</i>              | Parameter name. The parameter name must be preceded with a "\$." |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                                                             |
|---------------|------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                             |
| Release 3.8.0 | The <b>rib-metric-as-internal</b> and <b>rib-metric-as-external</b> keywords were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the IS-IS **set metric-type** command to control whether IS-IS treats the metric as an internal or external metric.

Use the **rib-metric-as-external** and **rib-metric-as-internal** keywords to preserve RIB metrics when redistributing routes from another ISIS router instance or another protocol.

#### Note

The **set metric-type** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

This command does not support parameterization.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

### Examples

In the following example, the IS-IS metric type is set to internal:

```
RP/0/0/CPU0:router(config-rpl)# set metric-type internal
```

## set metric-type (OSPF)

To control how Open Shortest Path First (OSPF) computes the cost for a route, use the **set metric-type** command in route-policy configuration mode.

**set metric-type** {*type-1*| *type-2*| *parameter*}

### Syntax Description

|                  |                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------|
| <b>type-1</b>    | Uses the cost set on the route plus the topology-related costs in the calculation for Type 1 metrics. |
| <b>type-2</b>    | Uses only the cost set on the route in the calculation for Type 2 metrics.                            |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."                                      |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the OSPF **set metric-type** command to control whether OSPF treats the cost as a Type 1 or Type 2 metric.

#### Note

The **set metric-type** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

The value of Type 1 or Type 2 controls how OSPF computes the cost for this route. For Type 2 metrics, only the cost set on the route is used. For Type 1 metrics, the cost set on the route plus the topology-related costs are used in the calculation.

This command does not support parameterization.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the OSPF metric type is set to Type 1:

```
RP/0/0/CPU0:router(config-rpl)# set metric-type type-1
```

## set next-hop

To replace the next-hop associated with a given route, use the **set next-hop** command in route-policy configuration mode.

**set next-hop** {*ipv4-address*|*ipv6-address*|**peer-address**|*parameter*|**self**} [**destination-vrf**]

### Syntax Description

|                        |                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv4-address</i>    | Valid IPv4 address.                                                                                                                                                             |
| <i>ipv6-address</i>    | Valid IPv6 address.                                                                                                                                                             |
| <b>peer-address</b>    | Sets the next-hop to the IP address of the remote Border Gateway Protocol (BGP) peer.                                                                                           |
| <i>parameter</i>       | Parameter name. The parameter name must be preceded with a "\$."                                                                                                                |
| <b>self</b>            | Sets itself as the next-hop.                                                                                                                                                    |
| <b>destination-vrf</b> | (Optional) Specifies that the next-hop of the route should be resolved in destination VRF context. This keyword is available when an IPv4 or IPv6 address or parameter is used. |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                                  |
|---------------|-----------------------------------------------|
| Release 3.2   | This command was introduced.                  |
| Release 3.3.0 | The <b>self</b> keyword was added.            |
| Release 3.4.0 | The <b>destination-vrf</b> keyword was added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set next-hop** command to replace the next-hop associated with a specific address.

**Note**

The **set next-hop** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Use the **set next-hop peer-address** command to set the next-hop to the address of the BGP neighbor, where this policy is attached.

The next-hop is a valid IPv4 address entered as a dotted decimal or an IPv6 address entered as a colon-separated hexadecimal.

It is not possible to use this command to set the BGP IPv6 link-local next-hop.

The **destination-vrf** keyword is used mainly in Layer 3 VPN networks when importing routes.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the next-hop is set to a valid IPv4 address:

```
RP/0/0/CPU0:router(config-rpl)# set next-hop 10.0.0.5
```

In this example, the next-hop is set to a parameter value \$nexthop:

```
RP/0/0/CPU0:router(config-rpl)# set next-hop $nexthop
```

In this example, the next-hop is set to a valid IPv4 address with a destination VRF context:

```
RP/0/0/CPU0:router(config-rpl)# set next-hop 10.0.0.5 destination-vrf
```

# set origin

To change the Border Gateway Protocol (BGP) origin attribute, use the **set origin** command in route-policy configuration mode.

**set origin** {**igp**|**incomplete**|**egp**| *parameter*}

## Syntax Description

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| <b>igp</b>        | Sets the origin type to Interior Gateway Protocol (IGP).         |
| <b>incomplete</b> | Sets the origin type to incomplete.                              |
| <b>egp</b>        | Sets the origin type to Exterior Gateway Protocol (EGP).         |
| <i>parameter</i>  | Parameter name. The parameter name must be preceded with a "\$." |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set origin** command to change the origin attribute.

### Note

The **set origin** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

The origin of a Border Gateway Protocol (BGP) route is **igp** , **egp** , or **incomplete** .

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the origin attribute is set to EGP:

```
RP/0/0/CPU0:router(config-rpl)# set origin egp
```

# set ospf-metric

To set an Open Shortest Path First (OSPF) protocol metric attribute value, use the **set ospf-metric** command in route-policy configuration mode.

**set ospf-metric** {*number*|*parameter*}

## Syntax Description

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 24-bit unsigned integer. Range is 0 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."       |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set ospf-metric** command to set the metric for routes that are redistributed into OSPF. The OSPF metric operator accepts either an integer value or a parameter.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the OSPF metric attribute value is set to 1000:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set ospf-metric 1000
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set path-selection

To set path selection criteria and install or advertise the path for the Border Gateway Protocol, use the **set path-selection** command in route-policy configuration mode.

**set path-selection** {*backup number*| **group-best**| **all**| **best-path**} [**install**] [**multipath-protect**] [**advertise**]

## Syntax Description

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <b>backup</b>            | Specifies the BGP backup path.                                            |
| <i>number</i>            | Specifies the BGP backup path number. 3 bit decimal number. Range is 0-7. |
| <b>group-best</b>        | Specifies the BGP group best path.                                        |
| <b>all</b>               | Specifies all BGP paths.                                                  |
| <b>best-path</b>         | Specifies the BGP best path.                                              |
| <b>install</b>           | Installs the path.                                                        |
| <b>multipath-protect</b> | Installs and advertises the multipath protect.                            |
| <b>advertise</b>         | Advertises the path.                                                      |

## Command Default

None

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                    |
|---------------|-------------------------------------------------|
| Release 4.0.0 | This command was introduced.                    |
| Release 4.0.1 | The <b>multipath-protect</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID      | Operation   |
|--------------|-------------|
| route-policy | read, write |

## Examples

The following example shows how to set the path selection as **advertise backup path 3** for route-policy *path\_selection\_plcy*:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# route-policy path_selection_plcy
RP/0/0/CPU0:router(config-rpl)# set path-selection backup 3 advertise
```

## Related Commands

| Command                           | Description                                                                        |
|-----------------------------------|------------------------------------------------------------------------------------|
| <b>additional-paths selection</b> | Configures additional paths selection capability for a prefix                      |
| <b>additional-paths send</b>      | Configures send capability of multiple paths for a prefix to the capable peers,    |
| <b>additional-paths receive</b>   | Configures receive capability of multiple paths for a prefix to the capable peers. |
| <b>advertise best-external</b>    | Advertises the best-external path to the iBGP and route-reflector peers,           |

## set qos-group (RPL)

To set the quality of service (QoS) group, use the **set qos-group** command in route-policy configuration mode:

**set qos-group** {*number*|*parameter*}

### Syntax Description

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <i>number</i>    | QoS group ID. Range is from 0 to 31.                             |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$." |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set qos-group** command to set the QoS group to classify packets.

This command is supported at the BGP table-policy attachpoint. Prefixes are marked for subsequent processing in the forwarding plane. After QoS Policy Propagation through Border Gateway Protocol (BGP) (QPPB) is enabled on an interface, corresponding traffic shaping and policing is completed using packet classification based on the IP precedence or QoS group ID. See the *Cisco IOS XR Modular Quality of Service Configuration Guide for the Cisco XR 12000 Series Router* for information on QPPB.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

### Examples

This example shows how to use **set qos-group** command:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set qos-group 12
```

```
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set rib-metric

To set the Routing Information Base (RIB) metric attribute value for a table policy, use the **set rib-metric** command in route-policy configuration mode:

**set rib-metric** {*number*|*parameter*}

## Syntax Description

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 32-bit unsigned integer. Range is 0 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."       |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set rib-metric** command set the RIB metric attribute value for BGP routes.

Every route in the RIB has a metric associated with it, signifying the cost to reach a specific destination based on link characteristics. The **set rib-metric** command modifies the RIB metric while installing BGP routes into RIB, enabling the upgrading or downgrading of the BGP route installed in RIB.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the RIB metric attribute is set to 1000:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set rib-metric 1000
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set rip-metric

To set Routing Information Protocol (RIP) metric attributes, use the **set rip-metric** command in route-policy configuration mode.

**set rip-metric** {*number*|*parameter*}

## Syntax Description

|                  |                                                                    |
|------------------|--------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 4-bit unsigned integer. Range is from 0 to 16. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."   |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                                               |
|---------------|------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                               |
| Release 3.4.0 | The <i>number</i> range of 0 to 15 was changed to 0 to 16. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set rip-metric** command to set the cost attribute for routes that are redistributed into RIP.

You can use the **add** command to increment the RIP metric value.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the RIP metric number is adjusted for route policy policy\_1:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set rip-metric 10
RP/0/0/CPU0:router(config-rpl)# end-policy
```

**Related Commands**

| Command                                            | Description                          |
|----------------------------------------------------|--------------------------------------|
| <a href="#">add</a> , <a href="#">on page 1544</a> | Adds an offset to an existing value. |

## set rip-tag

To set a route tag attribute for Routing Information Protocol (RIP) routes, use the **set rip-tag** command in route-policy configuration mode.

**set rip-tag** {*number*|*parameter*}

### Syntax Description

|                  |                                                                        |
|------------------|------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 16-bit unsigned integer. Range is from 0 to 65535. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."       |

### Command Default

No default behavior or values

### Command Modes

Route-policy configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set rip-tag** command to set the RIP tag attribute for routes that are redistributed into RIP. The RIP tag operator accepts either an integer value or a parameter.

### Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

### Examples

In the following example, the RIP tag is adjusted for route policy policy\_1:

```
RP/0/0/CPU0:router(config)# route-policy policy_1
RP/0/0/CPU0:router(config-rpl)# set rip-tag 1000
RP/0/0/CPU0:router(config-rpl)# end-policy
```

# set rpf-topology

To set reverse-path forwarding (RPF) to any default or nondefault tables for particular sources and groups, use the **set rpf-topology** command in routing policy configuration mode.

**set rpf-topology** [**vrf** *vrf-name*] {**ipv4**|**ipv6**} {**unicast**|**multicast**|*parameter*} **topology** *table-name*

## Syntax Description

|                            |                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>vrf</b> <i>vrf-name</i> | [Optional] Specifies a VPN routing and forwarding (VRF) instance. Required when configuring extranet topologies |
| <b>ipv4</b>                | [Optional] Specifies IPv4 address prefixes.                                                                     |
| <b>ipv6</b>                | [Optional] Specifies IPv6 address prefixes.                                                                     |
| <b>unicast</b>             | Specifies unicast address prefixes.                                                                             |
| <b>multicast</b>           | Specifies multicast address prefixes.                                                                           |
| <i>parameter</i>           | Parameter name. The parameter name must be preceded with a "\$."                                                |
| <b>topology</b>            | Specifies the default or nondefault topology table for the source or group.                                     |
| <i>table-name</i>          | Alphanumeric name string.                                                                                       |

## Command Default

Default or current topology setting.

## Command Modes

Routing policy configuration

## Command History

| Release       | Modification                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.7.0 | This command was introduced.                                                                                                        |
| Release 3.8.0 | This command was supported for MVPN extranet routing configuration. The <b>vrf</b> <i>vrf-name</i> keyword and argument were added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When using this command for MVPN extranet routing configuration, only the **vrf** *vrf-name* keyword and argument are required.

When using this command in the context of multitopology routing, all keywords and arguments with the exception of **vrf** *vrf-name* keyword and argument are required.

## Task ID

| Task ID   | Operations |
|-----------|------------|
| multicast | read       |

## Examples

The following example shows how to execute the **set rpf-topology** command:

```
RP/0/0/CPU0:router# config
RP/0/0/CPU0:router(config)# route-policy green
RP/0/0/CPU0:router(config-rpl)# set rpf-topology ipv6 multicast topology t12
```

The following example shows the use of **set rpf-topology** command in the context of creating an RPF for a topology table in multiple topologies:

```
route-policy mt4-p1
  if destination in (225.0.0.1, 225.0.0.11) then
    set rpf-topology ipv4 multicast topology t201
  elseif destination in (225.0.0.2, 225.0.0.12) then
    set rpf-topology ipv4 multicast topology t202

## Related Commands

| Command      | Description                                                                       |
|--------------|-----------------------------------------------------------------------------------|
| rpf topology | Assigns a route policy in PIM to select a reverse-path forwarding (RPF) topology. |

# set spf-priority

To set OSPF Shortest Path First (SPF) priority, use the set spf-priority command in route-policy configuration mode.

**set spf-priority {critical| high| medium}**

## Syntax Description

|                 |                                |
|-----------------|--------------------------------|
| <b>critical</b> | Sets critical priority for SPF |
| <b>high</b>     | Sets high priority for SPF     |
| <b>medium</b>   | Sets medium priority for SPF   |

## Command Default

None

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID      | Operation   |
|--------------|-------------|
| route-policy | read, write |

## Examples

This example sets SPF priority as critical:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#route-policy policy_spf_priority
RP/0/0/CPU0:router(config-rpl)#set spf-priority critical
```

**Related Commands**

| Command                           | Description                                                                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>spf prefix-priority (OSPF)</b> | Prioritizes OSPFv2 prefix installation into the global Routing Information Base (RIB) during Shortest Path First (SPF) run. |

# set tag

To set the tag attribute, use the **set tag** command in route-policy configuration mode.

**set tag** {*number*|*parameter*}

## Syntax Description

|                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 32-bit unsigned integer. Range is from 0 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."            |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set tag** command to set the tag attribute.

### Note

The **set tag** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Tags are routing-protocol independent 32-bit integers that can be associated with a given route in the Routing Information Base (RIB).

For the Border Gateway Protocol (BGP), the tag attribute can be set only at the table-policy attach point.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the tag attribute is set to 10:

```
RP/0/0/CPU0:router(config-rpl)# set tag 10
```

In this example, the tag attribute is set to a parameter value \$tag\_param:

```
RP/0/0/CPU0:router(config-rpl)# set tag $tag_param
```

# set traffic-index

To set the traffic index attribute, use the **set traffic-index** command in route-policy configuration mode.

**set traffic-index** {*number*|*parameter*|**ignore**}

## Syntax Description

|                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| <i>number</i>    | Integer value assigned to the traffic index attribute. Range is 1 to 63.    |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."            |
| <b>ignore</b>    | Specifies that Border Gateway Protocol (BGP) policy accounting is not done. |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set traffic-index** command to set the traffic index attribute.

### Note

The **set traffic-index** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

Traffic index is a special attribute for BGP. It is used as an index to a set of counters that are maintained by forwarding hardware. It is also used to track packet and byte counters that are forwarded using routes with specific attributes. These counters can be enabled and disabled on an individual interface basis.

The traffic index attribute can be set only at the table-policy attach point, and can take a value from 1 to 63, or a value of **ignore**. If the traffic index is set to **ignore**, then BGP policy accounting is not done. Parameterization of this value is also supported.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, a policy is created in which the traffic index is set to 10 for all routes that originated in autonomous system 1234:

```
RP/0/RSP0RP0/CPU0:router(config)# route-policy count-as-1234
RP/0/RSP0RP0/CPU0:router(config-rpl)# if as-path originates-from '1234' then
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# set traffic-index 10
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# else
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# pass
RP/0/RSP0RP0/CPU0:router(config-rpl-if)# endif
RP/0/RSP0RP0/CPU0:router(config-rpl)# end-policy
```

This policy could then be attached using the BGP **table-policy** command. The counters could then be enabled on various interfaces with the appropriate commands.

# set vpn-distinguisher

To change the Border Gateway Protocol (BGP) VPN distinguisher attribute, use the **set vpn-distinguisher** command in route-policy configuration mode.

**set vpn-distinguisher** {*number*|*parameter*}

## Syntax Description

|                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 32-bit unsigned integer. Range is from 1 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."            |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set vpn-distinguisher** command to change the VPN distinguisher attribute.

### Note

The **set origin** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

A VPN distinguisher is used in Layer 3 VPN networks for enhanced individual VPN control and to avoid route target mapping at AS boundaries in inter-AS VPN networks. Route target extended communities are removed at neighbor outbound, and the VPN distinguisher value is applied on the BGP route as an extended community. When the route is received on a neighboring router in another AS, the VPN distinguisher is removed and mapped to a route target extended community.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the VPN distinguisher attribute is set to 456:

```
RP/0/0/CPU0:router(config-rpl)# set vpn-distinguisher 456
```

# set weight

To set the weight value for Border Gateway Protocol (BGP) routes, use the **set weight** command in route-policy configuration mode.

**set weight** {*number*|*parameter*}

## Syntax Description

|                  |                                                                                             |
|------------------|---------------------------------------------------------------------------------------------|
| <i>number</i>    | Number assigned to the weight value for BGP routes. Weight is 16 bits. Range is 0 to 65535. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."                            |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set weight** command to set the weight value for BGP routes.

### Note

The **set weight** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

A weight is a value that can be applied to a route to override the BGP local preference. This is not a BGP attribute announced to BGP peer routers. RPL can be used to set the weight value.

Given two BGP routes with the same network layer reachability information (NLRI), a route with a higher weight is selected, no matter what the values of other BGP attributes may be. However, weight only has significance on the local router. It is not sent from one BGP speaker to another, even within the same autonomous system.

On Cisco routers, if a BGP route is sourced by the local router, its weight is automatically set to 32768; if the BGP route is learned from another router, its weight is automatically set to 0. Thus, by default, locally sourced routes are preferred over BGP learned routes.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the weight of the route is set to 10 and then to a parameter value \$weight\_param:

```
RP/0/0/CPU0:router(config-rpl)# set weight 10
RP/0/0/CPU0:router(config-rpl)# set weight $weight_param
```

# show rpl

To display system-wide RPL configuration, use the **show rpl** command in EXEC mode.

**show** [**running-config**] **rpl** [**maximum** {*lines configuration-limit*| **policies** *policies-limit*}] **editor** {**emacs**|**nano**|**vim**}]

## Syntax Description

|                                         |                                                                                                                                                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>running-config</b>                   | (Optional) Displays configuration-limit argument.                                                                                                                                                               |
| <b>maximum</b>                          | (Optional) Displays the maximum number of lines of configuration and number of policies.                                                                                                                        |
| <b>lines</b> <i>configuration-limit</i> | (Optional) Displays the number of lines to which configuration is limited. Range is 1 to 131072.<br><br>The <i>configuration-limit</i> argument is available if the <b>running-config</b> keyword is specified. |
| <b>policies</b> <i>policies-limit</i>   | (Optional) Displays the limit on the number of policies. Range is 1 to 5000.<br><br>The <i>configuration-limit</i> argument is available if the <b>running-config</b> keyword is specified.                     |
| <b>editor</b>                           | (Optional) Specifies the default RPL editor. This keyword is available if the <b>running-config</b> keyword is specified.                                                                                       |
| <b>emacs</b>                            | (Optional) Displays the default RPL editor to Micro Emacs.                                                                                                                                                      |
| <b>nano</b>                             | (Optional) Displays the default RPL editor to nano.                                                                                                                                                             |
| <b>vim</b>                              | (Optional) Displays the default RPL editor to Vim.                                                                                                                                                              |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|

# show rpl active community-set

To display the community sets that are referenced by at least one policy that is being used at an attach point, use the **show rpl active community-set** command in EXEC mode.

## show rpl active community-set [detail]

### Syntax Description

|               |                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| <b>detail</b> | (Optional) Displays the content of the object and all referenced objects for active community sets. |
|---------------|-----------------------------------------------------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

EXEC

### Command History

| Release       | Modification                         |
|---------------|--------------------------------------|
| Release 3.2   | This command was introduced.         |
| Release 3.3.0 | The <b>detail</b> keyword was added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl active community-set** command to display all community sets that are in use in the system and referenced either directly or indirectly at a policy attach point.

### Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

### Examples

This example shows the following sample configuration:

```
router bgp 2
  address-family ipv4 unicast
  !
  neighbor 10.0.101.2
    remote-as 100
    address-family ipv4 unicast
    route-policy policy_1 in
  !
```

**show rpl active community-set**

```

!
neighbor 10.0.101.3
remote-as 12
address-family ipv4 unicast
route-policy policy_2 in
!
!
!

RP/0/0/CPU0:router# show rpl route-policy policy_2 detail

prefix-set prefix_set_ex1
  10.0.0.0/16 ge 16 le 32,
  0.0.0.0/0 ge 25 le 32,
  0.0.0.0/0
end-set
!
community-set comm_set_ex1
  65500:1,
  65500:2,
  65500:3
end-set
!
extcommunity-set rt_ext_comm_set_rt_ex1
  1.2.3.4:34
end-set
!

route-policy policy_2
  if destination in prefix_set_ex1 then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity rt matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!

RP/0/0/CPU0:router# show rpl route-policy policy_1 detail

prefix-set prefix_set_ex1
  10.0.0.0/16 ge 16 le 32,
  0.0.0.0/0 ge 25 le 32,
  0.0.0.0/0
end-set
!
as-path-set as_path_set_ex1
  ios-regex '^_655--$',
  ios-regex '^_65501_$'
end-set
!
route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!

```

Given this sample configuration, the **show rpl active community-set** command displays the following information:

```

RP/0/0/CPU0:router# show rpl active community-set

ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced

```

```
The following community-sets are ACTIVE
-----
comm_set_ex1
```

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl active route-policy** command to display all policies that are in use in the system and that are referenced either directly or indirectly at a policy attach point.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
 remote-as 100
 address-family ipv4 unicast
```

```

    route-policy policy_1 in
    !
    !
neighbor 10.0.101.3
    remote-as 12
    address-family ipv4 unicast
    route-policy policy_2 in
    !
    !
    !
RP/0/0/CPU0:router# show rpl route-policy policy_1

route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
RP/0/0/CPU0:router# show rpl route-policy policy_2

route-policy policy_2
  if destination in prefix_set_ex1 then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity rt matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!
```

Given this sample configuration, the **show rpl active route-policy** command displays the following information:

```

RP/0/0/CPU0:router# show rpl active route-policy

ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced

The following policies are (ACTIVE)
-----
policy_1
policy_2
```

# show rpl as-path-set

To display the contents of AS path sets, use the **show rpl as-path-set** command in EXEC mode.

**show rpl as-path-set** [*name*] **states** [**brief**]

## Syntax Description

|               |                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------|
| <i>name</i>   | (Optional) Name of the AS path set.                                                                    |
| <b>states</b> | (Optional) Displays all unused, inactive, and active states.                                           |
| <b>brief</b>  | (Optional) Limits the display to a list of the names of all AS path sets without their configurations. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                                                   |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.                                                                                                   |
|             | The <b>summary</b> keyword was replaced with <b>brief</b> . The * keyword was removed and the <b>states</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the optional **brief** keyword to limit the display to a list of the names of all AS path sets without their configurations.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
RP/0/0/CPU0:router# show rpl route-policy policy_1
route-policy policy_1
```

```

    if (destination in prefix_set_ex1) then
        set local-preference 100
    endif
    if (as-path in as_path_set_ex1) then
        set community (10:333) additive
    endif
end-policy

```

Given this sample configuration, the **show rpl as-path-set as\_path\_set\_ex1** command displays the following information:

```

RP/0/0/CPU0:router# show rpl as-path-set as_path_set_ex1

as-path-set as_path_set_ex1
  ios-regex '^_65500_$',
  ios-regex '^_65501_$'
end-set

```

|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl as-path-set attachpoints** command to display all policies used at an attach point that reference the named set either directly or indirectly.

The AS path set name is required.

| Task ID | Task ID      | Operations |
|---------|--------------|------------|
|         | route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
   route-policy policy_1 in
 !
 !
 neighbor 10.0.101.3
```

```

remote-as 12
address-family ipv4 unicast
route-policy policy_2 in
!
!
RP/0/0/CPU0:router# show rpl route-policy policy_1

route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
RP/0/0/CPU0:router# show rpl route-policy policy_2

```

```

route-policy policy_2
  if (destination in prefix_set_ex1) then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!

```

Given this sample configuration, the **show rpl as-path-set as\_path\_set\_ex1 attachpoints** command displays the following information:

```

RP/0/0/CPU0:router# show rpl as-path-set as_path_set_ex1 attachpoints

BGP Attachpoint:Neighbor

Neighbor/Group  type  afi/safi  in/out  referring policy  attached policy
-----
10.0.101.2      --   IPv4/uni  in      policy_1          policy_1
10.0.101.3      --   IPv4/uni  in      policy_2          policy_2

```

This table describes the significant fields shown in the display.

**Table 174: show rpl as-path-set attachpoints Field Descriptions**

| Field            | Description                                                        |
|------------------|--------------------------------------------------------------------|
| BGP Attachpoint  | Location of the attach point.                                      |
| Neighbor/Group   | IP address of the attach point on the neighbor.                    |
| type             | Displays the address family mode.                                  |
| afi/safi         | Address family identifier or subsequent address family identifier. |
| in/out           | Import or export policy.                                           |
| referring policy | Policy that refers to the AS path set.                             |
| attached policy  | Policy used at the attach point.                                   |

# show rpl as-path-set references

To list all of the policies that reference the named AS path set, use the **show rpl as-path-set references** command in EXEC mode.

**show rpl as-path-set** *name* **references** [**brief**]

## Syntax Description

|              |                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------|
| <i>name</i>  | Name of the prefix set.                                                                                          |
| <b>brief</b> | (Optional) Limits the output to just the brief table and not the detailed information for the named AS path set. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                |
|-------------|-------------------------------------------------------------|
| Release 3.2 | This command was introduced.                                |
|             | The <b>summary</b> keyword was replaced with <b>brief</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl as-path-set references** command to display all policies that reference the named AS path set either directly or indirectly.

Use the optional **brief** keyword to limit the output to just a summary table and not the detailed information for the AS path set.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
```

```

!
neighbor 10.0.101.2
 remote-as 100
 address-family ipv4 unicast
  route-policy policy_1 in
!
!
RP/0/0/CPU0:router# show rpl route-policy policy_1

route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy

```

Given this sample configuration, the **show rpl as-path-set as\_path\_set\_ex1 references** command displays the following information:

```

RP/0/0/CPU0:router# show rpl as-path-set as_path_set_ex1 references

Usage Direct -- Reference occurs in this policy
Usage Indirect -- Reference occurs via an apply statement

Status UNUSED -- Policy is not in use at an attachpoint (unattached)
Status ACTIVE -- Policy is actively used at an attachpoint
Status INACTIVE -- Policy is applied by an unattached policy

      Usage/Status      count
-----
      Direct            1
      Indirect          0

      ACTIVE            1
      INACTIVE          0
      UNUSED            0

      route-policy      usage      policy status
-----
      policy_1          Direct      ACTIVE

```

This table describes the significant fields shown in the display.

**Table 175: show rpl as-path-set references Field Descriptions**

| Field        | Description                                                                                                                                                                                    |

    endif
    if (extcommunity rt matches-any ext_comm_set_rt_ex1) then <<<<<
      set community (10:999) additive
    endif
  endif
end-policy
!
```

Given this sample configuration, the **show rpl community-set attachpoints** command displays the following information:

```
RP/0/0/CPU0:router# show rpl community-set ext_comm_set_rt_ex1 attachpoints
```

```
BGP Attachpoint:Neighbor
```

```

Neighbor/Group  type  afi/safi  in/out  referring policy  attached policy
-----
10.0.101.3      --   IPv4/uni  in      policy_2         policy_2

```

This table describes the significant fields shown in the display.

**Table 176: show rpl community-set attachpoints Field Descriptions**

| Field            | Description                                                        |
|------------------|--------------------------------------------------------------------|
| BGP Attachpoint  | Location of the attach point.                                      |
| Neighbor/Group   | IP address of the attach point on the neighbor.                    |
| type             | Displays the address family mode.                                  |
| afi/safi         | Address family identifier or subsequent address family identifier. |
| in/out           | Import or export policy.                                           |
| referring policy | Policy that refers to the AS path set.                             |
| attached policy  | Policy used at the attach point.                                   |

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                |
|-------------|-------------------------------------------------------------|
| Release 3.2 | This command was introduced.                                |
|             | The <b>summary</b> keyword was replaced with <b>brief</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl community-set references** command to display all the policies that reference the named community set.

Use the optional **brief** keyword to limit the output to just a summary table and not the detailed information for the community set.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
```

```

!
neighbor 10.0.101.3
 remote-as 12
 address-family ipv4 unicast
  route-policy policy_2 in
!
!
!
route-policy policy_2
 if (destination in prefix_set_ex1) then
  if (community matches-any comm_set_ex1) then
   set community (10:666) additive
  endif
  if (extcommunity matches-any ext_comm_set_rt_ex1) then
   set community (10:999) additive
  endif
 endif
end-policy

```

Given this sample configuration, the **show rpl extcommunity-set comm\_set\_ex1 references** command displays the following information:

```
RP/0/0/CPU0:router# show rpl extcommunity-set comm_set_ex1 references
```

```

Usage Direct -- Reference occurs in this policy
Usage Indirect -- Reference occurs via an apply statement

Status UNUSED -- Policy is not in use at an attachpoint (unattached)
Status ACTIVE -- Policy is actively used at an attachpoint
Status INACTIVE -- Policy is applied by an unattached policy

```

| Usage/Status | count |
|--------------|-------|
| Direct       | 1     |
| Indirect     | 0     |
| ACTIVE       | 1     |
| INACTIVE     | 0     |
| UNUSED       | 0     |

  

| route-policy | usage  | policy status |
|--------------|--------|---------------|
| policy_2     | Direct | ACTIVE        |

This table describes the significant fields shown in the display.

**Table 177: show rpl community-set references Field Descriptions**

| Field        | Description                                                                                                                                                                                |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the optional **brief** keyword to limit the display to a list of the names of extended community sets without their configurations.

### Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

### Examples

In the following example, the configuration of an extended community is displayed for the RT community set named `ext_comm_set_rt_ex1`:

```
RP/0/0/CPU0:router# show rpl extcommunity-set rt ext_comm_set_rt_ex1
ext_comm_set_rt_ex1
  1.2.3.4:34
end-set
!
```

In the following example, the configuration of an extended community is displayed with all RT set objects:

```
RP/0/0/CPU0:router# show rpl extcommunity-set rt
Listing for all Extended Community RT Set objects

extcommunity-set rt extrt1
  66:60001
end-set
!
extcommunity-set rt rtset1
  10:615,
  10:6150,
  15.15.15.15:15
end-set
!
extcommunity-set rt rtset3
  11:11,
  11.1.1.1:3
end-set
```

```

!
extcommunity-set rt extsoo1
  66:70001
end-set
!
extcommunity-set rt rtset11
  100:121,
  100:122,
  100:123,
  100:124,
  100:125,
  100:126,
  100:127,
  100:128,
  7.7.7.7:21
end-set
!

```

In the following example, the configuration of an extended community is displayed with all cost set objects:

```
RP/0/0/CPU0:router# show rpl extcommunity-set cost
```

Listing for all Extended Community COST Set objects

```

extcommunity-set cost costset1
  IGP:90:914,
  Pre-Bestpath:91:915
end-set
!
extcommunity-set cost costset2
  IGP:92:916,
  Pre-Bestpath:93:917,
  IGP:94:918,
  Pre-Bestpath:95:919
end-set
!

```

In the following example, the configuration of an extended community is displayed with all SoO set objects:

Extended Community SOO Set objects

```

extcommunity-set soo sooset1
  10:151,
  100.100.100.1:153
end-set
!
extcommunity-set soo sooset3
  11:11,
  11.1.1.1:3
end-set
!

```

 `show rpl extcommunity-set`

# show rpl inactive as-path-set

To display the AS path sets that are referenced by a policy but not in any policy that is used at an attach point, use the **show rpl inactive as-path-set** command in EXEC mode.

**show rpl inactive as-path-set [detail]**

## Syntax Description

|               |                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| <b>detail</b> | (Optional) Displays the content of the object and all referenced objects for inactive AS path sets. |
|---------------|-----------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                     |
|---------------|----------------------------------|
| Release 3.2   | This command was introduced.     |
| Release 3.3.0 | Added the <b>detail</b> keyword. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl inactive as-path-set** command to display all AS path sets that are not in use at an attach point either directly or indirectly but are referenced by at least one policy in the system.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
   route-policy policy_1 in
 !
```

```

!
neighbor 10.0.101.3
remote-as 12
address-family ipv4 unicast
route-policy policy_2 in
!
!
route-policy sample
  if (destination in sample) then
    drop
  endif
end-policy
!
route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
route-policy policy_2
  if destination in prefix_set_ex1 then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity rt matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!
route-policy policy_3
  if (destination in prefix_set_ex2) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex2) then
    set community (10:333) additive
  endif
end-policy
!
route-policy policy_4
  if (destination in prefix_set_ex2) then
    if (community matches-any comm_set_ex2) then
      set community (10:666) additive
    endif
    if (extcommunity matches-any ext_comm_set_rt_ex2) then
      set community (10:999) additive
    endif
  endif
end-policy
!
route-policy policy_5
  apply sample1
  apply policy_3
end-policy

```

Given this sample configuration, the **show rpl inactive as-path-set** command displays the following information:

```
RP/0/0/CPU0:router# show rpl inactive as-path-set
```

```

ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced

```

```
The following as-path-sets are INACTIVE
```

```
-----
```

as\_path\_set\_ex2

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl inactive community-set** command to display all community sets that are not in use at an attach point either directly or indirectly but are referenced by at least one policy in the system.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
   route-policy policy_1 in
 !
```

```

!
neighbor 10.0.101.3
  remote-as 12
  address-family ipv4 unicast
  route-policy policy_2 in
!
!
route-policy sample2
  if (destination in sample2) then
    drop
  endif
end-policy
!
route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
route-policy policy_2
  if destination in prefix_set_ex1 then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity rt matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!
route-policy policy_3
  if (destination in prefix_set_ex2) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex2) then
    set community (10:333) additive
  endif
end-policy
!
route-policy policy_4
  if (destination in prefix_set_ex2) then
    if (community matches-any comm_set_ex2) then
      set community (10:666) additive
    endif
    if (extcommunity matches-any ext_comm_set_rt_ex2) then
      set community (10:999) additive
    endif
  endif
end-policy
!
route-policy policy_5
  apply sample2
  apply policy_3
end-policy

```

Given this sample configuration, the **show rpl inactive community-set** command displays the following information:

```
RP/0/0/CPU0:router# show rpl inactive community-set
```

```
ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced
```

```
The following community-sets are INACTIVE
```

```
-----
```

comm\_set\_ex2

# show rpl inactive route-policy

To display the route policies that are referenced by a policy but not in any policy that is used at an attach point, use the **show rpl inactive route-policy** command in EXEC mode.

## show rpl inactive route-policy [detail]

### Syntax Description

|               |                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------|
| <b>detail</b> | (Optional) Displays the content of the object and all referenced objects for inactive route policies. |
|---------------|-------------------------------------------------------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

EXEC

### Command History

| Release       | Modification                                                                                   |
|---------------|------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |
| Release 3.3.0 | The <b>detail</b> keyword was added.                                                           |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl inactive route-policy** command to display all policies that are not in use at an attach point either directly or indirectly but are referenced by at least one other policy in the system.

### Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

### Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
```

```

    route-policy policy_1 in
    !
    !
neighbor 10.0.101.3
    remote-as 12
    address-family ipv4 unicast
        route-policy policy_2 in
        !
    !
!
route-policy sample3
    if (destination in sample3) then
        drop
    endif
end-policy
!
route-policy policy_1
    if (destination in prefix_set_ex1) then
        set local-preference 100
    endif
    if (as-path in as_path_set_ex1) then
        set community (10:333) additive
    endif
end-policy
!
route-policy policy_2
    if destination in prefix_set_ex1 then
        if (community matches-any comm_set_ex1) then
            set community (10:666) additive
        endif
        if (extcommunity rt matches-any ext_comm_set_rt_ex1) then
            set community (10:999) additive
        endif
    endif
end-policy
!
route-policy policy_3
    if (destination in prefix_set_ex2) then
        set local-preference 100
    endif
    if (as-path in as_path_set_ex2) then
        set community (10:333) additive
    endif
end-policy
!
route-policy policy_4
    if (destination in prefix_set_ex2) then
        if (community matches-any comm_set_ex2) then
            set community (10:666) additive
        endif
        if (extcommunity matches-any ext_comm_set_rt_ex2) then
            set community (10:999) additive
        endif
    endif
end-policy
!
route-policy policy_5
    apply sample3
    apply policy_3
end-policy

```

Given this sample configuration, the **show rpl inactive route-policy** command displays the following information:

```
RP/0/0/CPU0:router# show rpl inactive route-policy
```

```

ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced

```

The following policies are (INACTIVE)

```
-----  
sample3  
policy_3
```

| <a href="#">show rpl inactive as-path-set, on page 1751</a>      | Displays the AS path sets that are referenced by a policy but not in any policy that is used at an attach point.            |
| <a href="#">show rpl inactive community-set, on page 1754</a>    | Displays the community sets that are referenced by a policy but not in any policy that is used at an attach point.          |
| <a href="#">show rpl inactive extcommunity-set, on page 1757</a> | Displays the extended community sets that are referenced by a policy but not in any policy that is used at an attach point. |
| <a href="#">show rpl inactive prefix-set, on page 1760</a>       | Displays the prefix sets that are referenced by a policy but not in any policy that is used at an attach point.             |
| <a href="#">show rpl inactive rd-set, on page 1763</a>           | Displays the RD sets that are referenced by a policy but not in any policy that is used at an attach point.                 |

# show rpl maximum

To display the maximum limits for lines of configuration and number of policies, use the **show rpl maximum** command in EXEC mode.

**show rpl maximum** [**lines**| **policies**]

## Syntax Description

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <b>lines</b>    | (Optional) Displays the number of lines of configuration limit. |
| <b>policies</b> | (Optional) Displays the number of policies limit.               |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl maximum** command to display the current total, current limit, and maximum limit for lines of configuration and policies.

Use the optional **lines** keyword to limit the display to the number of lines of configuration limits. Use the optional **policies** keyword to limit the display to the number of policies limits.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

The following example shows sample output from the **show rpl maximum** command:

```
RP/0/0/CPU0:router# show rpl maximum
              Current      Current      Max
              Total        Limit        Limit
-----
Lines of configuration      3      65536      131072
Policies                    1       3500       5000
```

```
Compiled policies size (kB)          0
```

Table 178: [show rpl maximum Field Descriptions](#), on page 1769 describes the significant fields shown in the display.

**Table 178: show rpl maximum Field Descriptions**

| Field                       | Description                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------|
| Lines of configuration      | Displays the current total, current limit, and maximum limit of lines for the policy. |
| Policies                    | Displays the current total, current limit, and maximum limit of policies.             |
| Compiled policies size (kB) | Displays the current compiled total for policies in kilobytes.                        |

# show rpl policy-global references

To display policy-global definitions, use the **show rpl policy-global references** command in EXEC mode.

**show rpl policy-global references [brief]**

## Syntax Description

|              |                                                              |
|--------------|--------------------------------------------------------------|
| <b>brief</b> | (Optional) Limits the display to a list of the policy names. |
|--------------|--------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
policy-global
  infinity '16'
end-global
!
route-policy set-rip-unreachable
  set rip-metric $infinity
end-policy
!
```

Given this sample configuration, the **show rpl policy-global references** command displays the following information:

```
RP/0/0/CPU0:router# show rpl policy-global references
```

```
Usage Direct -- Reference occurs in this policy Usage Indirect -- Reference occurs via an
```

apply statement

Status UNUSED -- Policy is not in use at an attachpoint (unattached) Status ACTIVE -- Policy is actively used at an attachpoint Status INACTIVE -- Policy is applied by an unattached policy

| Usage/Status |        | count               |
|--------------|--------|---------------------|
| -----        |        |                     |

| -----        |        |                     |
| Direct       | UNUSED | set-rip-unreachable |

# show rpl prefix-set

To display the configuration of prefix sets, use the **show rpl prefix-set** command in EXEC mode.

**show rpl prefix-set** [*name*] **states** [**brief**]

## Syntax Description

|               |                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| <i>name</i>   | (Optional) Name of the prefix set.                                                                                |
| <b>states</b> | (Optional) Shows all unused, inactive, and active states.                                                         |
| <b>brief</b>  | (Optional) Limits the display to a list of the names of all extended community sets without their configurations. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                                                                                             |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>summary</b> keyword was replaced with <b>brief</b> .<br>The <b>*</b> keyword was removed and the <b>states</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Because sets cannot hierarchically reference other sets or policies, no **detail** keyword exists as with the **show rpl policy** command.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

In the following example, the configuration of prefix set pset1 is displayed:

```
RP/0/0/CPU0:router# show rpl prefix-set pset1
!
```

```
prefix-set pset1
 10.0.0.1/0,
 10.0.0.2/0 ge 25 le 32,
 10.0.0.5/8 ge 8 le 32,
 10.168.0.0/16 ge 16 le 32,
 172.16.0.9/20 ge 20 le 32,
 192.168.0.5/20 ge 20 le 32
end-set
```

**Related Commands**

# show rpl prefix-set attachpoints

To display all the policies used at an attach point that reference the named prefix set, use the **show rpl prefix-set attachpoints** command in EXEC mode.

**show rpl prefix-set** *name* **attachpoints**

## Syntax Description

|             |                       |
|-------------|-----------------------|
| <i>name</i> | Name of a prefix set. |
|-------------|-----------------------|

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl prefix-set attachpoints** command to display all the policies used at an attach point that reference the named prefix set either directly or indirectly.

The prefix set name is required.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
  address-family ipv4 unicast
  !
  neighbor 10.0.101.2
    remote-as 100
    address-family ipv4 unicast
    route-policy policy_1 in
  !
  !
  neighbor 10.0.101.3
```

```

remote-as 12
address-family ipv4 unicast
route-policy policy_2 in
!
!
route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
route-policy policy_2
  if (destination in prefix_set_ex1) then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy

```

Given this sample configuration, the **show rpl prefix-set prefix\_set\_ex1 attachpoints** command displays the following information:

```
RP/0/0/CPU0:router# show rpl prefix-set prefix_set_ex1 attachpoints
```

```
BGP Attachpoint:Neighbor
```

| Neighbor/Group | type | afi/safi | in/out | referring policy | attached policy |
|----------------|------|----------|--------|------------------|-----------------|
| 10.0.101.2     | --   | IPv4/uni | in     | policy_1         | policy_1        |
| 10.0.101.3     | --   | IPv4/uni | in     | policy_2         | policy_2        |

This table describes the significant fields shown in the display.

**Table 179: show rpl prefix-set attachpoints Field Descriptions**

| Field            | Description                                                        |
|------------------|--------------------------------------------------------------------|

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                |
|-------------|---------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>summary</b> keyword was replaced with <b>brief</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl prefix-set references** command to list all the policies that reference the named prefix set.

Use the optional **brief** keyword to limit the output to just a summary table and not the detailed information for the named prefix set.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
prefix-set ten-net
 10.0.0.0/16 le 32
end-set
prefix-set too-specific
```

```

0.0.0.0/0 ge 25 le 32
end-set
route-policy example-one
  if destination in ten-net then
    drop
  else
    set local-preference 200
    apply set-comms
  endif
end-policy
route-policy set-comms
  set community (10:1234) additive
end-policy

route-policy example-three
  if destination in too-specific then
    drop
  else
    apply example-one
    pass
  endif
end-policy

```

The following example displays information showing the usage and status of each policy that references the prefix set **ten-net**. The **brief** keyword limits the display to just a summary table and not the detailed information for the prefix set.

```
RP/0/0/CPU0:router# show rpl prefix-set ten-net references brief
```

```

Usage Direct -- Reference occurs in this policy
Usage Indirect -- Reference occurs via an apply statement

Status UNUSED -- Policy is not in use at an attachpoint (unattached)
Status ACTIVE -- Policy is actively used at an attachpoint
Status INACTIVE -- Policy is applied by an unattached policy

```

| Usage/Status | count |
|--------------|-------|
| Direct       | 1     |
| Indirect     | 1     |
| ACTIVE       | 0     |
| INACTIVE     | 1     |
| UNUSED       | 1     |

This table describes the significant fields shown in the display.

**Table 180: show rpl prefix-set name references Field Descriptions**

| Field        | Description                                                                  |
|--------------|------------------------------------------------------------------------------|
| Usage/Status | Displays the usage and status of all policies that reference the prefix set. |
| count        | Number of policies that match each usage and status option.                  |

# show rpl rd-set attachpoints

To display all the policies used at an attach point that reference the named route distinguisher (RD) set, use the **show rpl rd-set attachpoints** command in EXEC mode.

**show rpl rd-set** *name* **attachpoints**

| Syntax Description |                    |
|--------------------|--------------------|
| <i>name</i>        | Name of an RD set. |

**Command Default** No default behavior or values

**Command Modes** EXEC

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.4.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl rd-set attachpoints** command to display all the policies used at an attach point that reference the named RD set either directly or indirectly.

| Task ID | Task ID      | Operations |
|---------|--------------|------------|
|         | route-policy | read       |

**Examples** This example shows the following sample configuration:

```
route-policy rdsetmatch
  if rd in rdset1 then
    set community (10:112)
  elseif rd in rdset2 then
    set community (10:223)
  endif
end-policy

router bgp 10
address-family vpnv4 unicast
exit
neighbor 10.0.101.1
```

```

remote-as 11
address-family vpnv4 unicast
route-policy rdsetmatch in
!

```

Given this sample configuration, the **show rpl rd-set rdset1 attachpoints** command displays the following information:

```
RP/0/0/CPU0:router# show rpl rd-set rdset attachpoints
```

```
BGP Attachpoint: Neighbor
```

```

Neighbor/Group  type  afi/safi  in/out  vrf name
-----
10.0.101.1      --   IPv4/vpn  in      default

```

This table describes the significant fields shown in the display.

**Table 181: show rpl rd-set attachpoints Field Descriptions**

| Field          | Description                                                       |
|----------------|-------------------------------------------------------------------|
| Neighbor/Group | BGP neighbor or neighbor group where the specified RD is used.    |
| afi/safi       | BGP address family or subaddress family where the RD set is used. |
| in/out         | Direction                                                         |
| vrf name       | VRF name where the RD set is used.                                |

# show rpl rd-set references

To list all the policies that reference the named route distinguisher (RD) set, use the **show rpl rd-set references** command in EXEC mode.

**show rpl rd-set** *name* **references** [**brief**]

## Syntax Description

|              |                                                                                                       |
|--------------|-------------------------------------------------------------------------------------------------------|
| <i>name</i>  | Name of the RD set.                                                                                   |
| <b>brief</b> | (Optional) Limits the output to just a summary table and not the detailed information for the RD set. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl rd-set references** command to list all the policies that reference the named RD set.

Use the optional **brief** keyword to limit the output to just a summary table and not the detailed information for the named RD set.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
route-policy rdsetmatch
  if rd in rdset1 then
    set community (10:112)
  elseif rd in rdset2 then
    set community (10:223)
  endif
```

```

end-policy
!
router bgp 10
 address-family vpnv4 unicast
 !
 neighbor 10.0.101.1
  remote-as 11
  address-family vpnv4 unicast
  route-policy rdsetmatch in
 !

```

Given this sample configuration, the **show rpl rd-set rdset1 references** command displays the following information:

```
RP/0/0/CPU0:router# show rpl rd-set rdset1 references
```

```
Usage Direct -- Reference occurs in this policy
Usage Indirect -- Reference occurs via an apply statement
```

```
Status UNUSED -- Policy is not in use at an attachpoint (unattached)
Status ACTIVE -- Policy is actively used at an attachpoint
Status INACTIVE -- Policy is applied by an unattached policy
```

| Usage/Status | count |
|--------------|-------|
| Direct       | 1     |
| Indirect     | 0     |
| ACTIVE       | 1     |
| INACTIVE     | 0     |
| UNUSED       | 0     |

  

| route-policy | usage  | policy status |
|--------------|--------|---------------|
| rdsetmatch   | Direct | ACTIVE        |

This table describes the significant fields shown in the display.

**Table 182: show rpl rd-set name references Field Descriptions**

| Field         | Description                                   |
|---------------|-----------------------------------------------|
| route-policy  | Name of the route policy.                     |
| usage         | Type of reference usage for the route policy. |
| policy status | Status of the route policy.                   |

# show rpl route-policy

To display the configuration of route policies, use the **show rpl route-policy** command in EXEC mode.

**show rpl route-policy** [*name* [**detail**]| **states**| **brief**]

## Syntax Description

|               |                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| <i>name</i>   | (Optional) Name of a route policy.                                                                                |
| <b>detail</b> | (Optional) Displays the configuration of all policies and sets that a policy uses.                                |
| <b>states</b> | (Optional) Shows all unused, inactive, and active states.                                                         |
| <b>brief</b>  | (Optional) Limits the display to a list of the names of all extended community sets without their configurations. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                                                                                                                                                               |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>summary</b> keyword was replaced with <b>brief</b> .<br>The <b>policy</b> keyword was changed to <b>route-policy</b> .<br>The <b>*</b> keyword was removed and the <b>states</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the optional **brief** keyword to limit the display to a list of the names of policies without their configurations.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

**Examples**

In the following example, the configuration of a route policy named `policy_1` is displayed.

```
RP/0/0/CPU0:router# show rpl route-policy policy_1

route-policy policy_1
  if destination in prefix_set_1 and not destination in sample1 then
    if as-path in aspath_set_1 then
      set local-preference 300
      set origin igp
    elseif as-path in as_allowed then
      set local-preference 400
      set origin igp
    else
      set origin igp
    endif
  endif
  else
    drop
  endif
  set med 120
  set community (8660:612) additive
  apply set_lpref_from_comm
end-policy
```

If the optional **detail** keyword is used, all routing policy language (RPL) policies and sets that route policy `policy_1` uses are displayed, as shown in the following example.

```
RP/0/0/CPU0:router# show rpl route-policy policy_1 detail

# show rpl route-policy attachpoints

To display all the policies used at an attach point that reference the named policy, use the **show rpl route-policy attachpoints** command in EXEC mode.

**show rpl route-policy** *name* **attachpoints**

## Syntax Description

*name*

Name of a policy.

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                   |
|-------------|------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl route-policy attachpoints** command to display all the policies used at an attach point that reference the named policy either directly or indirectly.

The policy name is required.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
   route-policy policy_1 in
 !
```

```

!
neighbor 10.0.101.3
  remote-as 12
  address-family ipv4 unicast
  route-policy policy_2 in
!
!
RP/0/0/CPU0:router# show rpl route-policy policy_1

route-policy policy_1
  if (destination in prefix_set_ex1) then
    set local-preference 100
  endif
  if (as-path in as_path_set_ex1) then
    set community (10:333) additive
  endif
end-policy
!
RP/0/0/CPU0:router# show rpl route-policy policy_2

route-policy policy_2
  if (destination in prefix_set_ex1) then
    if (community matches-any comm_set_ex1) then
      set community (10:666) additive
    endif
    if (extcommunity matches-any ext_comm_set_rt_ex1) then
      set community (10:999) additive
    endif
  endif
end-policy
!

```

The following command displays the route policy attach points for policy\_2:

```

RP/0/0/CPU0:router# show rpl route-policy policy_2 attachpoints

BGP Attachpoint: Neighbor

Neighbor/Group  type  afi/safi  in/out  vrf name
-----
10.0.101.2      --   IPv4/uni  in      default
10.0.101.2      --   IPv4/uni  out     default

```

This table describes the significant fields shown in the display.

**Table 183: show rpl route-policy attachpoints Field Descriptions**

| Field           | Description                                                        |

# show rpl route-policy inline

To display all policies and sets that a policy uses expanded inline, use the **show rpl route-policy inline** command in EXEC mode.

**show rpl route-policy** *name* **inline**

| Syntax Description | <i>name</i> | Name of a policy. |
|--------------------|-------------|-------------------|
|--------------------|-------------|-------------------|

|                 |                               |
|-----------------|-------------------------------|
| Command Default | No default behavior or values |
|-----------------|-------------------------------|

|               |      |
|---------------|------|
| Command Modes | EXEC |
|---------------|------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.5.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl route-policy inline** command to examine the configuration of a specified route policy. All policies and sets that a policy uses are gathered together and displayed expanded inline.

The policy name is required.

| Task ID | Task ID      | Operations |
|---------|--------------|------------|
|         | route-policy | read       |

## Examples

The following command displays the route policy policy\_1:

```
RP/0/0/CPU0:router# show rpl route-policy policy_1
!
route-policy policy_1
  if destination in prefix_set_1 and not destination in martians then
    if as-path in aspath_set_1 then
      set local-preference 300
      set origin igp
    elseif as-path in as_allowed then
      set local-preference 400
```

```

        set origin igp
    else
        set origin igp
    endif
else
    drop
endif
set med 120
set community (8660:612) additive
apply set_lpref_from_comm
end-policy

```

The following command displays the route policy policy\_1 and all the other sets or policies it refers too inline. Adding the inline keyword causes the configuration to be displayed inline for all RPL objects that the route-policy policy\_1 uses.

RP/0/0/CPU0:router#**show rpl policy policy\_1 inline**

```

route-policy policy_1
  if destination in (91.5.152.0/24 ge 24 le 32, 91.220.152.0/24 ge 24 le 32, 61.106.52.0/24

|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>summary</b> keyword was replaced with <b>brief</b> .<br>The <b>policy</b> keyword was replaced with <b>route-policy</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl route-policy references** command to list all the policies that reference the named policy.

Use the optional **brief** keyword to limit the output to just a summary table and not the detailed information for the policy.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
prefix-set ten-net
 10.0.0.0/16 le 32
```

```

end-set
prefix-set too-specific
  0.0.0.0/0 ge 25 le 32
end-set
route-policy example-one
  if destination in ten-net then
    drop
  else
    set local-preference 200
    apply set-comms
  endif
end-policy
route-policy set-comms
  set community (10:1234) additive
end-policy
route-policy example-three
  if destination in too-specific then
    drop
  else
    apply example-one
    pass
  endif
end-policy

```

The following command displays information about the policy set-comms and how it is referenced:

```
RP/0/0/CPU0:router# show rpl route-policy set-comms references
```

```

Usage Direct -- Reference occurs in this policy
Usage Indirect -- Reference occurs via an apply statement

Status UNUSED -- Policy is not in use at an attachpoint (unattached)
Status ACTIVE -- Policy is actively used at an attachpoint
Status INACTIVE -- Policy is applied by an unattached policy

```

| Usage/Status | count |
|--------------|-------|
| Direct       | 1     |
| Indirect     | 1     |
| ACTIVE       | 0     |
| INACTIVE     | 1     |
| UNUSED       | 1     |

  

| route-policy  | usage    | policy status |
|---------------|----------|---------------|
| example-one   | Direct   | INACTIVE      |
| example-three | Indirect | UNUSED        |

The direct usage indicates that the route policy example-one directly applies the policy set-comms, that is, example-one has a line in the form `apply set-comms`. The usage Indirect indicates that the route policy example-three does not directly apply the route policy set-comms. However, the route policy example-three does apply the policy example-one, which in turn applies the policy set-comms, so there is an indirect reference from example-three to the route policy set-comms.

The status column indicates one of three states. A policy is active if it is in use at an attach point. In the example provided, neither example-one nor example-three is in use at an attach point, which leaves two possible states: UNUSED or INACTIVE. The route policy example-one is inactive because it has some other policy (example-three) that references it, but neither example-one nor any of the policies that reference it (example-one) are in use at an attach point. The route policy example-three has a status of unused because it is not used at an attach point and no other route policies in the system refer to it.

This table describes the significant fields shown in the display.

**Table 184: show rpl route-policy references Field Descriptions**

| Field         | Description                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Usage/Status  | Displays the usage and status of all policies that reference the specified policy.<br>Values for usage are Direct or Indirect.<br>Values for status are ACTIVE, INACTIVE, and UNUSED. |
| count         | Number of policies that match each usage and status option.                                                                                                                           |
| route-policy  | One name for multiple policies that reference the specified policy.                                                                                                                   |
| usage         | Type of usage for the policy.                                                                                                                                                         |
| policy status | Status of the policy.                                                                                                                                                                 |

# show rpl route-policy uses

To display information about a specified named policy, use the **show rpl route-policy uses** command in EXEC mode.

**show rpl route-policy** *name* **uses** {**policies**|**sets**|**all**} [**direct**]

## Syntax Description

|                 |                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>     | Name of a policy.                                                                                                                                                                |
| <b>policies</b> | Generates a list of all policies that the named policy uses.                                                                                                                     |
| <b>sets</b>     | Lists all named sets that are used by the policy.                                                                                                                                |
| <b>all</b>      | Generates a list of both sets and policies that the named policy references.                                                                                                     |
| <i>direct</i>   | (Optional) Lists only the policies or sets used directly in the named policy block. Set or policy references that occur as a result of an <b>apply</b> statement are not listed. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                                                                                   |
|-------------|------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl route-policy uses** command to display information about a specified named policy.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

**Examples**

This example shows the following sample configuration:

```
prefix-set ten-net
 10.0.0.0/16 le 32
end-set
prefix-set too-specific
 0.0.0.0/0 ge 25 le 32
end-set
route-policy example-one
 if destination in ten-net then
  drop
 else
  set local-preference 200
  apply set-comms
 endif
end-policy
route-policy set-comms
 set community (10:1234) additive
end-policy
route-policy example-three
 if destination in too-specific then
  drop
 else
  apply example-one
  pass
 endif
end-policy
```

The following command lists the policies one and set-comms. It also lists the prefix sets too-specific and ten-net.

```
RP/0/0/CPU0:router# show rpl route-policy example-three uses all
```

```
Policies directly and indirectly applied by this policy:
```

```
-----
example-one set-comms
```

```
Sets referenced directly and indirectly
-----
(via applied policies) in this policy:
```

```
type prefix-set:
ten-net too-specific
```

The sets example-one and set-comms are listed as policies that are used by the policy example-three. The policy example-one is listed because route policy example-three uses it in an **apply** statement. The policy set-comms is also listed because example-one applies it. Similarly, the prefix-set too-specific is used directly in the **if** statement in the policy example-three, and the prefix-set ten-net is used in the policy example-one. The optional **direct** keyword can be used to limit the output to just those sets and policies that are used within the example-three block itself, as shown in the following example:

```
RP/0/0/CPU0:router# show rpl route-policy example-three uses all direct
```

```
Policies directly applied by this policy:
```

```
-----
example-one
```

```
Sets used directly in this policy
-----
```

```
type prefix-set:
too-specific
```

As can be seen in the output, the route policy set-comms and the prefix set ten-net are no longer included in the output when the **direct** keyword is used. The **direct** form of the command considers only those sets or

policies used in the specified route policy and any additional policies or sets that may be used if you follow the hierarchy of **apply** statements.

This table describes the significant fields shown in the display.

**Table 185: show rpl route-policy uses Field Descriptions**

| Field | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| type  | Displays the type used in the policy configuration.<br>Values for type are prefix-set, community-set, extcommunity-set, and as-path-set. |

# show rpl unused as-path-set

To display the AS path sets that are defined but not used by a policy at an attach point or referenced in a policy using an **apply** statement, use the **show rpl unused as-path-set** command in EXEC mode.

**show rpl unused as-path-set [detail]**

## Syntax Description

|               |                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------|
| <b>detail</b> | (Optional) Displays the content of the object and all referenced objects for unused AS path sets. |
|---------------|---------------------------------------------------------------------------------------------------|

| Release 3.3.0 | The <b>detail</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl unused as-path-set** command to display all AS path sets that are not used in a policy at an attach point either directly or indirectly and are not referenced by any policies in the system.

## Task ID

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

## Examples

This example shows the following sample configuration:

```
router bgp 2
 address-family ipv4 unicast
 !
 neighbor 10.0.101.2
  remote-as 100
  address-family ipv4 unicast
   route-policy policy_1 in
 !
```

```

!
neighbor 10.0.101.3
remote-as 12
address-family ipv4 unicast
route-policy policy_2 in
!
!
!
as-path-set as_path_set_ex1
ios-regex '^_65500_$',
ios-regex '^_65501_$',
end-set
!
as-path-set as_path_set_ex2
ios-regex '^_65502_$',
ios-regex '^_65503_$',
end-set
!
as-path-set as_path_set_ex3
ios-regex '^_65504_$',
ios-regex '^_65505_$',
end-set
!
route-policy sample
if (destination in sample) then
drop
endif
end-policy
!
route-policy policy_1
if (destination in prefix_set_ex1) then
set local-preference 100
endif
if (as-path in as_path_set_ex1) then
set community (10:333) additive
endif
end-policy
!
route-policy policy_2
if (destination in prefix_set_ex1) then
if (community matches-any comm_set_ex1) then
set community (10:666) additive
endif
if (extcommunity matches-any ext_comm_set_rt_ex1) then
set community (10:999) additive
endif
endif
end-policy
!
route-policy policy_3
if (destination in prefix_set_ex2) then
set local-preference 100
endif
if (as-path in as_path_set_ex2) then
set community (10:333) additive
endif
end-policy
!
route-policy policy_4
if (destination in prefix_set_ex2) then
if (community matches-any comm_set_ex2) then
set community (10:666) additive
endif
if (extcommunity matches-any ext_comm_set_rt_ex2) then
set community (10:999) additive
endif
endif
end-policy
!
route-policy policy_5
apply sample
apply policy_3

```

```
end-policy
```

Given this sample configuration, the **show rpl unused as-path-set** command displays the following information:

```
RP/0/0/CPU0:router# show rpl unused as-path-set
```

```
ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced
```

```
The following as-path-sets are UNUSED
```

```
-----
as_path_set_ex3
```

## show rpl unused extcommunity-set

To display the extended community sets that are defined but not used by a policy at an attach point or referenced in a policy using an **apply** statement, use the **show rpl unused extcommunity-set** command in EXEC mode.

**show rpl unused extcommunity-set** [**cost**| **detail**| **rt**| **soo**]

### Syntax Description

|               |                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <b>cost</b>   | (Optional) Displays the unused extended-community cost objects.                                              |
| <b>rt</b>     | (Optional) Displays the unused extended community RT objects.                                                |
| <b>soo</b>    | (Optional) Displays the unused extended-community SoO objects.                                               |
| <b>detail</b> | (Optional) Displays the content of the object and all referenced objects for unused extended community sets. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show rpl unused extcommunity-set** command to display all extended community sets that are not used in a policy at an attach point either directly or indirectly and are not referenced by any policies in the system.

**Task ID**

| Task ID      | Operations |
|--------------|------------|
| route-policy | read       |

**Examples**

The following is sample output for the **show rpl unused extcommunity-set** command:

```
RP/0/0/CPU0:router:router# show rpl unused extcommunity-set
```

```
ACTIVE -- Referenced by at least one policy which is attached
INACTIVE -- Only referenced by policies which are not attached
UNUSED -- Not attached (directly or indirectly) and not referenced
```

The following extcommunity-sets are UNUSED

```
-----
ext_comm_set_ex3
```

# source in

To test the source of a Border Gateway Protocol (BGP) route against the address contained in either a named or an inline prefix set, use the **source in** command in route-policy configuration mode.

**source in** {*prefix-set-name*| *inline-prefix-set*| *parameter*}

## Syntax Description

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <i>prefix-set-name</i>   | Name of a prefix set.                                                     |
| <i>inline-prefix-set</i> | Inline prefix set. The inline prefix set must be enclosed in parentheses. |
| <i>parameter</i>         | Parameter name. The parameter name must be preceded with a "\$."          |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                             |
|---------------|------------------------------------------|
| Release 3.2   | This command was introduced.             |
| Release 3.4.0 | The <i>parameter</i> argument was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **source in** command as a conditional expression within an **if** statement to test the source of the route against the data in either a named or an inline prefix set. A comparison that references a prefix set with zero elements in it returns false.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

The source of a BGP route is the IP peering address of the neighboring router from which the route was received.

The prefix set can contain both IPv4 and IPv6 prefix specifications.

**Task ID**

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

**Examples**

In the following example, the source of a BGP route is tested against the data in the prefix set my-prefix-set:

```
RP/0/0/CPU0:router(config)# route-policy policy-A
RP/0/0/CPU0:router(config-rpl)# if source in my-prefix-set then
```

In this example, the source of a BGP route is tested against the data in an inline IPv4 prefix set:

```
RP/0/0/CPU0:router(config)# route-policy policy-B
RP/0/0/CPU0:router(config-rpl)# if source in (10.0.0.8, 10.0.0.20) then
```

In this example, the source of a route is tested against the data in an inline IPv6 prefix set:

```
RP/0/0/CPU0:router(config)# route-policy policy-C
RP/0/0/CPU0:router(config-rpl)# if source in (2001:0:0:1::/64, 2001:0:0:2::/64) then
```

**Related Commands**

| Command                                  | Description                                                      |
|------------------------------------------|------------------------------------------------------------------|
| <a href="#">prefix-set, on page 1638</a> | Enters a prefix set configuration mode and defines a prefix set. |

# suppress-route

To indicate that a given component of a BGP aggregate should be suppressed, use the **suppress-route** command in route-policy configuration mode.

**suppress-route**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **suppress-route** command to indicate that a given component of an aggregate should be suppressed, that is, not advertised by BGP. See the [unsuppress-route, on page 1823](#) command for information on overriding the **suppress-route** command for individual neighbors.

The **suppress-route** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** In the following example, if the destination is in 10.1.0.0/16, then the route is not advertised:

```
RP/0/0/CPU0:router(config)# route-policy check-aggregator
RP/0/0/CPU0:router(config-rpl)# if destination in (10.1.0.0/16) then
RP/0/0/CPU0:router(config-rpl-if)# suppress-route

RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl-if)# end-policy
```

# tag

To match a specific tag value, use the **tag** command in route-policy configuration mode.

**tag** {**eq**|**ge**|**le**|**is**} {*integer*|*parameter*}

## Syntax Description

|                                               |                                                                  |
|-----------------------------------------------|------------------------------------------------------------------|
| <b>eq</b>   <b>ge</b>   <b>le</b>   <b>is</b> | Equal to; greater than or equal to; less than or equal to.       |
| <i>integer</i>                                | Integer value. Range is 0 to 4294967295.                         |
| <i>parameter</i>                              | Parameter name. The parameter name must be preceded with a "\$." |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **tag** command as a conditional expression within an **if** statement to match a specific tag value.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

A tag is a 32-bit integer that can be associated with a given route within the RIB.

The **eq** operator matches either a specific tag value or a parameter value. Its variants **ge** and **le** match a range of tag values that are either greater than or equal to or less than or equal to the supplied value or parameter.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, if the tag equals 10, then the condition returns true:

```
RP/0/RSP0RP0/CPU0:router(config-rpl)# if tag eq 10 then
```

# unsuppress-route

To indicate that a given component of a BGP aggregate should be unsuppressed, use the **unsuppress-route** command in route-policy configuration mode.

**unsuppress-route**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No default behavior or values

**Command Modes** Route-policy configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **unsuppress-route** command to indicate that a given component of an aggregate should be unsuppressed, that is, allowed to be advertised by BGP again. This command affects routes that have been suppressed in the generation of BGP aggregates. If the request to unsuppress a route is encountered in a policy at a neighbor-out attach point, it guarantees that the routes that it affects are advertised to that neighbor even if that route was suppressed using the **suppress-route** command in a policy at the aggregation attach point.

The **unsuppress-route** command can be used as an action statement within an **if** statement. For a list of all action statements available within an **if** statement, see the **if** command.

| Task ID | Task ID      | Operations  |
|---------|--------------|-------------|
|         | route-policy | read, write |

**Examples** In the following example, if the destination is in 10.1.0.0/16, then the route is not advertised:

```
RP/0/0/CPU0:router(config)# route-policy check-aggregate
RP/0/0/CPU0:router(config-rpl)# if destination in (10.1.0.0/16) then
RP/0/0/CPU0:router(config-rpl-if)# unsuppress-route

RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
```

Assuming that the policy is attached at a neighbor-out attach point, if the route 10.1.0.0/16 was suppressed in a policy at an aggregation attach point, 10.1.0.0/16 is advertised to the neighbor. Routes continue to be suppressed in advertisements to other BGP neighbors unless a specific policy is attached to unsuppress the route.

**Related Commands**

|-----------------------------------------------|---------------------------------------------------------------------------|
| <a href="#">suppress-route</a> , on page 1819 | Indicates that a given component of a BGP aggregate should be suppressed. |

# vpn-distinguisher is

To match a specific Border Gateway Protocol (BGP) VPN distinguisher, use the **vpn-distinguisher is** command in route-policy configuration mode.

**vpn-distinguisher is** {*number*|*parameter*}

## Syntax Description

|                  |                                                                             |
|------------------|-----------------------------------------------------------------------------|
| <i>number</i>    | Value assigned to a 32-bit unsigned integer. Range is from 1 to 4294967295. |
| <i>parameter</i> | Parameter name. The parameter name must be preceded with a "\$."            |

## Command Default

No default behavior or values

## Command Modes

Route-policy configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vpn-distinguisher is** command as a conditional expression within an **if** statement to test the value of the origin attribute.

A VPN distinguisher is used in Layer 3 VPN networks for enhanced individual VPN control and to avoid route target mapping at AS boundaries in inter-AS VPN networks. Route target extended communities are removed at neighbor outbound and the VPN distinguisher value is applied on the BGP route as an extended community. When the route is received on a neighboring router in another AS, the VPN distinguisher is removed and mapped to a route target extended community.

### Note

For a list of all conditional expressions available within an **if** statement, see the **if** command.

This command can be parameterized.

## Task ID

| Task ID      | Operations  |
|--------------|-------------|
| route-policy | read, write |

## Examples

In the following example, the origin is tested within an **if** statement to learn if it is either **igp** or **egp** :

```
RP/0/0/CPU0:router(config-rpl)# if origin is igp or origin is egp then
```

In the following example, a parameter is used to match a specific origin type:

```
RP/0/0/CPU0:router(config)# route-policy bar($origin)
RP/0/0/CPU0:router(config-rpl)# if origin is $origin then
RP/0/0/CPU0:router(config-rpl-if)# set med 20
RP/0/0/CPU0:router(config-rpl-if)# endif
RP/0/0/CPU0:router(config-rpl)#
```

## Static Routing Commands

---

This module describes the commands used to establish static routes.

For detailed information about static routing concepts, configuration tasks, and examples, see the *Implementing Static Routes on Cisco IOS XR Software* module in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

- [address-family \(static\)](#), [page 1828](#)
- [maximum path \(static\)](#), [page 1830](#)
- [route \(static\)](#), [page 1832](#)
- [router static](#), [page 1836](#)
- [track \(static\)](#), [page 1838](#)
- [vrf \(static\)](#), [page 1840](#)

## address-family (static)

To enter various address family configuration modes while configuring static routes, use the **address-family** command in the appropriate configuration mode. To disable support for an address family, use the **no** form of this command.

**address-family** {ipv4| ipv6} {unicast| multicast}

**no address-family** {ipv4| ipv6} {unicast| multicast}

### Syntax Description

|                  |                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>      | Specifies IP Version 4 address prefixes.                                                                    |
| <b>ipv6</b>      | Specifies IP Version 6 address prefixes. This option is available only in static router configuration mode. |
| <b>unicast</b>   | Specifies unicast address prefixes.                                                                         |
| <b>multicast</b> | Specifies multicast address prefixes. This option is available only in static router configuration mode.    |

### Command Default

All static routes belong to the default VRF if you enter address family configuration mode without entering VRF configuration mode.

### Command Modes

Router static configuration  
VRF router static configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address-family** command to enter various address family configuration modes while configuring static routing sessions. From address family configuration mode, you can configure static routes using the **route** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| static  | read, write |

## Examples

The following example shows how to enter IPv6 unicast address family mode:

```
RP/0/0/CPU0:router(config)# router static  
RP/0/0/CPU0:router(config-static)# address-family ipv6 unicast  
RP/0/0/CPU0:router(config-static-afi)#
```

## Related Commands

| Command                                                       | Description                 |
|---------------------------------------------------------------|-----------------------------|
| <a href="#">route (static)</a> , <a href="#">on page 1832</a> | Establishes a static route. |

## maximum path (static)

To change the maximum number of allowable static routes, use the **maximum path** command in static router configuration mode. To remove the **maximum path** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**maximum path** {ipv4| ipv6} *value*

**no maximum path** {ipv4| ipv6} *value*

### Syntax Description

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>ipv4   ipv6</b> | Specifies IP Version 4 (IPv4) or IP Version 6 (IPv6) address prefixes.       |
| <i>value</i>       | Maximum number of static routes for the given AFI. The range is 1 to 140000. |

### Command Default

*value* : 4000

### Command Modes

Static router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you use the **maximum path** command to reduce the configured maximum allowed number of static routes for a given table below the number of static routes currently configured, the change is rejected. In addition, if you commit a batch of routes that would, when grouped, push the number of static routes configured above the maximum allowed, the first *n* routes in the batch and the number previously configured are accepted, and the remainder rejected. The *n* argument is the difference between the maximum number allowed and the number previously configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| static  | read, write |

## Examples

The following example shows how to set the maximum number of static IPv4 routes to 100000:

```
RP/0/0/CPU0:router(config-static)# maximum path ipv4 100000
```

The following example shows how to remove the preceding configuration and set the maximum number of static IPv4 routes back to the default:

```
RP/0/0/CPU0:router(config-static)# no maximum path ipv4 100000
```

## Related Commands

| Command                                       | Description                                    |
|-----------------------------------------------|------------------------------------------------|
| <a href="#">route (static)</a> , on page 1832 | Enters static router configuration mode.       |
| <b>show route static</b>                      | Displays the static routes in a routing table. |

## route (static)

To establish static routes, use the **route** command in address family configuration mode. To remove the **route** command from the configuration, use the **no** form of this command.

```
prefix/mask [vrf vrf-name] {ip-address| type interface-path-id [ip-address| type interface-path-id] [track
track-object-name] [tunnel-id tunnel-id] [vrflabel vrf-label] [ distance ] [description text] [tag tag]
[permanent]}
```

```
no prefix/mask [vrf vrf-name] {ip-address| type interface-path-id [ip-address| type interface-path-id] [track
track-object-name] [tunnel-id tunnel-id] [vrflabel vrf-label] [ distance ] [description text] [tag tag]
[permanent]}
```

### Syntax Description

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>prefix / mask</i>       | <p>IP route prefix and prefix mask for the destination.</p> <p>The network mask can be specified in either of two ways:</p> <ul style="list-style-type: none"> <li>• The network mask can be a four-part, dotted-decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.</li> <li>• The network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address.</li> </ul>                                                                                                      |
| <b>vrf</b> <i>vrf-name</i> | <p>(Optional) Specifies a destination VRF. This option is available when IPv4 address families are specified.</p> <p>The following names cannot be used: all, default, and global.</p> <p>The following example shows how to configure IPv4 VRF:</p> <pre>router static  address-family ipv4 unicast   10.1.1.0/24 vrf vrf_a 192.168.1.1  router static  vrf vrf_a  address-family ipv4 unicast   10.1.1.0/24 192.168.1.1</pre>                                                                                                                                                                                                                                                      |
| <i>ip-address</i>          | <p>IP address of the next hop that can be used to reach that network.</p> <ul style="list-style-type: none"> <li>• For IPv4 address—the IP address is required, not optional, if the interface type and interface-path-id arguments are not specified. You can specify an IP address and an interface type and interface path.</li> <li>• For IPv6 link-local address—the interface type and interface-path-id arguments are required. The route is not valid, if the interface type and interface-path-id arguments are not specified.</li> </ul> <p><b>Note</b> A forwarding router's IP address or an interface or virtual interface path ID can be configured, in any order.</p> |
| <i>type</i>                | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interface-path-id</i>                 | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function.<br><br><b>Note</b> A forwarding router's IP address or an interface or virtual interface path ID can be configured, in any order. |
| <i>distance</i>                          | (Optional) Administrative distance. Range is 1 to 254.                                                                                                                                                                                                                                                                                                                                                              |
| <b>description</b> <i>text</i>           | (Optional) Specifies a description of the static route.                                                                                                                                                                                                                                                                                                                                                             |
| <b>tag</b> <i>tag</i>                    | (Optional) Specifies a tag value that can be used as a match for controlling redistribution using route policies. Range is 1 to 4294967295.                                                                                                                                                                                                                                                                         |
| <b>permanent</b>                         | (Optional) Specifies that the route is not removed from the routing table, even if the next-hop interface shuts down or next-hop IP address is not reachable.                                                                                                                                                                                                                                                       |
| <b>track</b><br><i>track-object-name</i> | Enables object tracking for static route.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>tunnel-id</b> <i>tunnel-id</i>        | Specifies a Tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>vrf-label</b> <i>vrf-label</i>        | Specifies a VRF label.                                                                                                                                                                                                                                                                                                                                                                                              |

**Command Default**

No static route is established.

**vrf** *vrf-name* : If no VRF is specified, the vrf where the configuration takes place is used.

**Command Modes**

Address family configuration

**Command History**

| Release     | Modification                                                                                                                                                                                                             |

| Release 3.2 | This command was introduced.<br><br>The { <b>unicast</b>   <b>multicast</b> } keywords were changed from optional to mandatory.<br>The { <i>ip-address</i>   <i>type interface-path-id</i> } arguments became mandatory. |

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                        |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was moved from global configuration mode to router static configuration mode. The <b>vrf</b> <i>vrf-name</i> keyword and argument was added. The following keywords were removed: <ul style="list-style-type: none"> <li>• <b>route</b></li> <li>• <b>ipv4</b></li> <li>• <b>ipv6</b></li> <li>• <b>unicast</b></li> <li>• <b>multicast</b></li> </ul> |
| Release 3.5.0 | The <b>description</b> <i>text</i> keyword and argument were added.                                                                                                                                                                                                                                                                                                 |
| Release 4.2.1 | The <b>track</b> <i>track-object-name</i> keyword and argument were added.                                                                                                                                                                                                                                                                                          |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

A static route is appropriate when the software cannot dynamically build a route to the destination.

Static routes have a default administrative distance of 1, in which a low number indicates a preferred route. By default, static routes are preferred to routes learned by routing protocols. You can configure an administrative distance with a static route if you want the static route to be overridden by dynamic routes. For example, you could have routes installed by the Open Shortest Path First (OSPF) protocol with an administrative distance of 120. To have a static route that would be overridden by an OSPF dynamic route, specify an administrative distance greater than 120.

The routing table considers the static routes that point to an interface as “directly connected.” Directly connected networks are advertised by IGP routing protocols if a corresponding **interface** command is contained under the router configuration stanza of that protocol.

A static route is always associated with a VPN routing and forwarding (VRF) instance. The VRF can be the default VRF or a specified VRF. Specifying a VRF allows you to enter VRF configuration mode where you can configure a static route. If you do not specify a VRF you can configure a default VRF static route.

Use the **router static** command to configure static routes. To configure a static route, you must enter router static configuration mode and then enter an address family configuration mode or VRF configuration mode. See the **vrf (static)** command for information on configuring a static route in VRF configuration mode. After you enter an address family mode, you can enter multiple static routes. The following example shows how to configure multiple static routes in IPv4 and IPv6 address family configuration modes:

#### Note

You cannot create a VRF named default, but you can reference the default VRF.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| static  | read, write |

**Examples**

The following example shows how to configure IPv6 unicast address family static routes:

```
RP/0/0/CPU0:router(config)# router static
RP/0/0/CPU0:router(config-static)# address-family ipv6 unicast
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 GigabitEthernet0/2/0/7
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 GigabitEthernet0/6/0/0
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 2b11::2f01:4c
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 2b11::2f01:4d
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 2b11::2f01:4e
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 2b11::2f01:4f
RP/0/0/CPU0:router(config-static-afi)# 2b11::327a:7b00/120 2b11::2f01:50
```

# router static

To enter static router configuration mode, use the **router static** command in global configuration mode. To remove all static route configurations and terminate the static routing process, use the **no** form of this command.

**router static**

**no router static**

**Syntax Description** This command has no arguments or keywords.

**Command Default** No static routing process is enabled.

**Command Modes** Global configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID                                            | Operations  |
|----------------------------------------------------|-------------|
| static                                             | read, write |
| bgp, ospf, hsrp, isis, vrrp, multicast, or network | read, write |

**Examples** The following example shows how to enter static router configuration mode:

```
RP/0/0/CPU0:router(config)# router static
RP/0/0/CPU0:router(config-static)#
```

| Command                                                                | Description                               |
|------------------------------------------------------------------------|-------------------------------------------|
| <a href="#">address-family (static)</a> , <a href="#">on page 1828</a> | Enters address family configuration mode. |

| Command                                       | Description                                                           |
|-----------------------------------------------|-----------------------------------------------------------------------|
| <b>show route</b>                             | Displays the current contents of the routing table.                   |
| <b>show route static</b>                      | Displays the static routes in a routing table.                        |
| <b>show route summary</b>                     | Displays the current contents of the routing table in summary format. |
| <a href="#">route (static)</a> , on page 1832 | Establishes a static route.                                           |
| <b>vrf (static)</b>                           | Enters VRF static route configuration mode.                           |

## track (static)

To enable object tracking for static routes, use the **track** command in an appropriate configuration mode. To disable object tracking, use the **no** form of this command.

*ip-address / length* [**vrf** *vrf-name*] {*nexthop*| *type interface-path-id*} [**track** *object-name*]

**no** *ip-address / length* [**vrf** *vrf-name*] {*nexthop*| *type interface-path-id*} [**track** *object-name*]

### Syntax Description

|                            |                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address / length</i> | Specifies the destination prefix.                                                                                                                                                                                                                                             |
| <b>vrf</b> <i>vrf-name</i> | Specifies vrf for the nexthop.. This option is available when IPv4 and IPv6 address families are specified. These names cannot be used for <i>vrf-name</i> : all, default, and global.                                                                                        |
| <i>nexthop</i>             | Specifies the forwarding router's address.                                                                                                                                                                                                                                    |
| <i>type</i>                | Specifies the interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                           |
| <i>interface-path-id</i>   | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <i>object-name</i>         | Specifies the name of the object to be tracked.                                                                                                                                                                                                                               |

### Command Default

Object tracking is disabled. No object is specified for tracking.

### Command Modes

Static IPv4 address family  
Static VRF IPv4 address family

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Up to 32 characters are allowed for specifying an object name. If the specified objects are not existing in IOS XR database, those objects are forward-referenced until created. However, objects that are forward-referenced by the tracking configuration are treated as 'down'.

When a failure between the first hop router and core occurs, the tracking object will go Down. The static router withdraws the primary paths, which were tracking this object and installs the back-up paths, if present.

#### Task ID

| Task ID | Operation   |
|---------|-------------|
| static  | read, write |

#### Examples

This example shows how to enable tracking for an object *object1*:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router static
RP/0/0/CPU0:router(config-static)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-static-afi)#100.0.24.0/24 204.0.23.2 track object1
```

## vrf (static)

To configure a VPN routing and forwarding (VRF) instance and enter VRF configuration mode, use the **vrf** command in router configuration mode. To remove the VRF instance from the configuration file and restore the system to its default condition, use the **no** form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

### Syntax Description

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Name of the VRF instance. The following names cannot be used: all, default, and global. |
|-----------------|-----------------------------------------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

Static router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vrf** command to configure a VRF instance. A VRF instance is a collection of VPN routing and forwarding tables maintained at the provider edge (PE) router.

A static route is always associated with a VRF, which is entirely user configurable. Static route is unique within a VRF. A static route can point to a next-hop interface, next-hop IP address, or both, which can be resided in the same VRF configured for the static route or in a different VRF. For example, routes 172.168.40.0/24 and 172.168.50.0/24 are configured as follows:

```
router static
vrf vrf_A
address_ipv4 unicast
172.168.40.0/24 loopback 1
172.168.50.0/24 vrf vrf_B 192.168.1.2
```

Routes 172.168.40.0/24 and 172.168.50.0/24 belong to vrf\_A. Route 172.168.50.0/24 is not installed in vrf\_A until next-hop 192.168.1.2 (a vrf\_B route) is reachable.

If you are configuring a default VRF route, you do not need to enter VRF configuration mode. For example, routes 192.168.1.0/24 and 192.168.2.0/24 are configured as follows:

```
router static
```

```
address ipv4 unicast
 192.168.1.0/24 loopback 5
 192.168.2.0/24 10.1.1.1
```

Routes 192.168.1.0/24 and 192.168.2.0/24 are default VRF routes.

**Note**

You cannot create a VRF named default, but you can reference the default VRF.

You must remove IPv4/IPv6 addresses from an interface prior to assigning, removing, or changing a VRF on an IP interface. If this is not done in advance, any attempt to change the VRF on an IP interface is rejected.

**Task ID****Task ID****Operations**

static

read, write

**Examples**

The following example shows how to configure a VRF instance and enter VRF configuration mode:

```
RP/0/0/CPU0:router(config)# router static
RP/0/0/CPU0:router(config-static)# vrf vrf-1
RP/0/0/CPU0:router(config-static-vrf)#
```

# router-convergence

To configure route convergence monitoring and enter router convergence monitoring and diagnostics (rcmd) configuration mode, use the **router-convergence** command in global configuration mode. To remove all router convergence monitoring configurations and exit the rcmd mode, use the **no** form of this command.

**router-convergence [disable]**

**no router-convergence**

| Syntax Description | disable | [Optional] Disables the monitoring of route convergence on the entire router. |
|--------------------|---------|-------------------------------------------------------------------------------|
|--------------------|---------|-------------------------------------------------------------------------------|

| Command Default | RCMD is disabled. |
|-----------------|-------------------|
|-----------------|-------------------|

| Command Modes | Global configuration |
|---------------|----------------------|
|---------------|----------------------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.2.0 | This command was introduced. |

| Usage Guidelines | To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Task ID | Task ID | Operation   |
|---------|---------|-------------|
|         | rcmd    | read, write |

| Examples | This example shows how to configure router-convergence command and enable rcmd configuration mode: |
|----------|----------------------------------------------------------------------------------------------------|
|----------|----------------------------------------------------------------------------------------------------|

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#
```

| Related Commands | Command                                                                    | Description                                              |
|------------------|----------------------------------------------------------------------------|----------------------------------------------------------|
|                  | <a href="#">monitor-convergence (IS-IS)</a> , <a href="#">on page 1846</a> | Enables route convergence monitoring for IS-IS protocol. |

| Command                                                  | Description                                |
|----------------------------------------------------------|--------------------------------------------|
| <a href="#">monitor-convergence (OSPF), on page 1848</a> | Enables OSPF route convergence monitoring. |

# monitor-convergence (IS-IS)

To enable route convergence monitoring for IS-IS protocol, use the **monitor-convergence** command in address family configuration mode. To disable, route convergence monitoring, use the **no** form of this command.

**monitor-convergence**

**no monitor-convergence**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Route convergence monitoring is disabled.

**Command Modes**

- Address family IPv4 unicast
- Address family IPv4 multicast
- Address family IPv6 unicast
- Address family IPv6 multicast

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Operation   |
|---------|-------------|
| isis    | read, write |

**Examples** This example shows how to configure route convergence monitoring for IS-IS under IPv6 multicast SAFI:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router isis isp
RP/0/0/CPU0:router(config-isis)#address-family ipv6 multicast
RP/0/0/CPU0:router(config-isis-af)#monitor-convergence
```

**Related Commands**

# monitor-convergence (OSPF)

To enable OSPF route convergence monitoring, use the **monitor-convergence** command in router OSPF configuration mode. To disable OSPF route convergence monitoring, use the **no** form of this command.

**monitor-convergence**

**no monitor-convergence**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Monitor Convergence is disabled.

**Command Modes** Router configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.2.0 | This command was introduced. |

| Task ID | Task ID | Operation   |
|---------|---------|-------------|
|         | ospf    | read, write |

**Examples** This example shows how to enable route convergence monitoring for an OSPF process:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router ospf 100
RP/0/0/CPU0:router(config-ospf)#monitor-convergence
```

| Related Commands | Command                                                    | Description                                                                                                                 |
|------------------|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
|                  | <a href="#">router-convergence</a> , on page 1844          | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |
|                  | <a href="#">monitor-convergence (IS-IS)</a> , on page 1846 | Enables route convergence monitoring for IS-IS protocol.                                                                    |

## collect-diagnostics (RCMD)

To collect diagnostics on specified node, use the **collect-diagnostic** command in router-convergence configuration mode. To disable collection of diagnostics, use the **no** form of this command.

**collect-diagnostics** *location*

**no collect-diagnostics** *location*

### Syntax Description

|                 |                                   |
|-----------------|-----------------------------------|
| <i>location</i> | Specifies the line-card location. |
|-----------------|-----------------------------------|

### Command Default

Diagnostics collection is disabled.

### Command Modes

Router-convergence configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For enabling diagnostics collection on specific line-card locations, you can user can specify partially qualified semantics. However, it is not allowed to configure over-lapping locations so as to avoid errors. The following combinations of Rack and Slot are accepted:

- \*/\*/\*
- R/\*/\*
- R/S/\*

If a wildcard combination for any location is already disabled, then any other combination that overlaps with it would be rejected. For example,

- If \*/\*/\* is disabled, then all other disable commands will be rejected
- If R/\*/\* is disabled, then disable for \*/\*/\* and R/S/\* will be rejected
- If R/S/\* is disabled, then disable for \*/\*/\* and R/\*/\* will be rejected

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| rcmd    | read, write |

**Examples**

This example shows how to enable RCMD diagnostics collection on node 0/3/CPU0:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router#router-convergence
RP/0/0/CPU0:router(config-rcmd)#collect-diagnostics 0/3/CPU0
```

**Related Commands**

| Command                                          | Description                                                                                                                 |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence, on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

## event-buffer-size (RCMD)

To specify event buffer size (in terms of number of events) for storing event traces, use the **event-buffer-size** command in router-convergence configuration mode. To disable buffer size configuration, use the **no** form of this command.

**event-buffer-size** *number*

**no event-buffer-size**

| Syntax Description |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <i>number</i>      | Specifies the Specify the number of events. The range is 100 to 500. |

| Command Default | 100 events. |
|-----------------|-------------|
|-----------------|-------------|

| Command Modes | Router-convergence configuration |
|---------------|----------------------------------|
|---------------|----------------------------------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.2.0 | This command was introduced. |

| Usage Guidelines | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>The event-buffer-size configuration controls the ltrace buffer size. Ltraces will be stored for only the configured number of events. The default is 100 events and can be set based on the expected churn in the network. Value for event buffer impact memory usage on all RPs and monitored LCs.</p> |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | rcmd    | read, write |

| Examples | <p>This example shows how to configure event buffer size as 500 events:</p> <pre>RP/0/0/CPU0:router#configure RP/0/0/CPU0:router(config)#router-convergence RP/0/0/CPU0:router(config-rcmd)#event-buffer-size 500</pre> |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Related Commands**

| Command                                          | Description                                                                                                                 |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence, on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

## max-events-stored (RCMD)

To configure maximum number of events to be stored in the RCMD server, use the **max-events-stored** command in router-convergence configuration mode. To remove the number of events to be stored, use the **no** form of this command.

**max-events-stored** *number*

### Syntax Description

|               |                                                                        |
|---------------|------------------------------------------------------------------------|
| <i>number</i> | Specifies the maximum number of events stored. The range is 10 to 500. |
|---------------|------------------------------------------------------------------------|

### Command Default

100 events.

### Command Modes

Router-convergence configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The max-events-stored configuration controls the number of events that are stored in RCMD server, before the older events are deleted. The default is 100 events and can be set based on the expected churn in the network. Value for events stored impact memory usage by RCMD server.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

### Examples

This example shows how to configure 500 number of events to be stored in RCMD server:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#max-events-stored 500
```

## monitoring-interval (RCMD)

To configure interval (in minutes) in which to collect logs, use the **monitoring-interval** command in router-convergence configuration mode. To disable monitoring interval configuration, use the **no** form of this command.

**monitoring-interval** *minutes*

**no monitoring-interval** *minutes*

### Syntax Description

|                |                                                                                         |
|----------------|-----------------------------------------------------------------------------------------|
| <i>minutes</i> | Specifies the interval (in minutes) for collecting logs. The range is 5 to 120 minutes. |
|----------------|-----------------------------------------------------------------------------------------|

### Command Default

Periodic monitoring interval is 15 minutes.

### Command Modes

Router-convergence configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The monitoring-interval timer controls the collection, processing, and archival (optional) of convergence data by RCMD server.

Periodic processing can get triggered if number of events detected exceed configured sizing parameters to prevent loss of data . However, this is not guaranteed since the mechanism is throttled.

To collect logs manually, use the **rcmd trigger-data-collect** command. Syslogs are generated when high churn is detected and collection mechanism is getting throttled. This indicates possible loss of data for some events. Throttling mechanism is for one processing every minute.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

### Examples

This example shows how to configure monitoring interval as 5 minutes:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#monitoring-interval 5
```

### Related Commands

| Command                                                           | Description                                                                                                                 |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence</a> , <a href="#">on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

## node disable (RCMD)

To disable monitoring of route convergence on specified location, use the **node disable** command in router-convergence configuration mode. To reinstate, monitoring on specified location, use the **no** form of this command.

**node** *node-id* **disable**

**no** **node** *node-id* **disable**

### Syntax Description

|                |                                                                                                                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>node-id</i> | Specifies line card locations for which RCMD monitoring be disabled. Disables RCMD monitoring on the specified node. No data from this node will be available in the reports that are generated. You can enter specific LCs or use wild cards. |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

Update times are gathered and reported for all LCs. Diagnostic mode is disabled on all LCs.

### Command Modes

Router-convergence configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Disable monitoring on specific LCs or racks for better scalability. Disable monitoring on LCs whose update times is not going to impact the core IGP/LDP convergence that RCMD is measuring.

On LCs where monitoring is enabled, the diagnostic mode can be enabled (with threshold value) for triggering script using EEM infra for debug data collection from the router. Use diagnostic mode only for debugging purpose since it is more CPU intensive as compared to normal RCMD monitoring.

Only the following combinations of Rack and Slot are acceptable:

- \*/\*/\*
- R/\*/\*
- R/S/\*

If a wildcard combination for any location is already disabled, then any other combination that overlaps with it would be rejected. For example,

- If \*/\*/\* is disabled, then all other disable commands would be rejected

- If R/\*/\* is disabled, then disable for \*/\*/\* and R/S/\* would be rejected
- If R/S/\* is disabled, then disable for \*/\*/\* and R/\*/\* would be rejected

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

**Examples**

This example shows how to disable monitoring on all nodes with Rack 0 and any slot (used wild card \*) :

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#node 0/*/* disable
```

**Related Commands**

| Command                                          | Description                                                                                                                 |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence, on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

## priority (RCMD)

To configure RCMD reporting parameters for low/high/critical/medium priority updates, use the **priority** command in RCMD protocol configuration mode. To disable setting up priority use the **no** form of this command.

**priority** {Critical| High| Low| Medium} [disable] [leaf-network *leaf-network-number*] [threshold *value*]  
**no priority** {Critical| High| Low| Medium}

### Syntax Description

|                            |                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Critical</b>            | Configures the monitoring of route convergence for critical routes.                                                                                        |
| <b>High</b>                | Configures the monitoring of route convergence for high priority routes.                                                                                   |
| <b>Low</b>                 | Configures the monitoring of route convergence for low priority routes.                                                                                    |
| <b>Medium</b>              | Configures the monitoring of route convergence for medium priority routes.                                                                                 |
| <b>disable</b>             | Disables the monitoring of route convergence for specified priority.                                                                                       |
| <b>leaf-network</b>        | Configures the monitoring of route convergence for leaf networks. Lists up to 100 leaf networks that were added or deleted as part of SPF.                 |
| <i>leaf-network-number</i> | Specifies the maximum number of leaf networks monitored. The range is 10 to 100.                                                                           |
| <b>threshold</b>           | Sets the threshold value for convergence in milliseconds. If the convergence time exceeds this configured value, diagnostics collection will be triggered. |
| <i>value</i>               | Specifies the threshold value (in msec). The range is 0 to 4294967295.                                                                                     |

### Command Default

None

### Command Modes

Router-convergence protocol configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **priority** command for collecting data and applying threshold for particular protocol and prefix priority. Maximum of 100 leaf networks can get logged because of scalability reasons. No default value available for threshold and this needs to be determined with deployment experience for specific network. Threshold specification is required for triggering diagnostics collection. Disable monitoring for medium and or low priority routes to help scale better. No specific order is guaranteed for leaf networks and first N prefixes that change are logged.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

**Examples**

This example shows how Configures the monitoring of route convergence for critical routes for 100 leaf networks and at a threshold value of 1 millisecond for OSPF protocol:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#protocol OSPF
RP/0/0/CPU0:router(config-rcmd-proto)#priority high
RP/0/0/CPU0:router(config-rcmd-proto-prio)#leaf-network 100
RP/0/0/CPU0:router(config-rcmd-proto-prio)#threshold 1
```

**Related Commands**

| Command                                                           | Description                                                                                                                 |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence</a> , <a href="#">on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

# protocol (RCMD)

To specify the protocol for which to configure RCMD parameters, use the **protocol** command in router-convergence configuration mode. To remove the protocol from RCMD, use the **no** form of this command.

**protocol** {ISIS| OSPF}

**no protocol** {ISIS| OSPF}

## Syntax Description

|             |                                                             |
|-------------|-------------------------------------------------------------|
| <b>ISIS</b> | Configures parameters related to OSPF protocol within RCMD  |
| <b>OSPF</b> | Configures parameters related to IS-IS protocol within RCMD |

## Command Default

None

## Command Modes

Router-convergence configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

RCMD monitoring needs to be enabled for a specific OSPF or ISIS protocol instance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

## Examples

This example shows how to enable RCMD parameters for OSPF protocol:

```
RP/0/0/CPU0:router(config)#router
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#protocol OSPF
RP/0/0/CPU0:router(config-rcmd-proto)#priority high
RP/0/0/CPU0:router(config-rcmd-proto-prio)#leaf-network 100
RP/0/0/CPU0:router(config-rcmd-proto-prio)#threshold 1
```

**Related Commands**

| Command                                          | Description                                                                                                                 |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router-convergence, on page 1844</a> | Configures route convergence monitoring and enters router convergence monitoring and diagnostics (rcmd) configuration mode. |

## storage-location

To specify where to store the extended routing-diagnostics that are collected when threshold exceeds, use the **storage-location** command in router-convergence configuration mode. To disable storing routing-diagnostics to a specific location, use the **no** form of this command.

**storage-location** [**diagnostics** *directory-path* | **diagnostics-size** *maximum-directory-size* | **reports** *directory-path* | **reports-size** *maximum-directory-size*]

**no storage-location**

### Syntax Description

|                               |                                                                              |
|-------------------------------|------------------------------------------------------------------------------|
| <b>diagnostics</b>            | Specifies an absolute directory path for storing diagnostic reports.         |
| <i>directory-path</i>         | Specifies the path of the absolute directory for storing diagnostic reports. |
| <b>diagnostics-size</b>       | Specifies the maximum size of diagnostics directory.                         |
| <i>maximum-directory-size</i> | Specified the size of the diagnostics directory. The range is 5% to 80%.     |
| <b>reports</b>                | Specifies an absolute directory path for storing reports.                    |
| <i>directory-path</i>         | Specifies the path of the absolute directory for storing reports.            |
| <b>reports-size</b>           | Specifies the maximum size of the reports directory. The range is 5% to 80%. |

### Command Default

No default storage location. Mechanism is disabled.

### Command Modes

Router-convergence configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The storage location can be local disk or remote tftp space.

RCMD server can periodically archive reports in XML format for persistency. This mechanism is enabled when archival location is configured. Debug data collected in diagnostics mode is dumped to the configured diagnostic location (else it would get lost). When using local disk, the percentage of disk space to be used can

be specified, and RCMD server will delete older reports on reaching the limit. Archival (specifically on local disk) is CPU intensive. Use a remote XML server to periodically collect reports from the router and archive on the server's local storage.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| rcmd    | read, write |

### Examples

This example shows how to configure storage location as *tftp://202.153.144.25/auto/tftp-chanvija-blr/rcmd/dump/reports* for reports and */harddisk:/rcmd\_logs* for diagnostics:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router-convergence
RP/0/0/CPU0:router(config-rcmd)#storage-location
RP/0/0/CPU0:router(config-rcmd-store)#diagnostics /harddisk:/rcmd_logs
RP/0/0/CPU0:router(config-rcmd-store)#reports
tftp://202.153.144.25/auto/tftp-chanvija-blr/rcmd/dump/reports
```

### Related Commands
