### CHAPTER 1

#### Border Gateway Protocol Commands 1

- accept-own 8
- additional-paths install backup 9
- additional-paths receive 11
- additional-paths selection 13
- additional-paths send 15
- address-family (BGP) 17
- advertise best-external 21
- advertisement-interval 23
- af-group 25
- aggregate-address 27
- allocate-label 30
- allowas-in 32
- as-format 34
- as-override 35
- as-path-loopcheck out disable 37
- attribute-filter group 39
- bfd (BGP) 41
- bgp as-path-loopcheck 46
- bgp attribute-download 47
- bgp auto-policy-soft-reset disable 49
- bgp bestpath as-path ignore 51
- bgp bestpath compare-routerid 53

|                                          |     |
|------------------------------------------|-----|
| bgp bestpath cost-community ignore       | 55  |
| bgp bestpath med always                  | 57  |
| bgp bestpath med confed                  | 59  |
| bgp bestpath med missing-as-worst        | 61  |
| bgp client-to-client reflection disable  | 63  |
| bgp cluster-id                           | 65  |
| bgp confederation identifier             | 67  |
| bgp confederation peers                  | 69  |
| bgp dampening                            | 71  |
| bgp default local-preference             | 74  |
| bgp enforce-first-as disable             | 75  |
| bgp fast-external-fallover disable       | 77  |
| bgp graceful-restart                     | 79  |
| bgp graceful-restart graceful-reset      | 81  |
| bgp graceful-restart purge-time          | 83  |
| bgp graceful-restart restart-time        | 85  |
| bgp graceful-restart stalepath-time      | 87  |
| bgp import-delay                         | 89  |
| bgp label-delay                          | 91  |
| bgp log neighbor changes disable         | 93  |
| bgp maximum neighbor                     | 95  |
| bgp redistribute-internal                | 96  |
| bgp router-id                            | 98  |
| bgp scan-time                            | 100 |
| bgp update-delay                         | 102 |
| bgp write-limit                          | 104 |
| capability orf prefix                    | 106 |
| capability suppress 4-byte-as            | 109 |
| clear bgp                                | 112 |
| clear bgp dampening                      | 115 |
| clear bgp external                       | 118 |
| clear bgp flap-statistics                | 120 |
| clear bgp nexthop performance-statistics | 123 |
| clear bgp nexthop registration           | 126 |
| clear bgp peer-drops                     | 128 |

## CHAPTER 3

### Enhanced Interior Gateway Routing Protocol Commands 593

- address-family (EIGRP) 595
- authentication keychain 597
- auto-summary (EIGRP) 599
- autonomous-system 601
- bandwidth-percent (EIGRP) 603
- clear eigrp neighbors 605
- clear eigrp topology 607
- default-information 609
- default-metric (EIGRP) 611
- distance (EIGRP) 613
- hello-interval (EIGRP) 615
- hold-time (EIGRP) 616
- interface (EIGRP) 618
- log-neighbor-changes 620
- log-neighbor-warnings 622
- maximum-paths (EIGRP) 624
- maximum-prefix (EIGRP) 626

- metric (EIGRP) 629
- metric maximum-hops 631
- metric weights 633
- neighbor (EIGRP) 636
- neighbor maximum-prefix 638
- next-hop-self disable 641
- nsf disable (EIGRP) 642
- passive-interface (EIGRP) 644
- redistribute (EIGRP) 645
- redistribute maximum-prefix 648
- route-policy (EIGRP) 651
- router eigrp 653
- router-id (EIGRP) 654
- show eigrp accounting 656
- show eigrp interfaces 659
- show eigrp neighbors 663
- show eigrp topology 666
- show eigrp traffic 669
- show protocols (EIGRP) 671
- site-of-origin (EIGRP) 674
- split-horizon disable (EIGRP) 676
- stub (EIGRP) 677
- summary-address (EIGRP) 680
- timers active-time 682
- timers nsf route-hold (EIGRP) 684
- variance 686
- vrf (EIGRP) 688

---

**CHAPTER 4****IS-IS Commands 691**

- address-family (IS-IS) 695
- address-family multicast topology (IS-IS) 697
- adjacency-check disable 699
- advertise passive-only 701
- attached-bit receive ignore 702
- attached-bit send 703

## Preface

The *Cisco IOS XR Routing Command Reference for the Cisco XR 12000 Series Router* preface contains these sections:

- [Changes to This Document](#), page xxvii
- [Obtaining Documentation and Submitting a Service Request](#), page xxvii

## Changes to This Document

This table lists the technical changes made to this document since it was first printed.

| Revision    | Date            | Change Summary                                                                  |
|-------------|-----------------|---------------------------------------------------------------------------------|
| OL-26052-03 | September, 2012 | Republished with documentation updates for Cisco IOS XR Release 4.2.3 features. |
| OL-26052-02 | June, 2012      | Republished with documentation updates for Cisco IOS XR Release 4.2.1 features. |
| OL-26052-01 | December, 2011  | Initial release of this document.                                               |

## Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

Subscribe to the *What's New in Cisco Product Documentation* as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS version 2.0.

## Border Gateway Protocol Commands

This chapter describes the commands used to configure and monitor Border Gateway Protocol (BGP) for IP Version 4 (IPv4), IP Version 6 (IPv6), Virtual Private Network Version 4 (VPNv4), Virtual Private Network Version 6 (VPNv6), and multicast distribution tree (MDT) routing sessions.

For detailed information about BGP concepts, configuration tasks, and examples, see the *Implementing BGP* chapter in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

### Note

Running the **show bgp** command immediately after configuring a large and complex route policy may result in timeout of the system database shown through an error message (SYSDB-SYSDB-6-TIMEOUT\_EDM). It is recommended, that the show command be run, after the new route policy takes effect.

## accept-own

To enable handling of self-originated VPN routes containing ACCEPT\_OWN community attribute, use the **accept-own** command in neighbor VPNv4 or VPNv6 address family configuration mode. To disable this functionality, either use the **no** form of this command or use the command with **inheritance-disable** keyword.

**accept-own [inheritance-disable]**

**no accept-own**

### Syntax Description

|                            |                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | Disables handling of self-originated VPN routes containing ACCEPT_OWN community attribute and prevents inheritance of Accept Own from a parent configuration. |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

Disabled

### Command Modes

Neighbor address family VPNv4

Neighbor address family VPNv6

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to enable handling of accept-own community:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#neighbor 10.2.3.4
RP/0/0/CPU0:router(config-bgp-nbr)#address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)#accept-own
```

# additional-paths install backup

## Note

Effective with Release 4.0.0, the **additional-paths install backup** command was deprecated and replaced by the **additional-paths selection** command. See the [additional-paths selection, on page 13](#) command for more information.

To install a backup path into the forwarding table and provide prefix independent convergence (PIC) in case of a PE-CE link failure, use the **additional-paths install backup** command in an appropriate address family configuration mode. To prevent installing the backup path, use the **no** form of this command. To disable prefix independent convergence, use the **disable** keyword.

**additional-paths install backup [disable]**

**no additional-paths install backup**

## Syntax Description

|                |                                                            |
|----------------|------------------------------------------------------------|
| <b>disable</b> | Disables installing backup path into the forwarding table. |
|----------------|------------------------------------------------------------|

## Command Default

None

## Command Modes

VRF IPv4 address family configuration  
 VRF IPv6 address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration

## Command History

| Release       | Modification                                                                           |
|---------------|----------------------------------------------------------------------------------------|
| Release 3.9.0 | This command was introduced.                                                           |
| Release 4.0.0 | This command was deprecated replaced by the <b>additional-paths selection</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to enable installing a backup path into the forwarding table in VPNv4 address family mode:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#additional-paths install backup
```

## Related Commands

| Command                                              | Description                                                              |
|------------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">advertise best-external</a> , on page 21 | Advertises the best-external path to the iBGP and route-reflector peers. |
| <a href="#">retain local-label</a> , on page 239     | Retains the local label until the network is converged.                  |

## additional-paths receive

To configure receive capability of multiple paths for a prefix to the capable peers, use the **additional-paths receive** command in address-family configuration mode. To disable receive capability, use the **no** form of this command. To disable add-path receive capability for all neighbors belonging to a particular VRF address-family, use the **disable** option.

**additional-paths receive [disable]**

**no additional-paths receive**

### Syntax Description

|                |                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | Disables advertising additional paths receive capability.                                                                                   |
| <b>Note</b>    | Use the <b>disable</b> keyword option to disable add-path receive capability for all neighbors belonging to a specified VRF address-family. |

### Syntax Description

This command has no keywords or arguments.

### Command Default

None

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **additional-paths receive** command to allow add-path receive capability to be negotiated for a specified address family. When the **additional-paths receive** command is configured, the receive capability is automatically enabled for all internal BGP neighbors for a specified address family. When this command is either not configured or explicitly disabled, none of the neighbors are allowed to negotiate receive capability for the address family.

After enabling the receive capability, the session needs to be reset for the configuration to take into effect.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to enable additional paths receive capability under VPNv4 unicast address family:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# additional-paths receive
```

This example shows how to disable additional paths receive capability for all neighbors belonging to a particular VRF address-family (vrf1):

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config-bgp)#vrf vrf1
RP/0/0/CPU0:router(config-bgp-vrf)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)#additional-paths receive disable
```

## Related Commands

| Command                                             | Description                                                                     |
|-----------------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">additional-paths send, on page 15</a>   | Configures send capability of multiple paths for a prefix to the capable peers. |
| <a href="#">capability additional-paths send</a>    | Advertises capability of sending additional paths to the peer.                  |
| <a href="#">capability additional-paths receive</a> | Advertises additional paths receive capability.                                 |

## additional-paths selection

To configure additional paths selection mode for a prefix, use the **additional-paths selection** command in address-family configuration mode. To disable the additional-paths selection mode for a prefix, use the **no** form of this command. To disable the additional-paths selection mode for a particular VRF address-family, use the **disable** option.

**additional-paths selection** {**route-policy** *route-policy-name*| **disable**}

**no additional-paths selection route-policy** *route-policy-name*

### Syntax Description

|                                              |                                                                           |
|----------------------------------------------|---------------------------------------------------------------------------|
| <b>route-policy</b> <i>route-policy-name</i> | Specifies the name of a route policy used for additional paths selection. |
| <b>disable</b>                               | Disables add-path selection for a particular VRF address-family.          |

### Command Default

None

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

To configure additional paths selection mode for some or all prefixes, use the **additional-paths selection** command by specifying a route-policy.

Use the **additional-path selection** command with an appropriate route-policy to calculate backup paths and to enable Prefix Independent Convergence (PIC) functionality. Refer *BGP Prefix Independent Convergence Unipath Primary/Backup* section in *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router* for details on the PIC functionality.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

**Examples**

This example shows how to enable selection of additional paths:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# additional-paths selection route-policy ap1
```

This example shows how to disable add-path selection for a particular VRF address-family (vrf1):

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config-bgp)#vrf vrf1
RP/0/0/CPU0:router(config-bgp-vrf)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)#additional-paths selection disable
```

This example shows how to enable add-path selection for a particular VRF address-family (vrf2):

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config-bgp)#vrf vrf2
RP/0/0/CPU0:router(config-bgp-vrf)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)#additional-paths selection route-policy ap2
```

# additional-paths send

To configure send capability of multiple paths for a prefix to the capable peers, use the **additional-paths send** command in address-family configuration mode. To disable the send capability, use the **no** form of this command.

**additional-paths send [disable]**

**no additional-paths send**

## Syntax Description

|                |                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>disable</b> | Disables advertising additional paths send capability.                                                                            |
| <b>Note</b>    | Use the <b>disable</b> option to disable add-path send capability for all neighbors belonging to a particular VRF address-family. |

## Command Default

None

## Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
VPNv4 address family configuration  
VPNv6 address family configuration  
VRF IPv4 address family configuration  
VRF IPv6 address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the additional-paths send command to allow add-path send capability to be negotiated for a specified address family. When the **additional-paths send** command is configured, the send capability is automatically enabled for all internal BGP neighbors for the specified address family. When the command is either not configured or explicitly disabled, none of the neighbors are allowed to negotiate send capability for the address family.

After enabling the send capability, the session needs to be reset for the configuration to take into effect.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

**Examples**

This example shows how to enable additional paths send capability under VPNv4 4 unicast address family:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# additional-paths send
```

This example shows how to enable add-path selection for a particular VRF address-family (vrf1):

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config-bgp)#vrf vrf1
RP/0/0/CPU0:router(config-bgp-vrf)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)#additional-paths send disable
```

**Related Commands**

| Command                                              | Description                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">additional-paths receive, on page 11</a> | Configures receive capability of multiple paths for a prefix to the capable peers. |
| <a href="#">capability additional-paths send</a>     | Advertises capability of sending additional paths to the peer.                     |
| <a href="#">capability additional-paths receive</a>  | Advertises additional paths receive capability.                                    |

## address-family (BGP)

To enter various address family configuration modes while configuring Border Gateway Protocol (BGP), use the **address-family** command in an appropriate configuration mode. To disable support for an address family, use the **no** form of this command.

**address-family** {ipv4 {labeled-unicast| mdt| multicast| mvpn| rt-filter| tunnel| unicast}| ipv6 {labeled-unicast| multicast| mvpn| unicast}| l2vpn vpls-vpws| vpnv4 unicast| vpnv6 unicast}

**no address-family** {ipv4 {labeled-unicast| mdt| multicast| mvpn| rt-filter| tunnel| unicast}| ipv6 {labeled-unicast| multicast| mvpn| unicast}| l2vpn vpls-vpws| vpnv4 unicast| vpnv6 unicast}

### Syntax Description

|                             |                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4 unicast</b>         | Specifies IP Version 4 (IPv4) unicast address prefixes.                                                                                                        |
| <b>ipv4 multicast</b>       | Specifies IPv4 multicast address prefixes.                                                                                                                     |
| <b>ipv4 labeled-unicast</b> | Specifies IPv4 labeled-unicast address prefixes. This option is available in IPv4 neighbor configuration mode and VRF neighbor configuration mode.             |
| <b>ipv4 tunnel</b>          | Specifies IPv4 tunnel address prefixes.                                                                                                                        |
| <b>ipv4 mdt</b>             | Specifies IPv4 multicast distribution tree (MDT) address prefixes. This option is available in router configuration mode and IPv4 neighbor configuration mode. |
| <b>ipv6 unicast</b>         | Specifies IP Version 6 (IPv6) unicast address prefixes.                                                                                                        |
| <b>ipv6 multicast</b>       | Specifies IPv6 multicast address prefixes.                                                                                                                     |
| <b>ipv6 labeled-unicast</b> | Specifies IPv6 labeled-unicast address prefixes. This option is available in IPv6 neighbor configuration mode.                                                 |
| <b>vpnv4 unicast</b>        | Specifies VPN Version 4 (VPNv4) unicast address prefixes. This option is not available in VRF or VRF neighbor configuration mode.                              |
| <b>vpnv6 unicast</b>        | Specifies VPN Version 6 (VPNv6) unicast address prefixes. This option is not available in VRF or VRF neighbor configuration mode.                              |
| <b>l2vpn vpls-vpws</b>      | Specifies L2VPN vpls-vpws address prefixes.                                                                                                                    |
| <b>ipv4 rt-filter</b>       | Specifies IPv4 rt-filter address prefixes.                                                                                                                     |
| <b>ipv4 mvpn</b>            | Specifies IPv4 mvpn address prefixes.                                                                                                                          |
| <b>ipv6 mvpn</b>            | Specifies IPv6 mvpn address prefixes.                                                                                                                          |

**Command Default**

An address family must be explicitly configured in the router configuration mode for the address family to be active in BGP. Similarly, an address family must be configured under the neighbor for the BGP session to be established for that address family. An address family must be configured in router configuration mode before it can be configured under a neighbor.

**Command Modes**

Router configuration  
 Neighbor configuration  
 Neighbor group configuration  
 VRF configuration  
 VRF neighbor configuration (IPv4 address families)

**Command History**

| Release       | Modification                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                               |
| Release 3.3.0 | This command was supported in VRF and VRF neighbor configuration modes.<br>The <b>vpn4 unicast</b> keywords were added.                                                                                    |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported                                                                                                                                                           |
| Release 3.5.0 | The following keywords were added: <ul style="list-style-type: none"> <li>• <b>vpn6 unicast</b></li> <li>• <b>ipv4 tunnel</b></li> <li>• <b>ipv4 mdt</b></li> <li>• <b>ipv6 labeled-unicast</b></li> </ul> |
| Release 3.7.0 | The Address Family Submode Support table was added.                                                                                                                                                        |
| Release 3.9.0 | L2VPN Address Family support was added.                                                                                                                                                                    |
| Release 4.2.0 | The mvpn SAFI was introduced under IPv4 and IPv6.                                                                                                                                                          |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address-family** command to enter various address family configuration modes while configuring BGP routing sessions. When you enter the **address-family** command from router configuration mode, you enable the address family and enter global address family configuration mode.

The IPv4 unicast address family must be configured in router configuration mode before configuring the IPv4 labeled-unicast address family for a neighbor in neighbor configuration mode. The IPv6 unicast address family must be configured in router configuration mode before configuring the IPv6 labeled-unicast address family for a neighbor in neighbor configuration mode. See [Table 1: Address Family Submode Support](#), on page 19

**Table 1: Address Family Submode Support**

| Address Family       | Supported in Router Submode | Supported in Neighbor Submode | Comments                                                                                                                                                                                                 |
|----------------------|-----------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipv4 unicast         | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv4 multicast       | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv4 mdt             | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv4 tunnel          | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv4 labeled-unicast | no                          | yes                           | The ipv4 labeled-unicast address family can be configured only as a neighbor address family; however, it requires that the ipv4 unicast address family be configured as the router address family first. |
| vpnv4 unicast        | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv6 unicast         | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv6 multicast       | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv6 labeled-unicast | no                          | yes                           | The ipv6 labeled-unicast address family can be configured only as a neighbor address family; however, it requires that the ipv6 unicast address family be configured as the router address family first. |
| vpnv6 unicast        | yes                         | yes                           | —                                                                                                                                                                                                        |
| l2vpn vpls-vpws      | yes                         | yes                           | —                                                                                                                                                                                                        |
| ipv4 rt-filter       | yes                         | yes                           | —                                                                                                                                                                                                        |

| Address Family | Supported in Router Submode | Supported in Neighbor Submode | Comments |
|----------------|-----------------------------|-------------------------------|----------|
| ipv4 mvpn      | yes                         | yes                           | —        |
| ipv6 mvpn      | yes                         | yes                           | —        |

When you enter the **address-family** command from neighbor configuration mode, you activate the address family on the neighbor and enter neighbor address family configuration mode. IPv4 neighbor sessions support IPv4 unicast, multicast, labeled-unicast, and VPNv4 unicast address families. IPv6 neighbor sessions support IPv6 unicast and multicast address families.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to place the router in global address family configuration mode for the IPv4 address family:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#
```

The following example shows how to activate IPv4 multicast for neighbor 10.0.0.1 and place the router in neighbor address family configuration mode for the IPv4 multicast address family:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router# router bgp 1
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-af)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)#
```

The following example shows how to place the router in global address family configuration mode for the IPv4 tunnel address family:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 12
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 tunnel
RP/0/0/CPU0:router(config-bgp-af)#
```

# advertise best-external

To advertise the best-external path to the iBGP and route-reflector peers, when a locally selected bestpath is from an internal peer, use the **advertise best-external** command in an appropriate address family configuration mode. To prevent advertising the best-external path, use the **no** form of this command. To disable advertising the best-external path, use the **disable** keyword.

**advertise best-external [disable]**

**no advertise best-external**

## Syntax Description

|                |                                                   |
|----------------|---------------------------------------------------|
| <b>disable</b> | Disables best-external configuration for the VRF. |
|----------------|---------------------------------------------------|

## Command Default

None

## Command Modes

VRF IPv4 address family configuration  
VRF IPv6 address family configuration  
L2VPN address family configuration  
VPNv4 address family configuration  
VPNv6 address family configuration  
IPv4 address family configuration  
IPv6 address family configuration

## Command History

| Release       | Modification                                                                 |
|---------------|------------------------------------------------------------------------------|
| Release 3.9.0 | This command was introduced.                                                 |
| Release 4.0.0 | This command was supported in global IPv4 and IPv6 unicast address-families. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to enable advertising the best-external path VPNv4 unicast address family mode:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# advertise best-external
```

## Related Commands

| Command                                                                     | Description                                                                                                                         |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">additional-paths install backup</a> , <a href="#">on page 9</a> | Installs a backup path into the forwarding table and provides prefix independent convergence (PIC) in case of a PE-CE link failure. |
| <a href="#">retain local-label</a> , <a href="#">on page 239</a>            | Retains the local label until the network is converged.                                                                             |

# advertisement-interval

To set the minimum interval between the sending of Border Gateway Protocol (BGP) routing updates, use the **advertisement-interval** command in an appropriate configuration mode. To remove the **advertisement-interval** command from the configuration file and restore the system to its default interval values, use the **no** form of this command.

**advertisement-interval** *seconds*

**no advertisement-interval** [ *seconds* ]

## Syntax Description

|                |                                                                                       |
|----------------|---------------------------------------------------------------------------------------|
| <i>seconds</i> | Minimum interval between sending BGP routing updates (in seconds). Range is 0 to 600. |
|----------------|---------------------------------------------------------------------------------------|

## Command Default

Default minimum interval:  
For internal BGP (iBGP) peers is 0 seconds  
For external BGP (eBGP) peers is 30 seconds  
For customer edge (CE) peers is 0 seconds

## Command Modes

Neighbor configuration  
Neighbor group configuration  
Session group configuration  
VRF neighbor configuration

## Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If this command configures a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the minimum time between sending BGP routing updates to 10 seconds:

```
RP/0/0/CPU0:router(config)# router bgp 5
RP/0/0/CPU0:router(config-bgp)# neighbor 10.1.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:router(config-bgp-nbr)# advertisement-interval 10
```

**Related Commands**

| Command                                     | Description                                                            |
|---------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a> | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.   |

# af-group

To create an address family group for Border Gateway Protocol (BGP) neighbors and enter address family group configuration mode, use the **af-group** command in router configuration mode. To remove an address family group, use the **no** form of this command.

**af-group** *af-group-name* **address-family**  
**no af-group**

## Syntax Description

|                             |                                                                    |
|-----------------------------|--------------------------------------------------------------------|
| <i>af-group-name</i>        | Address family group name.                                         |
| <b>address-family</b>       | Enters address family configuration mode.                          |
| <b>ipv4 unicast</b>         | Specifies IP Version 4 (IPv4) unicast address prefixes.            |
| <b>ipv4 multicast</b>       | Specifies IPv4 multicast address prefixes.                         |
| <b>ipv4 labeled-unicast</b> | Specifies IPv4 labeled unicast address prefixes.                   |
| <b>ipv4 tunnel</b>          | Specifies IPv4 tunnel address prefixes.                            |
| <b>ipv4 mdt</b>             | Specifies IPv4 multicast distribution tree (MDT) address prefixes. |
| <b>ipv6 unicast</b>         | Specifies IP Version 6 (IPv6) unicast address prefixes.            |
| <b>ipv6 multicast</b>       | Specifies IPv6 multicast address prefixes.                         |
| <b>ipv6 labeled-unicast</b> | Specifies IPv6 labeled unicast address prefixes.                   |
| <b>vpn4 unicast</b>         | Specifies VPN Version 4 (VPNv4) unicast address prefixes.          |
| <b>vpn6 unicast</b>         | Specifies VPN Version 6 (VPNv6) unicast address prefixes.          |

## Command Default

No BGP address family group is configured.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                            |
|---------------|-------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                            |
| Release 3.3.0 | The <b>vpn4 unicast</b> and <b>labeled-unicast</b> keywords were added. |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                       |

| Release       | Modification                                                                                                          |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| Release 3.5.0 | The <b>vpn6 unicast</b> , <b>ipv6 labeled-unicast</b> , <b>ipv4 tunnel</b> , and <b>ipv4 mdt</b> keywords were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **af-group** command to group address family-specific neighbor commands within an IPv4 or IPv6 address family. Neighbors that have address family configuration are able to use the address family group. Further, neighbors inherit the configuration parameters of the entire address family group.

You cannot define two address family groups with the same name in different address families.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to create address family group group1 and enter address family group configuration mode for IPv4 unicast. Group1 contains the next-hop-self feature, which is inherited by neighbors that use address family group1.

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# next-hop-self
```

### Related Commands

| Command                                     | Description                                                                           |
|---------------------------------------------|---------------------------------------------------------------------------------------|
| <a href="#">neighbor (BGP), on page 187</a> | Enters neighbor configuration mode for configuring BGP routing sessions.              |
| <a href="#">neighbor-group, on page 189</a> | Creates a neighbor group and enters neighbor group configuration mode.                |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.                  |
| <a href="#">use, on page 509</a>            | Inherits configuration from a neighbor group, session group, or address family group. |

# aggregate-address

To create an aggregate entry in a Border Gateway Protocol (BGP) routing table, use the **aggregate-address** command in an appropriate configuration mode. To remove the **aggregate-address** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**aggregate-address** *address/mask-length* [**as-set**] [**as-confed-set**] [**summary-only**] [**route-policy** *route-policy-name*]

**no aggregate-address**

## Syntax Description

|                                              |                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <i>address</i>                               | Aggregate address.                                                                                             |
| <i>/mask-length</i>                          | Aggregate address mask length.                                                                                 |
| <b>as-set</b>                                | (Optional) Generates autonomous system set path information and community information from contributing paths. |
| <b>as-confed-set</b>                         | (Optional) Generates autonomous system confederation set path information from contributing paths.             |
| <b>summary-only</b>                          | (Optional) Filters all more-specific routes from updates.                                                      |
| <b>route-policy</b> <i>route-policy-name</i> | (Optional) Specifies the name of a route policy used to set the attributes of the aggregate route.             |

## Command Default

When you do not specify this command, no aggregate entry is created in the BGP routing table.

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was supported in VRF IPv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can implement aggregate routing in BGP either by redistributing an aggregate route into BGP using the **network** command or the **aggregate-address** command.

Use the **aggregate-address** command without optional arguments to create an aggregate entry in the BGP routing table if any more-specific BGP routes are available that fall in the specified range. The aggregate route is advertised as coming from your autonomous system and has the atomic aggregate attribute set to show that information might be missing. (By default, the atomic aggregate attribute is set unless you specify the **as-set** keyword.)

Use of the **as-set** keyword creates an aggregate entry using the same rules that the command follows without this keyword. However, the advertised path for this route is an AS\_SET, a set of all autonomous systems contained in all paths that are being summarized.

Do not use this form of the **aggregate-address** command when aggregating many paths because this route must be continually withdrawn and updated as autonomous system path reachability information for the summarized routes changes.

Use the **as-confed-set** keyword to create an AS\_CONFED\_SET in the autonomous system path of the aggregate from any confederation segments in the paths being summarized. This keyword takes effect only if the **as-set** keyword is also specified.

Use of the **summary-only** keyword creates an aggregate entry (for example, 10.0.0.0/8) but suppresses advertisements of more-specific routes to all neighbors. If you want to suppress only advertisements to certain neighbors, use the **route-policy (BGP)** command in neighbor address family configuration mode with caution. If a more-specific route leaks out, all BGP speakers (the local router) prefer that route over the less-specific aggregate you generate (using longest-match routing).

Use the **route-policy** keyword to specify a routing policy for the aggregate entry. The **route-policy** keyword is used to select which more-specific information to base the aggregate entry on and which more-specific information to suppress. You can also use the keyword to modify the attributes of the aggregate entry.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to create an aggregate address. The path advertised for this route is an autonomous system set consisting of all elements contained in all paths that are being summarized.

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# aggregate-address 10.0.0.0/8 as-set
```

**Related Commands**

| Command                                         | Description                                                                       |
|-------------------------------------------------|-----------------------------------------------------------------------------------|
| <a href="#">network (BGP), on page 191</a>      | Specifies the list of networks for the BGP routing process.                       |
| <a href="#">route-policy (BGP), on page 243</a> | Applies a routing policy to updates advertised to or received from a BGP neighbor |
| route-policy (RPL)                              | Defines a route policy and enters route-policy configuration mode.                |

# allocate-label

To allocate Multiprotocol Label Switching (MPLS) labels for specific IPv4 unicast or IPv6 unicast or VPN routing and forwarding (VRF) IPv4 unicast routes so that the BGP router can send labels with BGP routes to a neighboring router configured for labeled-or VPN routing and forwarding (VRF) IPv6 unicast sessions, use the **allocate-label** command in the appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**allocate-label** {**route-policy** *route-policy-name*| **all**}

**no allocate-label** {**route-policy** *route-policy-name*| **all**}

## Syntax Description

|                                              |                                                              |
|----------------------------------------------|--------------------------------------------------------------|
| <b>all</b>                                   | Allocates labels for all prefixes                            |
| <b>route-policy</b> <i>route-policy-name</i> | Uses a route policy to select prefixes for label allocation. |

## Command Default

No default behavior or values

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.4.0 | The <b>all</b> keyword was added.<br><br>The command was supported in VRF IPv4 address family configuration mode.    |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and VRF IPv6 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **allocate-label** command with a route policy to trigger BGP to allocate labels for all or a filtered set of global routes (as dictated by the route policy). The command enables autonomous system border routers (ASBRs) that have labeled unicast sessions to exchange Multiprotocol Label Switching (MPLS) labels with

the routes to the other autonomous system (AS) in Layer 3 Virtual Private Network (L3VPN) inter-AS deployments.

**Note**

The **allocate-label all** command is functionally equivalent to the **allocate-label route-policy route-policy-name** command when the route policy is a pass-all policy.

See *Cisco IOS XR MPLS Configuration Guide for the Cisco XR 12000 Series Router* for information on using the **allocate-label** command for L3VPN inter-AS deployments and carrier-supporting-carrier IPv4 BGP label distribution.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to enable allocating labels for IPv4 routes:

```
RP/0/0/CPU0:router(config)# router bgp 6  
RP/0/0/CPU0:router(config-bgp)# address family ipv4 unicast  
RP/0/0/CPU0:router(config-bgp-af)# allocate-label route-policy policy_A
```

# allowas-in

To allow an AS path with the provider edge (PE) autonomous system number (ASN) a specified number of times, use the **allowas-in** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**allowas-in** [ *as-occurrence-number* ]

**no allowas-in** [ *as-occurrence-number* ]

## Syntax Description

|                             |                                                                   |
|-----------------------------|-------------------------------------------------------------------|
| <i>as-occurrence-number</i> | (Optional) Number of times a PE ASN is allowed. Range is 1 to 10. |
|-----------------------------|-------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

Address family group configuration  
Neighbor address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Hub and spoke VPN networks require looping back of routing information to the hub PE through the hub customer edge (CE). See *Cisco IOS XR MPLS Configuration Guide for the Cisco XR 12000 Series Router* for information on hub and spoke VPN networks. This looping back, in addition to the presence of the PE ASN, causes the looped-back information to be dropped by the hub PE.

The **allowas-in** command prevents the looped-back information from being dropped by replacing the neighbor autonomous system number (ASN) with the PE ASN in the AS path. This allows the VPN customer to see a specified number of occurrences of the PE ASN in the AS path.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to allow five occurrences of the PE ASN:

```
RP/0/0/CPU0:router(config)# router bgp 6  
RP/0/0/CPU0:router(config-bgp)# af-group group_1 address-family vpnv4 unicast  
RP/0/0/CPU0:router(config-bgp-afgrp)# allowas-in 5
```

# as-format

To configure the router's Autonomous system number (ASN) notation to asdot format, use the **as-format** command in global configuration mode. To restore the system to its default condition, use the **no** form of this command.

**as-format asdot**

**no as-format**

## Syntax Description

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| <b>asdot</b> | Specifies the Autonomous system number (ASN) notation to asdot format. |
|--------------|------------------------------------------------------------------------|

## Command Default

The default value, if the as-format command is not configured, is asplain.

## Command Modes

Global configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure the ASN notation to the asdot format:

```
RP/0/0/CPU0:router(config)# as-format asdot
```

# as-override

To configure a provider edge (PE) router to override the autonomous system number (ASN) of a site with the ASN of a provider, use the **as-override** command in VRF neighbor address family configuration mode. To restore the system to its default condition, use the **no** form of this command.

**as-override** [**inheritance-disable**]

**no as-override** [**inheritance-disable**]

## Syntax Description

|                            |                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Prevents the <b>as-override</b> command from being inherited from a parent group. |
|----------------------------|----------------------------------------------------------------------------------------------|

## Command Default

Automatic override of the ASN is disabled.

## Command Modes

VRF neighbor address family configuration

## Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                         |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **as-override** command in conjunction with the site-of-origin (SoO) feature, identifying the site where a route originated, and preventing routing loops between routers within a VPN.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure an ASN override:

```
RP/0/0/CPU0:router(config)# router bgp 6
RP/0/0/CPU0:router(config-bgp)# vrf vrf_A
RP/0/0/CPU0:router(config-bgp-vrf)# neighbor 192.168.70.24
```

```
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# remote-as 10
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-nbr-af)# as-override
```

**Related Commands**

|---------------------------------------------------|------------------------------------------|
| <a href="#">site-of-origin (BGP), on page 473</a> | Configures the site of origin filtering. |

# as-path-loopcheck out disable

To disable AS PATH loop checking for outbound updates, use the **as-path-loopcheck out disable** command in an appropriate address family configuration mode. To re-enable the default AS PATH loop checking, use the **no** form of this command.

**as-path-loopcheck out disable**

**no as-path-loopcheck out disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** AS PATH loop checking for outbound updates is enabled if there is only one neighbor and disabled if there are multiple neighbors in the update group.

**Command Modes**

- IPv4 address family
- IPv6 address family
- L2VPN address family
- VPNv4 address family
- VPNv6 address family

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Configure the **as-path-loopcheck out disable** command to disable the default behavior of PE router not announcing BGP routes to the CE router if the routes contain an AS number matching the AS number of the receiving CE router.

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to configure **as-path-loopcheck out disable** under IPv6 unicast address family:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family ipv6 unicast
RP/0/0/CPU0:router(config-bgp-af)#as-path-loopcheck out disable
```

# attribute-filter group

To configure attribute-filter group command mode, use the attribute-filter group command in an appropriate configuration mode. To disable attribute-filter group command mode, use the no form of this command.

**attribute-filter group** *group-name*

**no attribute-filter group** *group-name*

## Syntax Description

|                   |                                                   |
|-------------------|---------------------------------------------------|
| <i>group-name</i> | Specifies the name of the attribute-filter group. |
|-------------------|---------------------------------------------------|

## Command Default

Attribute-filter group command mode is disabled.

## Command Modes

Router configuration  
Neighbor configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.3 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **attribute-filter group** command in neighbor configuration mode to configure a specific attribute filter group for a BGP neighbor.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to configure the attribute-filter group command mode:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#attribute-filter group ag_discard_med
RP/0/0/CPU0:router(config-bgp-attrfg)#
```

This example shows how to configure the attribute filter group for a BGP neighbor:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#neighbor 10.0.1.101
RP/0/0/CPU0:router(config-bgp-nbr)#remote-as 6461
RP/0/0/CPU0:router(config-bgp-nbr)#update in filtering
RP/0/0/CPU0:router(config-nbr-upd-filter)#attribute-filter group ag_discard_med
```

## bfd (BGP)

To specify a bidirectional forwarding detection (BFD) **multiplier** and **minimum-interval** arguments per neighbor, use the **bfd** command in neighbor address family independent configuration mode. To return to the system defaults, use the **no** form of this command.

Previous to this enhancement, BFD could be configured only in global scope in BGP. This change makes available two new command-line arguments under neighbor address family independent configuration:

**bfd** {**multiplier** | **minimum-interval**} *value*

**no bfd** {**multiplier** | **minimum-interval**} *value*

### Syntax Description

|                                      |                                                                      |
|--------------------------------------|----------------------------------------------------------------------|
| <b>multiplier</b> <i>value</i>       | Specifies the BFD session's multiplier value for the neighbor.       |
| <b>minimum-interval</b> <i>value</i> | Specifies the BFD session's minimum-interval value for the neighbor. |

### Command Default

No default per neighbor parameters are set.

### Command Modes

Neighbor address family independent configuration

### Command History

| Release       | Modification                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Release 3.4.0 | This command was introduced.                                                                                                      |
| Release 3.6.0 | The arguments <b>multiplier</b> and <b>minimum-interval</b> were added for the neighbor address family independent configuration. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If the minimum interval is changed using the **bfd minimum-interval** command, the new parameter updates all affected BFD sessions under the command mode in which the minimum interval was changed.

If the multiplier is changed using the **bfd multiplier** command, the new parameter is used to update only the BFD sessions associated with the affected neighbor gets affected.

The assumption is that when BFD fast-detect is enabled under neighbor address family independent configuration, the values for the **multiplier** and **minimum-interval** values are always derived from the per-neighbor values if they are configured; otherwise, they are to be taken from the global BGP configuration mode. In the event that this has not been explicitly stated, then these values are taken to be the default values.

Also, the **bfd** arguments can be configured under neighbor-group and session-group and the inheritance adheres to the standard way of BGP configuration inheritance.

Accordingly, there are four cases in which bfd-fast detect is enabled.

This is shown in table below where the BFD value is either multiplier or minimum-interval. Local indicates per NBR value, global is the BGP global value.

| BFD value (global) | BFD value (local) | Result              |
|--------------------|-------------------|---------------------|
| Yes                | Yes               | BFD value (local)   |
| Yes                | No                | BFD value (global)  |
| No                 | Yes               | BFD value (local)   |
| No                 | No                | BFD value (default) |

## Examples

The following example shows how to specify the BFD session's multiplier value for the neighbor:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 65000
RP/0/0/CPU0:router(config-bgp-nbrgrp)#neighbor 3.3.3.2
RP/0/0/CPU0:router(config-bgp-nbr)# bfd minimum-interval 311
RP/0/0/CPU0:router(config-bgp-nbr)# bfd multiplier 7
RP/0/0/CPU0:router(config-bgp-nbr)# neighbor 5.5.5.2
RP/0/0/CPU0:router(config-bgp-nbr)# bfd minimum-interval 318
RP/0/0/CPU0:router(config-bgp-nbr)# bfd multiplier 4
RP/0/0/CPU0:router(config-bgp-nbr)# vrf one
RP/0/0/CPU0:router(config-bgp-vrf)# neighbor 3.12.1.2
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# bfd minimum-interval 119
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# bfd multiplier 10
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# commit
```

```
RP/0/0/CPU0:router# show bfd session
```

# bgp as-path-loopcheck

To enable loop checking in the autonomous system path of the prefixes advertised by internal Border Gateway Protocol (iBGP) peers, use the **bgp as-path-loopcheck** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**bgp as-path-loopcheck**

**no bgp as-path-loopcheck**

## Syntax Description

This command has no keywords or arguments.

## Command Default

When you do not specify this command, loop checking is performed only for external peers.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was supported in VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure an autonomous system path for loop checking iBGP peers:

```
RP/0/0/CPU0:router(config)# router bgp 6
RP/0/0/CPU0:router(config-bgp)# bgp as-path-loopcheck
```

# bgp attribute-download

To enable Border Gateway Protocol (BGP) attribute download, use the **bgp attribute-download** command in an appropriate configuration mode. To disable BGP attribute download, use the **no** form of this command.

**bgp attribute-download**

**no bgp attribute-download**

**Syntax Description** This command has no keywords or arguments.

**Command Default** BGP attribute download is not enabled.

**Command Modes** IPv4 unicast address family configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When BGP attribute download is enabled using the **bgp attribute-download** command, BGP reinstalls all routes whose attributes are not currently in the RIB. Likewise, if the user disables BGP attribute download using the no form of the command, BGP reinstalls previously installed routes with a null key, and removes the attributes from the RIB.

Use the **bgp attribute-download** command to enable the Netflow BGP data export function. When attribute download is enabled, BGP downloads the attribute information for prefixes (community, extended community, and as-path) to the Routing Information Base (RIB) and Forwarding Information Base (FIB). This enables FIB to associate the prefixes with attributes and send the Netflow statistics along with the associated attributes.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows the BGP routes before and after BGP attribute download is enabled and shows how to enable BGP attribute download on BGP router 50:

```
RP/0/0/CPU0:router# show route bgp
```

```
B    100.0.1.0/24 [200/0] via 10.0.101.1, 00:00:37
B    100.0.2.0/24 [200/0] via 10.0.101.1, 00:00:37
B    100.0.3.0/24 [200/0] via 10.0.101.1, 00:00:37
B    100.0.4.0/24 [200/0] via 10.0.101.1, 00:00:37
B    100.0.5.0/24 [200/0] via 10.0.101.1, 00:00:37

RP/0/0/CPU0:router(config)# router bgp 50
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# bgp attribute-download
!
!
!
RP/0/0/CPU0:router# show route bgp

B    100.0.1.0/24 [200/0] via 10.0.101.1, 00:00:01
      Attribute ID 0x2
B    100.0.2.0/24 [200/0] via 10.0.101.1, 00:00:01
      Attribute ID 0x2
B    100.0.3.0/24 [200/0] via 10.0.101.1, 00:00:01
      Attribute ID 0x2
B    100.0.4.0/24 [200/0] via 10.0.101.1, 00:00:01
      Attribute ID 0x2
B    100.0.5.0/24 [200/0] via 10.0.101.1, 00:00:01
      Attribute ID 0x2
```

# bgp auto-policy-soft-reset disable

To disable an automatic soft reset of Border Gateway Protocol (BGP) peers when their configured route policy is modified, use the **bgp auto-policy-soft-reset disable** command in an appropriate configuration mode. To re-enable automatic soft reset of BGP peers, use the **no** form of this command.

**bgp auto-policy-soft-reset disable**

**no bgp auto-policy-soft-reset disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Automatic soft reset of peers is enabled.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                                                                       |
|-----------------|---------------|----------------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.<br>The <b>disable</b> keyword was changed from optional to mandatory. |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode.                                              |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note** If the inbound policy changes, it is not always possible to perform a soft reset. This is the case if the neighbor does not support route refresh and soft-reconfiguration inbound is not configured for the neighbor. In such instances, a message is logged in the system log indicating that a manual hard reset is needed.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

## Examples

The following example shows how to disable an automatic soft reset of BGP peers when their configured route policy is modified:

```
RP/0/0/CPU0:router(config)# router bgp 6  
RP/0/0/CPU0:router(config-bgp)# bgp auto-policy-soft-reset disable
```

# bgp bestpath as-path ignore

To ignore the autonomous system path length when calculating preferred paths, use the **bgp bestpath as-path ignore** command in an appropriate configuration mode. To return the software to the default state in which it considers the autonomous system path length when calculating preferred paths, use the **no** form of this command.

**bgp bestpath as-path ignore**

**no bgp bestpath as-path ignore**

**Syntax Description** This command has no keywords or arguments.

**Command Default** The autonomous system path length is used (not ignored) when a best path is selected.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |
|-----------------|---------------|-------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                          |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode. |
|                 |               |                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp bestpath as-path ignore** command to ignore the length of autonomous system paths when the software selects a preferred path. When the best path is selected, if this command is specified, all steps are performed as usual except comparison of the autonomous path length between candidate paths.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows how to configure the software to ignore the autonomous system length when performing best-path selection:

```
RP/0/0/CPU0:router(config)# router bgp 65000
```

```
RP/0/0/CPU0:router(config-bgp)# bgp bestpath as-path ignore
```

| <a href="#">bgp bestpath med missing-as-worst</a> , on page 61 | Enables the software to consider a missing MED attribute in a path as having a value of infinity.                                          |

# bgp bestpath compare-routerid

To compare identical routes received from external BGP (eBGP) peers during the best-path selection process and select the route with the lowest router ID, use the **bgp bestpath compare-routerid** command in an appropriate configuration mode. To disable comparing identical routes received from eBGP peers during best-path selection, use the **no** form of this command.

**bgp bestpath compare-routerid**

**no bgp bestpath compare-routerid**

**Syntax Description** This command has no keywords or arguments.

**Command Default** The software does not select a new best path if it is the same as the current best path (according to the BGP selection algorithm) except for the router ID.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |
|-----------------|---------------|-------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                          |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode. |
|                 |               |                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp bestpath compare-routerid** command to affect how the software selects the best path, in the case where there are two paths of equal cost according to the BGP selection algorithm. This command is used to force the software to select the path with the lower router ID as the best path. If this command is not used, the software continues to use whichever path is currently the best path, regardless of which has the lower router ID.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

## Examples

The following example shows how to configure the BGP speaker in autonomous system 500 to compare the router IDs of similar paths:

```
RP/0/0/CPU0:router(config)# router bgp 500  
RP/0/0/CPU0:router(config-bgp)# bgp bestpath compare-routerid
```

## Related Commands

| <a href="#">show bgp, on page 265</a> | Displays entries in the BGP routing table. |

# bgp bestpath cost-community ignore

To configure a router that is running the Border Gateway Protocol (BGP) to not evaluate the cost community attribute during the best-path selection process, use the **bgp bestpath cost-community ignore** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**bgp bestpath cost-community ignore**

**no bgp bestpath cost-community ignore**

## Syntax Description

This command has no keywords or arguments.

## Command Default

The behavior of this command is enabled by default until the cost community attribute is manually configured.

## Command Modes

Router configuration

VRF configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp bestpath cost-community ignore** command to disable the evaluation of the cost community attribute to help isolate problems and troubleshoot issues that relate to BGP path selection. This command can also be used to delay the activation of cost community attribute evaluation so that cost community filtering can be deployed in a large network at the same time.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure a router to not evaluate the cost community attribute during the best-path selection process:

```
RP/0/0/CPU0:router(config)# router bgp 500  
RP/0/0/CPU0:router(config-bgp)# bgp bestpath cost-community ignore
```

# bgp bestpath med always

To allow the comparison of the Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems, use the **bgp bestpath med always** command in an appropriate configuration mode. To disable considering the MED attribute in comparing paths, use the **no** form of this command.

**bgp bestpath med always**

**no bgp bestpath med always**

**Syntax Description** This command has no keywords or arguments.

**Command Default** The software does not compare MEDs for paths from neighbors in different autonomous systems.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |
|-----------------|---------------|-------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                          |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode. |
|                 |               |                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The MED is one of the parameters that is considered by the software when selecting the best path among many alternative paths. The software chooses the path with the lowest MED.

By default, during the best-path selection process, the software makes a MED comparison only among paths from the same autonomous system. This command changes the default behavior of the software by allowing comparison of MEDs among paths regardless of the autonomous system from which the paths are received.

When the **bgp bestpath med always** command is not enabled and distributed BGP is configured, speakers calculate partial best paths only (executes the best-path steps up to the MED comparison) and send them to BGP Routing Information Base (bRIB). bRIB calculates the final best path (executes all the steps in the best-path calculation). When the **bgp bestpath med always** command is enabled and distributed BGP is configured, speakers can compare the MED across all ASs, allowing the speaker to calculate a single best path to send it to bRIB. bRIB is the ultimate process that calculates the final best path, but when the **bgp bestpath med always** command is enabled, the speakers send a single best path instead of potentially sending multiple, partial best paths

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to configure the Border Gateway Protocol (BGP) speaker in autonomous system 100 to compare MEDs among alternative paths, regardless of the autonomous system from which the paths are received:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# bgp bestpath med always
```

**Related Commands**

| <a href="#">bgp bestpath med missing-as-worst, on page 61</a> | Specifies that the software consider a missing MED attribute in a path as having a value of infinity, making the path without a MED value the least desirable path. |
| <a href="#">show bgp, on page 265</a>                         | Displays entries in the BGP routing table.                                                                                                                          |

# bgp bestpath med confed

To enable Multi Exit Discriminator (MED) comparison among paths learned from confederation peers, use the **bgp bestpath med confed** command in an appropriate configuration mode. To disable the software from considering the MED attribute in comparing paths, use the **no** form of this command.

**bgp bestpath med confed**

**no bgp bestpath med confed**

## Syntax Description

This command has no keywords or arguments.

## Command Default

The software does not compare the MED of paths containing only confederation segments, or paths containing confederation segments followed by an AS\_SET, with the MED of any other paths.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the MED of the following paths is not compared with the MED of any other path:

- Paths with an empty autonomous system path
- Paths beginning with an AS\_SET
- Paths containing only confederation segments
- Paths containing confederation segments followed by an AS\_SET

Use the **bgp bestpath med confed** command to affect how the following types of paths are treated in the BGP best-path algorithm:

- Paths containing only confederation segments
- Paths containing confederation segments followed by an AS\_SET

The MED for paths that start with an AS\_SEQUENCE or that start with confederation segments followed by an AS\_SEQUENCE only is compared with the MED of other paths that share the same first autonomous system number in the autonomous system sequence (the neighbor autonomous system number). This behavior is not affected by the **bgp bestpath med confed** command.

As an example, suppose that autonomous systems 65000, 65001, 65002, and 65004 are part of a confederation, but autonomous system 1 is not. Suppose that for a particular route, the following paths exist:

- Path 1: 65000 65004, med = 2, IGP metric = 20
- Path 2: 65001 65004, med = 3, IGP metric = 10
- Path 3: 65002 1, med = 1, IGP metric = 30

If the **bgp bestpath med confed** command is enabled, the software selects path 1 as the best path because it:

- Has a lower MED than path 2
- Has a lower IGP metric than path 3

The MED is not compared with path 3 because it has an external autonomous system number (that is, an AS\_SEQUENCE) in the path. If the **bgp bestpath med confed** command is not enabled, then MED is not compared between any of these paths. Consequently, the software selects path 2 as the best path because it has the lowest IGP metric.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following command shows how to enable Border Gateway Protocol (BGP) software to compare MED values for paths learned from confederation peers:

```
RP/0/0/CPU0:router(config)# router bgp 210
RP/0/0/CPU0:router(config-bgp)# bgp bestpath med confed
```

# bgp bestpath med missing-as-worst

To have the software consider a missing Multi Exit Discriminator (MED) attribute in a path as having a value of infinity, making the path without a MED value the least desirable path, use the **bgp bestpath med missing-as-worst** command in an appropriate configuration mode. To disable considering the MED attribute in comparing paths, use the **no** form of this command.

**bgp bestpath med missing-as-worst**

**no bgp bestpath med missing-as-worst**

**Syntax Description** This command has no keywords or arguments.

**Command Default** The software assigns a value of 0 to the missing MED, causing the path with the missing MED attribute to be considered as the best possible MED.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |

# bgp client-to-client reflection disable

To disable reflection of routes between route-reflection clients using a Border Gateway Protocol (BGP) route reflector, use the **bgp client-to-client reflection disable** command in address family configuration mode. To re-enable client-to-client reflection, use the **no** form of this command.

**bgp client-to-client reflection** [*cluster-id cluster-id*] **disable**

**no bgp client-to-client reflection** [*cluster-id cluster-id*] **disable**

## Syntax Description

|                                     |                                                                                                                                                                                             |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cluster-id</b> <i>cluster-id</i> | (Optional) Cluster ID for which intra-cluster route reflection is to be disabled; maximum of 4 bytes. Cluster ID can be entered either as an IP address or value. Range is 1 to 4294967295. |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

Client-to-client reflection is enabled.

## Command Modes

Address family configuration

## Command History

| Release       | Modification                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>disable</b> keyword was changed from optional to mandatory. |
| Release 3.8.0 | Support was added for multiple cluster-IDs.                                                        |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the clients of a route reflector that are part of the same cluster are not required to be fully meshed and the routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required. If the cluster-id is not specified, then this command disables intra-cluster route reflection for all clusters.

## Examples

In this example, the three neighbors are fully meshed, so client-to-client reflection is disabled:

```
RP/0/0/CPU0:router(config)# router bgp 65534
RP/0/0/CPU0:router(config-bgp)# bgp cluster-id 2
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# bgp client-to-client reflection cluster-id 2 disable
RP/0/0/CPU0:router(config-bgp-af)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor-group rrclients
RP/0/0/CPU0:router(config-bgp-nbrgrp)# remote-as 65534
```

```

RP/0/0/CPU0:router(config-bgp-nbrgrp)# bgp cluster-id 2
RP/0/0/CPU0:router(config-bgp-nbrgrp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# route-reflector-client
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# exit
RP/0/0/CPU0:router(config-bgp-nbrgrp)# exit

RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.253.21 use neighbor-group rrclients
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.253.22 use neighbor-group rrclients
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.253.23 use neighbor-group rrclients

```

## Related Commands

|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">bgp cluster-id, on page 65</a>          | Configures the cluster ID if the BGP cluster has more than one route reflector.                     |
| <a href="#">route-reflector-client, on page 246</a> | Configures the router as a BGP route reflector and configures the specified neighbor as its client. |
| <a href="#">show bgp, on page 265</a>               | Displays entries in the BGP routing table.                                                          |

## bgp cluster-id

To configure the cluster ID if the Border Gateway Protocol (BGP) cluster has more than one route reflector, use the **bgp cluster-id** command in an appropriate configuration mode. To remove the cluster ID, use the **no** form of this command.

**bgp cluster-id** *cluster-id*

**no bgp cluster-id** [ *cluster-id* ]

### Syntax Description

|            |                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster-id | Cluster ID of this router acting as a route reflector; maximum of 4 bytes. Cluster ID can be entered either as an IP address or value. Range is 1 to 4294967295. |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

A cluster ID is not configured.

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Together, a route reflector and its clients form a *cluster*. A cluster of clients usually has a single route reflector. In such instances, the cluster is identified by the software as the router ID of the route reflector. To increase redundancy and avoid a single point of failure in the network, a cluster might have more than one route reflector. If it does, all route reflectors in the cluster must be configured with the same 4-byte cluster ID so that a route reflector can recognize updates from route reflectors in the same cluster.

A single route reflector can also support multiple clusters. Each cluster is identified by a unique cluster-id. The cluster-id configured by the **bgp cluster-id** command is taken as the default. If **bgp cluster-id** is not configured, the router ID for the default VRF identifies the default cluster. A neighbor can be associated with one cluster only, and the corresponding cluster-id is configured in neighbor configuration mode. If the cluster-id is not configured for a neighbor and the neighbor is a route reflector client, then the neighbor is assigned to the default cluster.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure the local router as one of the route reflectors serving the cluster. Neighbor 192.168.70.24 is assigned to the default cluster with cluster-id 1.

```
RP/0/0/CPU0:router(config)# router bgp 65534
RP/0/0/CPU0:router(config-bgp)# bgp cluster-id 1
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.70.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65534
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# route-reflector-client
```

| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

One way to reduce the internal BGP (iBGP) mesh is to divide an autonomous system into multiple autonomous systems and group them into a single confederation. Each autonomous system is fully meshed within itself, and has a few connections to another autonomous system in the same confederation. Although the peers in different autonomous systems have external BGP (eBGP) sessions, they exchange routing information as if they are iBGP peers. Specifically, the confederation maintains the next hop and local preference information,

and that allows you to retain a single Interior Gateway Protocol (IGP) for all autonomous systems. To the outside world, the confederation looks like a single autonomous system.

Use the **bgp confederation identifier** command to specify the autonomous system number for the confederation. This autonomous system number is used when BGP sessions are established with external peers in autonomous systems that are not part of the confederation.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to divide the autonomous system into autonomous systems 4001, 4002, 4003, 4004, 4005, 4006, and 4007 with the confederation identifier 5. Neighbor 10.2.3.4 is a router inside the confederation. Neighbor 172.20.16.6 is outside the routing domain confederation. To the outside world, there appears to be a single autonomous system with the number 5.

```
RP/0/0/CPU0:router(config)# router bgp 4001
RP/0/0/CPU0:router(config-bgp)# bgp confederation identifier 5
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4002
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4003
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4004
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4005
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4006
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 4007
RP/0/0/CPU0:router(config-bgp)# neighbor 10.2.3.4
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 4002
RP/0/0/CPU0:router(config-bgp-nbr)# exit
RP/0/0/CPU0:router(config-bgp)# exit
RP/0/0/CPU0:router(config-bgp-nbr)# neighbor 172.20.16.6
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 4009
```

| <a href="#">bgp confederation peers</a> , on page 69 | Configures the autonomous systems that belong to the confederation. |

## bgp confederation peers

To configure the autonomous systems that belong to the confederation, use the **bgp confederation peers** command in an appropriate configuration mode. To remove the autonomous system from the confederation, use the **no** form of this command.

**bgp confederation peers** [ *as-number* ]

**no bgp confederation peers** [ *as-number* ]

### Syntax Description

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | Autonomous system (AS) numbers for Border Gateway Protocol (BGP) peers that belong to the confederation. <ul style="list-style-type: none"><li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li><li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li><li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li></ul> |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

No BGP peers are identified as belonging to the confederation.

### Command Modes

Router configuration

### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The autonomous systems specified in this command are visible internally to a confederation. Each autonomous system is fully meshed within itself. The [bgp confederation identifier](#), on page 67 command specifies the confederation to which the autonomous systems belong.

To specify multiple autonomous systems, enter BGP confederation peer configuration mode then enter one *autonomous-system-number* for each command line.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows that autonomous systems 1090 and 1093 belong to a single confederation:

```
RP/0/0/CPU0:router(config)# router bgp 1090
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers 1093
```

The following example shows that autonomous systems 1095, 1096, 1097, and 1098 belong to a single confederation:

```
RP/0/0/CPU0:router(config)# router bgp 1095
RP/0/0/CPU0:router(config-bgp)# bgp confederation peers
RP/0/0/CPU0:router(config-bgp-confed-peers)# 1096
RP/0/0/CPU0:router(config-bgp-confed-peers)# 1097
RP/0/0/CPU0:router(config-bgp-confed-peers)# 1098
```

# bgp dampening

To enable Border Gateway Protocol (BGP) route dampening or change various BGP route dampening factors, use the **bgp dampening** command in an appropriate configuration mode. To disable route dampening and reset default values, use the **no** form of this command.

**bgp dampening** [*half-life* [*reuse suppress max-suppress-time*]] **route-policy** *route-policy-name*

**no bgp dampening** [*half-life* [*reuse suppress max-suppress-time*]] **route-policy** *route-policy-name*

## Syntax Description

|                                                 |                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>half-life</i>                                | (Optional) Time (in minutes) after which a penalty is decreased. Once the route has been assigned a penalty, the penalty is decreased by half after the half-life period (which is 15 minutes by default). Penalty reduction happens every 5 seconds. Range of the half-life period is from 1 to 45 minutes. |
| <i>reuse</i>                                    | (Optional) Value for route reuse if the flapping route penalty decreases and falls below the reuse value. When this happens, the route is unsuppressed. The process of unsuppressing routes occurs at 10-second increments. Range is 1 to 20000.                                                             |
| <i>suppress</i>                                 | (Optional) Maximum penalty value. Suppress a route when its penalty exceeds the value specified. When this happens, the route is suppressed. Range is 1 to 20000.                                                                                                                                            |
| <i>max-suppress-time</i>                        | (Optional) Maximum time (in minutes) a route can be suppressed. Range is 1 to 255. If the <i>half-life</i> value is allowed to default, the maximum suppress time defaults to 60 minutes.                                                                                                                    |
| <b>route-policy</b><br><i>route-policy-name</i> | (Optional) Specifies the route policy to use to set dampening parameters.                                                                                                                                                                                                                                    |

## Command Default

Route dampening is disabled.

*half-life* : 15 minutes

*reuse* : 750

*suppress* : 2000

*max-suppress-time* : four times *half-life* value

## Command Modes

**Command History**

| Release       | Modification                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> .                                                                               |
| Release 3.3.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv4 address family</li> <li>• VRF IPv4 address family</li> </ul> |
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family</li> <li>• VRF IPv6 address family</li> </ul> |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp dampening** command without arguments to enable BGP route dampening with the default parameters. The parameters can be changed by setting them on the command line or specifying them with a routing policy.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the *half-life* value to 30 minutes, the *reuse* value to 1500, the *suppress* value to 10000, and the *max-suppress-time* to 120 minutes:

```
RP/0/0/CPU0:router(config)# router bgp 50
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# bgp dampening 30 1500 10000 120
```

**Related Commands**

# bgp default local-preference

To change the default local preference value, use the **bgp default local-preference** command in an appropriate configuration mode. To reset the local preference value to the default of 100, use the **no** form of this command.

**bgp default local-preference** *value*

**no bgp default local-preference** [*value*]

## Syntax Description

|              |                                                                                 |
|--------------|---------------------------------------------------------------------------------|
| <i>value</i> | Local preference value. Range is 0 to 4294967295. Higher values are preferable. |
|--------------|---------------------------------------------------------------------------------|

## Command Default

Enabled with a value of 100.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was supported in VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Generally, the default value of 100 allows you to easily define a particular path as less preferable than paths with no local preference attribute. The preference is sent to all networking devices in the local autonomous system.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to raise the default local preference value from the default of 100 to 200:

```
RP/0/0/CPU0:router(config)# router bgp 200
RP/0/0/CPU0:router(config-bgp)# bgp default local-preference 200
```

# bgp enforce-first-as disable

To disable the software from enforcing the first autonomous system path (known as the AS path) of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, use the **bgp enforce-first-as disable** command in an appropriate configuration mode. To re-enable enforcing the first AS path of a received route from an eBGP peer to be the same as the remote autonomous system, use the **no** form of this command.

**bgp enforce-first-as disable**

**no bgp enforce-first-as disable**

## Syntax Description

This command has no keywords or arguments.

## Command Default

By default, the software requires the first autonomous system (in the AS path) of a route received from an eBGP peer to be the same as the remote autonomous system configured.

## Command Modes

Router configuration

VRF configuration

## Command History

| Release       | Modification                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>disable</b> keyword was changed from optional to mandatory. |
| Release 3.3.0 | This command was supported in VRF configuration mode.                                              |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the software ignores any update received from an eBGP neighbor that does not have the autonomous system configured for that neighbor at the beginning of the AS path. When configured, the command applies to all eBGP peers of the router.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows a configuration in which incoming updates from eBGP neighbors are not checked to ensure the first AS number in the AS path is the same as the configured AS number for the neighbor:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# bgp enforce-first-as disable
```

## Related Commands

|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">enforce-first-as, on page 153</a>         | Disables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, in neighbor configuration mode, neighbor group configuration mode, and session group configuration mode. |
| <a href="#">enforce-first-as-disable, on page 155</a> | Disables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, in neighbor configuration mode, neighbor group configuration mode, and session group configuration mode. |
| <a href="#">show bgp, on page 265</a>                 | Displays entries in the BGP routing table.                                                                                                                                                                                                                                                                               |

## bgp fast-external-fallover disable

To disable immediately resetting the Border Gateway Protocol (BGP) sessions of any directly adjacent external peers if the link used to reach them goes down, use the **bgp fast-external-fallover disable** command in an appropriate configuration mode. To disable this function and perform an immediate reset of BGP sessions when a link between peers is lost, use the **no** form of this command.

**bgp fast-external-fallover disable**

**no bgp fast-external-fallover disable**

### Syntax Description

|                |                                      |
|----------------|--------------------------------------|
| <b>disable</b> | Disables BGP fast external failover. |
|----------------|--------------------------------------|

### Command Default

BGP sessions of any directly adjacent external peers are immediately reset if the link used to reach them goes down.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>disable</b> keyword was changed from optional to mandatory. |
| Release 3.3.0 | This command was supported in VRF configuration mode.                                              |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, BGP sessions of any directly adjacent external peers are immediately reset, which allows the network to recover faster when links go down between BGP peers.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to disable the automatic resetting of BGP sessions:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# bgp fast-external-fallover disable
```

# bgp graceful-restart

To enable graceful restart support, use the **bgp graceful-restart** command in an appropriate configuration mode. To disable this function, use the **no** form of this command.

**bgp graceful-restart**

**no bgp graceful-restart**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Graceful restart support is not enabled.

**Command Modes** Router configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp graceful-restart** command to enable graceful restart functionality on the router, and also to advertise graceful restart to neighboring routers.

**Note**

The **bgp graceful-restart** command with no options must be used to enable graceful restart before using the **bgp graceful-restart purge-time**, **bgp graceful-restart restart-time**, **bgp graceful-restart stalepath-time**, or **bgp graceful-restart graceful-reset** commands.

When graceful restart is enabled, the BGP graceful restart capability is negotiated with neighbors in the BGP OPEN message when the session is established. If the neighbor also advertises support for graceful restart, then graceful restart is activated for that neighbor session. If the neighbor does not advertise support for graceful restart, then graceful restart is not activated for that neighbor session even though it is enabled locally.

If you enter the **bgp graceful-restart** command after some BGP sessions are established, you must restart those sessions before graceful restart takes effect. Use the **clear bgp** command to restart sessions.

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to enable graceful restart:

```
RP/0/0/CPU0:router(config)#router bgp 3
RP/0/0/CPU0:router(config-bgp)#bgp graceful-restart
```

**Related Commands**

| <a href="#">bgp graceful-restart stalepath-time, on page 87</a> | Defines the maximum time to wait for the End-of-RIB message from a neighbor that has been restarted before deleting learned routes. |
| <a href="#">show bgp, on page 265</a>                           | Displays entries in the BGP routing table.                                                                                          |
| <a href="#">show bgp neighbors, on page 346</a>                 | Displays information about BGP connections to neighbors.                                                                            |
| <a href="#">show bgp process, on page 395</a>                   | Displays BGP process information.                                                                                                   |

# bgp graceful-restart graceful-reset

To invoke a graceful restart when configuration changes force a peer reset, use the **bgp graceful-restart graceful-reset** command in an appropriate configuration mode. To disable this function, use the **no** form of this command.

**bgp graceful-restart graceful-reset**  
**no bgp graceful-restart graceful-reset**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Graceful restart is not invoked when a configuration change forces a peer reset.

**Command Modes** Router configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

BGP graceful restart must be enabled using the **bgp graceful-restart** command before enabling graceful reset using the **bgp graceful-restart graceful-reset** command.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows how to enable graceful reset:

```
RP/0/0/CPU0:router(config)#router bgp 3  
RP/0/0/CPU0:router(config-bgp)# bgp graceful-restart graceful-reset
```

| Related Commands | Command                                           | Description                 |
|------------------|---------------------------------------------------|-----------------------------|
|                  | <a href="#">bgp graceful-restart</a> , on page 79 | Enables a graceful restart. |

| Command                                         | Description                                              |
|-------------------------------------------------|----------------------------------------------------------|

| <a href="#">show bgp neighbors, on page 346</a> | Displays information about BGP connections to neighbors. |
| <a href="#">show bgp process, on page 395</a>   | Displays BGP process information.                        |

## bgp graceful-restart purge-time

To specify the maximum time before stale routes are purged from the routing information base (RIB) when the local BGP process restarts, use the **bgp graceful-restart purge-time** command in an appropriate configuration mode. To set the purge timer time to its default value, use the **no** form of this command.

**bgp graceful-restart purge-time** *seconds*

**no bgp graceful-restart purge-time** *seconds*

### Syntax Description

|                |                                                                                   |
|----------------|-----------------------------------------------------------------------------------|
| <i>seconds</i> | Maximum time before stale routes are purged. Time in seconds. Range is 0 to 6000. |
|----------------|-----------------------------------------------------------------------------------|

### Command Default

*seconds* : 600

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

BGP graceful restart must be enabled using the **bgp graceful-restart** command before setting the purge time using the **bgp graceful-restart purge-time** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to change the BGP purge time to 800 seconds:

```
RP/0/0/CPU0:router(config)# router bgp 3  
RP/0/0/CPU0:router(config-bgp)# bgp graceful-restart purge-time 800
```

**Related Commands**

| Command                                          | Description                                              |
|--------------------------------------------------|----------------------------------------------------------|

| <a href="#">show bgp neighbors, on page 346</a>  | Displays information about BGP connections to neighbors. |
| <a href="#">show bgp process, on page 395</a>    | Displays BGP process information.                        |

## bgp graceful-restart restart-time

To specify a user-predicted local BGP process maximum restart time, which is advertised to neighbors during session establishment, use the **bgp graceful-restart restart-time** command in an appropriate configuration mode. To set this restart time to its default value, use the **no** form of this command.

**bgp graceful-restart restart-time** *seconds*

**no bgp graceful-restart restart-time** *seconds*

| Syntax Description | <i>seconds</i> | Maximum time advertised to neighbors. Time in seconds. Range is 1 to 4095. |
|--------------------|----------------|----------------------------------------------------------------------------|
|--------------------|----------------|----------------------------------------------------------------------------|

| Command Default | <i>seconds</i> : 120 |
|-----------------|----------------------|
|-----------------|----------------------|

| Command Modes | Router configuration |
|---------------|----------------------|
|---------------|----------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

| Usage Guidelines | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>BGP graceful restart must be enabled using the <b>bgp graceful-restart</b> command before setting the restart timer using the <b>bgp graceful-restart restart-time</b> command.</p> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

| Examples | The following example shows how to change the BGP graceful restart time to 400 seconds: |
|----------|-----------------------------------------------------------------------------------------|
|----------|-----------------------------------------------------------------------------------------|

```
RP/0/0/CPU0:router(config)#router bgp 3  
RP/0/0/CPU0:router(config-bgp)# bgp graceful-restart restart-time 400
```

**Related Commands**

# bgp graceful-restart stalepath-time

To specify the maximum time to wait for an End-of-RIB message after a neighbor restarts, use the **bgp graceful-restart stalepath-time** command in an appropriate configuration mode. To set the stalepath timer time to its default value, use the **no** form of this command.

**bgp graceful-restart stalepath-time** *seconds*

**no bgp graceful-restart stalepath-time** *seconds*

## Syntax Description

|                |                                                         |
|----------------|---------------------------------------------------------|
| <i>seconds</i> | Maximum wait time. Time in seconds. Range is 1 to 4095. |
|----------------|---------------------------------------------------------|

## Command Default

*seconds* : 360

## Command Modes

Router configuration

## Command History

| Release     | Modifications                |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

BGP graceful restart must be enabled using the **bgp graceful-restart** command before setting the stalepath time using the **bgp graceful-restart stalepath-time** command.

If the stalepath time is exceeded before an End-of-RIB message is received from a neighbor, paths learned from the neighbor are purged from the BGP routing table.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to change the stalepath time to 750 seconds:

```
RP/0/0/CPU0:router(config)# router bgp 3  
RP/0/0/CPU0:router(config-bgp)# bgp graceful-restart stalepath-time 750
```

**Related Commands**

# bgp import-delay

To enable delay for Border Gateway Protocol (BGP) batch import processing, use the **bgp import-delay** command in an appropriate configuration mode. To disable delay in batch import processing, use the no form of this command.

**bgp import-delay** *seconds milliseconds*

**no bgp import-delay**

## Syntax Description

|                     |                                                                                     |
|---------------------|-------------------------------------------------------------------------------------|
| <i>seconds</i>      | Specifies batch import processing delay in seconds. Range is 0 to 10 seconds.       |
| <i>milliseconds</i> | Specifies batch import processing delay in milliseconds. Range is 0 to 999 seconds. |

## Command Default

No delay is configured.

## Command Modes

Address-family VPNv4 Unicast  
Address-family VPNv6 Unicast

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set delay in batch import processing as two seconds and zero milliseconds:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#bgp import-delay 2 0
```

**Related Commands**

| Command                                      | Description                                                            |

| <a href="#">bgp label-delay</a> , on page 91 | Enables delay for Border Gateway Protocol (BGP) batch label processing |

# bgp label-delay

To enable delay for Border Gateway Protocol (BGP) batch label processing, use the **bgp import-delay** command in an appropriate configuration mode. To disable delay in batch import processing, use the no form of this command.

**bgp label-delay** *seconds milliseconds*

**no bgp label-delay**

## Syntax Description

|                     |                                                                                    |
|---------------------|------------------------------------------------------------------------------------|
| <i>seconds</i>      | Specifies batch label processing delay in seconds. Range is 0 to 10 seconds.       |
| <i>milliseconds</i> | Specifies batch label processing delay in milliseconds. Range is 0 to 999 seconds. |

## Command Default

No delay is configured.

## Command Modes

Address-family IPv4 Unicast  
Address-family IPv4 Multicast  
Address-family IPv6 Unicast  
Address-family IPv6 Multicast  
Address-family VPNv4 Unicast  
Address-family VPNv6 Unicast

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set delay in batch import processing as two seconds and zero milliseconds:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#bgp label-delay 2 0
```

| <a href="#">bgp import-delay</a> , on page 89 | Enables delay for Border Gateway Protocol (BGP) batch import processing |

# bgp log neighbor changes disable

To disable logging of Border Gateway Protocol (BGP) neighbor resets, use the **bgp log neighbor changes disable** command in an appropriate configuration mode. To re-enable logging of BGP neighbor resets, use the **no** form of this command.

**bgp log neighbor changes disable**

**no bgp log neighbor changes disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** BGP neighbor changes are logged.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                                                                       |
|-----------------|---------------|----------------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.<br>The <b>disable</b> keyword was changed from optional to mandatory. |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode.                                              |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Logging of BGP neighbor status changes (up or down) and resets is used for troubleshooting network connectivity problems and measuring network stability. Unexpected neighbor resets might indicate high error rates or high packet loss in the network, and should be investigated.

Status change message logging does not substantially affect performance, unlike, for example, enabling per-BGP update debugging. If the UNIX syslog facility is enabled, messages are sent by the software to the UNIX host running the syslog daemon so that the messages can be stored and archived on disk. If the UNIX syslog facility is not enabled, the status change messages are kept in the internal buffer of the router, and are not stored to disk.

The neighbor status change messages are not tracked if the **bgp log neighbor changes disable** command is disabled, except for the last reset reason, which is always available as output of the **show bgp neighbors** command.

Up and down messages for BGP neighbors are logged by the software by default. Use the **bgp log neighbor changes disable** command to stop logging BGP neighbor changes.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to prevent the logging of neighbor changes for BGP:

```
RP/0/0/CPU0:router(config)# router bgp 65530  
RP/0/0/CPU0:router(config-bgp)# bgp log neighbor changes disable
```

**Related Commands**

| Command                                         | Description                                                          |
|-------------------------------------------------|----------------------------------------------------------------------|
| <a href="#">show bgp neighbors, on page 346</a> | Displays information about the TCP and BGP connections to neighbors. |

# bgp maximum neighbor

To control the maximum number of neighbors that can be configured on the router, use the **bgp maximum neighbor** command in an appropriate configuration mode. To set the neighbor limit to the default value, use the **no** form of this command.

**bgp maximum neighbor** *limit*  
**no maximum neighbor** [ *limit* ]

## Syntax Description

|              |                                                   |
|--------------|---------------------------------------------------|
| <i>limit</i> | Maximum number of neighbors. Range is 1 to 15000. |
|--------------|---------------------------------------------------|

## Command Default

Default limit is 4000

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Any attempt to configure the neighbor limit below 1 or above 15000 fails. Similarly, attempting to configure the limit below the number of neighbors currently configured fails. For example, if there are 3250 neighbors configured, you cannot set the *limit* below 3250.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | write      |

## Examples

The following example shows how to change the default maximum neighbor limit and set it to 1200:

```
RP/0/0/CPU0:router(config)#router bgp 65530  
RP/0/0/CPU0:router(config-bgp)# bgp maximum neighbor 1200
```

# bgp redistribute-internal

To allow the redistribution of internal Border Gateway Protocol (iBGP) routes into an Interior Gateway Protocol (IGP), such as Intermediate System-to-Intermediate System (IS-IS) or Open Shortest Path First (OSPF), use the **bgp redistribute-internal** command in an appropriate configuration mode. To disable the redistribution of iBGP routes into IGPs, use the **no** form of this command.

**bgp redistribute-internal**

**no bgp redistribute-internal**

**Syntax Description** This command has no keywords or arguments.

**Command Default** By default, iBGP routes are not redistributed into IGPs.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |
|-----------------|---------------|-------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                          |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode. |
|                 |               |                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use of the **bgp redistribute-internal** command requires the **clear route \*** command to be issued to reinstall all BGP routes into the IP routing table.

**Note** Redistributing iBGP routes into IGPs may cause routing loops to form within an autonomous system. Use this command with caution.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

## Examples

The following example shows how to redistribute iBGP routes into OSPF:

```
RP/0/0/CPU0:router(config)#router bgp 1
RP/0/0/CPU0:router(config-bgp)# bgp redistribute-internal
RP/0/0/CPU0:router(config-bgp)# exit
RP/0/0/CPU0:router(config)# router ospf area1
RP/0/0/CPU0:router(config-router)# redistribute bgp 1
RP/0/0/CPU0:router(config-router)# end
RP/0/0/CPU0:router# clear route *
```

## Related Commands

| Command                                  | Description               |
|------------------------------------------|---------------------------|
| <a href="#">clear bgp, on page 112</a> * | Resets all BGP neighbors. |
| <b>clear route *</b>                     | Resets all routes.        |

# bgp router-id

To configure a fixed router ID for a Border Gateway Protocol (BGP)-speaking router, use the **bgp router-id** command in an appropriate configuration mode. To disable a fixed router ID, use the **no** form of this command.

**bgp router-id** *ip-address*

**no bgp router-id** [*ip-address*]

## Syntax Description

|                   |                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i> | IP Version 4 (IPv4) address to use as the router ID. Normally, this should be an IPv4 address assigned to the router. |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|

## Command Default

If no router ID is configured in BGP, BGP attempts to use the global router ID if one is configured and available. Otherwise, BGP uses the highest IP address configured on a loopback interface.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                                                                                               |
|---------------|----------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                               |
| Release 3.3.0 | This command was supported in VRF configuration mode. The <i>interface-type interface-instance</i> arguments were removed. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you do not use the **bgp router-id** command to configure a router ID, an IP address is not configured on any loopback interface, and no global router ID is configured, BGP neighbors remain down.

For more details on router IDs, see the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure the local router with the router ID of 192.168.70.24:

```
RP/0/0/CPU0:router(config)# router bgp 100  
RP/0/0/CPU0:router(config-bgp)#bgp router-id 192.168.70.24
```

## Related Commands

| Command                               | Description                                |
|---------------------------------------|--------------------------------------------|
| <a href="#">show bgp, on page 265</a> | Displays entries in the BGP routing table. |

# bgp scan-time

To configure scanning intervals of Border Gateway Protocol (BGP)-speaking networking devices, use the **bgp scan-time** command in an appropriate configuration mode. To restore the scanning interval to its default value, use the **no** form of this command.

**bgp scan-time** *seconds*

**no bgp scan-time** *seconds*

## Syntax Description

|                |                                                                                        |
|----------------|----------------------------------------------------------------------------------------|
| <i>seconds</i> | Scanning interval (in seconds) of BGP routing information. Range is 5 to 3600 seconds. |
|----------------|----------------------------------------------------------------------------------------|

## Command Default

The default scanning interval is 60 seconds.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                           |
|---------------|------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                           |
| Release 3.3.0 | This command was supported in VPNv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in VPNv6 address family configuration mode. |
| Release 4.0.0 | Support was removed for all address family configuration modes.        |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp scan-time** command to change how frequently the software processes scanner tasks, such as conditional advertisement, dynamic MED changes, and periodic maintenance tasks.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set the scanning interval to 20 seconds:

```
RP/0/0/CPU0:router(config)# router bgp 64500  
RP/0/0/CPU0:router(config-bgp-af)# bgp scan-time 20
```

## Related Commands

| Command                               | Description                                |
|---------------------------------------|--------------------------------------------|
| <a href="#">show bgp, on page 265</a> | Displays entries in the BGP routing table. |

# bgp update-delay

To set the maximum initial delay for a Border Gateway Protocol (BGP)-speaking router to send the first updates, use the **bgp update-delay** command in an appropriate configuration mode. To restore the initial delay to its default value, use the **no** form of this command.

**bgp update-delay** *seconds* [**always**]

**no****bgp update-delay** [*seconds*][**always**]

## Syntax Description

|                |                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Delay in seconds for the router to send the first updates. Range is 0 to 3600.                                                                        |
| <b>always</b>  | (Optional) Specifies that the router always wait for the update delay time, even if all neighbors have finished sending their initial updates sooner. |

## Command Default

120 seconds

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When BGP is started, it waits a specified period of time for its neighbors to establish peering sessions and to complete sending their initial updates. After all neighbors complete their initial updates, or after the update delay timer expires, the best path is calculated for each route, and the software starts sending advertisements out to its peers. This behavior improves convergence time. If the software were to advertise a route as soon as it learned it, it would have to readvertise the route each time it learned a new path that was preferred over all previously learned paths.

Use the **bgp update-delay** command to tune the maximum time the software waits after the first neighbor is established until it starts calculating best paths and sending out advertisements.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to set the maximum initial delay to 240 seconds:

```
RP/0/0/CPU0:router(config)#router bgp 64530  
RP/0/0/CPU0:router(config-bgp)# bgp update-delay 240
```

# bgp write-limit

## Note

The **bgp write-limit** command is deprecated in Release 4.2.0, and replaced with **update limit** commands. For more information, see the commands [update limit](#), on page 496, [update limit address-family](#), on page 498, [update limit sub-group](#), on page 500.

To modify the upper bounds on update message queue lengths or to enable desynchronization, use the **bgp write-limit** command in an appropriate configuration mode. To return the bounds to their default values and to disable desynchronization, use the **no** form of this command.

**bgp write-limit** *group-limit global-limit* [**desynchronize**]

**no bgp write-limit** [*group-limit global-limit*] [**desynchronize**]

## Syntax Description

|                      |                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group-limit</i>   | Per-update group limit on the number of update messages the software queues. Range is 500 to 100000000. Group limit cannot be greater than the global limit. |
| <i>global-limit</i>  | Global limit on the number of update messages the software queues. Range is 500 to 100000000.                                                                |
| <b>desynchronize</b> | (Optional) Enables desynchronization.                                                                                                                        |

## Command Default

*group-limit* : 50,000  
*global-limit* : 250,000  
 Desynchronization is off.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                                   |
|---------------|--------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                   |
| Release 3.3.0 | The <i>group-limit</i> and <i>global-limit</i> default values have changed.    |
| Release 4.2.0 | This command was deprecated and replaced with the <b>update limit</b> command. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **bgp write-limit** command to configure both a per-update group and a global limit on the number of messages the software queues when updating peers. Increasing these limits can result in faster Border Gateway Protocol (BGP) convergence, but also may result in higher memory use during convergence. In addition, this command can be used to enable desynchronization. Desynchronization can decrease memory use and speed up convergence for the fastest neighbors if one or more neighbors in an update group process updates significantly slower than other neighbors in the same group. However, enabling desynchronization can cause a significant degradation in overall convergence time, especially if the router is experiencing high CPU utilization. For this reason, enabling desynchronization is discouraged.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to configure BGP to operate with a per-update group limit of 9000 messages and a global limit of 27,000 messages:

```
RP/0/0/CPU0:router(config)# router bgp 65000  
RP/0/0/CPU0:router(config-bgp)#bgp write-limit 9000 27000
```

# capability orf prefix

To advertise prefix list-based Outbound Route Filter (ORF) capability to the Border Gateway Protocol (BGP) peer, use the **capability orf prefix** command in an appropriate configuration mode. To remove the **capability orf prefix** command from the configuration file and restore the system to its default condition in which the software does not advertise the capability, use the **no** form of this command.

**capability orf prefix** {receive| send| both| none}

**no capability orf prefix** [receive| send| both| none]

## Syntax Description

|                |                                                                                    |
|----------------|------------------------------------------------------------------------------------|
| <b>receive</b> | Sets the capability to receive the ORF from a specified neighbor.                  |
| <b>send</b>    | Sets the capability to send the ORF to a specified neighbor.                       |
| <b>both</b>    | Sets the capability to receive and send the ORF from or to a specified neighbor.   |
| <b>none</b>    | Sets the capability to no for ORF receive or send from or to a specified neighbor. |

## Command Default

The routing device does not receive or send route prefix filter lists.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 IPv4 neighbor address family configuration  
 VRF neighbor IPv4 address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration

## Command History

| Release       | Modification                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                         |
| Release 3.3.0 | This command was changed from <b>capability orf prefix-list</b> to <b>capability orf prefix</b> . This command was supported in VRF neighbor IPv4 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The advertisement of the prefix list ORF capability by a BGP speaker indicates whether the speaker can send prefix lists to the specified neighbor and whether it accepts prefix lists from the neighbor. The speaker sends a prefix list if it indicated the ability to send them, and if the neighbor indicated it was willing to accept them. Similarly, the neighbor sends a prefix list to the speaker if it indicated the ability to send them and the speaker indicated the willingness to accept them.

**Note**

The `capability orf` and prefix list filter specified by `orf route-policy` must be explicitly configured.

If the neighbor sends a prefix list and the speaker accepts it, the speaker applies the received prefix list, plus any locally configured outbound filters, to limit its outbound routing updates to the neighbor. Increased filtering prevents unwanted routing updates between neighbors and reduces resource requirements for routing update generation and processing.

Use the **capability orf prefix** command to set whether to advertise send and receive capabilities to the specified neighbor.

**Note**

Sending a receive capability can adversely affect performance, because updates sent to that neighbor cannot be replicated for any other neighbors.

If this command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to configure the **capability orf prefix** command:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# route-policy orfq
RP/0/0/CPU0:router(config-rpl)# if orf prefix in (10.0.0.0/8 ge 20) then
RP/0/0/CPU0:router(config-rpl)# pass
RP/0/0/CPU0:router(config-rpl)# endif
RP/0/0/CPU0:router(config-rpl)# if orf prefix in (1910::16 ge 120) then
RP/0/0/CPU0:router(config-rpl)# pass
RP/0/0/CPU0:router(config-rpl)# endif
RP/0/0/CPU0:router(config-rpl)# end-policy
RP/0/0/CPU0:router(config)# router bgp 65530
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.101.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65534
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# route-policy pass-all out
RP/0/0/CPU0:router(config-bgp-nbr-af)# capability orf prefix both
RP/0/0/CPU0:router(config-bgp-nbr-af)# orf route-policy orfq
```

# capability suppress 4-byte-as

To suppress 4-byte AS capability from being advertised to the BGP peer, use the **capability suppress 4-byte-as** command in the appropriate configuration mode. To remove the **capability suppress 4-byte-as** command from the configuration and restore the system to the default condition, in which the software advertises the capability, use the **no** form of this command.

**capability suppress 4-byte-as** [**inheritance-disable**]

**no capability suppress 4-byte-as**

## Syntax Description

|                            |                                                                         |
|----------------------------|-------------------------------------------------------------------------|
| <b>inheritance-disable</b> | Prevents capability suppress 4-type-as being inherited from the parent. |
|----------------------------|-------------------------------------------------------------------------|

## Command Default

4-byte-as capability is advertised to the BGP peer.

## Command Modes

Neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.4.1 | This command was introduced.                                                         |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the software advertises the 4-byte AS capability to BGP peers. To override this default behavior, use the **capability suppress 4-byte-as** command under the command modes listed in the "Command Modes" section. If configured under the neighbor group or session group, all neighbors using the group inherit the configuration. Use the **no** option to remove the command.

### Caution

The BGP session resets automatically, if the 4-byte AS capability of an existing BGP session is changed by configuring **capability suppress 4-byte-as** or **capability suppress 4-byte-as inheritance-disable**.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure the **capability suppress 4-byte-as** command:

```
RP/0/0/CPU0:router# show bgp nei 10.3.3.3 conf
neighbor 10.3.3.3
  remote-as 65000 [n:internal]
  description PE3 []
  update-source Loopback0 [n:internal]
  address-family ipv4 unicast [n:internal]

RP/0/0/CPU0:router#show bgp nei 10.3.3.3
BGP neighbor is 10.3.3.3
  Remote AS 65000, local AS 65000, internal link
  Description: PE3
  Remote router ID 10.3.3.3
  BGP state = Established, up for 1w0d
  Last read 00:00:17, hold time is 180, keepalive interval is 60 seconds
  Precedence: internet
  Neighbor capabilities:
    Route refresh: advertised and received
    4-byte AS: advertised and received
    Address family IPv4 Unicast: advertised and received
  Received 25962 messages, 0 notifications, 0 in queue
  Sent 25968 messages, 1 notifications, 0 in queue
  Minimum time between advertisement runs is 0 seconds

For Address Family: IPv4 Unicast
  BGP neighbor version 1
  Update group: 0.3
  Route refresh request: received 0, sent 0
  0 accepted prefixes, 0 are bestpaths
  Prefix advertised 0, suppressed 0, withdrawn 0, maximum limit 524288
  Threshold for warning message 75%
  An EoR was received during read-only mode

Connections established 2; dropped 1
Last reset 1w0d, due to BGP Notification sent: hold time expired
Time since last notification sent to neighbor: 1w0d
Error Code: hold time expired
Notification data sent: None

RP/0/0/CPU0:router(config)#router bgp 65000
RP/0/0/CPU0:router(config-bgp)#neighbor 10.3.3.3
RP/0/0/CPU0:router(config-bgp-nbr)#capability suppress 4-byte-as
RP/0/0/CPU0:router(config-bgp-nbr)#commit
RP/0/0/CPU0:router(config-bgp-nbr)#end

RP/0/0/CPU0:router# show bgp nei 10.3.3.3

BGP neighbor is 10.3.3.3
  Remote AS 65000, local AS 65000, internal link
  Description: PE3
  Remote router ID 10.3.3.3
  BGP state = Established, up for 00:00:16
  Last read 00:00:11, hold time is 180, keepalive interval is 60 seconds
  Precedence: internet
  Neighbor capabilities:
    Route refresh: advertised and received
    Address family IPv4 Unicast: advertised and received
    Capability 4-byte-as suppress is configured
  Received 25966 messages, 0 notifications, 0 in queue
```

```
Sent 25972 messages, 1 notifications, 0 in queue
Minimum time between advertisement runs is 0 seconds
```

```
For Address Family: IPv4 Unicast
BGP neighbor version 1
Update group: 0.2
Route refresh request: received 0, sent 0
0 accepted prefixes, 0 are bestpaths
Prefix advertised 0, suppressed 0, withdrawn 0, maximum limit 524288
Threshold for warning message 75%
An EoR was received during read-only mode

Connections established 3; dropped 2
Last reset 00:00:43, due to Capabilty 4-byte-as configuration changed
Time since last notification sent to neighbor: 1w0d
Error Code: hold time expired
Notification data sent: None
```

With the **inheritance-disable** keyword:

```
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.101.1
RP/0/0/CPU0:router(config-bgp-nbr)# capability suppress 4-byte-as inheritance-disable

RP/0/0/CPU0:router# show bgp neighbor 10.0.101.1 config
neighbor 10.0.101.1
  remote-as 1 []
  address-family ipv4 unicast []

RP/0/0/CPU0:router# show bgp neighbor 10.0.101.1
BGP neighbor is 10.0.101.1
  Remote AS 1, local AS 100, external link
  Remote router ID 0.0.0.0
  BGP state = Idle
  Last read 00:00:00, hold time is 180, keepalive interval is 60 seconds
  Precedence: internet
  Received 0 messages, 0 notifications, 0 in queue
  Sent 0 messages, 0 notifications, 0 in queue
  Minimum time between advertisement runs is 30 seconds
```

# clear bgp

To reset a group of Border Gateway Protocol (BGP) neighbors, use the **clear bgp** command in EXEC mode.

```
clear bgp [ipv4 {unicast| multicast| labeled-unicast| all| tunnel| mdt}| ipv6 {unicast| multicast| all|
labeled-unicast}| all {unicast| multicast| all| labeled-unicast| mdt| tunnel}| vpnv4 unicast| vrf {vrf-name|
all} {ipv4 {unicast| labeled-unicast}| ipv6 unicast}| vpnv6 unicast]
```

## Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies IPv4 multicast distribution tree (MDT) address prefixes.       |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF).                              |
| <i>vrf-name</i>                           | Name of a VRF.                                                                      |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast and labeled-unicast address families.    |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address prefixes.                        |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address prefixes.                                |

| Release 3.5.0 | <p>The following keywords were added:</p> <ul style="list-style-type: none"> <li>• <b>tunnel</b></li> <li>• <b>mdt</b></li> <li>• <b>ipv6 unicast</b></li> <li>• <b>vpn6 unicast</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported for <b>ipv6</b> and <b>all</b> address families.</p>                                                                                                                      |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear bgp** command to reset the sessions of the specified group of neighbors (hard reset); it removes the TCP connection to the neighbor, removes all routes received from the neighbor from the BGP table, and then re-establishes the session with the neighbor.

If the **graceful** keyword is specified, the routes from the neighbor are not removed from the BGP table immediately, but are marked as stale. After the session is re-established, any stale route that has not been received again from the neighbor is removed.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

### Examples

The following example shows how to hard reset neighbor 10.0.0.1:

```
RP/0/0/CPU0:router# clear bgp 10.0.0.1
```

### Related Commands

| Command                                                | Description                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------|
| <a href="#">clear bgp self-originated, on page 130</a> | Clears self-originated routes.                                       |
| <a href="#">clear bgp soft, on page 135</a>            | Soft resets a group of BGP neighbors.                                |
| <a href="#">show bgp, on page 265</a>                  | Displays entries in the BGP routing table.                           |
| <a href="#">show bgp neighbors, on page 346</a>        | Displays information about the TCP and BGP connections to neighbors. |

# clear bgp dampening

To clear Border Gateway Protocol (BGP) route dampening information and unsuppress the suppressed routes, use the **clear bgp dampening** command in EXEC mode.

**clear bgp dampening**

## Syntax Description

|                                           |                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------|
| <b>ipv4</b>                               | Specifies IP Version 4 address prefixes.                                         |
| <b>unicast</b>                            | Specifies unicast address prefixes.                                              |
| <b>multicast</b>                          | Specifies multicast address prefixes.                                            |
| <b>labeled-unicast</b>                    | Specifies labeled unicast address prefixes.                                      |
| <b>all</b>                                | For subaddress families, specifies prefixes for all subaddress families.         |
| <b>ipv6</b>                               | Specifies IP Version 6 address prefixes.                                         |
| <b>all</b>                                | For address family, specifies prefixes for all address families.                 |
| <b>vpn4 unicast</b>                       | Specifies VPNv4 unicast address families.                                        |
| <b>vrf</b>                                | Specifies VPN routing and forwarding (VRF).                                      |
| <i>vrf-name</i>                           | Name of a VRF.                                                                   |
| <b>all</b>                                | For VRF, specifies all VRFs.                                                     |
| <b>ipv4 { unicast   labeled-unicast }</b> | For VRF, specifies IPv4 unicast and labeled-unicast address families.            |
| <b>ipv6 unicast</b>                       | For VRF, specifies IPv6 unicast address families.                                |
| <b>vpn6 unicast</b>                       | Specifies VPNv6 unicast address families.                                        |
| <i>ip-address</i>                         | (Optional) IP address of the network about which to clear dampening information. |
| <i>/mask-length</i>                       | (Optional) Network mask applied to the IP address.                               |

## Command Default

If no IP address is specified, dampening information for all routes is cleared.

## Command Modes

EXEC

**Command History**

| Release       | Modification                                                                                                                                                                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                        |
| Release 3.3.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vpn4 unicast</b></li> <li>• <b>vrf</b></li> <li>• <i>vrf-name</i></li> <li>• <b>all</b></li> <li>• <b>ipv4 { unicast   labeled-unicast }</b></li> </ul> |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                   |
| Release 3.5.0 | The following keywords were added: <ul style="list-style-type: none"> <li>• <b>ipv6 unicast</b></li> <li>• <b>vpn6 unicast</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported for <b>ipv6</b> and <b>all</b> address families.</p>  |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Always use the **clear bgp dampening** command for an individual address-family. The **all** option for address-families with clear bgp dampening should never be used during normal functioning of the system.

For example, use

```
clear bgp ipv4 unicast dampening prefix x.x.x./y
```

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

**Examples**

The following example shows how to clear the route dampening information for all 172.20.0.0/16 IPv4 multicast paths:

```
RP/0/0/CPU0:router# clear bgp ipv4 multicast dampening 172.20.0.0/16
```

|------------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">bgp dampening, on page 71</a>            | Enables BGP route dampening or changes various BGP route dampening factors. |
| <a href="#">show bgp dampened-paths, on page 322</a> | Displays BGP dampened routes.                                               |

# clear bgp external

To clear all Border Gateway Protocol (BGP) external peers, use the **clear bgp external** command in EXEC mode.

## clear bgp external

### Syntax Description

|                                           |                                                                                                                                                  |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                                                                              |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                                                                                   |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                                                                                 |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                                                                                           |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families.                                                              |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                                                                              |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.                                                                      |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                                                                             |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF).                                                                                           |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                                                                                        |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                                                                                          |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.                                                                  |
| ipv6 unicast                              | (Optional) For VRF, specifies IPv6 unicast address families.                                                                                     |
| vpn6 unicast                              | (Optional) Specifies VPNv6 unicast address families.                                                                                             |
| graceful                                  | (Optional) Clears all external peers with a hard reset and a graceful restart. This option is available when an address family is not specified. |

### Command Default

No default behavior or value

### Command Modes

EXEC

**Command History**

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.5.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

**Examples**

The following example shows how to clear all BGP external peers:

```
RP/0/0/CPU0:router# clear bgp external
```

## clear bgp flap-statistics

To clear Border Gateway Protocol (BGP) flap counts for a specified group of routes, use the **clear bgp flap-statistics** command in EXEC mode.

**clear bgp flap-statistics**

### Syntax Description

|                                              |                                                                                                  |
|----------------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                                  | Specifies IP Version 4 address prefixes.                                                         |
| <b>unicast</b>                               | Specifies unicast address prefixes.                                                              |
| <b>multicast</b>                             | Specifies multicast address prefixes.                                                            |
| <b>labeled-unicast</b>                       | Specifies labeled unicast address prefixes.                                                      |
| <b>all</b>                                   | For subaddress families, specifies prefixes for all subaddress families.                         |
| <b>ipv6</b>                                  | Specifies IP Version 6 address prefixes.                                                         |
| <b>all</b>                                   | For address family, specifies prefixes for all address families.                                 |
| <b>vpn4 unicast</b>                          | Specifies VPNv4 unicast address families.                                                        |
| <b>vrf</b>                                   | Specifies VPN routing and forwarding (VRF).                                                      |
| <i>vrf-name</i>                              | Name of a VRF.                                                                                   |
| <b>all</b>                                   | For VRF, specifies all VRFs.                                                                     |
| <b>ipv4 { unicast   labeled-unicast }</b>    | For VRF, specifies IPv4 unicast or labeled-unicast address families.                             |
| <b>ipv6 unicast</b>                          | For VRF, specifies IPv6 unicast address families.                                                |
| <b>vpn6 unicast</b>                          | Specifies VPNv6 unicast address families.                                                        |
| <b>regex</b> <i>regex</i>                    | (Optional) Clears flap statistics for routes whose AS paths match the regular expression.        |
| <b>route-policy</b> <i>route-policy-name</i> | (Optional) Clears flap statistics for the specific route policy.                                 |
| <i>network</i>                               | (Optional) Network for which flap counts are to be cleared.                                      |
| <i>/mask-length</i>                          | (Optional) Network mask of the network for which flap counts are to be cleared.                  |
| <i>ip-address</i>                            | (Optional) Neighbor address. Clears only flap statistics for routes received from this neighbor. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | bgp     | execute    |

## Examples

The following example shows how to clear the flap count for all routes (in all address families) originating in autonomous system 1:

```
RP/0/0/CPU0:router#clear bgp all all flap-statistics regexp _1$
```

The following example shows how to clear the flap count for all IPv4 unicast routes received from neighbor 172.20.1.1:

```
RP/0/0/CPU0:router# clear bgp ipv4 unicast flap-statistics 172.20.1.1
```

# clear bgp nexthop performance-statistics

To reset the number of received notifications and the cumulative processing time for the Border Gateway Protocol (BGP) next hop, use the **clear bgp nexthop performance-statistics** command in EXEC mode.

**clear bgp {ipv4 {unicast | multicast | labeled-unicast | all | tunnel | mdt} | ipv6 {unicast | multicast | all | labeled-unicast} | all {unicast | multicast | all | labeled-unicast | mdt | tunnel} | vpnv4 unicast | vrf {vrf-name | all} {ipv4 {unicast | labeled-unicast} | ipv6 unicast} vpnv6 unicast} nexthop performance-statistics**

## Syntax Description

|                                           |                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------|
| <b>ipv4</b>                               | Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | Specifies IPv4 multicast distribution tree (MDT) address prefixes.       |
| <b>ipv6</b>                               | Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | Specifies VPN routing and forwarding (VRF).                              |
| <i>vrf-name</i>                           | Name of a VRF.                                                           |
| <b>all</b>                                | For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | Specifies VPNv6 unicast address families.                                |

|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.4.0 | This command was introduced.                                                                                                                                                                                                                                                                             |
| Release 3.5.0 | <p>The following keywords were added:</p> <ul style="list-style-type: none"> <li>• <b>tunnel</b></li> <li>• <b>mdt</b></li> <li>• <b>ipv6 unicast</b></li> <li>• <b>vpn6 unicast</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported for <b>ipv6</b> and <b>all</b> address families.</p> |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear bgp nexthop performance-statistics** command to reset the total number of notifications received from the Routing Information Base (RIB) and the cumulative next-hop processing time. The following information is cleared from the **show bgp nexthops** command output:

- Total critical notifications received
- Total noncritical notifications received
- Best path deleted after last walk
- Best path changed after last walk
- Next-hop table total number of critical and noncritical notifications (Notf) and the time of the last notification received from the RIB (LastRIB) columns (only entries that have a status of unreachable [UR])

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

**Examples**

The following example shows how to clear next-hop performance statistics:

```
RP/0/0/CPU0:router# clear bgp vrf vrf_A nexthop performance statistics
```

| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

## Examples

The following example shows how to clear the performance statistics for all address families:

```
RP/0/0/CPU0:router# clear bgp performance-statistics
```

# clear bgp self-originated

To clear Border Gateway Protocol (BGP) routes that are self-originated, use the **clear bgp self-originated** command in EXEC mode.

**clear bgp** {**ipv4**{**unicast** | **multicast** | **labeled-unicast** | **all**} | **ipv6** {**unicast** | **multicast** | **labeled-unicast** | **all**} | **all** {**unicast** | **multicast** | **labeled-unicast** | **all**} | **vpnv4 unicast** | **vrf** {*vrf-name* | **all**} | **vpnv6 unicast**} **self-originated**

## Syntax Description

|                                           |                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------|
| <b>ipv4</b>                               | Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | For subaddress families, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                               | Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | Specifies VPN routing and forwarding (VRF).                              |
| <i>vrf-name</i>                           | Name of a VRF.                                                           |
| <b>all</b>                                | For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | Specifies VPNv6 unicast address families.                                |

| Release 3.5.0 | <p>The following keywords were added:</p> <ul style="list-style-type: none"> <li>• <b>ipv6 unicast</b></li> <li>• <b>vpn6 unicast</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported for <b>ipv6</b> and <b>all</b> address families.</p> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Self-originated routes are routes locally originated by the **network** command, **redistribute** command, or **aggregate-address** command.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

### Examples

The following example shows how to clear self-originated IPv4 routes:

```
RP/0/0/CPU0:router# clear bgp ipv4 unicast self-originated
```

### Related Commands

| Command                                        | Description                                                                                             |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">aggregate-address</a> , on page 27 | Creates an aggregate entry in a BGP routing table.                                                      |
| <a href="#">network (BGP)</a> , on page 191    | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |

| Command                                          | Description                                                  |
|--------------------------------------------------|--------------------------------------------------------------|
| <a href="#">redistribute (BGP)</a> , on page 225 | Redistributes routes from another routing protocol into BGP. |

# clear bgp shutdown

To clear all Border Gateway Protocol (BGP) neighbors that shut down due to low memory, use the **clear bgp shutdown** command in EXEC mode.

**clear bgp** {**ipv4**{**unicast** | **multicast** | **labeled-unicast** | **all**} | **ipv6** {**unicast** | **multicast** | **labeled-unicast** | **all**} } | **all** {**unicast** | **multicast** | **labeled-unicast** | **all**} | **vpnv4 unicast** | **vrf** {*vrf-name* | **all**} | **vpnv6 unicast**} **shutdown**

## Syntax Description

|                                           |                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------|
| <b>ipv4</b>                               | Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | For subaddress families, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                               | Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | Specifies VPN routing and forwarding (VRF).                              |
| <i>vrf-name</i>                           | Name of a VRF.                                                           |
| <b>all</b>                                | For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | Specifies VPNv6 unicast address families.                                |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

**Examples**

The following example shows how to clear all shut-down BGP neighbors:

```
RP/0/0/CPU0:router# clear bgp shutdown
```

**Related Commands**

| Command                                         | Description                                                          |
|-------------------------------------------------|----------------------------------------------------------------------|
| <a href="#">show bgp, on page 265</a>           | Displays entries in the BGP routing table.                           |
| <a href="#">show bgp neighbors, on page 346</a> | Displays information about the TCP and BGP connections to neighbors. |

# clear bgp soft

To soft reset a group of Border Gateway Protocol (BGP) neighbors, use the **clear bgp soft** command in EXEC mode.

```
clear bgp {ipv4{unicast | multicast | labeled-unicast | all | tunnel | mdt} | ipv6 {unicast | multicast |
labeled-unicast | all } | all {unicast | multicast | labeled-unicast | all | tunnel | mdt} | vpnv4 unicast | vrf
{vrf-name | all} | vpnv6 unicast} {* | ip-address | as| as-number | external}soft[[in| {prefix-filter} | out]]
```

## Syntax Description

|                                           |                                                                                                                                                      |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | Specifies IP Version 4 address prefixes.                                                                                                             |
| <b>unicast</b>                            | Specifies unicast address prefixes.                                                                                                                  |
| <b>multicast</b>                          | Specifies multicast address prefixes.                                                                                                                |
| <b>labeled-unicast</b>                    | Specifies labeled unicast address prefixes.                                                                                                          |
| <b>all</b>                                | For subaddress families, specifies prefixes for all subaddress families.                                                                             |
| <b>tunnel</b>                             | Specifies tunnel address prefixes.                                                                                                                   |
| <b>mdt</b>                                | Specifies IPv4 multicast distribution tree (MDT) address prefixes.                                                                                   |
| <b>ipv6</b>                               | Specifies IP Version 6 address prefixes.                                                                                                             |
| <b>all</b>                                | For address family, specifies prefixes for all address families.                                                                                     |
| <b>vpnv4 unicast</b>                      | Specifies VPNv4 unicast address families.                                                                                                            |
| <b>vrf</b>                                | Specifies VPN routing and forwarding (VRF).                                                                                                          |
| <i>vrf-name</i>                           | Name of a VRF.                                                                                                                                       |
| <b>all</b>                                | For VRF, specifies all VRFs.                                                                                                                         |
| <b>ipv4 { unicast   labeled-unicast }</b> | For VRF, specifies IPv4 unicast or labeled-unicast address families.                                                                                 |
| <b>ipv6 unicast</b>                       | For VRF, specifies IPv6 unicast address families.                                                                                                    |
| <b>vpnv6 unicast</b>                      | Specifies VPNv6 unicast address families.                                                                                                            |
| <b>*</b>                                  | Soft resets all BGP neighbors.                                                                                                                       |
| <i>ip-address</i>                         | IP address of the neighbor to be reset.                                                                                                              |
| <b>as as-number</b>                       | Autonomous system (AS) number for all neighbors to be reset. Range for 2-byte numbers is 1 to 65535. Range for 4-byte numbers is 1.0 to 65535.65535. |

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>external</b>      | Specifies clearing of all external peers.                                                                                                                 |
| <b>in</b>            | (Optional) Triggers an inbound soft reset. If the <b>in</b> or <b>out</b> keyword is not specified, both inbound and outbound soft resets are triggered.  |
| <b>prefix-filter</b> | (Optional) Specifies to send a new Outbound Route Filter (ORF) to the neighbor. Neighbor installs the new ORF and resends its routes.                     |
| <b>out</b>           | (Optional) Triggers an outbound soft reset. If the <b>in</b> or <b>out</b> keyword is not specified, both inbound and outbound soft resets are triggered. |

**Command Default** No default behavior or value

**Command Modes** EXEC

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>                                                                                                                                                                                                                                                          |
|------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | Release 3.2    | This command was introduced.                                                                                                                                                                                                                                                 |
|                        | Release 3.3.0  | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vpnv4 unicast</b></li> <li>• <b>vrf</b></li> <li>• <i>vrf-name</i></li> <li>• <b>all</b></li> <li>• <b>ipv4 { unicast   labeled-unicast }</b></li> </ul>                         |
|                        | Release 3.4.0  | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.<br>The <b>labeled-unicast</b> keyword was supported.                                                                                                                                              |
|                        | Release 3.5.0  | The following keywords were added: <ul style="list-style-type: none"> <li>• <b>tunnel</b></li> <li>• <b>ipv6 unicast</b></li> <li>• <b>vpnv6 unicast</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported for <b>ipv6</b> and <b>all</b> address families.</p> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear bgp soft** command to trigger a soft reset of the specified address families for the specified group of neighbors. This command is useful if you change the inbound or outbound policy for the neighbors, or any other configuration that affects the sending or receiving of routing updates.

If an outbound soft reset is triggered, BGP resends all routes for the address family to the given neighbors.

If an inbound soft reset is triggered, BGP by default sends a REFRESH request to the neighbor, if the neighbor has advertised the ROUTE\_REFRESH capability. To determine whether the neighbor has advertised the ROUTE\_REFRESH capability, use the **show bgp neighbors** command, and look for the following line of output:

```
Received route refresh capability from peer.
```

If the neighbor does not support route refresh, but the **soft-reconfiguration inbound** command is configured for the neighbor, then BGP uses the routes cached as a result of the **soft-reconfiguration inbound** command to perform the soft reset.

If you want BGP to use the cached routes even if the neighbor supports route refresh, you can use the **always** keyword when configuring the **soft-reconfiguration inbound** command.

If the neighbor does not support route refresh and the **soft-reconfiguration inbound** command is not configured, then inbound soft reset is not possible. In this case, an error is printed.

#### Note

By default, if the configuration for an inbound or outbound route policy is changed, BGP performs an automatic soft reset. Use the **bgp auto-policy-soft-reset disable** command to disable this behavior.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | execute    |

### Examples

The following example shows how to trigger an inbound soft clear for IPv4 unicast routes received from neighbor 10.0.0.1:

```
RP/0/RP0/CPU0:router# clear bgp ipv4 unicast 10.0.0.1 soft in
```

## default-information originate (BGP)

To allow origination of a default route to be redistributed into the Border Gateway Protocol (BGP) from another protocol, use the **default-information originate** command in an appropriate configuration mode. To disable this function, use the **no** form of this command.

**default-information originate**

**no default-information originate**

**Syntax Description** This command has no arguments or keywords.

**Command Default** BGP does not permit redistribution of a default route into BGP.

**Command Modes** Router configuration  
VRF configuration

| Command History | Release       | Modification                                          |
|-----------------|---------------|-------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                          |
|                 | Release 3.3.0 | This command was supported in VRF configuration mode. |
|                 |               |                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **redistribute** command to redistribute routes from another protocol into BGP. By default, if these routes include the default route (0.0.0.0/0 for IPv4 or ::/0 for IPv6), the default route is ignored. Use the **default-information originate** command to change this behavior so that the default route is not ignored and is redistributed into BGP along with the other routes for the protocol being redistributed.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows how to configure BGP to redistribute the default route into BGP:

```
RP/0/0/CPU0:router(config)#router bgp 164  
RP/0/0/CPU0:router(config-bgp)# default-information originate
```

**Related Commands**

# default-metric (BGP)

To set default metric values for the Border Gateway Protocol (BGP), use the **default-metric** command in an appropriate configuration mode. To disable metric values, use the **no** form of this command.

**default-metric** *value*

**no default-metric** [*value*]

## Syntax Description

|              |                                                                                                |
|--------------|------------------------------------------------------------------------------------------------|
| <i>value</i> | Default metric value appropriate for the specified routing protocol. Range is 1 to 4294967295. |
|--------------|------------------------------------------------------------------------------------------------|

## Command Default

A metric is not set.

## Command Modes

Router configuration  
VRF configuration

## Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was supported in VRF configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-metric** command to set the Multi Exit Discriminator (MED) to advertise to peers for routes that do not already have a metric set (routes that were received with no MED attribute).

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to set the BGP default metric:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# default-metric 10
```

# default-originate

To cause a Border Gateway Protocol (BGP) speaker (the local router) to send the default route 0.0.0.0/0 to a neighbor for use as a default route, use the **default-originate** command in an appropriate configuration mode. To disable this function, use the **no** form of this command.

**default-originate** [**inheritance-disable**| **route-policy** *route-policy-name*]

**no default-originate** [**inheritance-disable**| **route-policy** *route-policy-name*]

## Syntax Description

|                                              |                                                                                                                                                        |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b>                   | (Optional) Prevents the <b>default-originate</b> command characteristics from being inherited from a parent group.                                     |
| <b>route-policy</b> <i>route-policy-name</i> | (Optional) Specifies the name of a route policy. The route policy allows route 0.0.0.0 to be injected conditionally. IPv6 address family is supported. |

## Command Default

The default route is not advertised to BGP neighbors.

## Command Modes

IPv4 neighbor address family configuration  
 IPv6 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 IPv4 address family group configuration  
 IPv6 address family group configuration  
 VRF IPv4 neighbor address family configuration  
 VRF IPv6 neighbor address family configuration

## Command History

| Release       | Modification                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.               |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **default-originate** command does not require the presence of the default route (0.0.0.0/0 for IPv4 or ::/0 for IPv6) in the local router. When the **default-originate** command is used with a route policy, the default route is advertised if any route in the BGP table matches the policy.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to unconditionally advertise the route 0.0.0.0/0 to the neighbor 172.20.2.3:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.2.3
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 200
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# default-originate
```

The following example shows how to advertise the route 0.0.0.0/0 to the neighbor 172.20.2.3 only if a route exists in the BGP table that matches the route policy called default-default-policy:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.2.3
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 200
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# default-originate route-policy default-default-policy
```

**Related Commands**

## description (BGP)

To annotate a neighbor, neighbor group, VPN routing and forwarding (VRF) neighbor, or session group, use the **description** command in an appropriate configuration mode. To remove the annotation, use the **no** form of this command.

**description** *text*

**no description** [*text*]

### Syntax Description

|             |                                                              |
|-------------|--------------------------------------------------------------|
| <i>text</i> | Meaningful description or comment. Maximum of 80 characters. |
|-------------|--------------------------------------------------------------|

### Command Default

No comment or description exists.

### Command Modes

Neighbor group configuration

Neighbor configuration

Session group configuration

VRF neighbor configuration

### Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **description** command to provide a description of a neighbor, neighbor group, VRF neighbor, or session group. The description is used to save user comments and does not affect software function.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure the description “Our best customer” on the neighbor 192.168.13.4:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)#router bgp 65000
RP/0/0/CPU0:router(config-bgp)#neighbor 192.168.13.4
RP/0/0/CPU0:router(config-bgp-nbr)#description Our best customer
```

# distance bgp

To allow the use of external, internal, and local administrative distances that could be used to prefer one class of routes over another, use the **distance bgp** command in an appropriate configuration mode. To disable the use of administrative distances, use the **no** form of this command.

**distance bgp** *external-distance internal-distance local-distance*

**no distance bgp** [*external-distance internal-distance local-distance*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>external-distance</i> | Administrative distance for Border Gateway Protocol (BGP) external routes. External routes are routes for which the best path is learned from a neighbor external to the autonomous system. Range is 1 to 255. Routes with a distance of 255 are not installed in the routing table.                                                               |
| <i>internal-distance</i> | Administrative distance for BGP internal routes. Internal routes are those routes that are learned from another BGP entity within the same autonomous system. Range is 1 to 255. Routes with a distance of 255 are not installed in the routing table.                                                                                             |
| <i>local-distance</i>    | Administrative distance for BGP local routes. The <i>local-distance</i> argument applies to locally generated aggregate routes (such as the routes generated by the <b>aggregate-address</b> command) and backdoor routes installed in the routing table. Range is 1 to 255. Routes with a distance of 255 are not installed in the routing table. |

## Command Default

*external-distance* : 20

*internal-distance* : 200

*local-distance* : 200

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was supported in VRF IPv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **distance bgp** command if another protocol is known to be able to provide a better route to a node than was actually learned using external BGP, or if some internal routes should be preferred by BGP.

**Note**

Changing the administrative distance of BGP internal routes is considered risky and is not recommended. One problem that can arise is the accumulation of routing table inconsistencies, which can interfere with routing.

An administrative distance is a rating of the trustworthiness of a routing information source. Numerically, an administrative distance is an integer from 1 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows that iBGP routes are preferable to locally generated routes, so the administrative distance values are set accordingly:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#distance bgp 20 20 200
```

**Related Commands**

| Command          | Description                                                                              |
|------------------|------------------------------------------------------------------------------------------|
| distance (IS-IS) | Defines the administrative distance assigned to routes discovered by the IS-IS protocol. |
| distance (OSPF)  | Defines OSPF route administrative distances based on route type.                         |

## dscp (BGP)

To set the differentiated services code point (DSCP) value, use the **dscp** command in the appropriate configuration mode. To remove the **dscp** command from the configuration file and restore the system to its default interval values, use the no form of this command.

**dscp** *value*

**no dscp** [*value*]

### Syntax Description

|              |                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | Value of the DSCP. The DSCP value can be a number from 0 to 63, or it can be one of the following keywords: <b>default</b> , <b>ef</b> , <b>af11</b> , <b>af12</b> , <b>af13</b> , <b>af21</b> , <b>af22</b> , <b>af23</b> , <b>af31</b> , <b>af32</b> , <b>af33</b> , <b>af41</b> , <b>af42</b> , <b>af43</b> , <b>cs1</b> , <b>cs2</b> , <b>cs3</b> , <b>cs4</b> , <b>cs5</b> , <b>cs6</b> , or <b>cs7</b> . |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

Neighbor configuration  
Neighbor session group configuration  
Neighbor group configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **dscp** command to change the minimum and maximum packet thresholds for the DSCP value.

[Table 2: dscp Default Settings](#), on page 148 lists the DSCP default settings used by the **dscp** command. The DSCP value, corresponding minimum threshold, maximum threshold, and mark probability are listed. The last row of the table (the row labeled "default") shows the default settings used for any DSCP value not specifically shown in the table.

**Table 2: dscp Default Settings**

| DSCP (Precedence) | Minimum Threshold | Maximum Threshold | Mark Probability |
|-------------------|-------------------|-------------------|------------------|
| af11              | 32                | 40                | 1/10             |
| af12              | 28                | 40                | 1/10             |

| DSCP (Precedence) | Minimum Threshold | Maximum Threshold | Mark Probability |
|-------------------|-------------------|-------------------|------------------|
| af13              | 24                | 40                | 1/10             |
| af21              | 32                | 40                | 1/10             |
| af22              | 28                | 40                | 1/10             |
| af23              | 24                | 40                | 1/10             |
| af31              | 32                | 40                | 1/10             |
| af32              | 28                | 40                | 1/10             |
| af33              | 24                | 40                | 1/10             |
| af41              | 32                | 40                | 1/10             |
| af42              | 28                | 40                | 1/10             |
| af43              | 24                | 40                | 1/10             |
| cs1               | 22                | 40                | 1/10             |
| cs1               | 24                | 40                | 1/10             |
| cs3               | 26                | 40                | 1/10             |
| cs4               | 28                | 40                | 1/10             |
| cs5               | 30                | 40                | 1/10             |
| cs6               | 32                | 40                | 1/10             |
| cs7               | 34                | 40                | 1/10             |
| ef                | 36                | 40                | 1/10             |
| default           | 20                | 40                | 1/10             |

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to set the DSCP value to af32:

```
RP/0/0/CPU0:router(config)# router bgp 5  
RP/0/0/CPU0:router(config-bgp)#neighbor 10.1.1.1  
RP/0/0/CPU0:router(config-bgp-nbr)#remote-as 100  
RP/0/0/CPU0:router(config-bgp-nbr)# dscp af32
```

# ebgp-multihop

To accept and attempt Border Gateway Protocol (BGP) connections to external peers residing on networks that are not directly connected, use the **ebgp-multihop** command in an appropriate configuration mode. To disable connections to external peers and allow only direct connections between neighbors, use the **no** form of this command.

**ebgp-multihop** [*ttl-value*] [**mpls**]

**no ebgp-multihop** [*ttl-value*] [**mpls**]

## Syntax Description

|                  |                                                              |
|------------------|--------------------------------------------------------------|
| <i>ttl-value</i> | (Optional) Time-to-live (TTL) value. Range is 1 to 255 hops. |
| <b>mpls</b>      | (Optional) Disables BGP label rewrite.                       |

## Command Default

Default TTL value is 255.

## Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |
| Release 4.0.0 | The <b>mpls</b> keyword was supported.                         |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **ebgp-multihop** command to enable multihop peerings with external BGP neighbors. The BGP protocol states that external neighbors must be directly connected (one hop away). The software enforces this by default; however, the **ebgp-multihop** command can be used to override this behavior.

Use of the **mpls** option in the **ebgp-multihop** command prevents BGP from enabling MPLS on the peering interface and also prevents allocation of Implicit-NULL rewrite labels for nexthop addresses learned from the peer. This is useful in some scenarios in which MPLS forwarding labels to the nexthops have already been learned via BGP labeled-unicast or LDP.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to allow a BGP connection to neighbor 172.20.16.6 of up to 255 hops away:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.16.6
RP/0/0/CPU0:router(config-bgp-nbr)# ebgp-multihop
```

### Related Commands

| Command                                     | Description                                                            |
|---------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a> | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.   |

# enforce-first-as

To enable the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, use the **enforce-first-as** command in an appropriate configuration mode. To disable enforcing the first autonomous system in the AS path of a route received from an eBGP peer to be the same as the remote autonomous system, use the **no** form of this command.

**enforce-first-as**

**no enforce-first-as**

**Syntax Description** This command has no arguments or keywords.

**Command Default** By default, the software requires the first autonomous system (in the AS path) of a route received from an eBGP peer to be the same as the remote autonomous system configured.

**Command Modes**

- Neighbor configuration
- Neighbor group configuration
- Session group configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the software ignores any update received from an eBGP neighbor that does not have the autonomous system configured for that neighbor at the beginning of the AS path. When configured, the command applies to all eBGP peers under the neighbor, neighbor group or session group.

At any given time, either the **enforce-first-as** command or the [enforce-first-as-disable](#), on page 155 command can be configured under a given neighbor, neighbor group or session group. Configuring one command overwrites the other command.

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows a configuration in which incoming updates from eBGP neighbors are checked to ensure the first AS number in the AS path is the same as the configured AS number for the neighbor:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# neighbor 10.2.3.4
RP/0/0/CPU0:router(config-bgp-nbr)# enforce-first-as
```

## Related Commands

|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">bgp enforce-first-as disable, on page 75</a> | Disables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, in router configuration mode and VRF configuration mode.                                                 |
| <a href="#">enforce-first-as-disable, on page 155</a>    | Disables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, in neighbor configuration mode, neighbor group configuration mode, and session group configuration mode. |

# enforce-first-as-disable

To disable the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, use the **enforce-first-as-disable** command in an appropriate configuration mode. To re-enable enforcing first autonomous system in the AS path of a route received from an eBGP peer to be the same as the remote autonomous system, use the **no** form of this command.

**enforce-first-as-disable**

**no enforce-first-as-disable**

**Syntax Description** This command has no arguments or keywords.

**Command Default** By default, the software requires the first autonomous system (in the AS path) of a route received from an eBGP peer to be the same as the remote autonomous system configured.

**Command Modes**

- Neighbor configuration
- Neighbor group configuration
- Session group configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

By default, the software ignores any update received from an eBGP neighbor that does not have the autonomous system configured for that neighbor at the beginning of the AS path. When configured, the command applies to all eBGP peers under the neighbor, neighbor-group or session-group.

At any given time, either the **enforce-first-as-disable** command or the [enforce-first-as](#), on page 153 command can be configured under a given neighbor, neighbor group or session group. Configuring one command overwrites the other command.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

## Examples

The following example shows a configuration in which incoming updates from eBGP neighbors are not checked to ensure the first AS number in the AS path is the same as the configured AS number for the neighbor:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# neighbor 10.2.3.4
RP/0/0/CPU0:router(config-bgp-nbr)# enforce-first-as-disable
```

|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">bgp enforce-first-as disable, on page 75</a> | Disables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, in router configuration mode and VRF configuration mode.                                                   |
| <a href="#">enforce-first-as, on page 153</a>            | Enables the software to enforce the first autonomous system in the AS path of a route received from an external Border Gateway Protocol (eBGP) peer to be the same as the configured remote autonomous system, under neighbor configuration mode, neighbor group configuration mode, and session group configuration mode. |

# export route-policy

To configure an export route policy, use the **export route-policy** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**export route-policy** *policy-name*

**no export route-policy** [*policy-name*]

## Syntax Description

|                    |                                      |
|--------------------|--------------------------------------|
| <i>policy-name</i> | Name of the configured route policy. |
|--------------------|--------------------------------------|

## Command Default

No default behavior or values

## Command Modes

Global VRF IPv4 address family configuration  
Global VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                                     |
|---------------|----------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                     |
| Release 3.5.0 | This command was supported in global VRF IPv6 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **export route-policy** command to define the conditions that allow specified routes to be tagged with specified route-targets.

## Task ID

| Task ID     | Operations  |
|-------------|-------------|
| bgp         | read, write |
| ip-services | read, write |

## Examples

The following example shows how to configure an export route policy:

```
RP/0/0/CPU0:router(config)# vrf vrf-1
```

```
RP/0/0/CPU0:router(config-vrf)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-vrf-af)# export route-policy policy-A
```

**Related Commands**

| Command                                          | Description                                                      |
|--------------------------------------------------|------------------------------------------------------------------|
| <a href="#">import route-policy, on page 162</a> | Specifies a route policy to import routes into the VRF instance. |

## export route-target

To configure a VPN routing and forwarding (VRF) export route-target extended community, use the **export route-target** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**export route-target** [*as-number:nn* | *ip-address:nn*]

**no export route-target** [*as-number:nn* | *ip-address:nn*]

### Syntax Description

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number:nn</i>  | (Optional) <i>as-number</i> —Autonomous system (AS) number of the route-target extended community. <ul style="list-style-type: none"> <li>• <i>as-number</i> <ul style="list-style-type: none"> <li>◦ Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> </li> <li>• <i>nn</i>—32-bit number</li> </ul> |
| <i>ip-address:nn</i> | (Optional) IP address of the route-target extended community. <ul style="list-style-type: none"> <li>• <i>ip-address</i>—32-bit IP address</li> <li>• <i>nn</i>—16-bit number</li> </ul>                                                                                                                                                                                                                                                                                                                                                |

### Command Default

No default behavior or values

### Command Modes

Global VRF IPv4 address family configuration  
Global VRF IPv6 address family configuration

### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Export route-target extended communities are associated with prefixes when advertised to remote provider edge (PE) routers. The remote PE routers import the route-target extended communities into a VRF instance that has the import route-targets that match the exported route-target extended communities.

To specify multiple route targets, enter export route target configuration mode then enter one route target for each command line.

**Task ID**

| Task ID     | Operations  |
|-------------|-------------|
| bgp         | read, write |
| ip-services | read, write |

**Examples**

The following example shows how to specify an export route-target:

```
RP/0/0/CPU0:router(config)# vrf vrf-1
RP/0/0/CPU0:router(config-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-vrf-af)# export route-target 500:1
```

**Related Commands**

| Command                                          | Description                        |
|--------------------------------------------------|------------------------------------|
| <a href="#">import route-target, on page 164</a> | Specifies the import route-target. |

# ibgp policy out enforce-modifications

To allow an outbound route policy for an internal BGP (iBGP) peer to modify all BGP route attributes, only when an iBGP route is sent to another iBGP peer (only on route-reflectors), use the **ibgp policy out enforce-modifications** command in router configuration mode. To disable this feature, use the **no** form of this command.

**ibgp policy out enforce-modifications**

**no ibgp policy out enforce-modifications**

**Syntax Description** This command has no arguments or keywords.

**Command Default** ibgp policy out enforce-modifications is disabled.

**Command Modes** Router configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **ibgp policy out enforce-modifications** command to set and modify BGP route attributes for updates to iBGP peers.

If the **ibgp policy out enforce-modifications** command is configured under router BGP configuration, then all the changes made by the outbound policy for an iBGP peer will be present in an update message sent to the peer.

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples** The following example shows how to set the ibgp policy out enforce-modifications:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 6500
RP/0/0/CPU0:router(config-bgp)# ibgp policy out enforce-modifications
```

# import route-policy

To configure an import route policy, use the **import route-policy** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**import route-policy** *policy-name*

**no import route-policy** [*policy-name*]

## Syntax Description

|                    |                                      |
|--------------------|--------------------------------------|
| <i>policy-name</i> | Name of the configured route policy. |
|--------------------|--------------------------------------|

## Command Default

No default behavior or values

## Command Modes

Global VRF IPv4 address family configuration  
Global VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                                     |
|---------------|----------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                     |
| Release 3.5.0 | This command was supported in global VRF IPv6 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **import route-policy** command to define the conditions that allow specified routes to be imported into the VPN routing and forwarding (VRF) instance if the routes are tagged with specified route-targets.

## Task ID

| Task ID     | Operations  |
|-------------|-------------|
| bgp         | read, write |
| ip-services | read, write |

## Examples

The following example shows how to allow only policy-B to be imported to VRF:

```
RP/0/0/CPU0:router(config)# vrf vrf-1
```

```
RP/0/0/CPU0:router(config-vrf)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-vrf-af)# import route-policy policy-B
```

**Related Commands**

| Command                                          | Description                                                      |
|--------------------------------------------------|------------------------------------------------------------------|
| <a href="#">export route-policy, on page 157</a> | Specifies a route policy to export routes from the VRF instance. |

# import route-target

To configure a VPN routing and forwarding (VRF) import route-target extended community, use the **import route-target** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**import route-target** [*as-number:nn* | *ip-address:nn*]

**noimport route-target** [*as-number:nn* | *ip-address:nn*]

## Syntax Description

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number:nn</i>  | (Optional) Autonomous system (AS) number of the route-target extended community. <ul style="list-style-type: none"> <li>• <i>as-number</i> <ul style="list-style-type: none"> <li>◦ Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> </li> <li>• <i>nn</i> —32-bit number</li> </ul> |
| <i>ip-address:nn</i> | (Optional) IP address of the route-target extended community. <ul style="list-style-type: none"> <li>• <i>ip-address</i> —32-bit IP address</li> <li>• <i>nn</i> —16-bit number</li> </ul>                                                                                                                                                                                                                                                                                                                             |

## Command Default

No default behavior or values

## Command Modes

Global VRF IPv4 address family configuration

Global VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **import route-target** command to specify that prefixes associated with the configured import route-target extended communities are imported into the VRF instance.

To specify multiple route targets, enter import route target configuration mode, then enter one route target for each command line.

### Task ID

| Task ID     | Operations  |
|-------------|-------------|
| bgp         | read, write |
| ip-services | read, write |

### Examples

The following example shows how to specify an import route-target:

```
RP/0/0/CPU0:router(config)#vrf vrf-1
RP/0/0/CPU0:router(config-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-vrf-af)# import route-target 500:99
```

### Related Commands

| Command                                          | Description                        |
|--------------------------------------------------|------------------------------------|
| <a href="#">export route-target, on page 159</a> | Specifies the export route-target. |

# ignore-connected-check

To enable the software to bypass the directly connected next hop check for single-hop eBGP peering, use the **ignore-connected-check** command in an appropriate configuration mode. To re-enable the directly connected next hop check, use the **no** form of this command.

**ignore-connected-check** [**inheritance-disable**]

**no ignore-connected-check**

## Syntax Description

|                     |                                                                                          |
|---------------------|------------------------------------------------------------------------------------------|
| inheritance-disable | Prevents the <b>ignore-connected-check</b> command from being inherited from the parent. |
|---------------------|------------------------------------------------------------------------------------------|

## Command Default

Ability to bypass the directly connected next hop check is disabled.

## Command Modes

Neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.8.0 | This command was introduced.                                                         |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to enable ignore-connected check configuration for neighbor 10.2.3.4:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# neighbor 10.2.3.4
```

```
RP/0/0/CPU0:router(config-bgp-nbr)# ignore-connected-check
```

# keychain

To apply key chain-based authentication on a TCP connection between two Border Gateway Protocol (BGP) neighbors, use the **keychain** command in an appropriate configuration mode. To disable key chain authentication, use the **no** form of this command.

**keychain** *name*

**no keychain** [*name*]

## Syntax Description

|             |                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| <i>name</i> | Key chain name configured using the <b>keychain</b> command. The name must be a maximum of 32 alphanumeric characters. |
|-------------|------------------------------------------------------------------------------------------------------------------------|

## Command Default

When this command is not specified in the appropriate configuration mode, key chain authentication is not enabled on a TCP connection between two BGP neighbors.

## Command Modes

Neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Specify a key chain to enable key chain authentication between two BGP peers. Use the **keychain** command to implement hitless key rollover for authentication.

If this command is configured for a neighbor group or a session group, a neighbor using the group inherits the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Note

BGP only supports HMAC-MD5 and HMAC-SHA1-12 cryptographic algorithms.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure neighbor 172.20.1.1 to use the key chain authentication configured in the keychain\_A key chain:

```
RP/0/0/CPU0:router(config)# router bgp 140  
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1  
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1  
RP/0/0/CPU0:router(config-bgp-nbr)# keychain keychain_A
```

## Related Commands

| Command                                        | Description                                                                                              |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">keychain-disable</a> , on page 170 | Overrides any inherited keychain configuration from a neighbor group or session group for BGP neighbors. |

# keychain-disable

## Note

Effective with Release 3.9.0, the **keychain-disable** command was replaced by the **keychain inheritance-disable** command. See the [keychain inheritance-disable, on page 172](#) command for more information.

To override any inherited key chain configuration from a neighbor group or session group for Border Gateway Protocol (BGP) neighbors, use the **keychain-disable** command in an appropriate configuration mode. To disable overriding any inherited key chain command, use the **no** form of this command.

**keychain-disable**

**no keychain-disable**

## Syntax Description

This command has no arguments or keywords.

## Command Default

Configured key chains for neighbor and session groups are inherited.

## Command Modes

Neighbor configuration

Neighbor group configuration

Session group configuration

## Command History

| Release       | Modification                                                                  |
|---------------|-------------------------------------------------------------------------------|
| Release 3.4.0 | This command was introduced.                                                  |
| Release 3.9.0 | This command was replaced by the <b>keychain inheritance-disable</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you specify a key chain on a neighbor group or session group, all users of the group inherit the key chain. Specifying a different **keychain** command specifically on a neighbor that uses the group overrides the inherited value. Specifying **keychain-disable** on a neighbor that uses the group disables key chain authentication for the neighbor.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to disable key chain authentication for neighbor 172.20.1.1, preventing it from inheriting the key chain keychain\_A from session group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# session-group group1
RP/0/0/CPU0:router(config-bgp-sngrp)# keychain keychain_A
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)#neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2
RP/0/0/CPU0:router(config-bgp-nbr)#use session-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# keychain-disable
```

## Related Commands

| <a href="#">keychain</a> , on page 168 | Enables key chain authentication on a TCP connection between two BGP neighbors. |

# keychain inheritance-disable

To override any inherited key chain configuration from a neighbor group or session group for Border Gateway Protocol (BGP) neighbors, use the **keychain inheritance-disable** command in an appropriate configuration mode. To disable overriding any inherited key chain command, use the **no** form of this command.

**keychain inheritance-disable**

**no keychain inheritance-disable**

## Syntax Description

This command has no arguments or keywords.

## Command Default

Configured key chains for neighbor and session groups are inherited.

## Command Modes

Neighbor configuration

Neighbor group configuration

Session group configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you specify a key chain on a neighbor group or session group, all users of the group inherit the key chain. Specifying a different **keychain** command specifically on a neighbor that uses the group overrides the inherited value. Specifying **keychain inheritance-disable** on a neighbor that uses the group disables key chain authentication for the neighbor.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to disable key chain authentication for neighbor 172.20.1.1, preventing it from inheriting the key chain keychain\_A from session group group1:

```
RP/0/0/CPU0:router(config)#router bgp 140
RP/0/0/CPU0:router(config-bgp)# session-group group1
RP/0/0/CPU0:router(config-bgp-sngrp)# keychain keychain_A
```

```
RP/0/0/CPU0:router(config-bgp-sngrp)# exit  
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1  
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2  
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group1  
RP/0/0/CPU0:router(config-bgp-nbr)# keychain inheritance-disable
```

| <a href="#">keychain, on page 168</a> | Enables key chain authentication on a TCP connection between two BGP neighbors. |

# label-allocation-mode

To set the MPLS/VPN label allocation mode, use the **label-allocation-mode** command in VRF configuration mode. To remove the **label-allocation-mode** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**label-allocation-mode** [**per-ce** | **per-vrf**]

**no label-allocation-mode** [**per-ce** | **per-vrf**]

## Syntax Description

|                |                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <b>per-ce</b>  | Specifies that the same label is used for all the routes advertised from a unique customer edge (CE) peer or router. |
| <b>per-vrf</b> | Specifies that the same label is used for all the routes advertised from a unique VRF.                               |

## Command Default

Per-prefix is the default label allocation mode.

## Command Modes

VRF configuration

## Command History

| Release       | Modification                          |
|---------------|---------------------------------------|
| Release 3.3.0 | This command was introduced.          |
| Release 3.8.0 | The <b>per-vrf</b> keyword was added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Each prefix that belongs to a VRF instance is advertised with a single label, causing an additional lookup to be performed in the VRF forwarding table to determine the customer edge (CE) next hop for the packet. Use the **label-allocation-mode** command with the **per-ce** keyword to avoid the additional lookup on the PE router and conserve label space. This mode allows the PE router to allocate one label for every immediate next hop. The label is directly mapped to the next hop so there is no VRF route lookup performed during data forwarding. However, the number of labels allocated is one for each CE rather than one for each prefix.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to set the label allocation mode to customer edge:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# vrf vrf-1  
RP/0/0/CPU0:router(config-bgp-vrf)# label-allocation-mode per-ce
```

The following example shows how to set the label allocation mode to VRF:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# vrf vrf-1  
RP/0/0/CPU0:router(config-bgp-vrf)# label-allocation-mode per-vrf
```

# local-as

To allow customization of the autonomous system number for external Border Gateway Protocol (eBGP) neighbor peerings, use the **local-as** command in an appropriate configuration mode. To disable customization of local autonomous system values for eBGP neighbor peerings, use the **no** form of this command.

**local-as** {*as-number* [**no-prepend** [**replace-as** [**dual-as**]]] **inheritance-disable**}

**no local-as** [*as-number* [**no-prepend** [**replace-as** [**dual-as**]]] **inheritance-disable**]

## Syntax Description

|                            |                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>           | Valid autonomous system number.<br><br>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.<br><br>Cannot be the autonomous system number to which the neighbor belongs. |
| <b>no-prepend</b>          | (Optional) Specifies that local autonomous system values are not prepended to announcements from the neighbor.                                                                                                                                                                                                                                                                      |
| <b>replace-as</b>          | (Optional) Specifies that prepend only local autonomous system values to announcements to the neighbor.                                                                                                                                                                                                                                                                             |
| <b>dual-as</b>             | (Optional) Dual-AS mode.                                                                                                                                                                                                                                                                                                                                                            |
| <b>inheritance-disable</b> | Prevents local AS from being inherited from the parent.                                                                                                                                                                                                                                                                                                                             |

## Command Default

The BGP autonomous system number specified in the **router bgp** command is used, except when confederations are in use. The confederation autonomous system is used for external neighbors in an autonomous system that is not part of the confederation.

## Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release     | Modification                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br><br>The <b>no-prepend</b> and <b>disable</b> keywords were added. |

| Release       | Modification                                                                                                                                                                                           |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode.                                                                                                                                         |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.                                                                                                                             |
| Release 3.8.0 | The <b>replace-as</b> keyword was added.                                                                                                                                                               |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The <b>dual-as</b> keyword was added. The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You can specify the autonomous system number the local BGP uses to peer with each neighbor. The autonomous system number specified with this command cannot be the local BGP autonomous system number (specified with the **router bgp** command) or the autonomous system number of the neighbor (specified with the **remote-as** command). This command cannot be specified for internal neighbors or for external neighbors in an autonomous system that is part of a confederation.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows BGP using autonomous system 30 for the purpose of peering with neighbor 172.20.1.1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 300
RP/0/0/CPU0:router(config-bgp-nbr)# local-as 30
```

### Related Commands

|---------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a> | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.   |

## maximum-paths (BGP)

To control the maximum number of parallel routes that Border Gateway Protocol (BGP) installs in the routing table, use the **maximum-paths** command in an appropriate configuration mode. To set the maximum number of parallel routes the software installs to the default value, use the **no** form of this command.

**maximum-paths** {**ebgp**|**ibgp**|**eibgp**} *maximum* [**unequal-cost**]

**no maximum-paths** {**ebgp**|**ibgp**|**eibgp**} [*maximum*] [**unequal-cost**]

### Syntax Description

|                     |                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ebgp</b>         | Specifies external BGP multipath peers.                                                                                                                                  |
| <b>ibgp</b>         | Specifies internal BGP multipath peers.                                                                                                                                  |
| <b>eibgp</b>        | Specifies internal and external BGP multipath peers. eiBGP allows simultaneous use of internal and external paths.                                                       |
| <i>maximum</i>      | Maximum number of parallel routes that BGP installs in the routing table. Range is 2 to 8                                                                                |
| <b>unequal-cost</b> | (Optional) Allows iBGP multipaths to have different BGP next-hop Interior Gateway Protocol (IGP) metrics. This option is available when the <b>ibgp</b> keyword is used. |

### Command Default

One path is installed in the routing table.

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

### Command History

| Release       | Modification                                                                                                                                      |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The <b>ebgp</b> and <b>ibgp</b> keywords were added and the <i>maximum</i> range was changed from 1–8 to 2–8. |
| Release 3.3.0 | This command was supported in VRF IPv4 address family configuration mode. The <b>eibgp</b> and <b>unequal-cost</b> keywords were added.           |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode.                                                                         |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum-paths** command to allow the BGP protocol to install multiple paths into the routing table for each prefix. Multiple paths are installed for external peers that are from the same autonomous system and are equal cost (according to the BGP best-path algorithm). Similarly, multiple paths are installed for internal peers that are equal cost based on the BGP best-path algorithm. The IGP metric to the BGP next hop is the same as the best-path IGP metric unless the router is configured for unequal cost iBGP multipath or eBGP multipath. See *Implementing BGP* in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router* for information on the BGP best-path algorithm.

**Note**

The **maximum-paths** command with the **eibgp** keyword cannot be configured if the **ibgp** or **ebgp** keywords have been configured, because the **eibgp** keyword is a superset of the **ibgp** or **ebgp** keywords.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to allow a maximum of four paths to a destination installed into the IPv4 unicast routing table:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# maximum-paths ebgp 4
```

## maximum-prefix (BGP)

To control how many prefixes can be received from a neighbor, use the **maximum-prefix** command in an appropriate configuration mode. To set the prefix limits to the default values, use the **no** form of this command.

**maximum-prefix** *maximum* [*threshold*] [**warning-only**] [**restart** *time-interval*]

**no maximum-prefix** *maximum* [*threshold*] [**warning-only**] [**restart** *time-interval*]

### Syntax Description

|                                     |                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>maximum</i>                      | Maximum number of prefixes allowed from this neighbor. Range is 1 to 4294967295.<br><b>Note</b> When using additional-paths feature, each path with a unique path ID received from a peer is counted separately for the purpose of maximum-prefix functionality. Hence, the <i>maximum</i> value should be configured appropriately when the peer is capable of sending additional-paths. |
| <i>threshold</i>                    | (Optional) Integer specifying at what percentage of the <i>maximum</i> argument value the software starts to generate a warning message. Range is 1 to 100.                                                                                                                                                                                                                               |
| <b>warning-only</b>                 | (Optional) Instructs the software to generate a log message only when the <i>maximum</i> argument value is exceeded, and not terminate the peering.                                                                                                                                                                                                                                       |
| <b>restart</b> <i>time-interval</i> | (Optional) Sets the time interval (in minutes) after which peering session should be reestablished.<br>Configure restart time interval in minutes. Range is 1 to 65535.                                                                                                                                                                                                                   |

### Command Default

When this command is not specified, the following defaults apply:

IPv4 unicast: 1048576 prefixes

IPv4 multicast: 131,072 prefixes

IPv4 tunnel: 524, 288 prefixes

IPv6 unicast: 524, 288 prefixes

IPv6 multicast: 131,072 prefixes

VPNv4 unicast: 209, 7152 prefixes

VPNv6 unicast: 104, 8576 prefixes

The default threshold when a warning message is generated is 75 percent.

### Command Modes

IPv4 address family group configuration

IPv6 address family group configuration

VPNv4 address family group configuration

IPv4 neighbor address family configuration

IPv6 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 IPv4 tunnel neighbor address family configuration  
 IPv4 tunnel neighbor group address family configuration  
 IPv4 tunnel address family group configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                               |
| Release 3.3.0 | This command was supported in VPNv4 address family, VPNv4 neighbor address, and VPNv4 neighbor group address family configuration modes.                                                                                                                                                                   |
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> <li>• IPv4 tunnel address family</li> </ul>                              |
| Release 4.2.1 | The default prefix limit was increased for IPv4 unicast, IPv6 unicast, VPNv4 unicast, and VPNv6 unicast address families as: <ul style="list-style-type: none"> <li>• IPv4 unicast: 1048576</li> <li>• IPv6 unicast: 524288</li> <li>• VPNv4 unicast: 2097152</li> <li>• VPNv6 unicast: 1048576</li> </ul> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum-prefix** command to configure a maximum number of prefixes that a BGP router is allowed to receive from a neighbor. It adds another mechanism (besides routing policy) to control prefixes received from a peer.

When the number of received prefixes exceeds the maximum number configured, the software terminates the peering, by default, after sending a cease notification to the neighbor. However, if the **warning-only** keyword is configured, the software writes only a log message, but continues peering with the sender. If the peer is terminated, the peer stays down until the **clear bgp** command is issued or the **restart time-interval** option is used.

This command takes effect immediately if configured on an established neighbor unless the number of prefixes received from the neighbor already exceeds the configured limits.

If this command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows the maximum number of IP Version 6 (IPv6) unicast prefixes allowed from neighbor 192.168.40.25 set to 5000, threshold value 80%, and restart time interval 20 minutes:

```
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#neighbor 192.168.40.25
RP/0/0/CPU0:router(config-bgp-nbr)#remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)#address-family ipv6 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)#maximum-prefix 5000 80 restart 20
```

This example shows the maximum number of IP Version 4 (IPv4) unicast prefixes allowed from the neighbor 192.168.40.24 set to 1000:

```
RP/0/0/CPU0:router(config-bgp)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# maximum-prefix 1000
```

## Related Commands

## mpls activate (BGP)

To enable Multiprotocol Label Switching (MPLS) on an interface basis for ASBR and CSC configurations whenever a bgp confederation configuration is used, use the **mpls activate** command in bgp configuration mode. This is needed for InterAS (option B and C) and Carrier Supporting Carrier (CSC) configurations with confederations.

The normal InterAS and CSC configurations (without confederations) do not need to enable this.

To restore the system to its default condition, use the **no** form of this command.

**mpls activate** *interface id*

**no mpls activate** *interface id*

### Syntax Description

|                     |                        |
|---------------------|------------------------|
| <i>interface id</i> | Name of the interface. |
|---------------------|------------------------|

### Command Default

No default behavior or values

### Command Modes

Router configuration  
Neighbor configuration  
IPv4 address family group configuration  
VPNv4 address family group configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **mpls activate** command enables MPLS on the interface specified and also adds the implicit null rewrite corresponding to the peer associated with the interface. The interface specified must be the one corresponding to the inter-AS ASBR or CSC peer.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to activate MPLS for InterAS Option B (with confederations):

```
RP/0/0/CPU0:router(config)#router bgp 1
```

```

  bgp confederation peers
    2002
  !
  bgp confederation identifier 4589
  bgp router-id 3.3.3.3
  mpls activate
    interface GigabitEthernet0/1/0/0
  !
  address-family ipv4 unicast
    redistribute connected
  !
  address-family vpnv4 unicast
    retain route-target all
  !
  neighbor 10.0.0.9
    remote-as 2002
    address-family ipv4 unicast
      route-policy pass in
      route-policy pass out
    !
    address-family vpnv4 unicast
      route-policy pass in

```

The following example shows how to activate MPLS for CSC (with confederations):

```

router bgp 2002
  bgp confederation peers
    1
  !
  bgp confederation identifier 4589
  bgp router-id 4.4.4.4
  address-family ipv4 unicast
    allocate-label all
  !
  address-family vpnv4 unicast
    retain route-target all
  !
  vrf foo
    rd 1:1
    mpls activate
      interface GigabitEthernet0/1/0/2

```

```

!
address-family ipv4 unicast
 redistribute connected
 allocate-label all
!
neighbor 10.0.0.1
 remote-as 1
 address-family ipv4 unicast
!
 address-family ipv4 labeled-unicast
  route-policy pass in
  route-policy pass out
!
!
!
RP/0/0/CPU0:router#show mpls forwarding

| <a href="#">address-family (BGP), on page 17</a> | Enters address family configuration mode for configuring BGP routing sessions. |

# mvpn

To enable BGP instance to connect to PIM/PIM6, use the **mvpn** command in router configuration mode. To disable BGP instance -PIM/PIM6 connection, use the **no** form of this command.

**mvpn**

**no mvpn**

## Syntax Description

This command has no keywords or arguments.

## Command Default

PIM/PIM connection is disabled.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to configure mvpn and enable PIM/PIM6 connection:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#mvpn
```

## neighbor (BGP)

To enter neighbor configuration mode for configuring Border Gateway Protocol (BGP) routing sessions, use the **neighbor** command in an appropriate configuration mode. To delete all configuration for a neighbor and terminate peering sessions with the neighbor, use the **no** form of this command.

**neighbor** *ip-address*

**no neighbor** *ip-address*

### Syntax Description

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| <i>ip-address</i> | IPv4 or IPv6 IP address of the BGP-speaking neighbor. |
|-------------------|-------------------------------------------------------|

### Command Default

Neighbor mode is not specified.

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was supported in VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

From router configuration mode, you can use this command to enter neighbor configuration mode.

From neighbor configuration mode, you can enter address family configuration for the neighbor by using the **address-family** command, which allows you to configure routing sessions for IP Version 4 and IP Version 6 address prefixes.

The **neighbor** command does not cause the neighbor to be configured and does not result in a peering to be established with the neighbor. To create the neighbor, you configure a remote autonomous system number by entering the **remote-as** command, or the neighbor can inherit a remote autonomous system from a neighbor group or session group if the **use** command is applied.

#### Note

A neighbor must have a remote autonomous system number, and an IP address and address family must be enabled on the neighbor.

Unlike IPv4, IPv6 must be enabled before any IPv6 neighbors can be defined. Enable IPv6 in router configuration mode using the **address-family** command.

**Note**

Configuration for the neighbor cannot occur (peering is not established) until the neighbor is given a remote as-number and neighbor address.

The **no** form of this command causes the peering with the neighbor to be terminated and all configuration that relates to the neighbor to be removed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to place the router in neighbor configuration mode for BGP routing process 1 and configure the neighbor IP address 172.168.40.24 as a BGP peer:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 172.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65000
```

The following example shows how to enable IPv6 for BGP, then place the router in neighbor configuration mode for an IPv6 neighbor, 3000::1, and configure neighbor 3000::1 as a BGP peer:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family ipv6 unicast
RP/0/0/CPU0:router(config-bgp-af)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 3000::1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2002
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv6 unicast
```

**Related Commands**

# neighbor-group

To create a neighbor group and enter neighbor group configuration mode, use the **neighbor-group** command in router configuration mode. To remove a neighbor group and delete all configuration associated with the group, use the **no** form of this command.

**neighbor-group** *name*

**no neighbor-group** *name*

## Syntax Description

|             |                      |
|-------------|----------------------|
| <i>name</i> | Neighbor group name. |
|-------------|----------------------|

## Command Default

No neighbor group mode is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **neighbor-group** command puts the router in neighbor group configuration mode and creates a neighbor group.

A neighbor group helps you apply the same configuration to one or more neighbors. After a neighbor group is configured, each neighbor can inherit the configuration through the **use** command. If a neighbor is configured to use a neighbor group, the neighbor, by default, inherits the entire configuration of the neighbor group, which includes the address family-independent and address family-specific configurations. The inherited configuration can be overridden if you directly configure commands for the neighbor or if you configure session groups or address family groups with the **use** command.

From neighbor group configuration mode, you can configure address family-independent parameters for the neighbor group. To enter address family-specific configuration for the neighbor group, use the **address-family** command when in the neighbor group configuration mode.

### Note

If an address family is configured for a neighbor group, neighbors that use the neighbor group attempt to exchange routes in that address family.

The **no** form of this command ordinarily causes all configuration for the neighbor group to be removed. If using the **no** form would result in a neighbor losing its remote autonomous system number, the configuration is rejected. In this scenario, the neighbor configuration must be either removed or configured with a remote autonomous system number before the neighbor group configuration can be removed.

**Note**

Neighbor groups should not be configured with a mixture of IPv4 and IPv6 address families, because such a neighbor group is not usable by any neighbor. Note that within the Cisco IOS XR system configuration architecture, it is possible to create such a neighbor group; however, any attempt to use it is rejected.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to create a neighbor group called group1 that has IP Version 4 (IPv4) unicast and IPv4 multicast activated along with various configuration features. The neighbor group is used by neighbor 10.0.0.1 and neighbor 10.0.0.2, which allows them to inherit the entire group1 configuration.

```
RP/0/0/CPU0:router(config)# router bgp 65530
RP/0/0/CPU0:router(config-bgp)# neighbor-group group1
RP/0/0/CPU0:router(config-bgp-nbrgrp)# remote-as 65535
RP/0/0/CPU0:router(config-bgp-nbrgrp)# advertisement-interval 2
RP/0/0/CPU0:router(config-bgp-nbrgrp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# send-community-ebgp
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# exit
RP/0/0/CPU0:router(config-bgp-nbrgrp)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# next-hop-self
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# exit
RP/0/0/CPU0:router(config-bgp-nbrgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/0/CPU0:router(config-bgp-nbr)# use neighbor-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.2
RP/0/0/CPU0:router(config-bgp-nbr)# use neighbor-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# exit
```

**Related Commands**

## network (BGP)

To specify that the Border Gateway Protocol (BGP) routing process should originate and advertise a locally known network to its neighbors, use the **network** command in an appropriate configuration mode. To disable originating or advertising the network to neighbors, use the **no** form of this command.

**network** {*ip-address/prefix-length* | *ip-address mask*} [**route-policy** *route-policy-name*]

**no network**{*ip-address/prefix-length* | *ip-address mask*} [**route-policy** *route-policy-name*]

### Syntax Description

|                                              |                                                                                                                                                                                                                                |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip- address</i>                           | Network that BGP advertises.                                                                                                                                                                                                   |
| <i>/ prefix-length</i>                       | Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value. |
| <i>ip-address mask</i>                       | Network mask applied to the <i>ip-address</i> argument.                                                                                                                                                                        |
| <b>route-policy</b> <i>route-policy-name</i> | (Optional) Specifies a route policy to use to modify the attributes of the network.                                                                                                                                            |

### Command Default

No networks are specified.

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

### Command History

| Release       | Modification                                                                                   |
|---------------|------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br>The <b>policy</b> keyword was changed to <b>route-policy</b> . |
| Release 3.3.0 | This command was supported in VRF IPv4 address family configuration mode.                      |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode.                      |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

A network specified with this command is originated and advertised to neighbors only if there exists a route for the network in the routing table. That is, there must be a route learned using local or connected networks, static routing, or a dynamic IGP such as IS-IS or OSPF.

Other than the available system resources on the router, no limit exists on the number of network commands that can be configured.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to configure the local router to originate the IPv4 unicast network 172.20.0.0/16:

```
RP/0/0/CPU0:router(config)#router bgp 120
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# network 172.20.0.0/16
```

**Related Commands**

|--------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">network backdoor</a> , on page 193   | Specifies a backdoor route to a BGP border router that provides better information about the network. |
| <a href="#">redistribute (BGP)</a> , on page 225 | Redistributes routes from one routing domain into another routing domain.                             |

# network backdoor

To set the administrative distance on an external Border Gateway Protocol (eBGP) route to that of a locally sourced BGP route, causing it to be less preferred than an Interior Gateway Protocol (IGP) route, use the **network backdoor** command in an appropriate configuration mode. To disable setting the administrative distance to the value for locally sourced BGP routes, use the **no** form of this command.

**network** {*ip-address/prefix-length* | *ip-address mask*} **backdoor**

**no network** {*ip-address/prefix-length* | *ip-address mask*} **backdoor**

## Syntax Description

|                        |                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>      | Network that provides a backdoor route.                                                                                                                                                                                        |
| <i>/ prefix-length</i> | Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value. |
| <i>mask</i>            | Network mask applied to the <i>ip-address</i> argument.                                                                                                                                                                        |

## Command Default

No backdoor routes are installed.

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.3.0 | This command was supported in VRF IPv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Configuring the **network backdoor** command does not cause BGP to originate a network, even if an IGP route for the network exists. Ordinarily, the backdoor network would be learned through both an eBGP and IGP. The BGP best-path selection algorithm does not change when a network is configured as a backdoor network.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows IP Version 4 (IPv4) unicast network 192.168.40.0/24 configured as a backdoor network:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# network 192.168.40.0/24 backdoor
```

### Related Commands

| Command                                     | Description                                                                                             |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">network (BGP)</a> , on page 191 | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |

## next-hop-self

To disable next-hop calculation and insert your own address in the next-hop field of Border Gateway Protocol (BGP) updates, use the **next-hop-self** command in an appropriate configuration mode. To enable next-hop calculation, use the **no** form of this command.

**next-hop-self** [**inheritance-disable**]

**no next-hop-self** [**inheritance-disable**]

### Syntax Description

|                            |                                                                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Allows a next-hop calculation override when this feature may be inherited from a neighbor group or address family group. |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

When this command is not specified, the software calculates the next hop for BGP updates accepted by the router.

### Command Modes

IPv4 address family group configuration  
IPv6 address family group configuration  
VPNv4 address family group configuration  
IPv4 neighbor address family configuration  
VPNv4 neighbor address family configuration  
IPv4 neighbor group address family configuration  
IPv6 neighbor group address family configuration  
VPNv4 neighbor group address family configuration  
VPNv6 address family group configuration  
VPNv6 neighbor address family configuration  
VPNv6 neighbor group address family configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                       |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                       |
| Release 3.3.0 | This command is supported in the following configuration modes: <ul style="list-style-type: none"><li>• VPNv4 address family group</li><li>• VPNv4 neighbor address family</li><li>• VPNv4 neighbor group address family</li></ul> |

| Release       | Modification                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul> |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.                                                                                                                                                    |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **next-hop-self** command to set the BGP next-hop attribute of routes being advertised over a peering session to the local source address of the session.

This command is useful in nonmeshed networks in which BGP neighbors may not have direct access to all other neighbors on the same IP subnet.

If this command is configured for a neighbor group or address family group, a neighbor using the group inherits the configuration. Configuring the command specifically for a neighbor overrides any inherited value.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to set the next hop of the update field for all IP Version 4 (IPv4) unicast routes advertised to neighbor 172.20.1.1 to an address of the local router:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# next-hop-self
```

The following example shows how to disable the **next-hop-self** command for neighbor 172.20.1.1. If not overridden, the next hop would be inherited from address family group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# next-hop-self
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# next-hop-self inheritance-disable
```

**Related Commands**

# next-hop-unchanged

To disable overwriting of the next hop before advertising to external Border Gateway Protocol (eBGP) peers, use the **next-hop-unchanged** command in an appropriate configuration mode. To enable overwriting of the next hop, use the **no** form of this command.

**next-hop-unchanged** [**inheritance-disable**]

**no next-hop-unchanged** [**inheritance-disable**]

## Syntax Description

|                            |                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Allows overwriting of the next hop before advertising to eBGP peers when this feature may be inherited from a neighbor group or address family group. |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

Overwriting of the next hop is allowed.

## Command Modes

VPNv4 address family group configuration  
 VPNv4 neighbor address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration  
 IPv4 labeled-unicast address family configuration  
 IPv6 labeled-unicast address family configuration  
 IPv4 address family configuration  
 IPv6 address family configuration

## Command History

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                            |
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul> |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.                                                                                                                                                    |

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                        |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 4.0.0 | <p>This command was supported in the following address family configuration modes:</p> <ul style="list-style-type: none"> <li>• IPv4 labeled-unicast address family configuration</li> <li>• IPv6 labeled-unicast address family configuration</li> <li>• IPv4 unicast address family configuration</li> <li>• IPv6 unicast address family configuration</li> </ul> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **next-hop-unchanged** command to propagate the next hop unchanged for multihop eBGP peering sessions. This command should not be configured on a route reflector, and the **next-hop-self** command should not be used to modify the next-hop attribute for a route reflector when this feature is enabled for a route reflector client.

#### Note

Incorrectly setting BGP attributes for a route reflector can cause inconsistent routing, routing loops, or a loss of connectivity. Setting BGP attributes for a route reflector should be attempted only by an experienced network operator.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to disable the overwriting of next hops before advertising to eBGP peers:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# next-hop-unchanged disable
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
```

# nexthop resolution prefix-length minimum

To set minimum prefix-length for nexthop resolution, use the **nexthop resolution prefix-length minimum** command in an appropriate configuration mode. To disable the minimum prefix-length for nexthop resolution, use the **no** form of this command.

**nexthop resolution prefix-length minimum** *prefix-length-value*

**no nexthop resolution prefix-length minimum** *prefix-length-value*

## Syntax Description

*prefix-length-value*

Sets the minimum prefix-length. Range is 0 to 32.

## Command Default

Nexthop resolution for minimum prefix-length is disabled.

## Command Modes

VPNv4 Unicast address family

VRF IPv4 Unicast address family

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set the minimum prefix-length for nexthop resolution as 32:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)#nexthop resolution prefix-length minimum 32
```

## nexthop route-policy

To specify that BGP routes are resolved using only next hops whose routes match specific characteristics, use the **nexthop route-policy** command in the appropriate configuration mode. To remove the **nexthop route-policy** command from the configuration file and restore the system to its default behavior, use the **no** form of this command.

**nexthop route-policy** *route-policy-name*

**no nexthop route-policy** *route-policy-name*

### Syntax Description

|                          |                                                       |
|--------------------------|-------------------------------------------------------|
| <i>route-policy-name</i> | Route policy to use for filtering based on next hops. |
|--------------------------|-------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration

### Command History

| Release       | Modification                                                           |
|---------------|------------------------------------------------------------------------|
| Release 3.4.0 | This command was introduced.                                           |
| Release 3.5.0 | This command was supported in VPNv6 address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **nexthop route-policy** command to configure route policy filtering using next hops.

The BGP next-hop tracking feature allows you to specify that BGP routes are resolved using only next hops whose routes have the following characteristics:

- To avoid the aggregate routes, the prefix length must be greater than a specified value.
- The source protocol must be from a selected list, ensuring that BGP routes are not used to resolve next hops that could lead to oscillation.

This route policy filtering is possible because RIB identifies the source protocol of a route that resolves a next hop as well as the mask length associated with the route.

The next-hop attach point supports matching using the protocol name and mask length. BGP marks all next hops that are rejected by the route policy as invalid, and no best path is calculated for the routes that use the invalid next hop. The invalid next hops continue to stay in the active cache and can be displayed as part of the **show bgp nexthop** command with an invalid status.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to specify the route policy nexthop\_A as the policy to use for filtering next hops:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-bgp-af)# nexthop route-policy nexthop_A
```

### Related Commands

| Command                                                         | Description                                                        |
|-----------------------------------------------------------------|--------------------------------------------------------------------|
| route-policy (RPL)                                              | Defines a route policy and enters route-policy configuration mode. |
| <a href="#">show bgp nexthops</a> , <a href="#">on page 370</a> | Display statistical information about the BGP next hops.           |

# nexthop trigger-delay

To specify the delay for triggering next-hop calculations, use the **nexthop trigger-delay** command in the appropriate configuration mode. To set the trigger delay to the default value, use the **no** form of this command.

**nexthop trigger-delay** {*critical delay*| *non-critical delay*}

**no nexthop trigger-delay** {*critical delay*| *non-critical delay*}

## Syntax Description

|                     |                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------|
| <b>critical</b>     | Specifies critical next-hop events. For example, when the next hop is unreachable.                  |
| <i>delay</i>        | Trigger delay, in milliseconds. Range is 0 to 4294967295.                                           |
| <b>non-critical</b> | Specifies noncritical next-hop events. For example, Interior Gateway Protocol (IGP) metric changes. |

## Command Default

**critical** : 3000 msec for IPv4 address family and IPv6 address family

**critical** : msec for VPNv4 address family and VPNv6 address family

**non-critical** : 10000 msec IPv4, IPv6, VPNv4, and VPNv6 address families

## Command Modes

IPv4 address family configuration

Pv6 address family configuration

VPNv4 address family configuration

VPNv6 address family configuration

## Command History

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Release 3.4.0 | <p>This command was changed from <b>bgp nexthop-trigger-delay</b> to <b>nexthop trigger-delay</b>.</p> <p>The supported command mode was changed from Router configuration to the following configuration modes:</p> <ul style="list-style-type: none"> <li>• IPv4 address family configuration</li> <li>• IPv6 address family configuration</li> <li>• VPNv4 address family configuration</li> </ul> <p>The <b>critical</b> and <b>non-critical</b> keywords have been added. The <i>delay</i> range has changed from 0 to 300 seconds to 0 to 4294967295 msec.</p> |

| Release       | Modification                                                                                          |
|---------------|-------------------------------------------------------------------------------------------------------|
| Release 3.5.0 | This command was supported in VPNv6 address family configuration mode.                                |
| Release 3.8.0 | The default critical delay value for VPNv4 address family and VPNv6 address family was set to 0 msec. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **nexthop trigger-delay** command to allow for a dynamic way for Interior Gateway Protocol (IGP) to converge. This convergence allows BGP to accumulate all notifications and trigger fewer walks, resulting in fewer interprocess communications (IPCs) to the Routing Information Base (RIB) for route addition, deletion, and modification and fewer updates to peers.

#### Note

A high *delay* value can be configured to effectively turn off next-hop tracking.

The **non-critical** *delay* value must always be set to at least equal or greater than the **critical** *delay* value.

The *delay* should be slightly higher than the time it takes for the IGP to settle into a steady state after some event (IGP convergence time).

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to set the critical next-hop trigger delay to 3500 milliseconds:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# nexthop trigger-delay critical 3500
```

## nsr (BGP)

To activate Border Gateway Protocol (BGP) nonstop routing (NSR), use the **nsr** command in BGP global configuration mode. To deactivate BGP NSR, use the **no** form of this command.

**nsr**

**no nsr**

**Syntax Description** This command has no arguments or keywords.

**Command Default** BGP NSR is not activated.

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **nsr** command to enable the Border Gateway Protocol (BGP) Nonstop Routing (NSR) with Stateful Switchover (SSO). This enables all bgp peerings to maintain the BGP state to ensure continuous packet forwarding during events that could interrupt service.

BGP supports 5000 NSR sessions.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows how to enable BGP NSR:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 120
RP/0/0/CPU0:router(config-bgp)# nsr
```

The following example shows how to disable BGP NSR:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 120
```

```
RP/0/0/CPU0:router(config-bgp)# no nsr
```

**Related Commands**

|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router bgp, on page 249</a>   | Configures the Border Gateway Protocol (BGP) routing process.                                                                                                                                                                |
| nsr process-failures switchover           | Configures failover as a recovery action in case of process failures for active instances to switch over to a standby route processor (RP) or a standby distributed route processor (DRP) to maintain nonstop routing (NSR). |
| <a href="#">show bgp nsr, on page 379</a> | Displays Border Gateway Protocol (BGP) nonstop routing (NSR) information.                                                                                                                                                    |

# orf

To specify Outbound Route Filter (ORF) and inbound filtering criteria, use the **orf route-policy** command in an appropriate configuration mode. To restore the system to its default condition, use the **no** form of this command.

**orf route-policy** *route-policy-name*

**no orf route-policy** *route-policy-name*

## Syntax Description

|                          |                           |
|--------------------------|---------------------------|
| <i>route-policy-name</i> | Name of the route policy. |
|--------------------------|---------------------------|

## Command Default

No ORF route policy is defined.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 IPv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VRF IPv6 neighbor address family configuration

## Command History

| Release       | Modification                                                                       |
|---------------|------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                       |
| Release 3.5.0 | This command was supported in VRF IPv6 neighbor address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure outbound and inbound filtering criteria:

```
RP/0/0/CPU0:router(config)#router bgp 6  
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1  
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1  
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-bgp-nbr-af)#orf route-policy policy_A
```

## Related Commands

| Command                                         | Description                                                                        |
|-------------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">route-policy (BGP), on page 243</a> | Applies a routing policy to updates advertised to or received from a BGP neighbor. |

## password (BGP)

To enable Message Digest 5 (MD5) authentication on a TCP connection between two Border Gateway Protocol (BGP) neighbors, use the **password** command in an appropriate configuration mode. To disable MD5 authentication, use the **no** form of this command.

**password** {**clear**|**encrypted**} *password*

**no password** [**clear** *password*|**encrypted** *password*]

### Syntax Description

|                  |                                                                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>clear</b>     | Specifies that an unencrypted password follows. The password must be a case-sensitive, clear-text unencrypted password.                                                                                                                                  |
| <b>encrypted</b> | Specifies that an encrypted password follows. The password must be a case-sensitive, encrypted password.                                                                                                                                                 |
| <i>password</i>  | Password of up to 80 characters. The password can contain any alphanumeric characters. However, if the first character is a number or the password contains a space, the password must be enclosed in double quotation marks; for example, "2 password." |

### Command Default

When this command is not specified in the appropriate configuration mode, MD5 authentication is not enabled on a TCP connection between two BGP neighbors.

### Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

### Command History

| Release       | Modification                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The <b>0</b> and <b>7</b> keywords were replaced with the <b>clear</b> and <b>encrypted</b> keywords and the <b>accept</b> keyword was removed. |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode.                                                                                                                      |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Configure a password to enable authentication between two BGP peers. Use the **password** command to verify each segment sent on the TCP connection between the peers. The same password must be configured on both networking devices, otherwise a connection cannot be made. The authentication feature uses the MD5 algorithm. Specifying this command causes the software to generate and check the MD5 digest on every segment sent on the TCP connection.

Configuring a neighbor password does not cause the existing session for a neighbor to end. However, until the new password is configured on the remote router, the local BGP process does not receive keepalive messages from the remote device. If the password is not updated on the remote device by the end of the hold time, the session ends. The hold time can be changed using the **timers** command or the **timers bgp** command.

If this command is configured for a neighbor group or neighbor address family group, a neighbor using the group inherits the configuration. Values of commands configured specifically for a neighbor overrides inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to configure neighbor 172.20.1.1 to use MD5 authentication with the password password1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)#neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)#remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)#password clear password1
```

### Related Commands

| Command                                       | Description                                                                                              |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a>   | Creates a neighbor group and enters neighbor group configuration mode.                                   |
| <a href="#">password-disable, on page 214</a> | Overrides any inherited password configuration from a neighbor group or session group for BGP neighbors. |
| <a href="#">session-group, on page 261</a>    | Creates a session group and enters session group configuration mode.                                     |
| <a href="#">timers (BGP), on page 486</a>     | Set the timers for a specific BGP neighbor.                                                              |

## password (rpki-server)

To specify a SSH password for the RPKI cache-server, use the **password** command in rpki-server configuration mode. To remove the SSH passwords, use the **no** form of this command.

**password** *password*

**no password** *password*

### Syntax Description

|                 |                                                               |
|-----------------|---------------------------------------------------------------|
| <i>password</i> | Enters a password to be used for the SSH transport mechanism. |
|-----------------|---------------------------------------------------------------|

### Command Default

Password is not configured.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

SSH expects to use an authentication method to connect to a remote server. The SSH authentication method to connect to RPKI server is password-based. So, the RPKI cache-server must be configured with username and password. A username and password must be configure for each server configured under BGP that uses the SSH transport

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to configure a username (*rpki-user*) and password (*rpki-ssh-pass*) for the RPKI cache-server SSH transport mechanism:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
```

```
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
```

# password-disable

To override any inherited password configuration from a neighbor group or session group for Border Gateway Protocol (BGP) neighbors, use the **password-disable** command in an appropriate configuration mode. To disable overriding any inherited password command, use the **no** form of this command.

**password-disable**

**no password-disable**

**Syntax Description** This command has no arguments or keywords.

**Command Default** Configured passwords for neighbor and session groups are inherited.

**Command Modes**

- Neighbor configuration
- VRF neighbor configuration
- Neighbor group configuration
- Session group configuration

| Command History | Release       | Modification                                                   |
|-----------------|---------------|----------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                   |
|                 | Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |
|                 |               |                                                                |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you specify a password on a neighbor group or session group, all users of the group inherit the password. Specifying a different **password** command specifically on a neighbor that uses the group overrides the inherited value. Specifying **password-disable** on a neighbor that uses the group disables password authentication for the neighbor.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples**

The following example shows how to disable MD5 authentication for neighbor 172.20.1.1, preventing it from inheriting the password password1 from session group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# session-group group1
RP/0/0/CPU0:router(config-bgp-sngrp)# password clear password1
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# password-disable
```

**Related Commands**

| Command                                      | Description                                                                                  |
|----------------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">neighbor-group</a> , on page 189 | Creates a neighbor group and enters neighbor group configuration mode.                       |
| <a href="#">password (BGP)</a> , on page 210 | Enables MD5 authentication on a TCP connection between two BGP neighbors.                    |
| <a href="#">session-group</a> , on page 261  | Creates a session group and enters session group configuration mode.                         |
| <a href="#">use</a> , on page 509            | Inherits characteristics from a neighbor group, a session group, or an address family group. |

# precedence

To set the precedence level, use the **precedence** command in the appropriate configuration mode. To remove the **precedence** command from the configuration file and restore the system to its default interval values, use the **no** form of this command.

**precedence** *value*

**no precedence** [*value*]

## Syntax Description

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | Value of the precedence. The precedence value can be a number from 0 to 7, or it can be one of the following keywords:<br><br><b>critical</b> —Set packets with critical precedence (5)<br><b>flash</b> — Set packets with flash precedence (3)<br><b>flash-override</b> —Set packets with flash override precedence (4)<br><b>immediate</b> —Set packets with immediate precedence (2)<br><b>internet</b> —Set packets with internetwork control precedence (6)<br><b>network</b> —Set packets with network control precedence (7)<br><b>priority</b> —Set packets with priority precedence (1)<br><b>routine</b> —Set packets with routine precedence (0) |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

Neighbor configuration  
 Neighbor session group configuration  
 Neighbor group configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **precedence** command to set the precedence value.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the precedence to 2:

```
RP/0/0/CPU0:router(config)# router bgp 5  
RP/0/0/CPU0:router(config-bgp)# neighbor 10.1.1.1  
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 100  
RP/0/0/CPU0:router(config-bgp-nbr)# precedence 2
```

## preference (rpki-server)

To specify a preference value for the RPKI cache-server, use the **preference** command rpki-server configuration mode. To remove the preference value, use the **no** form of this command.

**preference** *preference-value*

**no preference** *preference-value*

### Syntax Description

*preference-value*

Specifies a RPKI cache preference value. Range is 1 to 10.

**Note** A lower value is recommended

### Command Default

Preference value is not set.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to set preference value for RPKI configuration as 1:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
RP/0/0/CPU0:router(config-bgp-rpki-cache)#preference 1
```

## purge-time (rpki-server)

To configure the time BGP waits to keep routes from RPKI cache-server after the cache session drops, use the **purge-time** command in rpki-server configuration mode. To remove the purge-time configuration, use the **no** form of this command.

**purge-time** *time-in-seconds*

**no purge-time** *time-in-seconds*

### Syntax Description

*time-in-seconds*

Sets the purge time in seconds. Range is 30 to 360 seconds.

### Command Default

Purge time is not set.

### Command Modes

RPKI server configuration

### Command History

#### Release

Release 4.2.1

#### Modification

This command was introduced.

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a cache session is dropped then a "purge-timer" is started for that cache. If the session re-establishes within the timer interval, then the purge timer is stopped and no further action is taken. If the cache session does not re-establish within the timer interval, only then does BGP remove all ROAs from the cache.

### Task ID

#### Task ID

bgp

#### Operation

read, write

### Examples

This example shows how to set the purge-time for RPKI cache as 30 seconds:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki cache 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
```

**purge-time (rpki-server)**

```
RP/0/0/CPU0:router(config-bgp-rpki-cache)#preference 1  
RP/0/0/CPU0:router(config-bgp-rpki-cache)#purge-time 30
```

# rd

To configure a route distinguisher, use the **rd** command in VRF configuration mode. To disable the route distinguisher, use the **no** form of this command.

**rd** {*as-number* : *nn*| *ip-address* : *nn*| **auto**}

**no rd** {*as-number* : *nn*| *ip-address* : *nn*| **auto**}

## Syntax Description

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number:nn</i>  | <ul style="list-style-type: none"> <li>• <i>as-number</i> —16-bit Autonomous system (AS) number of the route distinguisher <ul style="list-style-type: none"> <li>◦ Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>◦ Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> </li> <li>• <i>nn</i> —32-bit number</li> </ul> |
| <i>ip-address:nn</i> | IP address of the route distinguisher. <ul style="list-style-type: none"> <li>• <i>ip-address</i> —32-bit IP address</li> <li>• <i>nn</i> —16-bit number</li> </ul>                                                                                                                                                                                                                                                                                                                                    |
| <b>auto</b>          | Automatically assigns a unique route distinguisher.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Command Default

No default behavior or values

## Command Modes

VRF configuration

## Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.5.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **rd** command to make the prefix unique across multiple VRFs.

Auto assignment of route distinguishers can be done only if a router ID is assigned using the **bgp router-id** command in BGP router configuration mode. The unique router ID is used for automatic route distinguisher generation.

The following are restrictions when configuring route distinguishers:

- BGP router-id must be configured before **rd auto** can be configured
- Route distinguisher cannot be changed or removed when an IPv4 unicast address family is configured under VRF.
- BGP router-id cannot be changed or removed when **rd auto** is configured under a VRF.
- When **rd auto** is configured under a VRF, the IP address for the router distinguisher configured under another VRF must be different from that of the BGP router-id
- If a route distinguisher with same IP address as BGP router-id exists, the **rd auto** is not permitted.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to automatically assign a unique route distinguisher to VRF instance vrf-1:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# vrf vrf-1
RP/0/0/CPU0:router(config-bgp-vrf)# rd auto
```

**Related Commands**

| <a href="#">import route-target, on page 164</a> | Configures a VRF import route-target extended community. |

## receive-buffer-size

To set the size of the receive buffers for a Border Gateway Protocol (BGP) neighbor, use the **receive-buffer-size** command in an appropriate configuration mode. To remove the **receive-buffer-size** command from the configuration file and restore the system to its default condition in which the software uses the default size, use the **no** form of this command.

**receive-buffer-size** *socket-size* [*bgp-size*]

**no receive-buffer-size** [*socket-size*] [*bgp-size*]

### Syntax Description

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <i>socket-size</i> | Size, in bytes, of the receive-side socket buffer. Range is 512 to 131072.       |
| <i>bgp-size</i>    | (Optional) Size, in bytes, of the receive buffer in BGP. Range is 512 to 131072. |

### Command Default

*socket-size* : 32,768 bytes

*bgp-size* : 4,032 bytes

### Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

### Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **receive-buffer-size** command to increase the buffer size when receiving updates from a neighbor. Using larger buffers can improve convergence time because it allows the software to process a larger number of packets simultaneously. However, allocating larger buffers consumes more memory on the router.

**Note**

Increasing the socket buffer size uses more memory only when more messages are waiting to be processed by the software. In contrast, increasing the BGP buffer size uses extra memory indefinitely.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the receive buffer sizes for neighbor 172.20.1.1 to be 65,536 bytes for the socket buffer and 8192 bytes for the BGP buffer:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# receive-buffer-size 65536 8192
```

**Related Commands**

|---------------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a>             | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">send-buffer-size, on page 253</a>           | Sets the size of the send buffers for a BGP neighbor.                  |
| <a href="#">session-group, on page 261</a>              | Creates a session group and enters session group configuration mode.   |
| <a href="#">socket receive-buffer-size, on page 475</a> | Sets the size of the receive buffers for all BGP neighbors.            |

# redistribute (BGP)

To redistribute routes from one routing domain into Border Gateway Protocol (BGP), use the **redistribute** command in an appropriate configuration mode. To disable route redistribution, use the **no** form of this command.

## Connected

**redistribute connected** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

**no redistribute connected** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

## Enhanced Interior Gateway Routing Protocol (EIGRP)

**redistribute eigrp** *process-id* [**match** {**external**|**internal**}] [**metric** *metric-value*] [**route-policy** *route-policy-name*]

**no redistribute eigrp** *process-id* [**match** {**external**|**internal**}] [**metric** *metric-value*] [**route-policy** *route-policy-name*]

## Intermediate System-to-Intermediate System (IS-IS)

**redistribute isis** *process-id* [**level** {**1**|**1-inter-area**|**2**}] [**metric** *metric-value*] [**route-policy** *route-policy-name*]

**no redistribute isis** *process-id* [**level** {**1**|**1-inter-area**|**2**}] [**metric** *metric-value*] [**route-policy** *route-policy-name*]

## Open Shortest Path First (OSPF)

**redistribute ospf** *process-id*

**no redistribute ospf** *process-id*

## OSPFv3

**redistribute ospf** *process-id*

**no redistribute ospf** *process-id*

## Routing Information Protocol

**redistribute rip** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

**no redistribute rip** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

## Static

**redistribute static** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

**no redistribute static** [**metric** *metric-value*] [**route-policy** *route-policy-name*]

## Syntax Description

|                  |                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>connected</b> | Redistributes connected routes. Connected routes are established automatically when IP is enabled on an interface. |
|------------------|--------------------------------------------------------------------------------------------------------------------|

|                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metric</b> <i>metric-value</i>                                                                                                  | <p>(Optional) Specifies the Multi Exit Discriminator (MED) attribute used for the redistributed route. Range is 0 to 4294967295. Use a value consistent with the destination protocol.</p> <p>By default, the Interior Gateway Protocol (IGP) metric is assigned to the route. For connected and static routes the default metric is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>route-policy</b><br><i>route-policy-name</i>                                                                                    | (Optional) Specifies a configured routing policy to filter redistributed routes. A route policy is used to filter the importation of routes from this source routing protocol to BGP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>eigrp</b>                                                                                                                       | Specifies that routes are distributed from EIGRP. You must be in IPv4 unicast or multicast address family configuration mode or in VRF IPv4 address family configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>process-id</i>                                                                                                                  | <p>For the <b>eigrp</b> keyword, an EIGRP instance name from which routes are to be redistributed.</p> <p>For the <b>isis</b> keyword, an IS-IS instance name from which routes are to be redistributed.</p> <p>For the <b>ospf</b> keyword, an OSPF instance name from which routes are to be redistributed.</p> <p>The <i>process-id</i> value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>match</b> { <b>internal</b>  <br><b>external</b> [ <b>1</b>   <b>2</b> ]  <br><b>nssa-external</b> [ <b>1</b>   <b>2</b><br>] } | <p>(Optional) Specifies the criteria by which OSPF routes are redistributed into other routing domains. It can be one or more of the following:</p> <ul style="list-style-type: none"> <li>• <b>internal</b> —Routes that are internal to a specific autonomous system (intra- and inter-area OSPF routes).</li> <li>• <b>external</b> [ <b>1</b>   <b>2</b> ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 external routes.</li> <li>• <b>nssa-external</b> [ <b>1</b>   <b>2</b> ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 not-so-stubby area (NSSA) external routes.</li> </ul> <p>For the <b>external</b> and <b>nssa-external</b> options, if a type is not specified, then both Type 1 and Type 2 are assumed.</p> |
| <b>isis</b>                                                                                                                        | <p>Specifies that routes are distributed from the IS-IS protocol.</p> <p>Redistribution from IS-IS is allowed under IPv4 unicast, IPv4 multicast, IPv6 unicast, and IPV6 multicast address-families. Redistribution is not allowed under VPNv4 and VPNv6 address-families.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>level</b> { <b>1</b>   <b>1-inter-area</b>   <b>2</b> } | (Optional) Specifies the IS-IS level from which routes are redistributed. It can be one of the following: <ul style="list-style-type: none"> <li>• <b>1</b> —Routes are redistributed from Level 1 routes.</li> <li>• <b>1-inter-area</b> —Routes are redistributed from Level 1 interarea routes.</li> <li>• <b>2</b> —Routes are redistributed from Level 2 routes.</li> </ul> |
| <b>ospf</b>                                                | Specifies that routes are distributed from the OSPF protocol. You must be in IPv4 unicast or multicast address family configuration mode or in VRF IPv4 address family configuration mode.                                                                                                                                                                                       |
| <b>ospfv3</b>                                              | Specifies that routes are distributed from the OSPFv3 protocol. You must be in IPv6 unicast or multicast address family configuration mode or in VRF IPv4 address family configuration mode.                                                                                                                                                                                     |
| <b>rip</b>                                                 | Specifies that routes are distributed from RIP. You must be in IPv4 unicast or multicast address family configuration mode.                                                                                                                                                                                                                                                      |
| <b>static</b>                                              | Redistributes IP static routes.                                                                                                                                                                                                                                                                                                                                                  |

**Command Default**

Route redistribution is disabled.

For IS-IS, the default is to redistribute Level 1 and Level 2 routes.

For OSPF, the default is to redistribute internal, external, and NSSA external routes of Type 1 and Type 2.

For OSPFv3, the default is to redistribute internal, external, and NSSA external routes of Type 1 and Type 2.

By default, the Interior Gateway Protocol (IGP) metric is assigned to the route. For connected and static routes the default metric is 0.

**metric** *metric-value*: 0

**match** { **internal** | **external** [ **1** | **2** ] | **nssa-external** [ **1** | **2** ] } : If no match is specified, the default is to match all routes.

**Command Modes**

IPv4 address family configuration, both unicast and multicast (**connected**, **eigrp**, **isis**, **ospf**, **rip**, and **static** are supported)

IPv6 address family configuration, both unicast and multicast (**connected**, **eigrp**, **isis**, **ospfv3**, and **static** are supported)

VRF IPv4 address family configuration ( **connected** , **eigrp** , **ospf** , **rip** , and **static** are supported)

VRF IPv6 address family configuration ( **connected** , **eigrp** , and **static** are supported)

**Command History**

| Release     | Modification                                                                                                                                               |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced. The <b>policy</b> keyword was changed to <b>route-policy</b> . The <b>1-inter-area</b> and <b>opsfv3</b> keywords were added. |

| Release       | Modification                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | The <b>eigrp</b> and <b>rip</b> keywords were added. This command was supported in VRF IPv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 address family configuration mode.                                                      |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

When redistributing routes (into BGP) using both command keywords for setting or matching of attributes and a route policy, the routes are run through the route policy first, followed by the keyword matching and setting.

Each instance of a protocol may be redistributed independently of the others. Changing or removing redistribution for a particular instance does not affect the redistribution capability of other protocols or other instances of the same protocol.

Networks specified using the **network** command are not affected by the **redistribute** command; that is, the routing policy specified in the **network** command takes precedence over the policy specified through the **redistribute** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to redistribute IP Version 4 (IPv4) unicast OSPF routes from OSPF instance 110 into BGP:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# redistribute ospf 110
```

### Related Commands

| Command                                    | Description                                                                                             |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">network (BGP), on page 191</a> | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |

## refresh-time (rpki-server)

To configure the time BGP waits in between sending periodic serial queries to the RPKI server, use the **refresh-time** command in rpki-server configuration mode. To remove the refresh-time configuration, use the **no** form of this command.

**refresh-time** {*time-in-seconds*| **off**}

**no refresh-time** {*time-in-seconds*| **off**}

|                           |                        |                                                                |
|---------------------------|------------------------|----------------------------------------------------------------|
| <b>Syntax Description</b> | <b>off</b>             | Specifies not to send serial queries periodically.             |
|                           | <i>time-in-seconds</i> | Sets the refresh-time in seconds. Range is 30 to 3600 seconds. |

**Command Default** Refresh-time is not set.

**Command Modes** RPKI cache configuration

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | Release 4.2.1  | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

|                |                |                  |
|----------------|----------------|------------------|
| <b>Task ID</b> | <b>Task ID</b> | <b>Operation</b> |
|                | bgp            | read, write      |

**Examples** This example shows how to set the refresh-time for BGP to wait in between sending periodic serial queries to the server as 30 seconds:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
RP/0/0/CPU0:router(config-bgp-rpki-cache)#preference 1
```

```
RP/0/0/CPU0:router(config-bgp-rpki-cache)#purge-time 30  
RP/0/0/CPU0:router(config-bgp-rpki-cache)#refresh-time 30
```

## response-time (rpki-server)

To configure the time BGP waits for a response from the RPKI cache-server after sending a serial or reset query, use the **response-time** command in rpki-server configuration mode. To remove the response-time configuration, use the **no** form of this command.

**response-time** {*time-in-seconds*| **off**}

**no response-time** {*time-in-seconds*| **off**}

### Syntax Description

|                        |                                                                      |
|------------------------|----------------------------------------------------------------------|
| <b>off</b>             | Specifies to wait indefinitely for a response from the RPKI cache.   |
| <i>time-in-seconds</i> | Specifies the response-time in seconds. Range is 30 to 3600 seconds. |

### Command Default

Response-time is not set.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to set the time for BGP to wait for a response from the RPKI server as 30 seconds, after sending a serial or reset query:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 72.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)#transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
RP/0/0/CPU0:router(config-bgp-rpki-cache)#preference 1
```

```
RP/0/0/CPU0:router(config-bgp-rpki-cache)#purge-time 30
RP/0/0/CPU0:router(config-bgp-rpki-cache)#refresh-time 30
RP/0/0/CPU0:router(config-bgp-rpki-cache)#response-time 30
```

## remote-as (BGP)

To create a Border Gateway Protocol (BGP) neighbor and begin the exchange of routing information, use the **remote-as** command in an appropriate configuration mode. To delete the entry for the BGP neighbor, use the **no** form of this command.

**remote-as** *as-number*

**no remote-as** [*as-number*]

### Syntax Description

|                  |                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> | Autonomous system (AS) to which the neighbor belongs. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

No BGP neighbors exist.

### Command Modes

Neighbor configuration  
 VRF neighbor configuration  
 Neighbor group configuration  
 Session group configuration

### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode.              |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **remote-as** command to create a neighbor and assign it a remote autonomous system number. A neighbor must have a remote autonomous system number before any other commands can be configured for it. Removing the remote autonomous system from a neighbor causes the neighbor to be deleted. You cannot remove the autonomous system number if the neighbor has other configuration.

**Note**

We recommend that you use the **no neighbor** command rather than the **no remote-as** command to delete a neighbor.

A neighbor specified with a remote autonomous system number that matches the autonomous system number specified in the **router bgp** command identifies the neighbor as internal to the local autonomous system. Otherwise, the neighbor is considered external.

Configuration of the **remote-as** command for a neighbor group or session group using the **neighbor-group** command or **session-group** command causes all neighbors using the group to inherit the characteristics configured with the command. Configuring the command directly for the neighbor overrides the value inherited from the group.

In the neighbor configuration submode, configuring use of a session group or neighbor group for which **remote-as** is configured creates a neighbor and assigns it an autonomous system number if the neighbor has not already been created.

**Note**

Do not combine **remote-as** commands and **no use neighbor-group** commands, or **remote-as** commands and **no use session-group** commands, in the same configuration commit.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to assign autonomous system numbers on two neighbors, neighbor 10.0.0.1, (internal) and neighbor 192.168.0.1 (external), setting up a peering session that shares routing information between this router and each of these neighbors:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group group2
RP/0/0/CPU0:router(config-bgp-sngrp)# remote-as 1
RP/0/0/CPU0:router(config-bgp-sngrp)#exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/0/CPU0:router(config-bgp-nbr)#use session-group group2
```

The following example shows how to configure a session group called group2 with an autonomous system number 1. Neighbor 10.0.0.1 is created when it inherits the autonomous system number 1 from session group group2.

```
RP/0/0/CPU0:router(config)#router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group group2
RP/0/0/CPU0:router(config-bgp-sngrp)# remote-as 1
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group2
```

## Related Commands

| <a href="#">router bgp, on page 249</a>     | Configures the BGP routing process.                                                     |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.                    |
| <a href="#">use, on page 509</a>            | Inherits characteristics from a neighbor group, session group, or address family group. |

## remove-private-as

To remove private autonomous system numbers from autonomous system paths when generating updates to external neighbors, use the **remove-private-as** command in an appropriate configuration mode. To place the router in the default state in which it does not remove private autonomous system numbers, use the **no** form of this command.

**remove-private-as** [**inheritance-disable**] [**entire-aspath**]

**no remove-private-as** [**inheritance-disable**] [**entire-aspath**]

### Syntax Description

|                            |                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Permits the feature to be disabled from a neighbor group or address family group instead of being inherited.                  |
| <b>entire-aspath</b>       | (Optional) Removes the entire private autonomous system numbers from an autonomous system path only if all ASes in the path are private. |

### Command Default

When this command is not specified in the appropriate configuration mode, private autonomous system numbers are not removed from updates sent to external neighbors.

### Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 VPNv4 address family group configuration  
 IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                                                                                                                                                                                                                                              |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv4 address family group</li> <li>• VPNv4 neighbor address family group</li> <li>• VRF IPv4 neighbor address family</li> <li>• VPNv4 neighbor group address family</li> </ul> |
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VRF IPv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul>       |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.                                                                                                                                                                                                      |
| Release 3.9.2 | The <b>entire-aspath</b> keyword was supported.                                                                                                                                                                                                                                           |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This feature is available for external BGP (eBGP) neighbors only.

When an update is passed to the external neighbor, the software drops any leading autonomous system sequence in the autonomous system path if the sequence contains only private autonomous system numbers and does not contain the autonomous system number of the neighbor.

If this command is used in a BGP confederation, the element following the confederation portion of the autonomous system path, if a sequence, is considered the leading sequence.

The private autonomous system values range from 64512 to 65535.

If this command is configured for a neighbor group or address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

Use the **entire-aspath** to removes the entire private autonomous system numbers from an autonomous system path only if all ASes in the path are private.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows a configuration that removes the private autonomous system number from the IP Version 4 (IPv4) unicast updates sent to 172.20.1.1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# remove-private-as
```

The following example shows how to disable the remove private autonomous system number feature for neighbor 172.20.1.1, preventing this feature from being automatically inherited from address family group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# remove-private-as
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# remove-private-as inheritance-disable
```

## Related Commands

| Command                                       | Description                                                                                           |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------|
| <a href="#">af-group</a> , on page 25         | Creates an address family group for BGP neighbors and enters address family group configuration mode. |
| <a href="#">neighbor-group</a> , on page 189  | Creates a neighbor group and enters neighbor group configuration mode.                                |

# retain local-label

To retain the local label until the network is converged, use the **retain local-label** command in an appropriate address family configuration mode. To disable the retaining of the local label, use the **no** form of this command.

**retain local-label** *minutes*

**no retain local-label**

## Syntax Description

|                |                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------|
| <i>minutes</i> | Local retention time in minutes. The range is 3 to 60 minutes. The default retention time is 5 minutes. |
|----------------|---------------------------------------------------------------------------------------------------------|

## Command Default

*minutes* : 5

## Command Modes

L2VPN address family configuration  
VPNv4 address family configuration  
VPNv6 address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to enable local label retention for 5 minutes:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# retain local-label 5
```

|-------------------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">additional-paths install backup</a> , on page 9 | Installs a backup path into the forwarding table                         |
| <a href="#">advertise best-external</a> , on page 21        | Advertises the best-external path to the iBGP and route-reflector peers. |

## retain route-target

To accept received updates with specified route targets, use the **retain route-target** command in an appropriate configuration mode. To disable the retaining of routes tagged with specified route targets, use the **no** form of this command.

**retain route-target** {**all**| **route-policy** *route-policy-name*}

**no retain route-target** [**all**| **route-policy** *route-policy-name*]

### Syntax Description

|                                               |                                                                       |
|-----------------------------------------------|-----------------------------------------------------------------------|
| <b>all</b>                                    | Accepts received updates containing at least one route target.        |
| <b>route-policy</b> <i>router-policy-name</i> | Accepts received updates accepted by a specified route filter policy. |

### Command Default

The default is to accept all route targets.

### Command Modes

VPNv4 address family configuration  
VPNv6 address family configuration

### Command History

| Release       | Modification                                                           |
|---------------|------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                           |
| Release 3.5.0 | This command was supported in VPNv6 address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **retain route-target** command to configure a route reflector (RR) to retain routes tagged with specific route targets (RT).

The **retain route-target** is a required command for Inter-AS option B ASBR. By default, an Inter-AS option B ASBR needs the **retain route-target** configured to get VPNv4 BGP table from PE routers, either with the **all** or with the **route-policy** option.

A provider edge (PE) router is not required to hold all VPNv4 routes. The PE router holds only routes that match the import RT of the VPNs configured on it, but a RR must retain all VPNv4 routes because it may peer with PE routers and different PEs may require different RT-tagged VPNv4 routes. Configuring an RR to hold only routes that have a defined set of RT communities and configuring some of these RRs to service a different set of VPNs provides scalability to the RRs. A PE can be configured to peer with all RRs that service the VPN routing and forwarding (VRF) instances configured on the PE. When a new VRF is configured

with an RT for which the PE does not already hold routes, the PE issues route refresh requests to the RRs and gets the relevant VPN routes.

The **route-policy** *route-policy-name* keyword and argument takes the policy name that lists the extended communities that a path should have for the RR to retain the path.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to configure RR to retain all routes with the route filter policy ft-policy-A:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:router(config-bgp-af)# retain route-target route-filter ft-policy-A
```

| <a href="#">import route-target, on page 164</a> | Configures a VRF import route-target extended community. |

# route-policy (BGP)

To apply a routing policy to updates advertised to or received from a Border Gateway Protocol (BGP) neighbor, use the **route-policy** command in an appropriate configuration mode. To disable applying routing policy to updates, use the **no** form of this command.

**route-policy** *route-policy-name* [*parameter1*, *parameter2*, . . . , *parameterN*] {**in** | **out**}

**no route-policy** *route-policy-name* [*parameter1*, *parameter2*, . . . , *parameterN*] {**in** | **out**}

## Syntax Description

|                          |                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------|
| <i>route-policy-name</i> | Name of route policy. Up to 16 parameters can follow the route-policy-name, enclosed in brackets ([ ]). |
| <b>in</b>                | Applies policy to inbound routes.                                                                       |
| <b>out</b>               | Applies policy to outbound routes.                                                                      |

## Command Default

No policy is applied.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 VPNv4 address family group configuration  
 IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | <p>This command was supported in the following configuration modes:</p> <ul style="list-style-type: none"> <li>• VPNv4 address family group</li> <li>• VPNv4 neighbor address family</li> <li>• VRF IPv4 neighbor address family</li> <li>• VPNv4 neighbor group address family</li> </ul>                                                                            |
| Release 3.5.0 | <p>This command was supported in the following configuration modes:</p> <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VRF IPv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul> <p>Up to 16 parameters were supported following the route-policy-name.</p> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-policy** command to specify a routing policy for an inbound or outbound route. The policy can be used to filter routes or modify route attributes. The **route-policy** command is used to define a policy.

#### Note

Configuring a large number of uniquely named outbound neighbor policies can adversely affect performance. This is true even if the uniquely named route policies are functionally identical. The user is discouraged from configuring multiple functionally identical route policies for use with this command. For example, if Policy A and Policy B are identical but named for different neighbors, the two policies should be configured as a single policy.

If the **route-policy** command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to apply the In-Ipv4 policy to inbound IP Version 4 (IPv4) unicast routes from neighbor 172.20.1.1:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# route-policy In-Ipv4 in
```

## Related Commands

| <b>route-policy (RPL)</b>                                    | Defines a route policy and enters route-policy configuration mode.                                    |

# route-reflector-client

To configure the router as a Border Gateway Protocol (BGP) route reflector and configure the specified neighbor as its client, use the **route-reflector-client** command in an appropriate configuration mode. To disable configuring the neighbor as a client, use the **no** form of this command.

**route-reflector-client** [**inheritance-disable**]

**no route-reflector-client** [**inheritance-disable**]

## Syntax Description

|                            |                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Allows the configuration inherited from a neighbor group or address family group to be overridden. |
|----------------------------|---------------------------------------------------------------------------------------------------------------|

## Command Default

The neighbor is not treated as a route reflector client.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 VPNv4 address family group configuration  
 IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

| Release 3.2   | This command was introduced.                                                                                                                                                                                                            |
| Release 3.3.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv4 address family group</li> <li>• VPNv4 neighbor address family</li> <li>• VPNv4 neighbor group address family</li> </ul> |

| Release       | Modification                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul> |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.                                                                                                                                                    |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command is restricted to internal BGP (iBGP) neighbors only.

Use the **route-reflector-client** command to configure the local router as the route reflector and the specified neighbor as one of its clients. All neighbors configured with this command are members of the client group, and the remaining iBGP peers are members of the nonclient group for the local route reflector.

By default, all iBGP speakers in an autonomous system must be fully meshed with each other, and neighbors do not readvertise iBGP learned routes to other iBGP neighbors.

With route reflection, all iBGP speakers need not be fully meshed. An iBGP speaker, the route reflector, passes learned iBGP routes to some number of iBGP client neighbors. Learned iBGP routes eliminate the need for each router running BGP to communicate with every other device running BGP in the autonomous system.

The local router is a route reflector as long as it has at least one route reflector client.

If this command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows neighbor at 172.20.1.1 configured as a route reflector client for IP Version 4 (IPv4) unicast routes:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 140
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# route-reflector-client
```

The following example disables the route-reflector client for neighbor 172.20.1.1, preventing this feature from being automatically inherited from address family group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# route-reflector-client
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 140
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# route-reflector-client inheritance-disable
```

| Release       | Modification                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                     |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.                                                                                                                                                                                       |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system number notation was supported.                                                                                                                                                                                       |
| Release 4.2.0 | The <b>instance</b> and <i>instance-name</i> keyword and argument were added to support BGP Multi-Instance/Multi-AS feature. The command with the <b>instance</b> and <i>instance-name</i> keyword and argument replaced the <b>distributed speaker</b> command. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **router bgp** command to set up a distributed routing core that automatically guarantees the loop-free exchange of routing information between autonomous systems.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| rib     | read, write |

**Examples**

The following example shows how to configure a BGP process for autonomous system 120:

```
RP/0/0/CPU0:router(config)# router bgp 120
```

# rpki server

To enter resource public key infrastructure (RPKI) cache-server (rpki-server) configuration mode and enable rpki parameters configuration, use the **rpki server** command in Router BGP configuration mode. To remove the rpki-server configuration mode and delink cache-server from the cache list, use the **no** form of this command.

**rpki server** {*host-name*| *ip-address*}

**no rpki server** {*host-name*| *ip-address*}

## Syntax Description

|                   |                                       |
|-------------------|---------------------------------------|
| <i>host-name</i>  | Host name of the RPKI cache database. |
| <i>ip-address</i> | IP Address of the RPKI cache databse. |

## Command Default

RPKI server configuration is disabled.

## Command Modes

Router BGP configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to configure an rpki cache-server database and enter rpki-server configuration mode:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)#
```

# selective-vrf-download disable

To disable selective VRF download (SVD) on a line card to enable download all prefixes and labels to the line card, use the **selective-vrf-download disable** command in global configuration mode. To enable the SVD, use the **no** form of this command.

**selective-vrf-download disable**

**no selective-vrf-download disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** SVD is enabled.

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.1.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You must failover the active RP or reload the router after disabling SVD for the configuration change to get activated.

| Task ID | Task ID     | Operation   |
|---------|-------------|-------------|
|         | ip-services | read, write |

**Examples** This example shows how to disable selective vrf download:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#selective-vrf-download disable
```

| Related Commands | Command                                     | Description                                              |
|------------------|---------------------------------------------|----------------------------------------------------------|
|                  | <a href="#">show svd role, on page 467</a>  | Displays Selective VRF Download (SVD) role information.  |
|                  | <a href="#">show svd state, on page 469</a> | Displays Selective VRF Download (SVD) state information. |

## send-buffer-size

To set the size of the send buffers for a Border Gateway Protocol (BGP) neighbor, use the **send-buffer-size** command in an appropriate configuration mode. To set the size of the send buffers to the default values, use the **no** form of this command.

**send-buffer-size** *socket-size* [*bgp-size*]

**no send-buffer-size** [*socket-size*] [*bgp-size*]

### Syntax Description

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <i>socket-size</i> | Size, in bytes, of the send-side socket buffer. Range is 4096 to 131072.            |
| <i>bgp-size</i>    | (Optional) Size, in bytes, of the BGP process send buffer. Range is 4096 to 131072. |

### Command Default

*socket-size* : 10240 bytes

*bgp-size* : 4096 bytes

Use the **socket send-buffer-size** command to change the defaults.

### Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

### Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **send-buffer-size** command to increase the buffer size employed when sending updates to a neighbor. Using larger buffers can improve convergence time because the software can process more packets simultaneously. However, allocating larger buffers uses more memory on the router.

**Note**

Increasing the socket buffer size uses more memory only when more messages are waiting to be processed by the software. In contrast, increasing the BGP buffer size uses more memory indefinitely.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the send buffer sizes for neighbor 172.20.1.1 to be 8192 bytes for both the socket buffer and the BGP buffer:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# send-buffer-size 8192 8192
```

**Related Commands**

| Command                                               | Description                                                            |
|-------------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group</a> , on page 189          | Creates a neighbor group and enters neighbor group configuration mode. |

# send-community-ebgp

To specify that community attributes should be sent to an external Border Gateway Protocol (eBGP) neighbor, use the **send-community-ebgp** command in an appropriate configuration mode. To disable sending community attributes to an eBGP neighbor, use the **no** form of this command.

**send-community-ebgp** [**inheritance-disable**]

**no send-community-ebgp** [**inheritance-disable**]

## Syntax Description

|                            |                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Allows configuration inherited from a neighbor group or address family group to be overridden. |
|----------------------------|-----------------------------------------------------------------------------------------------------------|

## Command Default

Community (COMM) attributes are NOT sent to eBGP peers (including PE-CE peers).

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 IPv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor address family configuration

## Command History

| Release       | Modification                                                                           |
|---------------|----------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                           |
| Release 3.3.0 | This command was supported in the VRF IPv4 neighbor address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 neighbor address family configuration mode.     |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.   |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **send-community-ebgp** command to control whether community attributes are sent to eBGP neighbors. This command cannot be configured for iBGP neighbors as community attributes are always sent to iBGP neighbors.

When IOS XR BGP updates community attributes for eBGP VPN peers (VPNv4 or VPNv6), there is no need to configure the **send-community-ebgp** command separately. The community attributes are updated by default.

If this command is configured for a neighbor group or address family group, all neighbors using the group inherit the configuration. Configuring the command specifically for a neighbor overrides inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to disable the router that sends community attributes to neighbor 172.20.1.1 for IP Version 4 (IPv4) multicast routes:

```
RP/0/0/CPU0:router(config)#router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# send-community-ebgp
```

The following example shows how to disable the delivery of community attributes to neighbor 172.20.1.1, preventing this feature from being inherited from address family group group1:

```
RP/0/0/CPU0:router(config)#router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-afgrp)# send-community-ebgp
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# send-community-ebgp inheritance-disable
```

**Related Commands**

|------------------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">send-extended-community-ebgp</a> , on page 258 | Specifies that extended community attributes are sent to eBGP neighbors. |

## send-extended-community-ebgp

To specify that extended community attributes should be sent to external Border Gateway Protocol (eBGP) neighbors, use the **send-extended-community-ebgp** command in an appropriate configuration mode. To disable sending extended community attributes to eBGP neighbors, use the **no** form of this command.

**send-extended-community-ebgp** [**inheritance-disable**]

**no send-extended-community-ebgp** [**inheritance-disable**]

### Syntax Description

|                            |                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Allows configurations inherited from a neighbor group or address family group to be overridden. |
|----------------------------|------------------------------------------------------------------------------------------------------------|

### Command Default

Extended community (EXTCOMM) attributes are NOT sent to eBGP peers (including PE-CE peers).

### Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 IPv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor address family configuration

### Command History

| Release       | Modification                                                                           |
|---------------|----------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                           |
| Release 3.3.0 | This command was supported in the VRF IPv4 neighbor address family configuration mode. |
| Release 3.5.0 | This command was supported in VRF IPv6 neighbor address family configuration mode.     |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.   |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **send-extended-community-ebgp** command to control whether extended community attributes are sent to eBGP neighbors. This command cannot be used for iBGP neighbors as extended community attributes are always sent to iBGP neighbors.

When IOS XR BGP updates community attributes for eBGP VPN peers (VPNv4 or VPNv6), there is no need to configure the **send-extended-community-ebgp** command separately. The community attributes are updated by default.

If this command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to configure the router to send extended community attributes to neighbor 172.20.1.1 for IP Version 4 (IPv4) multicast routes:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# send-extended-community-ebgp
```

The following example shows how to disable the delivery of extended community attributes to neighbor 172.20.1.1, preventing this feature from being automatically inherited from address family group group1:

```
RP/0/0/CPU0:router(config)# router bgp 140
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-afgrp)# send-extended-community-ebgp
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# send-extended-community-ebgp inheritance-disable
```

**Related Commands**

## session-group

To create a session group and enter session group configuration mode, use the **session-group** command in router configuration mode. To remove a session group and delete all configurations associated with it, use the **no** form of this command.

**session-group** *name*

**no session-group** *name*

### Syntax Description

|             |                            |
|-------------|----------------------------|
| <b>name</b> | Name of the session group. |
|-------------|----------------------------|

### Command Default

No session groups are created.

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **session-group** command to create a session group from which neighbors can inherit configuration that is address family-independent. That is, session groups cannot have address family-specific configuration. This command enters the session group configuration mode in which configuration for a session group is entered.

Many commands can be configured in both session group configuration mode and neighbor configuration mode.

Use of session groups saves time and reduces the router configuration size. Because the configuration of a session group can be inherited by any number of neighbors, use of the group can eliminate the need to copy long or complex configurations on each of a large number of neighbors. A neighbor can inherit all configuration from a session group simply by configuring the **use** command. Specific inherited session group configuration commands can be overridden for a specific neighbor by explicitly configuring the command for the specific neighbor.

The **no** form of this command causes all of the configuration for the session group to be removed. You cannot use the **no** form of this command if removing the group would leave one or more neighbors without a configured remote autonomous system number.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows a session group called group1 that is used by two neighbors, 10.0.0.1 and 10.0.0.2. Because group1 is a session group, it contains only address family-independent configuration. And because group1 is used by neighbors 10.0.0.1 and 10.0.0.2, they inherit the configuration of the group.

```
RP/0/RSP0RP0/CPU0:router(config)# router bgp 1
RP/0/RSP0RP0/CPU0:router(config-bgp)# session-group group1
RP/0/RSP0RP0/CPU0:router(config-bgp-sngrp)# remote-as 1
RP/0/RSP0RP0/CPU0:router(config-bgp-sngrp)# advertisement-interval 2
RP/0/RSP0RP0/CPU0:router(config-bgp-sngrp)# exit
RP/0/RSP0RP0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/RSP0RP0/CPU0:router(config-bgp-nbr)# use session-group group1
RP/0/RSP0RP0/CPU0:router(config-bgp-nbr)# exit
RP/0/RSP0RP0/CPU0:router(config-bgp)# neighbor 10.0.0.2
RP/0/RSP0RP0/CPU0:router(config-bgp-nbr)# use session-group group1
```

The following example shows a session group called group1 used by two neighbors, 10.0.0.1 and 10.0.0.2. Because group1 is a session group, it contains only address family-independent configuration. And because group1 is used by neighbors 10.0.0.1 and 10.0.0.2, they inherit the configuration of the group. However, the **password password1** configuration from group1 is overridden for neighbor 10.0.0.2, using the **password-disable** command in the neighbor 10.0.0.2 configuration submenu.

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group group1
RP/0/0/CPU0:router(config-bgp-sngrp)# remote-as 1
RP/0/0/CPU0:router(config-bgp-sngrp)# advertisement-interval 2
RP/0/0/CPU0:router(config-bgp-sngrp)# password password1
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.1
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.0.0.2
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# password-disable
```

# session-open-mode

To establish a Border Gateway Protocol (BGP) session with a specific TCP open mode, use the **session-open-mode** command in an appropriate configuration mode. To restore the default state, use the **no** form of this command.

**session-open-mode** {**active-only**| **both**| **passive-only**}

**no session-open-mode** [**active-only**| **both**| **passive-only**]

## Syntax Description

|                     |                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>active-only</b>  | Ensures that the BGP session can be established only when the request is initiated by the local end (active-open request) and all passive-open requests (from the other end) are rejected by the local BGP. |
| <b>both</b>         | Allows BGP sessions to be established from both incoming or outgoing TCP connection requests, with one being rejected in the event of a request collision.                                                  |
| <b>passive-only</b> | Ensures that the local BGP does not initiate any TCP open requests and the session can be established only when the request comes from the remote end.                                                      |

## Command Default

The default is **both**.

## Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

BGP, by default, tries to initiate an active TCP connection whenever a new neighbor is configured. A remote neighbor may also initiate the TCP connection before the local BGP can initiate the connection. This initiation of a TCP connection by a remote neighbor is considered a passive-open request and it is accepted by the local BGP. This default behavior can be modified using the **session-open-mode** command.

**Note**

The BGP connection is not opened and, as a result the BGP session, is not established if both the peering neighbors use the same nondefault TCP session open mode—active-only or passive-only. If both ends are configured with active-only, each neighbor rejects the TCP open request from the other end. One neighbor must be configured as passive-only or both. Similarly, if both neighbors are configured with passive-only, neither neighbor initiates the TCP open request and the BGP session is not established. Again, one neighbor must be configured as active-only or both. There is one exception. A connection open request from a neighbor that is configured with the TCP session open mode to be passive-only is processed to detect whether there is a connection collision before the request is rejected. This exception enables the local BGP to reset the session if the remote neighbor goes down and it is not detected by the local router.

Use the **session-open-mode** command when it may be necessary to preconfigure a neighbor that does not exist. Ensure that BGP does not spend any time actively trying to set up a TCP session with the neighbor. A BGP session does not come up between two neighbors, both of which configure the same nondefault value (**active-only** or **passive-only** keyword) for this command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to enable a BGP session on router bgp 1:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 45.67.89.01
RP/0/0/CPU0:router(config-bgp-nbr)# session-open-mode active-only
```

# show bgp

To display entries in the Border Gateway Protocol (BGP) routing table, use the **show bgp** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast| all| tunnel| mdt}| ipv6 {unicast| multicast| all|
labeled-unicast}| all {unicast| multicast| all| labeled-unicast| mdt| tunnel}| vpnv4 unicast [rd rd-address]]
vrf {vrf-name| all} [ipv4 {unicast| labeled-unicast}| ipv6 unicast| vpnv6 unicast [rd rd-address]] [ip-address
[{mask| /prefix-length} [longer-prefixes| unknown-attributes| bestpath-compare]]] [standby] [detail]
```

## Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                |

|                           |                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>         | (Optional) Network address, entered to display a particular network in the BGP routing table. If the network address is omitted, then all networks in the BGP routing table are displayed. If the network mask and prefix length is omitted, then the software displays the longest matching prefix for the network address. |
| <i>mask</i>               | (Optional) Network mask of the BGP route to match.                                                                                                                                                                                                                                                                           |
| <i>/prefix-length</i>     | (Optional) Prefix length of the BGP route to match. A slash (/) must precede the decimal value.                                                                                                                                                                                                                              |
| <b>longer-prefixes</b>    | (Optional) Displays a route with the specified prefix length and more-specific routes if available. The <b>longer-prefixes</b> keyword is available when the <i>ip-address</i> and <i>mask</i> or <i>/prefix-length</i> arguments are specified.                                                                             |
| <b>unknown-attributes</b> | (Optional) Includes unknown, transitive attributes. The <b>unknown-attributes</b> keyword is available when the <i>ip-address</i> and <i>mask</i> or <i>/prefix-length</i> arguments are specified.                                                                                                                          |
| <b>bestpath-compare</b>   | (Optional) Displays route and best-path comparison information. The <b>bestpath-compare</b> keyword is available when the <i>ip-address</i> and <i>mask</i> or <i>/prefix-length</i> arguments are specified.                                                                                                                |
| <b>standby</b>            | (Optional) Displays information about the standby card.                                                                                                                                                                                                                                                                      |
| <b>detail</b>             | (Optional) Displays the prefix details.                                                                                                                                                                                                                                                                                      |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

| Release 4.0.0 | <p>The command output was modified to display BGP add-path information.</p>                                                                                                                                                                                                                                                                                                            |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

The **set default-afi** command is used to specify the default address family for the sessions and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each address family and subaddress family combination that has been configured. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for an address family or a subaddress family, each matching routing table is examined in turn.

#### Note

Running the **show bgp** command immediately after configuring a large and complex route policy may result in timeout of the system database shown through an error message (SYSDB-SYSDB-6-TIMEOUT\_EDM). It is recommended, that the show command be run, after the new route policy takes effect.

Use the **show bgp** *ip-address* { *mask* | */prefix-length* } command to display detailed information for a specific route. If the mask and prefix length are omitted, the details of the longest matching prefix for the IP address are displayed.

Use the **show bgp** command to display all routes in the specified BGP routing table. Use the **show bgp** *ip-address* { *mask* | */prefix-length* } **longer-prefixes** command to display those routes more specific than a particular prefix.

Use the **unknown-attributes** keyword to display details of any transitive attributes associated with a route that are not understood by the local system.

Use the **show bgp** *ip-address/prefix-length* **detail** command to display details of the specified prefix.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp** command in EXEC mode:

```
RP/0/0/CPU0:router#show bgp
BGP router identifier 172.20.1.1, local AS number 1820
BGP generic scan interval 60 secs
BGP table state: Active
Table ID: 0xe0000000
BGP main routing table version 3
Dampening enabled
BGP scan interval 60 secs

Status codes: s suppressed, d damped, h history, * valid, > best
               i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete

**Table 3: show bgp Field Descriptions**

| Field                          | Description                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                                                                                                                                                                                                                                                                                       |
| local AS number                | Autonomous system number for the local system. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| BGP generic scan interval      | Interval (in seconds) between scans of the BGP table by a generic scanner.                                                                                                                                                                                                                                                                                                 |
| BGP table state                | State of the BGP database.                                                                                                                                                                                                                                                                                                                                                 |
| Table ID                       | BGP database identifier.                                                                                                                                                                                                                                                                                                                                                   |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                                                                                                                                                                                                                                                                                           |
| Dampening enabled              | Dampening is enabled for the routes in this BGP routing table.                                                                                                                                                                                                                                                                                                             |
| BGP scan interval              | Interval (in seconds) between BGP scans for the specified address family and subaddress family.                                                                                                                                                                                                                                                                            |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was sourced by BGP using a network or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the path origin code.                                                                    |

The following is sample output from the **show bgp** command with the network specified:

```
RP/0/0/CPU0:router# show bgp 11.0.0.0/24
BGP router table entry for 11.0.0.0/24
Versions:
  Process          bRIB/RIB  SendTblVer

    10.4.101.2 from 10.4.101.2 (10.4.101.2)
      Origin IGP, localpref 100, valid, internal
```

This table describes the significant fields shown in the display.

**Table 4: show bgp prefix length Field Descriptions**

| Field                  | Description                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP router table entry | Network that is being displayed.                                                                                                                                                                                       |
| Versions               | List of the network versions in each BGP process.                                                                                                                                                                      |
| Process                | Name of the BGP process.                                                                                                                                                                                               |
| bRIB/RIB               | Version of the network for sending to the RIB. You can compare this version with the bRIB/RIB version for the process (at the top of <b>show bgp summary</b> ) to verify whether the network has been sent to the RIB. |

| Field                                                     | Description                                                                                                                                                                                                                         |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SendTblVer                                                | Version of the network for advertising to neighbors. This can be compared with the neighbor version to determine whether the network has been advertised to a particular neighbor.                                                  |
| Last Modified                                             | Timestamp when this route was last modified.                                                                                                                                                                                        |
| Paths                                                     | List of paths for the network (that is, routes to reach the network). The number of paths and the index of the best path are given.                                                                                                 |
| not advertised to any peer                                | Best path was received with a NO_ADVERTISE community and is not advertised to any neighbor.                                                                                                                                         |
| not advertised to EBGp peer                               | Best path was received with a NO_EXPORT community and is not advertised to any eBGp neighbor.                                                                                                                                       |
| not advertised outside local AS                           | Best path was received with a LOCAL_AS community and is not advertised to peers outside the local AS.                                                                                                                               |
| Advertisements of this net are suppressed by an aggregate | Network is a more-specific prefix of a configured aggregate and has been suppressed. It is not advertised to any neighbors unless they have an unsuppress-map configured.                                                           |
| Advertised to update-groups                               | List of update-groups to which the net has been advertised. Update-groups that have only one peer are not listed here.                                                                                                              |
| Advertised to peers                                       | List of neighbors to which the net has been advertised to. Neighbors that are in one of the update-groups listed above are not listed separately. Only neighbors that are in unique update-groups are listed.                       |
| Received by speaker 0                                     | BGP process where the path originated. This is always "speaker 0" for standalone mode. It will be the speaker-id when BGP is in distributed mode.                                                                                   |
| AS Path                                                   | Autonomous system (AS) path that was received for the path. If the AS path is empty, then "Local" is displayed. This is the case for paths that are locally generated on this router or on a neighboring router within the same AS. |
| aggregated by                                             | If the path is an aggregate, the router-id of the router that performed the aggregation.                                                                                                                                            |

| Field                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| suppressed due to dampening             | Path has been suppressed due to the configured path dampening.                                                                                                                                                                                                                                                                                                                                             |
| history entry                           | Path is withdrawn, but a copy is kept to store the dampening information.                                                                                                                                                                                                                                                                                                                                  |
| Received from a RR-client               | Path was received from a route reflector client.                                                                                                                                                                                                                                                                                                                                                           |
| received-only                           | If soft reconfiguration inbound is configured, the path was received but dropped by inbound policy, or was accepted and modified. In either event, the received-only value is a copy of the original, unmodified path.                                                                                                                                                                                     |
| received & used                         | If soft reconfiguration inbound is configured, the path was received and accepted by inbound policy, but not modified.                                                                                                                                                                                                                                                                                     |
| stale                                   | Neighbor from which the path was received is down, and the path is kept and marked as stale to support graceful restart.                                                                                                                                                                                                                                                                                   |
| <nexthop> from <neighbor> (<router-id>) | Next hop for the path. If the next hop is known by a mechanism outside BGP (for example, for redistributed paths), then 0.0.0.0 is displayed. After the next hop, the neighbor from whom the path was received is displayed, along with the neighbor's router-id. If the path was locally generated (for example, an aggregate or redistributed path), then 0.0.0.0 is displayed for the neighbor address. |
| Origin                                  | IGP: the path originated from an IGP.<br>EGP: the path originated from an EGP.<br>incomplete: the origin of the path is unknown.                                                                                                                                                                                                                                                                           |
| metric                                  | MED value of the path.                                                                                                                                                                                                                                                                                                                                                                                     |
| localpref                               | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system.                                                                                                                                                                                                                                      |
| weight                                  | Locally assigned weight (if not 0) of the path. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                                                                                                                                                                                                                            |
| valid                                   | Path is valid and can be considered in the best-path calculation.                                                                                                                                                                                                                                                                                                                                          |

| Field              | Description                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| redistributed      | Path is redistributed through a <b>redistribute</b> command.                                                      |
| aggregated         | Path is a locally generated aggregate created due to an <b>aggregate-address</b> command.                         |
| local              | Path is a local network source due to a <b>network</b> command.                                                   |
| internal           | Path was received from an iBGP neighbor.                                                                          |
| external           | Path was received from an eBGP neighbor.                                                                          |
| atomic-aggregate   | Path was received with the atomic-aggregate flag set. Some path information has been removed through aggregation. |
| best               | Path is the best path for the network and is used for routing and advertised to peers.                            |
| multipath          | Path is a multipath and is installed into the RIB along with the best path.                                       |
| Community          | List of communities attached to the path.                                                                         |
| Extended community | List of extended communities attached to the path.                                                                |
| Originator         | Originator of the path within the AS Cluster list if the path is reflected.                                       |
| AS Cluster list    | List of RR clusters the path has passed through if the path is reflected                                          |
| Dampinfo           | Penalty and reuse information if the path is dampened.                                                            |
| penalty            | Current penalty for the path.                                                                                     |
| flapped            | Number of times the path has flapped and the time since the first flap.                                           |
| reuse in           | Time until the path is re-used (undampened).                                                                      |
| half life          | Configured half-life for the path.                                                                                |
| suppress value     | Penalty at which the path is suppressed.                                                                          |
| reuse value        | Penalty at which the path is re-used.                                                                             |

| Field                 | Description                                                  |
|-----------------------|--------------------------------------------------------------|
| Maximum suppress time | Maximum length of time for which the path can be suppressed. |

The following is sample output from the **show bgp** command with the *ip-address/prefix-length detail* options:

```
RP/0/0/CPU0:router# show bgp 51.0.0.0/24 detail
Sat Mar 14 00:37:14.109 PST PDT

      Originator: 16.16.16.16, Cluster list: 88.88.88.88

```

The **show bgp** command output displays 'import suspect' when potential import oscillation has been detected for the prefix. Import of such a prefix is not affected. However, import of the prefix can be dampened in future if the oscillation continues. If the oscillation stops during the next import run, the prefix will no longer be marked 'import suspect'.

This is sample output from **show bgp vpnv4 unicast rd prefix/length** command that displays Accept Own prefix information:

```

RP/0/0/CPU0:router#show bgp vpnv4 unicast rd 10.10.10.10:1 110.1.1.1/32 detail

```

This table describes the significant fields shown in the display:

| Field                | Description                                                                          |
|----------------------|--------------------------------------------------------------------------------------|
| accept-own-self      | The Accept Own path in the customer VRF contains the "accept-own-self" keyword/flag. |
| accept-own           | The Accept Own path contains the "accept-own" keyword/flag.                          |
| Community:accept-own | List of communities attached to the path: accept-own.                                |
| Extended community   | List of extended communities attached to the path.                                   |
| Cluster list         | Router ID or cluster ID of all route reflectors through which the route has passed.  |

The output of **show bgp {vpnv4 | vpnv6} unicast rd** command may display the optional BGP attribute `not-in-vrf`. If a path in a VPNvX net is marked as not-in-vrf, it may be due to any of the following conditions:

- The RD of the VPNvX net is not the same as any of the RDs configured for VRFs on the router.
- The RD of the VPNvX net is the same as the RD configured for a specific VRF on the router, but the path is not imported to the specified VRF. For example, the route-targets attached to the path do not match any of the **import route-target** [*as-number:nn* | *ip-address:nn*] configured for VRF, *vrf\_1*.

If the not-in-vrf net is set, it indicates that the path does not belong to the VRF.

| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

This example displays sample output from **show bgp vrf vrf1 update in error** command:

```
RP/0/0/CPU0:router#show bgp update in error
```

```
VRF "default"
  Malformed Update messages: 0
  Neighbors that received malformed Update messages: 0
  Last malformed update received: --- (never)
```

# show bgp advertised

To display advertisements for neighbors or a single neighbor, use the **show bgp advertised** command in EXEC mode.

```
show bgp [ipv4 { all| labeled-unicast| mdt| multicast| tunnel| unicast}] advertised [neighbor ip-address]
[standby] [summary]
```

```
show bgp [ipv6 { all| labeled-unicast| multicast| unicast}] advertised [neighbor ip-address] [standby]
[summary]
```

```
show bgp [ all { all| labeled-unicast| multicast| tunnel| unicast } ] advertised [neighbor ip-address]
[standby] [summary]
```

```
show bgp [ vpnv4 unicast [rd rd-address]] advertised [neighbor ip-address] [standby] [summary]
```

```
show bgp [ vpnv6 unicast [ rd rd-address]] advertised [neighbor ip-address] [standby] [summary]
```

```
show bgp [ vrf {vrf-name| all} [ ipv4 | {labeled-unicast| unicast}| ipv6 unicast]] advertised [neighbor
ip-address] [standby] [summary]
```

## Syntax Description

|                        |                                                                             |
|------------------------|-----------------------------------------------------------------------------|
| <b>ipv4</b>            | (Optional) Specifies IP Version 4 address prefixes.                         |
| <b>unicast</b>         | (Optional) Specifies unicast address prefixes.                              |
| <b>multicast</b>       | (Optional) Specifies multicast address prefixes.                            |
| <b>labeled-unicast</b> | (Optional) Specifies labeled unicast address prefixes.                      |
| <b>all</b>             | (Optional) For address family, specifies prefixes for all address families. |
| <b>tunnel</b>          | (Optional) Specifies tunnel address prefixes.                               |
| <b>mdt</b>             | (Optional) Specifies multicast distribution tree (MDT) address prefixes.    |
| <b>ipv6</b>            | (Optional) Specifies IP Version 6 address prefixes.                         |
| <b>vpnv4 unicast</b>   | (Optional) Specifies VPNv4 unicast address families.                        |
| <b>rd rd-address</b>   | (Optional) Displays routes with a specific route distinguisher.             |
| <b>vrf</b>             | (Optional) Specifies VPN routing and forwarding (VRF) instance.             |
| <b>vrf-name</b>        | (Optional) Name of a VRF.                                                   |
| <b>all</b>             | (Optional) For VRF, specifies all VRFs.                                     |

|                                                         |                                                                                                                                                               |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.                                                                               |
| <b>ipv6 unicast</b>                                     | (Optional) For VRF, specifies IPv6 unicast address families.                                                                                                  |
| <b>vpnv6 unicast</b>                                    | (Optional) Specifies VPNv6 unicast address families.                                                                                                          |
| <b>neighbor</b>                                         | (Optional) Previews advertisements for a single neighbor. If the <b>neighbor</b> keyword is omitted, then the advertisements for all neighbors are displayed. |
| <i>ip-address</i>                                       | (Optional) IP address of the neighbor.                                                                                                                        |
| <b>standby</b>                                          | (Optional) Displays information about the standby card.                                                                                                       |
| <b>summary</b>                                          | (Optional) Displays a summary of advertisements.                                                                                                              |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                        |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                                                        |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpnv4 unicast</b> ] [ <b>rd</b> <i>rd-address</i>   <b>vrf</b> <i>vrf-name</i> ]</li> </ul>                                            |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                                                   |
| Release 3.5.0 | The <b>vpnv6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                               |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each address family and subaddress family combination that is configured. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined in turn.

Use the **show bgp advertised** command to display the routes that have been advertised to peers or a specific peer. To preview advertisements that would be sent to a peer under a particular policy, even if the corresponding update messages have not been generated yet, use the **show bgp policy** command.

**Note**

When you issue the **show bgp advertised** command, a route is not displayed in the output unless an advertisement for that route has already been sent (and not withdrawn). If an advertisement for the route has not yet been sent, the route is not displayed.

Use the **summary** keyword to display a summary of the advertised routes. If you do not specify the **summary** keyword, the software displays detailed information about the advertised routes.

**Note**

The **show bgp advertised** command does not display the application of any outbound policy in the route details it displays. Consequently, this command provides only an indication of whether a particular route has been advertised, rather than details of which attributes were advertised. Use the **show bgp policy sent-advertisements** command to display the attributes that are advertised.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp advertised** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp advertised neighbor 10.0.101.4 summary
```

| Network    | Next Hop   | From       | AS Path               |
|------------|------------|------------|-----------------------|
| 1.1.1.0/24 | 10.0.101.1 | 10.0.101.1 | 2 3 222 333 444 555 i |
| 1.1.2.0/24 | 10.0.101.1 | 10.0.101.1 | 3 4 5 6 7 i           |

```

1.1.3.0/24 10.0.101.1          10.0.101.1  77 88 33 44 55 99 99 99 i
1.1.4.0/24 10.0.101.1          10.0.101.1  2 5 6 7 8 i
1.1.7.0/24 10.0.101.1          10.0.101.1  3 5 i
1.1.8.0/24 10.0.101.1          10.0.101.1  77 88 99 99 99 i

```

This table describes the significant fields shown in the display.

**Table 6: show bgp advertised neighbor summary Field Descriptions**

| Field           | Description                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network         | IP prefix and prefix length for a network.                                                                                                                                           |
| Next Hop        | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network. |
| From            | IP address of the peer that advertised this route.                                                                                                                                   |
| AS Path         | AS path of the peer that advertised this route.                                                                                                                                      |
| Local           | Indicates the route originated on the local system.                                                                                                                                  |
| Local Aggregate | Indicates the route is an aggregate created on the local system.                                                                                                                     |
| Advertised to   | Indicates the peer to which this entry was advertised. This field is used in the output when displaying a summary of the advertisements to all neighbors.                            |

The following is sample output from the **show bgp advertised** command for detailed advertisement information:

```

RP/0/0/CPU0:router# show bgp advertised neighbor 172.72.77.1

172.16.0.0/24 is advertised to 172.72.77.1
  Path info:
    neighbor: Local          neighbor router id: 172.74.84.1
    valid redistributed best
  Attributes after inbound policy was applied:
  next hop: 0.0.0.0
    MET ORG AS
    origin: incomplete metric: 0
  aspath:
10.52.0.0/16 is advertised to 172.72.77.1
  Path info:
    neighbor: Local Aggregate neighbor router id: 172.74.84.1
    valid aggregated best
  Attributes after inbound policy was applied:
  next hop: 0.0.0.0
    ORG AGG ATOM
    origin: IGP aggregator: 172.74.84.1 (1)
  aspath:

```

This table describes the significant fields shown in the display.

**Table 7: show bgp advertised neighbor Field Descriptions**

| Field                               | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| is advertised to                    | IP address of the peer to which this route has been advertised. If the route has been advertised to multiple peers, the information is shown separately for each peer.                                                                                                                                                                                                                                     |
| neighbor                            | IP address of the peer that advertised this route, or one of the following:<br><br>Local—Route originated on the local system.<br><br>Local Aggregate—Route is an aggregate created on the local system.                                                                                                                                                                                                   |
| neighbor router id                  | BGP identifier for the peer, or the local system if the route originated on the local system.                                                                                                                                                                                                                                                                                                              |
| Not advertised to any peer          | Indicates the no-advertise well-known community is associated with this route. Routes with this community are not advertised to any BGP peers.                                                                                                                                                                                                                                                             |
| Not advertised to any EBGp peer     | Indicates the no-export well-known community is associated with this route. Routes with this community are not advertised to external BGP peers, even if those external peers are part of the same confederation as the local router.                                                                                                                                                                      |
| Not advertised outside the local AS | Indicates the local-AS well-known community is associated with this route. Routes with this community value are not advertised outside the local autonomous system or confederation boundary.                                                                                                                                                                                                              |
| (Received from a RR-client)         | Path was received from a route reflector client.                                                                                                                                                                                                                                                                                                                                                           |
| (received-only)                     | This path is not used for routing purposes. It is used to support soft reconfiguration, and records the path attributes before inbound policy was applied to a path received from a peer. A path marked “received-only” indicates that either the path was dropped by inbound policy, or the path information was modified by inbound policy and a separate copy of the modified path is used for routing. |
| (received & used)                   | Indicates that the path is used both for soft reconfiguration and routing purposes. A path marked “received and used,” implies the path information was not modified by inbound policy.                                                                                                                                                                                                                    |
| valid                               | Path is valid.                                                                                                                                                                                                                                                                                                                                                                                             |

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| origin      | <p>Origin of the path:</p> <p>IGP—Path originated from an Interior Gateway Protocol (IGP) and was sourced by BGP using a <b>network</b> or <b>aggregate-address</b> command.</p> <p>EGP—Path originated from an Exterior Gateway Protocol.</p> <p>incomplete—Origin of the path is not clear. For example, a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                |
| neighbor as | First autonomous system (AS) number in the AS path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| aggregator  | Indicates that the path was received with the aggregator attribute. The autonomous system number and router-id of the system that performed the aggregation are shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| metric      | Value of the interautonomous system metric, otherwise known as the MED metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| localpref   | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| aspath      | AS path associated with the route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| community   | <p>Community attributes associated with the path. Community values are displayed in AA:NN format, except for the following well-known communities:</p> <p>Local-AS—Community with value 4294967043 or hex 0xFFFFFFFF03. Routes with this community value are not advertised outside the local autonomous system or confederation boundary.</p> <p>no-advertise—Community with value 4294967042 or hex 0xFFFFFFFF02. Routes with this community value are not advertised to any BGP peers.</p> <p>no-export—Community with value 4294967041 or hex 0xFFFFFFFF01. Routes with this community are not advertised to external BGP peers, even if those peers are in the same confederation with the local router.</p> |

| Field              | Description                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extended community | Extended community attributes associated with the path. For known extended community types, the following codes may be displayed:<br><br>RT—Route target community<br>SoO—Site of Origin community<br>LB—Link Bandwidth community |
| Originator         | Router ID of the originating router when route reflection is used.                                                                                                                                                                |
| Cluster lists      | Router ID or cluster ID of all route reflectors through which the route has passed.                                                                                                                                               |

# show bgp af-group

To display information about Border Gateway Protocol (BGP) configuration for address family groups, use the **show bgp af-group** command in EXEC mode.

```
show bgp af-group group-name {configuration [defaults] [nvgen]] inheritance| users}
```

## Syntax Description

|                      |                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group-name</i>    | Name of the address family group to display.                                                                                                                                                                         |
| <b>configuration</b> | (Optional) Displays the effective configuration for the af-group, including any settings that have been inherited from af-groups used by this af-group.                                                              |
| <b>defaults</b>      | (Optional) Displays all configuration settings, including any default settings.                                                                                                                                      |
| <b>nvgen</b>         | (Optional) Displays output in the format of <b>show running-config</b> output.<br>If the <b>defaults</b> keyword is also specified, the output is not suitable for cutting and pasting into a configuration session. |
| <b>inheritance</b>   | Displays the af-groups from which this af-group inherits configuration settings.                                                                                                                                     |
| <b>users</b>         | Displays the neighbors, neighbor groups, and af-groups that inherit configuration from this af-group.                                                                                                                |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show bgp af-group** command with the *group-name* **configuration** argument and keyword to display the effective configuration of an af-group, taking into account any configuration that may be inherited from other af-groups through the **use af-group** command. The source of each command is shown.

If the **defaults** keyword is specified, all configuration for the af-group, including default values, is shown. Default configuration is identified in the show output. Use the **nvgen** keyword to display configuration

formatted in the style of the **show running-config** command. This output is suitable for cutting and pasting into configuration sessions.

Use the **show bgp af-group** command with the *group-name* **inheritance** argument and keyword to display the address family groups from which the specified af-group inherits configuration.

Use the **show bgp af-group** command with the *group-name* **users** argument and keyword to display the neighbors, neighbor groups, and af-groups that inherit configuration from the specified af-group.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following af-group configuration is used in the examples:

```
af-group group3 address-family ipv4 unicast
remove-private-AS
soft-reconfiguration inbound
!
af-group group1 address-family ipv4 unicast
use af-group group2
maximum-prefix 2500 75 warning-only
default-originate
soft-reconfiguration inbound disable
!
af-group group2 address-family ipv4 unicast
use af-group group3
send-community-ebgp
send-extended-community-ebgp
capability orf prefix both
```

The following is sample output from the **show bgp af-group** command with the **configuration** keyword in EXEC mode. The source of each command is shown in the right column. For example, **default-originate** is configured directly on **af-group group1**, and the **remove-private-AS** command is inherited from af-group group2, which in turn inherits it from af-group group3.

```
RP/0/0/CPU0:router# show bgp af-group group1 configuration
```

```
af-group group1 address-family ipv4 unicast
capability orf prefix both          [a:group2]
default-originate                   []
maximum-prefix 2500 75 warning-only []
remove-private-AS                   [a:group2 a:group3]
send-community                      [a:group2]
send-extended-community             [a:group2]
```

The following is sample output from the **show bgp af-group** command with the **users** keyword:

```
RP/0/0/CPU0:router# show bgp af-group group2 users
```

```
IPv4 Unicast: a:group1
```

The following is sample output from the **show bgp af-group** command with the **inheritance** keyword. This example shows that the specified af-group group1 directly uses the group2 af-group, which in turn uses the group3 af-group:

```
RP/0/RSP0RP0/CPU0:router# show bgp af-group group1 inheritance
```

```
IPv4 Unicast: a:group2 a:group3
```

[Table 8: show bgp af-group Field Descriptions, on page 301](#) describes the significant fields shown in the display.

This table describes the significant fields shown in the display.

**Table 8: show bgp af-group Field Descriptions**

| Field     | Description                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ ]       | Configures the command directly on the specified address family group.                                                                                                                 |
| a:        | Indicates the name that follows is an address family group.                                                                                                                            |
| n:        | Indicates the name that follows is a neighbor group.                                                                                                                                   |
| [dflt]    | Indicates the setting is not explicitly configured or inherited, and the default value for the setting is used. This field may be shown when the <b>defaults</b> keyword is specified. |
| <not set> | Indicates that the configuration is disabled by default. This field may be shown when the <b>defaults</b> keyword is specified.                                                        |

| <a href="#">use, on page 509</a> <b>af-group</b>     | Configures an af-group to inherit the configuration of a specified af-group.                                                                 |

# show bgp attribute-key

To display all existing attribute keys, use the **show bgp attribute-key** command in EXEC mode.

**show bgp {ipv4| ipv6| all| vpnv4 unicast| vrf| vpnv6 unicast} attribute-key [standby]**

## Syntax Description

|                                           |                                                                                   |
|-------------------------------------------|-----------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                               |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                    |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                  |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                            |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.       |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                     |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.          |
| <b>all</b>                                | (Optional) For subaddress family, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                               |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                              |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                   |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                         |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                           |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.   |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                      |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                              |
| <b>standby</b>                            | (Optional) Displays information about the standby card.                           |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes** EXEC

|-----------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                |
|                 | Release 3.3.0 | The <b>ipv4 { unicast   labeled-unicast }</b> keyword was added.                                                                                                                                                                                                            |
|                 | Release 3.4.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vpn4 unicast</b></li> <li>• <b>vrf ( vrf-name   all )</b></li> </ul> <p>The <b>labeled-unicast</b> keyword was supported.</p> <p>The <b>count-only</b> keyword was removed.</p> |
|                 | Release 3.5.0 | The <b>vpn6 unicast</b> keywords were added.                                                                                                                                                                                                                                |
|                 |               | The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.                                                                                                                                                             |
|                 |               | The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.                                                                                                                                                                     |
|                 |               | The <b>standby</b> keyword was removed.                                                                                                                                                                                                                                     |
|                 | Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                       |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | bgp     | read       |

**Examples**

The following is sample output from the **show bgp attribute-key** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp all all attribute-key

Address Family: IPv4 Unicast
=====

| local AS number                | Autonomous system number for the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| BGP generic scan interval      | Interval (in seconds) between scans of the BGP table by a generic scanner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| BGP scan interval              | Interval (in seconds) between scans.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Status codes                   | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes                   | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was sourced by BGP using a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Entry originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Network                        | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Field                                       | Description                                                                                                                                                                          |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Next Hop                                    | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network. |
| AttrKey                                     | Key associated with the route attribute.                                                                                                                                             |
| Processed <i>n</i> prefixes, <i>n</i> paths | Number of prefixes and number of paths processed for the table.                                                                                                                      |

| Command                 | Description                                                                   |
|-------------------------|-------------------------------------------------------------------------------|
| <b>set default-afi</b>  | Sets the default Address Family Identifier (AFI) for the current session.     |
| <b>set default-safi</b> | Sets the default Subaddress Family Identifier (SAFI) for the current session. |

# show bgp cidr-only

To display routes with nonnatural network masks, also known as classless interdomain routing (CIDR) routes, use the **show bgp cidr-only** command in EXEC mode.

**show bgp [ipv4|vrf] cidr-only [standby]**

## Syntax Description

|                                           |                                                                                 |
|-------------------------------------------|---------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies the IP Version 4 address family.                           |
| <b>unicast</b>                            | (Optional) Specifies the unicast address family.                                |
| <b>multicast</b>                          | (Optional) Specifies the multicast address family.                              |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                          |
| <b>all</b>                                | (Optional) For subaddress family, specifies all subaddress families.            |
| <b>tunnel</b>                             | (Optional) Specifies the tunnel address family.                                 |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.        |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                 |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                       |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                         |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families. |
| <b>standby</b>                            | (Optional) Displays information about the standby card.                         |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used. This command is applicable only for IPv4 prefixes. If the default address family is not IPv4, then the **ipv4** keyword must be used.

EXEC

## Command History

| Release     | Modification                             |
|-------------|------------------------------------------|
| Release 3.2 | This command was introduced.             |
|             | The <b>count-only</b> keyword was added. |

| Release       | Modification                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul> |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.<br>The <b>count-only</b> keyword was removed.                                                                                                                                                                                            |
| Release 3.5.0 | The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> address family.<br>The <b>standby</b> keyword was removed.                                                                                                                                                  |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                      |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

Border Gateway Protocol (BGP) contains a separate routing table for each address family and subaddress family combination that has been configured. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for subaddress family, all subaddress family routing tables are examined.

The **show bgp cidr-only** command applies only for IPv4 prefixes. If the **ipv4** keyword is not specified and the default address family is not IPv4, the command is not available.

Use the **show bgp cidr-only** command to display CIDR routes. Routes that have their correct class (class A, B, or C) prefix length are not displayed.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp cidr-only** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp cidr-only

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 2589
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network        Next Hop        Metric      LocPrf      Weight      Path
*> 192.0.0.0/8   192.168.72.24      0           1878        ?
*> 192.168.0.0/16 192.168.72.30      0           108         ?
```

This table describes the significant fields shown in the display.

**Table 10: show bgp cidr-only Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was sourced by BGP using a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Entry originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

### Related Commands

| Command                                          | Description                                                                       |
|--------------------------------------------------|-----------------------------------------------------------------------------------|
| <a href="#">route-policy (BGP)</a> , on page 243 | Applies a routing policy to updates advertised to or received from a BGP neighbor |
| <b>set default-afi</b>                           | Sets the default Address Family Identifier (AFI) for the current session.         |
| <b>set default-safi</b>                          | Sets the default Subaddress Family Identifier (SAFI) for the current session.     |
| <a href="#">show bgp</a> , on page 265           | Displays BGP routes.                                                              |

## show bgp community

To display routes that have the specified Border Gateway Protocol (BGP) communities, use the **show bgp community** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast | all| tunnel| mdt}] community community-list
[exact-match]
```

```
show bgp [ipv6 {unicast| multicast| labeled-unicast | all}] community community-list [exact-match]
```

```
show bgp [all {unicast| multicast| labeled-unicast | all| tunnel}] community community-list [exact-match]
```

```
show bgp [vpnv4 unicast [rd rd-address]] community community-list [exact-match]
```

```
show bgp [vrf {vrf-name| all}] [ipv4 | {unicast| labeled-unicast}| ipv6 unicast] community community-list
[exact-match]
```

```
show bgp [vpnv6 unicast [rd rd-address]] community community-list [exact-match]
```

### Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vpnv6 unicast</b>  | (Optional) Specifies VPNv6 unicast address families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>community</b>      | Specifies that only routes with communities specified by <i>community-list</i> is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>community-list</i> | <p>Between one and seven communities. Each community can be a number in the range from 1 to 4294967295, a community specified in AA:NN format, or one of the following well-known communities:</p> <p><b>local-AS</b> —Well-known community with value 4294967043 or hex 0xFFFFF03. Routes with this community value are not advertised outside the local autonomous system or confederation boundary.</p> <p><b>no-advertise</b> —Well-known community with value 4294967042 or hex 0xFFFFF02. Routes with this community value are not advertised to any BGP peers.</p> <p><b>no-export</b> —Well-known community with value 4294967041 or hex 0xFFFFF01. Routes with this community are not advertised to external BGP peers, even if those peers are in the same confederation as the local router.</p> <p><b>internet</b> —Well-known community whose value is not defined in BGP RFC. IOS XR BGP uses a value of 0 for the internet community. Routes with this community are advertised to all peers without any restrictions.</p> <p>For the AA:NN format:</p> <p>AA—Range is 0 to 65535.</p> <p>NN—Range is 1 to 4294967295.</p> <p>Up to seven community numbers can be specified.</p> |
| <b>exact-match</b>    | (Optional) Displays those routes that have communities exactly matching the specified communities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Command Default** If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes** EXEC

| Command History | Release     | Modification                             |
|-----------------|-------------|------------------------------------------|
|                 | Release 3.2 | This command was introduced.             |
|                 |             | The <b>count-only</b> keyword was added. |

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | <p>The following keywords and arguments were added:</p> <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul>                                                                                     |
| Release 3.4.0 | <p>The <b>labeled-unicast</b> keyword was supported.</p> <p>The <b>count-only</b> keyword was removed.</p>                                                                                                                                                                                                                                                                            |
| Release 3.5.0 | <p>The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.</p> <p>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.</p> <p>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.</p> <p>The <b>standby</b> keyword was removed.</p> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or the subaddress family, each matching routing table is examined in turn.

If more than seven communities are required, it is necessary to configure a route policy and use the [show bgp route-policy, on page 424](#) command.

Use the **exact-match** keyword to display only those routes with a set of communities exactly matching the list of specified communities. If you omit the **exact-match** keyword, those routes containing at least the specified communities are displayed.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp community** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp community 1820:1 exact-match

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 55
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop           Metric LocPrf Weight Path
*  10.13.0.0/16    192.168.40.24              0 1878 704 701 200 ?
*  10.16.0.0/16    192.168.40.24              0 1878 704 701 i
```

This table describes the significant fields shown in the display.

**Table 11: show bgp community Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

### Related Commands

| Command                                         | Description                                                                                             |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">aggregate-address, on page 27</a>   | Creates an aggregate entry in a BGP routing table.                                                      |
| <a href="#">network (BGP), on page 191</a>      | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |
| <a href="#">route-policy (BGP), on page 243</a> | Applies a routing policy to updates advertised to or received from a BGP neighbor                       |
| <b>set default-afi</b>                          | Sets the default Address Family Identifier (AFI) for the current session.                               |
| <b>set default-safi</b>                         | Sets the default Subaddress Family Identifier (SAFI) for the current session.                           |
| <a href="#">show bgp, on page 265</a>           | Displays BGP routes.                                                                                    |

# show bgp convergence

To display whether a specific address family has reached convergence, use the **show bgp convergence** command in EXEC mode.

**show bgp [ipv4 {unicast| multicast| labeled-unicast | all| tunnel| mdt}] convergence**

**show bgp [ipv6 {unicast| multicast| labeled-unicast | all}] convergence**

**show bgp [all {unicast| multicast| labeled-unicast | all| mdt| tunnel}] convergence**

**show bgp [vpn4 unicast ] convergence**

**show bgp [vpn6 unicast ] convergence**

## Syntax Description

|                        |                                                                          |
|------------------------|--------------------------------------------------------------------------|
| <b>ipv4</b>            | (Optional) Specifies the IP Version 4 address family.                    |
| <b>unicast</b>         | (Optional) Specifies the unicast address family.                         |
| <b>multicast</b>       | (Optional) Specifies the multicast address family.                       |
| <b>labeled-unicast</b> | (Optional) Specifies unicast address prefixes.                           |
| <b>all</b>             | (Optional) For subaddress family, specifies all subaddress families.     |
| <b>tunnel</b>          | (Optional) Specifies tunnel address prefixes.                            |
| <b>mdt</b>             | (Optional) Specifies multicast distribution tree (MDT) address prefixes. |
| <b>ipv6</b>            | (Optional) Specifies the IP Version 6 address family.                    |
| <b>all</b>             | (Optional) For address family, specifies all address families.           |
| <b>vpn4 unicast</b>    | (Optional) Specifies VPNv4 unicast address families.                     |
| <b>vpn6 unicast</b>    | (Optional) Specifies VPNv6 unicast address families.                     |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                                                                                                                                                                                                                                                                                             |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | The <b>vpn4 unicast</b> and <b>labeled-unicast</b> keywords were added.                                                                                                                                                                                                                                                                  |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                        |
| Release 3.5.0 | <p>The <b>vpn6 unicast</b> keywords were added.</p> <p>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.</p> <p>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.</p> <p>The <b>standby</b> keyword was removed.</p> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

Border Gateway Protocol (BGP) contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined in turn.

Use the **show bgp convergence** command to see if there is any pending work for BGP to perform. The software checks the following conditions to determine whether the specified address family has converged. If all the conditions are true, the address family is considered converged.

- All received updates have been processed and best routes selected.
- All selected routes have been installed in the global Routing Information Base (RIB).
- All selected routes have been advertised to peers, including any peers that are not established (unless those peers have been administratively shut down). See the **shutdown (BGP)** command for more information about administrative shutdown.

While testing that all selected routes have been advertised to peers, the **show bgp convergence** command checks the size of the write queue for each neighbor. Because this queue is shared by all address families, there is a small possibility that the command indicates the address family has not converged when, in fact, it has converged. This could happen if the neighbor write queue contained messages from some other address family.

If the specified address family has not converged, the **show bgp convergence** command output does not indicate the amount of work that is pending. To display this information, use the **show bgp summary** command.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following shows the result of using the **show bgp convergence** command for an address family that has converged:

```
RP/0/0/CPU0:router# show bgp convergence
```

```
Converged.
All received routes in RIB, all neighbors updated.
All neighbors have empty write queues.
```

The following shows the result of using the **show bgp convergence** command for an address family that has not converged:

```
RP/0/0/CPU0:router# show bgp convergence
```

```
Not converged.
Received routes may not be entered in RIB.
One or more neighbors may need updating.
```

This table describes the significant fields shown in the display.

**Table 12: show bgp convergence Field Descriptions**

| Field                            | Description                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Converged/Not converged          | Specifies whether or not all routes have been installed in the RIB and updates have been generated and sent to all neighbors.                                                                                                                                                                                                                          |
| [All] Received routes...         | For convergence, all routes must have been installed into the RIB and all updates must have been generated. For non-convergence, some routes may not be installed in the RIB, or some routes that have been withdrawn have not yet been removed from the RIB, or some routes that are up to date in the RIB have not been advertised to all neighbors. |
| [All   One or more] neighbors... | Specifies the status of neighbor updating.                                                                                                                                                                                                                                                                                                             |

## Related Commands

| Command                | Description                                                               |
|------------------------|---------------------------------------------------------------------------|
| <b>set default-afi</b> | Sets the default Address Family Identifier (AFI) for the current session. |

| Command                                        | Description                                                                   |
|------------------------------------------------|-------------------------------------------------------------------------------|
| <b>set default-safi</b>                        | Sets the default Subaddress Family Identifier (SAFI) for the current session. |
| <a href="#">show bgp summary</a> , on page 435 | Displays the status of BGP peer connections.                                  |
| <a href="#">shutdown (BGP)</a> , on page 470   | Disables a neighbor without removing all of its configuration.                |

## show bgp dampened-paths

To display Border Gateway Protocol (BGP) dampened routes, use the **show bgp dampened-paths** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast | all}] dampened-paths [standby]
show bgp [ipv6 {unicast| multicast| labeled-unicast | all}] dampened-paths [standby]
show bgp [all {unicast| multicast| labeled-unicast | all| tunnel}] dampened-paths [standby]
show bgp [vpn4 unicast [rd rd-address]] dampened-paths [standby]
show bgp [vrf {vrf-name| all} [ipv4 | {unicast| labeled-unicast}| ipv6 unicast]] dampened-paths [standby]
show bgp [vpn6 unicast [rd rd-address]] dampened-paths [standby]
```

### Syntax Description

|                                          |                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                              | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                           | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                         | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                   | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                               | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                              | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                               | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd rd-address</b>                     | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                               | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                          | (Optional) Name of a VRF.                                                           |
| <b>all</b>                               | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 {unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                      | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpn6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>standby</b>                           | (Optional) Displays information about the standby card.                             |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

| Release       | Modification                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                               |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul> |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                          |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed.                                            |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                      |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or for the subaddress family, each matching routing table is examined in turn.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp dampened-paths** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp dampened-paths

BGP router identifier 10.2.0.1, local AS number 3
BGP generic scan interval 60 secs
BGP main routing table version 7
Dampening enabled
BGP scan interval 60 secs
Status codes:s suppressed, d damped, h history, * valid, > best
               i - internal, S stale

Origin codes:i - IGP, e - EGP, ? - incomplete
  Network      From           Reuse      Path
*d 10.0.0.0    10.0.101.35    00:01:20  35 i
```

This table describes the significant fields shown in the display.

**Table 13: show bgp dampened-paths Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP generic scan interval      | Interval (in seconds) between scans of the BGP table by a generic scanner.                                  |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| From         | Neighbor from which the route was received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Reuse        | Time (in hours:minutes:seconds) after which the path is made available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Path         | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">aggregate-address, on page 27</a>         | Creates an aggregate entry in a BGP routing table.                                                      |
| <a href="#">bgp dampening, on page 71</a>             | Enables BGP route dampening or changes various BGP route dampening factors.                             |
| <a href="#">clear bgp dampening, on page 115</a>      | Clears BGP route dampening information and unsuppresses the suppressed routes.                          |
| <a href="#">network (BGP), on page 191</a>            | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |
| <b>set default-afi</b>                                | Sets the default Address Family Identifier (AFI) for the current session.                               |
| <b>set default-safi</b>                               | Sets the default Subaddress Family Identifier (SAFI) for the current session.                           |
| <a href="#">show bgp flap-statistics, on page 327</a> | Displays BGP routes that have flapped.                                                                  |
| <a href="#">show bgp neighbors, on page 346</a>       | Displays information about the TCP and BGP connections to neighbors.                                    |

# show bgp flap-statistics

To display information about Border Gateway Protocol (BGP) paths that have flapped, use the **show bgp flap-statistics** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast | all}] flap-statistics [regex
regular-expression|route-policy route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}]
[longer-prefixes] [detail] [standby]

show bgp [ipv6 {unicast| multicast| labeled-unicast | all}] flap-statistics [regex
regular-expression|route-policy route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}]
[longer-prefixes] [detail] [standby]

show bgp [all {unicast| multicast| labeled-unicast | all}] flap-statistics [regex
regular-expression|route-policy route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}]
[longer-prefixes] [detail] [standby]

show bgp [vpn4 unicast [rd rd-address]] flap-statistics [regex regular-expression|route-policy
route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}] [longer-prefixes] [detail] [standby]

show bgp [vrf {vrf-name| all} [ipv4 | {unicast| labeled-unicast}] ipv6 unicast] flap-statistics [regex
regular-expression|route-policy route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}]
[longer-prefixes] [detail] [standby]

show bgp [vpn6 unicast [rd rd-address]] flap-statistics [regex regular-expression|route-policy
route-policy-name |cidr-only [{ip-address} {mask} /prefix-length}}] [longer-prefixes] [detail] [standby]
```

## Syntax Description

|                             |                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                 | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>              | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>            | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>      | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                  | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                 | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                  | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>         | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i> | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                  | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>             | (Optional) Name of a VRF.                                                           |
| <b>all</b>                  | (Optional) For VRF, specifies all VRFs.                                             |

|                                                         |                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.                                                                                                                                                                                                                                            |
| <b>ipv6 unicast</b>                                     | (Optional) For VRF, specifies IPv6 unicast address families.                                                                                                                                                                                                                                                               |
| <b>vpnv6 unicast</b>                                    | (Optional) Specifies VPNv6 unicast address families.                                                                                                                                                                                                                                                                       |
| <b>regexp</b> <i>regular-expression</i>                 | (Optional) Displays flap statistics for all paths that match the regular expression.                                                                                                                                                                                                                                       |
| <b>route-policy</b><br><i>route-policy-name</i>         | (Optional) Displays flap statistics for a route policy.                                                                                                                                                                                                                                                                    |
| <b>cidr-only</b>                                        | (Optional) Displays only routes whose prefix length does not match the classful prefix length for that network. The <b>cidr-only</b> keyword can be specified only if the address family is IPv4.                                                                                                                          |
| <i>ip-address</i>                                       | (Optional) Flap statistics for a network address only.                                                                                                                                                                                                                                                                     |
| <i>mask</i>                                             | (Optional) Network mask applied to the <i>ip-address</i> argument.                                                                                                                                                                                                                                                         |
| <i>/ prefix-length</i>                                  | (Optional) Length of the IP address prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash (/) must precede the decimal value.                                                                                  |
| <b>longer-prefixes</b>                                  | (Optional) Displays flap statistics for the specified prefix and more-specific prefixes. The <b>longer-prefixes</b> keyword is available when the <i>ip-address</i> and <i>mask</i> or <i>/prefix-length</i> arguments are specified.                                                                                      |
| <b>detail</b>                                           | (Optional) Displays dampening parameters for the path. The <b>detail</b> keyword cannot be specified if the <b>longer-prefixes</b> keyword is specified. The <b>detail</b> keyword is available when the <i>ip-address</i> argument or <i>ip-address</i> and <i>mask</i> or <i>/prefix-length</i> arguments are specified. |
| <b>standby</b>                                          | (Optional) Displays information about the standby card.                                                                                                                                                                                                                                                                    |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

## Command History

| Release       | Modification                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The <b>filter-list</b> <i>access-list</i> keyword and argument were removed.<br><br>The <b>route-policy</b> <i>route-policy-name</i> keyword and argument were added.                                                                                  |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul> |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                          |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br><br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br><br>The <b>standby</b> keyword was removed.                                    |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                      |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined in turn.

Flap statistics are maintained only for paths if dampening is enabled using the **bgp dampening** command. If dampening is not enabled, the **show bgp flap-statistics** command does not display any paths.

If no arguments or keywords are specified, the software displays flap statistics for all paths for the specified address family. You can use the **regexp**, **filter-list**, **cidr-only**, and **longer-prefixes** options to limit the set of paths displayed.

If you specify a network address without a mask or prefix length, the longest matching prefix for the network address is displayed. When displaying flap statistics for a single route, use the **detail** keyword to display dampening parameters for the route.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp flap-statistics** command:

```
RP/0/0/CPU0:router# show bgp flap-statistics

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 26180
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network        From        Flaps  Duration Reuse      Path
*d 10.0.0.0      172.20.16.177  4      00:13:31 00:18:10 100
*d 10.10.0.0     172.20.16.177  4      00:02:45 00:28:20 100
```

The following is sample output from the **show bgp flap-statistics** command with the **detail** keyword in EXEC mode:

```
RP/0/0/CPU0:router# show bgp flap-statistics 172.31.12.166 detail

BGP router identifier 10.0.0.5, local AS number 1
BGP main routing table version 738
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network        From        Flaps  Duration Reuse      Path
h 172.31.12.166      10.0.101.1    6      00:03:28          2 2000 3000

Half life      Suppress      Reuse penalty  Max. supp. time
00:15:00       2000          750            01:00:00
```

This table describes the significant fields shown in the display.

**Table 14: show bgp flap-statistics Field Descriptions**

| Field                          | Description                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------|
| BGP route identifier           | BGP identifier for the local system.                                              |
| local AS number                | Autonomous system number for the local system.                                    |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.  |
| Dampening enabled              | Displayed if dampening has been enabled for the routes in this BGP routing table. |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP scan interval | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Status codes      | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes      | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a network or aggregate-address command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Network           | IP prefix and prefix length for a network that is dampened.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| From              | IP address of the peer that advertised this route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Flaps             | Number of times the route has flapped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Duration          | Time (in hours:minutes:seconds) since the first flap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Field          | Description                                                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reuse          | Time (in hours:minutes:seconds) after which the path is made available.                                                                                                                                             |
| Path           | Autonomous system path of the route that is being dampened.                                                                                                                                                         |
| Half life      | Half-life value used when dampening this route. The half-life is the amount of time that must elapse to reduce the reuse penalty by half. The half-life value is specified using the <b>bgp dampening</b> command.  |
| Suppress       | Suppress value used to dampen this route. The suppress value is the value that the penalty must exceed for the route to be suppressed. The suppress value can be configured using the <b>bgp dampening</b> command. |
| Reuse penalty  | Reuse penalty used to dampen this route. The penalty must fall below the reuse penalty for the route to be unsuppressed. The reuse penalty can be configured using the <b>bgp dampening</b> command.                |
| Max supp. time | Maximum length of time that the route may be suppressed due to dampening. The maximum suppress time can be configured using the <b>bgp dampening</b> command.                                                       |

## show bgp inconsistent-as

To display Border Gateway Protocol (BGP) routes originated from more than one autonomous system, use the **show bgp inconsistent-as** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast | all| tunnel| mdt}] inconsistent-as [standby]
show bgp [ipv6 {unicast| multicast| labeled-unicast | all}] inconsistent-as [standby]
show bgp [all {unicast| multicast| labeled-unicast | all| tunnel| mdt}] inconsistent-as [standby]
show bgp vpnv4 unicast [rd rd-address] inconsistent-as [standby]
show bgp [vrf {vrf-name| all} [ipv4 | {unicast| labeled-unicast}| ipv6 unicast]] inconsistent-as [standby]
show bgp [vpnv6 unicast [rd rd-address]] inconsistent-as [standby]
```

### Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                |

|                |                                                         |
|----------------|---------------------------------------------------------|
| <b>standby</b> | (Optional) Displays information about the standby card. |
|----------------|---------------------------------------------------------|

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                                                       |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul>                                                                         |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                                                  |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                              |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or for the subaddress family, each matching routing table is examined in turn.

Use the **show bgp inconsistent-as** command to search through all prefixes in the specified BGP routing table and display the paths for any prefix that has inconsistent originating autonomous system numbers. The originating autonomous system is the last autonomous system number displayed in the path field and should be the same for all paths.

If a prefix has one or more paths originating from different autonomous systems, all paths for that prefix are displayed.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp inconsistent-as** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp inconsistent-as

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 1129
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
               i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network        Next Hop        Metric      LocPrf Weight Path
* 10.0.0.0      172.16.232.55          0           0 300 88 90 99 ?
*>              172.16.232.52      2222           0 400 ?
* 172.16.0.0    172.16.232.55          0           0 300 90 99 88 200 ?
*>              172.16.232.52      2222           0 400 ?
* 192.168.199.0 172.16.232.55          0           0 300 88 90 99 ?
*>              172.16.232.52      2222           0 400 ?
```

This table describes the significant fields shown in the display.

**Table 15: show bgp inconsistent-as Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

### Related Commands

| Command                                          | Description                                                                                             |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">network (BGP)</a> , on page 191      | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |
| <a href="#">route-policy (BGP)</a> , on page 243 | Applies a routing policy to updates advertised to or received from a BGP neighbor.                      |
| <b>set default-afi</b>                           | Sets the default Address Family Identifier (AFI) for the current session.                               |
| <b>set default -safi</b>                         | Sets the default Subaddress Family Identifier (SAFI) for the current session.                           |

# show bgp labels

To display Border Gateway Protocol (BGP) routes and their incoming and outgoing labels, use the **show bgp labels** command in EXEC mode.

**show bgp labels**

## Syntax Description

|                                          |                                                                                     |
|------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                              | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                           | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                         | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                   | (Optional) Specifies labeled-unicast address prefixes.                              |
| <b>all</b>                               | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>ipv6</b>                              | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>vpnv4 unicast</b>                     | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vpnv6 unicast</b>                     | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>              | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                               | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                          | (Optional) Name of a VRF.                                                           |
| <b>all</b>                               | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 {unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                      | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>standby</b>                           | (Optional) Displays information about the standby card.                             |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

## Command Modes

EXEC

**Command History**

| Release       | Modification                                                                                                                                                                                             |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.4.0 | This command was introduced.                                                                                                                                                                             |
| Release 3.5.0 | The following keywords were added: <ul style="list-style-type: none"> <li>• <b>vpnv6 unicast</b></li> <li>• <b>ipv6 { unicast   labeled-unicast }</b></li> </ul> The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                    |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp labels** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp vrf BAR ipv4 unicast labels

BGP VRF BAR, state: Active BGP Route Distinguisher: 100:1 BGP router identifier 10.1.1.1,
local AS number 100
BGP table state: Active BGP main routing table version 12

Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop        Rcvd Label        Local Label
Route Distinguisher: 100:1 (default for vrf BAR)
*> 20.1.1.1/32      10.0.101.1        16                nolabel
*> 20.1.1.2/32      10.0.101.1        16                nolabel
*> 20.1.1.3/32      10.0.101.1        16                nolabel
*> 20.1.1.4/32      10.0.101.1        16                nolabel
*> 20.1.1.5/32      10.0.101.1        16                nolabel

Processed 5 prefixes, 5 paths
```

This table describes the significant fields shown in the display.

**Table 16: show bgp labels Field Descriptions**

| Field                   | Description              |
|-------------------------|--------------------------|
| BGP Route Distinguisher | BGP route distinguisher. |

| Field                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| local AS number                | Autonomous system number for the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| BGP table state                | State of the BGP routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Status codes                   | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes                   | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was sourced by BGP using a network or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Network                        | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Field       | Description                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Next Hop    | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network. |
| Rcvd Label  | Received label.                                                                                                                                                                      |
| Local Label | Local label.                                                                                                                                                                         |

# show bgp neighbor-group

To display information about the Border Gateway Protocol (BGP) configuration for neighbor groups, use the **show bgp neighbor-group** command in EXEC mode.

**show bgp neighbor-group** *group-name* {**configuration** [**defaults**] [**nvgen**]| **inheritance**| **users**}

## Syntax Description

|                      |                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group-name</i>    | Name of the address family group to display.                                                                                                                                                                   |
| <b>configuration</b> | (Optional) Displays the effective configuration for the neighbor group, including any configuration inherited by this neighbor group.                                                                          |
| <b>defaults</b>      | (Optional) Displays all configuration, including default configuration.                                                                                                                                        |
| <b>nvgen</b>         | (Optional) Displays output in <b>show running-config</b> command output.<br>If the <b>defaults</b> keyword is also specified, the output is not suitable for cutting and pasting into a configuration session. |
| <b>inheritance</b>   | Displays the af-groups, session groups, and neighbor groups from which this neighbor group inherits configuration.                                                                                             |
| <b>users</b>         | Displays the neighbors and neighbor groups that inherit configuration from this neighbor group.                                                                                                                |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show bgp neighbor-group** command with the *group-name* **configuration** argument and keyword to display the effective configuration of a neighbor group, including any configuration inherited from session groups, address family groups, and neighbor groups through application of the **use** command. The source of each configured command is also displayed.

Use the **defaults** keyword to display all configuration for the neighbor group, including default configuration. The command output identifies default onfiguration. Use the **nvgen** keyword to display configuration in the output form of **show running-config** command. Output in this form is suitable for cutting and pasting into a configuration session.

The **show bgp neighbor-group** command with the *group-name* **inheritance** argument and keyword displays the session groups, address family groups, and neighbor groups from which the specified neighbor group inherits configuration.

The **show bgp neighbor-group** *group-name* command displays the neighbors and neighbor groups that inherit configuration from the specified neighbor group.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The examples use the following configuration:

```
af-group group3 address-family ipv4 unicast
  remove-private-AS
  soft-reconfiguration inbound
!
af-group group2 address-family ipv4 unicast
  use af-group group3
  send-community-ebgp
  send-extended-community-ebgp
  capability orf prefix both
!
session-group group3
  dmzlink-bw
!
neighbor-group group3
  use session-group group3
  timers 30 90
!
neighbor-group group1
  remote-as 1982
  use neighbor-group group2
  address-family ipv4 unicast
!
neighbor-group group2
  use neighbor-group group3
  address-family ipv4 unicast
  use af-group group2
  weight 100
!
```

The following is sample output from the **show bgp neighbor-group** command with the **configuration** keyword:

```
RP/0/0/CPU0:router# show bgp neighbor-group group1 configuration

neighbor-group group1
  remote-as 1982                []
  timers 30 90                 [n:group2 n:group3]
  dmzlink-bw                   [n:group2 n:group3 s:group3]
  address-family ipv4 unicast  []
  capability orf prefix both   [n:group2 a:group2]
  remove-private-AS           [n:group2 a:group2 a:group3]
  send-community-ebgp         [n:group2 a:group2]
  send-extended-community-ebgp [n:group2 a:group2]
```

```

soft-reconfiguration inbound      [n:group2 a:group2 a:group3]
weight 100                       [n:group2]

```

The configuration source is shown to the right of each command. In the output, the **remote-as** command is configured directly on neighbor group group1, and the **send-community-ebgp** command is inherited from neighbor group group2, which in turn inherits the setting from af-group group2.

The following is sample output from the **show bgp neighbor-group** command with the **users** keyword. This output shows that the group1 neighbor group inherits session (address family-independent configuration parameters) from the group2 neighbor group. The group1 neighbor group also inherits IPv4 unicast configuration parameters from the group2 neighbor group:

```
RP/0/0/CPU0:router# show bgp neighbor-group group2 users
```

```

Session:      n:group1
IPv4 Unicast: n:group1

```

The following is sample output from the **show bgp neighbor-group** command with the **inheritance** keyword. This output shows that the specified neighbor group group1 inherits session (address family-independent configuration) from neighbor group group2, which inherits its own session from neighbor group group3. Neighbor group group3 inherited its session from session group group3. It also shows that the group1 neighbor-group inherits IPv4 unicast configuration parameters from the group2 neighbor group, which in turn inherits them from the group2 af-group, which itself inherits them from the group3 af-group:

```
RP/0/0/CPU0:router# show bgp neighbor-group group1 inheritance
```

```

Session:      n:group2 n:group3 s:group3
IPv4 Unicast: n:group2 a:group2 a:group3

```

This table describes the significant fields shown in the display.

**Table 17: show bgp neighbor-group Field Descriptions**

| Field     | Description                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ ]       | Configures the command directly on the specified address family group.                                                                                                                 |
| s:        | Indicates the name that follows is a session group.                                                                                                                                    |
| a:        | Indicates the name that follows is an address family group.                                                                                                                            |
| n:        | Indicates the name that follows is a neighbor group.                                                                                                                                   |
| [dflt]    | Indicates the setting is not explicitly configured or inherited, and the default value for the setting is used. This field may be shown when the <b>defaults</b> keyword is specified. |
| <not set> | Indicates that the default is for the setting to be disabled. This field may be shown when the <b>defaults</b> keyword is specified.                                                   |

# show bgp neighbors

To display information about Border Gateway Protocol (BGP) connections to neighbors, use the **show bgp neighbors** command in EXEC mode.

**show bgp neighbors** [**performance-statistics**| **missing-eor**] [**standby**]

**show bgp neighbors** *ip-address* [**advertised-routes**| **dampened-routes**| **flap-statistics**| **performance-statistics**| **received** | {**prefix-filter**| **routes**}| **routes**] [**standby**]

**show bgp neighbors** *ip-address* [**configuration**| [**defaults**] | **nvgen**| **inheritance**][**standby**]

## Syntax Description

|                                           |                                                                                                        |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                                    |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                                         |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                                       |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                                                 |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families.                    |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                                          |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.                               |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                                    |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.                            |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                                   |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                                        |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                                              |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                                                |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.                        |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                                           |
| <b>vpn6 unicast</b>                       | (Optional) Specifies VPNv6 unicast address families.                                                   |
| <b>performance-statistics</b>             | (Optional) Displays performance statistics relative to work done by the BGP process for this neighbor. |

|                                            |                                                                                                                                                                                                                           |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>missing-eor</b>                         | (Optional) Displays neighbors that did not send end-of-rib (EoR) notification in read-only mode.                                                                                                                          |
| <i>ip-address</i>                          | (Optional) IP address of the BGP-speaking neighbor. If you omit this argument, all neighbors are displayed.                                                                                                               |
| <b>advertised-routes</b>                   | (Optional) Displays all routes the router advertised to the neighbor.                                                                                                                                                     |
| <b>dampened-routes</b>                     | (Optional) Displays the dampened routes that are learned from the neighbor.                                                                                                                                               |
| <b>flap-statistics</b>                     | (Optional) Displays flap statistics of the routes learned from the neighbor.                                                                                                                                              |
| <b>received { prefix-filter   routes }</b> | (Optional) Displays information received from the BGP neighbor. The options are:<br><br><b>prefix-filter</b> — Displays the prefix list filter.<br><b>routes</b> —Displays routes from the neighbor before inbound policy |
| <b>routes</b>                              | (Optional) Displays routes learned from the neighbor.                                                                                                                                                                     |
| <b>configuration</b>                       | (Optional) Displays the effective configuration for the neighbor, including any settings that have been inherited from session groups, neighbor groups, or af-groups used by this neighbor.                               |
| <b>defaults</b>                            | (Optional) Displays all configuration settings, including any default settings.                                                                                                                                           |
| <b>nvgen</b>                               | (Optional) Displays output in the <b>show running-config</b> command output.                                                                                                                                              |
| <b>inheritance</b>                         | (Optional) Displays the session groups, neighbor groups, and af-groups from which this neighbor inherits configuration settings.                                                                                          |
| <b>standby</b>                             | (Optional) Displays information about the standby card.                                                                                                                                                                   |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

**Command History**

| Release     | Modification                                                                  |
|-------------|-------------------------------------------------------------------------------|
| Release 3.2 | This command was introduced.<br>The <b>received routes</b> keyword was added. |

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> }]</li> <li>• <b>vpn4 unicast</b></li> <li>• <b>missing-eor</b></li> </ul>                                                                                 |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                                                  |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                              |
| Release 3.9.0 | Asplain format for 4-byte autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations.                                                                                                                               |
| Release 4.1.1 | The command output was modified to display from BGP Accept Own configuration.                                                                                                                                                                                                                                                                                      |
| Release 4.0.0 | The command output was modified to include information on BGP additional paths send and receive information.                                                                                                                                                                                                                                                       |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

#### Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify which routing table should be examined. If the **all** keyword is specified for address family or subaddress family, each matching routing table is examined in turn.

Use the **show bgp neighbors** command to display detailed information about all neighbors or a specific neighbor. Use the **performance-statistics** keyword to display information about the work related to specific neighbors done by the BGP process.

Use the **show bgp neighbors** command with the *ip-address* **received** **prefix-filter** argument and keyword to display the Outbound Route Filter (ORF) received from a neighbor.

Use the **advertised-routes** keyword to display a summary of the routes advertised to the specified neighbor.

Use the **dampened-routes** keyword to display routes received from the specified neighbor that have been suppressed due to dampening. For more details, see the **show bgp dampened-paths** command.

To display information about flapping routes received from a neighbor, use the **flap-statistics** keyword. For more details, see the **show bgp flap-statistics** command.

To display the routes received from a neighbor, use the **routes** keyword. For more details, see the **show bgp** command.

Use the **show bgp neighbor** command with the *ip-address* **configuration** argument and keyword to display the effective configuration of a neighbor, including configuration inherited from session groups, neighbor groups, or af-groups through application of the **use** command. Use the **defaults** keyword to display the value of all configurations for the neighbor, including default configuration. Use the **nvgen** keyword to display configuration output format of the **show running-config** command. Output in this format is suitable for cutting and pasting into a configuration session. Use the **show bgp neighbors** command with the *ip-address* **inheritance** argument and keyword to display the session groups, neighbor groups, and af-groups from which the specified neighbor inherits configuration.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp neighbors** command:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.1

BGP neighbor is 10.0.101.1, remote AS 2, local AS 1, external link
  Description: routem neighbor
  Remote router ID 10.0.101.1
    BGP state = Established, up for 00:00:56
    TCP open mode: passive only
BGP neighbor is 1.1.1.2
  Remote AS 300, local AS 100, external link
  Remote router ID 0.0.0.0
    BGP state = Idle (LC/FIB for the neighbor in reloading)
    Last read 00:00:00, Last read before reset 00:05:12
    Hold time is 180, keepalive interval is 60 seconds
    Configured hold time: 180, keepalive: 60, min acceptable hold time: 3

  BFD enabled (session initializing)
    Last read 00:00:55, hold time is 180, keepalive interval is 60 seconds
    DMZ-link bandwidth is 1000 Mb/s
  Neighbor capabilities:
    Route refresh: advertised
    4-byte AS: advertised and received
    Address family IPv4 Unicast: advertised and received
    Address family IPv4 Multicast: advertised and received
  Received 119 messages, 0 notifications, 0 in queue
  Sent 119 messages, 22 notifications, 0 in queue
  Minimum time between advertisement runs is 60 seconds
```

```

For Address Family: IPv4 Unicast
BGP neighbor version 137
Update group: 1.3
Community attribute sent to this neighbor
AF-dependant capabilities:
  Outbound Route Filter (ORF) type (128) Prefix-list:
    Send-mode: advertised
    Receive-mode: advertised
Route refresh request: received 0, sent 0
Policy for incoming advertisements is pass-all
Policy for outgoing advertisements is pass-all
5 accepted prefixes, 5 are bestpaths
Prefix advertised 3, suppressed 0, withdrawn 0, maximum limit 1000000
Threshold for warning message 75%

For Address Family: IPv4 Multicast
BGP neighbor version 23
Update group: 1.2
Route refresh request: received 0, sent 0
Policy for incoming advertisements is pass-all
Policy for outgoing advertisements is pass-all
2 accepted prefixes, 2 are bestpaths
Prefix advertised 0, suppressed 0, withdrawn 0, maximum limit 131072
Threshold for warning message 75%

Connections established 9; dropped 8
Last reset 00:02:10, due to User clear requested (CEASE notification sent - administrative
reset)
Time since last notification sent to neighbor: 00:02:10
Error Code: administrative reset
Notification data sent:
  None

```

This table describes the significant fields shown in the display.

**Table 18: show bgp neighbors Field Descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP neighbor | IP address of the BGP neighbor and its autonomous system number. If the neighbor is in the same autonomous system as the router, then the link between them is internal; otherwise, it is considered external.                                                                                                                                                                                        |
| Description  | Neighbor specific description.                                                                                                                                                                                                                                                                                                                                                                        |
| remote AS    | <ul style="list-style-type: none"> <li>• Number of the autonomous system to which the neighbor belongs.</li> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) is asdot format is 1.0 to 65535.65535.</li> </ul> |

| Field                                | Description                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local AS                             | Autonomous system number of the local system. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| internal link                        | Neighbor is an internal BGP peer.                                                                                                                                                                                                                                                                                                                                         |
| external link                        | Neighbor is an external BGP peer.                                                                                                                                                                                                                                                                                                                                         |
| Administratively shut down           | Neighbor connection is disabled using the <b>shutdown</b> command.                                                                                                                                                                                                                                                                                                        |
| remote router ID                     | Router ID (an IP address) of the neighbor.                                                                                                                                                                                                                                                                                                                                |
| Neighbor under common administration | Neighbor is internal or a confederation peer.                                                                                                                                                                                                                                                                                                                             |
| BGP state                            | Internal state of this BGP connection.                                                                                                                                                                                                                                                                                                                                    |
| BFD enabled                          | Status of bidirectional forwarding detection.                                                                                                                                                                                                                                                                                                                             |
| TCP open mode                        | TCP mode used in establishing the BGP session. The following valid TCP mode are supported: <ul style="list-style-type: none"> <li>• default—Accept active/passive connections</li> <li>• passive-only—Accept only passive connections</li> <li>• active-only—Accept only active connections initiated by the router</li> </ul>                                            |
| Last read                            | Time since BGP last read a message from this neighbor.                                                                                                                                                                                                                                                                                                                    |
| hold time                            | Hold time (in seconds) used on the connection with this neighbor.                                                                                                                                                                                                                                                                                                         |
| keepalive interval                   | Interval for sending keepalives to this neighbor.                                                                                                                                                                                                                                                                                                                         |
| DMZ-link bandwidth                   | DMZ link bandwidth for this neighbor.                                                                                                                                                                                                                                                                                                                                     |

| Field                                   | Description                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Neighbor capabilities                   | BGP capabilities advertised and received from this neighbor. The following valid BGP capabilities are supported: <ul style="list-style-type: none"> <li>• Multi-protocol</li> <li>• Route refresh</li> <li>• Graceful restart</li> <li>• Outbound Route Filter (ORF) type (128) Prefix</li> </ul> |
| Route refresh                           | Indicates that the neighbor supports dynamic soft reset using the route refresh capability.                                                                                                                                                                                                       |
| 4-byte AS                               | Indicates that the neighbor supports the 4-byte AS capability.                                                                                                                                                                                                                                    |
| Address family                          | Indicates that the local system supports the displayed address family capability. If “received” is displayed, the neighbor also supports the displayed address family.                                                                                                                            |
| Received                                | Number of messages received from this neighbor, the number of notification messages received and processed from this neighbor, and the number of messages that have been received, but not yet processed.                                                                                         |
| Sent                                    | Number of messages sent to this neighbor, the number of notification messages generated to be sent to this neighbor, and the number of messages queued to be sent to this neighbor.                                                                                                               |
| Minimum time between advertisement runs | Advertisement interval (in seconds) for this neighbor.                                                                                                                                                                                                                                            |
| For Address Family                      | Information that follows is specific to the displayed address family.                                                                                                                                                                                                                             |
| BGP neighbor version                    | Last version of the BGP database that was sent to the neighbor for the specified address family.                                                                                                                                                                                                  |
| Update group                            | Update group to which the neighbor belongs.                                                                                                                                                                                                                                                       |
| Route reflector client                  | Indicates that the local system is acting as a route reflector for this neighbor.                                                                                                                                                                                                                 |

| Field                                                              | Description                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inbound soft reconfiguration allowed                               | <p>Indicates that soft reconfiguration is enabled for routes received from this neighbor.</p> <p><b>Note</b> If the neighbor has route refresh capability, then soft configuration received-only routes are not stored by the local system unless “override route refresh” is displayed.</p> |
| eBGP neighbor with no inbound or outbound policy: defaults to drop | Indicates that the neighbor does not have an inbound or outbound policy configured using the <b>route-policy (BGP)</b> command. Hence, no routes are accepted from or advertised to this neighbor.                                                                                           |
| Private AS number removed from updates to this neighbor            | Indicates that remove-private-AS is configured on the specified address family for this neighbor.                                                                                                                                                                                            |
| NEXT_HOP is always this router                                     | Indicates that next-hop-self is configured on the specified address family for this neighbor.                                                                                                                                                                                                |
| Community attribute sent to this neighbor                          | Indicates that send-community-ebgp is configured on the specified address family for this neighbor.                                                                                                                                                                                          |
| Extended community attribute sent to this neighbor                 | Indicates that send-extended-community-ebgp is configured on the specified address family for this neighbor.                                                                                                                                                                                 |
| Default information originate                                      | Indicates that default-originate is configured on the specified address family for this neighbor, together with the policy used, if one was specified in the default-originate configuration. An indication of whether the default route has been advertised to the neighbor is also shown.  |
| AF-dependant capabilities                                          | <p>BGP capabilities that are specific to a particular address family. The following valid AF-dependent BGP capabilities are supported:</p> <ul style="list-style-type: none"> <li>• route refresh capability</li> <li>• route refresh capability OLD value</li> </ul>                        |

| Field                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Outbound Route Filter                                           | <p>Neighbor has the Outbound Route Filter (ORF) capability for the specified address family. Details of the capabilities supported are also shown:</p> <p>Send-mode—"advertised" is shown if the local system can send an outbound route filter to the neighbor. "received" is shown if the neighbor can send an outbound route filter to the local system.</p> <p>Receive-mode—"advertised" is shown if the local system can receive an outbound route filter from the neighbor. "received" is shown if the neighbor can receive an outbound route filter from the local system.</p> |
| Graceful Restart Capability                                     | Indicates whether graceful restart capability has been advertised to and received from the neighbor for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Neighbor preserved the forwarding state during latest restart   | Indicates that when the neighbor connection was last established, the neighbor indicated that it preserved its forwarding state for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Local restart time                                              | Restart time (in seconds) advertised to this neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RIB purge time                                                  | RIB purge time (in seconds) used for graceful restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Maximum stalepath time                                          | Maximum time (in seconds) a path received from this neighbor may be marked as stale if the neighbor restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Remote Restart time                                             | Restart time received from this neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Route refresh request                                           | Number of route refresh requests sent and received from this neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Outbound Route Filter (ORF)                                     | <p>"sent" indicates that an outbound route filter has been sent to this neighbor. "received" indicates that an outbound route filter has been received from this neighbor.</p> <p><b>Note</b> A received outbound route filter may be displayed using the <b>show bgp neighbors</b> command with the <b>received prefix-filter</b> keywords.</p>                                                                                                                                                                                                                                      |
| First update is deferred until ORF or ROUTE-REFRESH is received | If the local system advertised the receive capability and the neighbor has advertised send capability, no updates are generated until specifically asked by the neighbor (using a ROUTE-REFRESH or ORF with immediate request).                                                                                                                                                                                                                                                                                                                                                       |

| Field                                    | Description                                                                                                                                                                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scheduled to send the Prefix-list filter | Indicates the local system is due to send an outbound route filter request in order to receive updates from the neighbor.                                                                                                                                               |
| Inbound path policy                      | Indicates if an inbound path policy is configured.                                                                                                                                                                                                                      |
| Outbound path policy                     | Indicates if an outbound path policy is configured.                                                                                                                                                                                                                     |
| Incoming update prefix filter list       | Indicates a prefix list is configured to filter inbound updates from the neighbor.                                                                                                                                                                                      |
| Default weight                           | Default weight for routes received from the neighbor.                                                                                                                                                                                                                   |
| Policy for incoming advertisements       | Indicates a route policy is configured to be applied to inbound updates from the neighbor.                                                                                                                                                                              |
| Policy for outgoing advertisements       | Indicates a route policy is configured to be applied to outbound updates to the neighbor.                                                                                                                                                                               |
| Type                                     | Indicates whether the condition map selects routes that should be advertised, or routes that should not be advertised:<br><br>Exist—Routes advertised if permitted by the condition route map.<br><br>Non-exist—Routes advertised if denied by the condition route map. |
| accepted prefixes                        | Number of prefixes accepted.                                                                                                                                                                                                                                            |
| Prefix advertised                        | Number of prefixes advertised to the neighbor during the lifetime of the current connection with the neighbor.                                                                                                                                                          |
| suppressed                               | Number of prefix updates that were suppressed because no transitive attributes changed from one best path to the next.<br><br><b>Note</b> Update suppression occurs only for external BGP neighbors.                                                                    |
| withdrawn                                | Number of prefixes withdrawn from the neighbor during the lifetime of the current connection with the neighbor.                                                                                                                                                         |
| maximum limit                            | Maximum number of prefixes that may be received from the neighbor. If "(warning-only)" is displayed, a warning message is generated when the limit is exceeded, otherwise the neighbor connection is shut down when the limit is exceeded.                              |

| Field                                               | Description                                                                                       |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Threshold for warning message                       | Percentage of maximum prefix limit for the neighbor at which a warning message is generated.      |
| Connections established                             | Number of times the router has established a BGP peering session with the neighbor.               |
| dropped                                             | Number of times that a good connection has failed or been taken down.                             |
| Last reset due to                                   | Reason that the connection with the neighbor was last reset.                                      |
| Time since last notification sent to neighbor       | Amount of time since a notification message was last sent to the neighbor.                        |
| Error Code                                          | Type of notification that was sent. The notification data, if any, is also displayed.             |
| Time since last notification received from neighbor | Amount of time since a notification message was last received from the neighbor.                  |
| Error Code                                          | Type of notification that was received. The notification data received, if any, is also displayed |
| External BGP neighbor may be up to <n> hops away    | Indicates ebgp-multihop is configured for the neighbor.                                           |
| External BGP neighbor not directly connected        | Indicates that the neighbor is not directly attached to the local system.                         |
| Notification data sent:                             | Data providing more details on the error along with the error notification sent to the neighbor.  |

The following is sample output from the **show bgp neighbors** command with the **advertised-routes** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 172.20.16.178 routes

BGP router identifier 172.20.16.181, local AS number 1
BGP main routing table version 27
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
               i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network        Next Hop        Metric LocPrf Weight Path
*> 10.0.0.0      172.20.16.178          40             0 10 ?
*> 10.22.0.0     172.20.16.178          40             0 10 ?
```

The following is sample output from the **show bgp neighbors** command with the **routes** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.1 dampened-routes
```

```

BGP router identifier 10.0.0.5, local AS number 1
BGP main routing table version 48
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        From        Reuse      Path
*d 10.0.0.0        10.0.101.1    00:59:30  2 100 1000 i

```

This table describes the significant fields shown in the display.

**Table 19: show bgp neighbors routes Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

The following is sample output from the **show bgp neighbors** command with the **dampened-routes** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.1 flap-statistics

BGP router identifier 10.0.0.5, local AS number 1
BGP main routing table version 48
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network          From          Flaps Duration Reuse      Path

```

This table describes the significant fields shown in the display.

**Table 20: show bgp neighbors dampened-routes Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| From         | Neighbor from which the route was received.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Reuse        | Time (in hours:minutes:seconds) after which the path is made available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Path         | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The following is sample output from the **show bgp neighbors** command with the **flap-statistics** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.2 performance-statistics

BGP neighbor is 10.0.101.2, remote AS 1
  Read 3023 messages (58639 bytes) in 3019 calls (time spent: 1.312 secs)
  Read throttled 0 times
  Processed 3023 inbound messages (time spent: 0.198 secs)
  Wrote 58410 bytes in 6062 calls (time spent: 3.041 secs)
  Processing write list: wrote 0 messages in 0 calls (time spent: 0.000 secs)
  Processing write queue: wrote 3040 messages in 3040 calls (time spent: 0.055 secs)

  Received 3023 messages, 0 notifications, 0 in queue
  Sent 3040 messages, 0 notifications, 0 in queue
```

This table describes the significant fields shown in the display.

**Table 21: show bgp neighbors flap-statistics Field Descriptions**

| Field                          | Description                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------|
| BGP route identifier           | BGP identifier for the local system.                                                                             |
| local AS number                | Autonomous system number for the local system.                                                                   |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                                 |
| Dampening enabled              | Displayed if dampening has been enabled for the routes in this BGP routing table.                                |
| BGP scan interval              | Interval (in seconds) between when the BGP process scans for the specified address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                        |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| From         | IP address of the peer that advertised this route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Flaps        | Number of times the route has flapped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Duration     | Time (in hours:minutes:seconds) since the router noticed the first flap.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Reuse        | Time (in hours:minutes:seconds) after which the path is made available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Path         | Autonomous system path to reach the destination network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The following is sample output from the **show bgp neighbors** command with the **performance-statistics** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.2 performance-statistics
BGP neighbor is 10.0.101.2, remote AS 1
  Read 3023 messages (58639 bytes) in 3019 calls (time spent: 1.312 secs)
  Read throttled 0 times
  Processed 3023 inbound messages (time spent: 0.198 secs)
  Wrote 58410 bytes in 6062 calls (time spent: 3.041 secs)
  Processing write list: wrote 0 messages in 0 calls (time spent: 0.000 secs)
  Processing write queue: wrote 3040 messages in 3040 calls (time spent: 0.055 secs)
  Received 3023 messages, 0 notifications, 0 in queue
  Sent 3040 messages, 0 notifications, 0 in queue
```

This table describes the significant fields shown in the display.

**Table 22: show bgp neighbors performance-statistics Field Descriptions**

| Field                  | Description                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Read                   | Indicates the number of messages received from the neighbor, the total size of received messages, the number of read operations performed, and the real time spent (in seconds) by the process performing read operations for this neighbor. |
| Read throttled         | Number of times that reading from the TCP connection to this neighbor has been throttled. Throttling is due to a backlog of messages that have been read but not processed.                                                                  |
| inbound messages       | Number of read messages that have been processed, and the real time spent processing inbound messages for this neighbor.                                                                                                                     |
| Wrote                  | Amount of data that has been sent to this neighbor, number of write operations performed, and the real time spent by the process performing write operations for this neighbor.                                                              |
| Processing write list  | Number of messages written from the write list to this neighbor, number of times the write list has been processed, and real time spent processing the write list.<br><br><b>Note</b> Write lists typically contain only update messages.    |
| Processing write queue | Number of messages written from the write queue to this neighbor, number of times the write queue has been processed, and real time spent processing the write queue.                                                                        |

| Field    | Description                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Received | Number of messages received from this neighbor, number of notification messages received and processed from this neighbor, and number of messages that have been received, but not yet processed. |
| Sent     | Number of messages sent to this neighbor, number of notification messages generated to be sent to this neighbor, and number of messages queued to be sent to this neighbor.                       |

The following is sample output from the **show bgp neighbors** command with the **configuration** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors 10.0.101.1 configuration
neighbor 10.0.101.1
  remote-as 2 []
  bfd fast-detect []
  address-family ipv4 unicast []
  policy pass-all in []
  policy pass-all out []
  address-family ipv4 multicast []
  policy pass-all in []
  policy pass-all out []
```

This table describes the significant fields shown in the display.

**Table 23: show bgp neighbors configuration Field Descriptions**

| Field                     | Description                                                            |
|---------------------------|------------------------------------------------------------------------|
| neighbor                  | IP address configuration of the neighbor.                              |
| remote-as                 | Remote autonomous system configured on the neighbor.                   |
| bfd fast-detect           | BFD parameter configured on the neighbor.                              |
| address-family            | Address family and subsequent address family configured on the router. |
| route-policy pass-all in  | Route policy configured for inbound updates.                           |
| route-policy pass-all out | Route policy configured for outbound updates.                          |

The following sample output shows sample output from **show bgp neighbors** command with additional paths send and receive capabilities advertised to neighbors:

```
BGP neighbor is 80.0.0.30
  Remote AS 100, local AS 100, internal link
  Remote router ID 33.33.33.33
```

```

# show bgp neighbors nsr

To display Border Gateway Protocol (BGP) nonstop routing (NSR) information across neighbors, use the **show bgp neighbors nsr** command in EXEC mode.

**show bgp** [**ipv4** {**unicast**|**multicast**|**all**}|**ipv6** {**unicast**|**multicast**|**all**}|**vpn4** **unicast**|**vpn6** **unicast**|**vrf** {**all**|*vrf\_name*}] **neighbors nsr** [**standby**]

## Syntax Description

|                     |                                                                             |
|---------------------|-----------------------------------------------------------------------------|
| <b>ipv4</b>         | (Optional) Specifies IP Version 4 address prefixes.                         |
| <b>ipv6</b>         | (Optional) Specifies IP Version 6 address prefixes.                         |
| <b>unicast</b>      | (Optional) Specifies unicast address prefixes.                              |
| <b>multicast</b>    | (Optional) Specifies multicast address prefixes.                            |
| <b>all</b>          | (Optional) For address family, specifies prefixes for all address families. |
| <b>vpn4 unicast</b> | (Optional) Specifies VPNv4 unicast address families.                        |
| <b>vpn6 unicast</b> | (Optional) Specifies VPNv6 unicast address families.                        |
| <b>vrf</b>          | (Optional) Specifies VPN routing and forwarding (VRF) instance.             |
| <i>vrf_name</i>     | (Optional) Name of a VRF.                                                   |
| <b>all</b>          | (Optional) For VRF, specifies all VRFs.                                     |
| <b>standby</b>      | (Optional) Displays information about the standby card.                     |

## Command Default

No default behavior or values.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp neighbors nsr** command with the **standby** keyword:

```
RP/0/0/CPU0:router# show bgp neighbors nsr standby
```

```
BGP neighbor is 2.2.2.2
  BGP state = Established, up for 5d04h
  NSR state = NSR Ready
  Outstanding Postits: 0
```

```
BGP neighbor is 10.0.101.5
  BGP state = Established, up for 05:19:00
  NSR state = NSR Ready
  Outstanding Postits: 0
```

```
BGP neighbor is 10.1.0.5
  BGP state = Established, up for 5d04h
  NSR state = NSR Ready
  Outstanding Postits: 0
```

This table describes the significant fields shown in the display.

**Table 24: show bgp neighbors nsr Field Descriptions**

| Field               | Description                                     |
|---------------------|-------------------------------------------------|
| BGP state           | Displays BGP neighbor peering state.            |
| NSR state           | Displays BGP neighbor NSR state.                |
| Outstanding Postits | Displays the postit counters of pending events. |

**Related Commands**

| Command                                           | Description                                                                   |
|---------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">nsr (BGP), on page 206</a>            | Activates the Border Gateway Protocol (BGP) nonstop routing (NSR).            |
| <a href="#">show bgp summary nsr, on page 441</a> | Displays the Border Gateway Protocol (BGP) nonstop routing (NSR) information. |

|                 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show bgp nexthops** command displays statistical information about next-hop notifications, the time spent processing the notifications, and details about each next-hop that has been registered with the Routing Information Base (RIB).

Use the **vrf** *vrf-name* keyword and argument to display only the next-hops present in the specified VPN routing and forwarding (VRF) instance.

The next-hop information is displayed for all active speaker processes in distributed mode. Each speaker displays a set of next-hops that belongs to the prefixes received by the speaker and next hops that belong to best paths that were received by other speaker processes. Use the **speaker** *speaker-id* keyword and argument to display information for only the specified speaker process.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | bgp     | read       |

**Examples**

The following is sample output from the **show bgp nexthops** command with the VRF specified:

```
RP/0/0/CPU0:router# show bgp vrf all nexthops

This table describes the significant fields shown in the display.

**Table 25: show bgp vrf all nexthops Field Descriptions**

| Field                                     | Description                                                                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| VRF                                       | Name of the VRF.                                                                                                                                        |
| Total Nexthop Processing Time Spent       | Time spent processing trigger delays for critical and noncritical events for the VRF or address family. The time is specified in seconds.               |
| Maximum Nexthop Processing                | Time that has passed since the nexthop notification was received that resulted in spending the maximum amount of processing time for all notifications. |
| Last Notification Processing              | Time that has passed since the last nexthop notification was received.                                                                                  |
| IPv4 Unicast is active.                   | VRF specified output that indicates the IPv4 unicast address family is active within the VRF.                                                           |
| Nexthop Count                             | Number of next hops for the VRF or address family.                                                                                                      |
| Critical Trigger Delay                    | Configured critical trigger delay.                                                                                                                      |
| Non-critical Trigger Delay                | Configured noncritical trigger delay.                                                                                                                   |
| Total Critical Notifications Received     | Number of critical notifications received.                                                                                                              |
| Total Non-critical Notifications Received | Number of noncritical notifications received.                                                                                                           |
| Bestpaths Deleted After Last Walk         | Number of best paths deleted due to the last notification.                                                                                              |
| Bestpaths Changed After Last Walk         | Number of best paths modified due to the last notification.                                                                                             |

| Field          | Description                                                                                  |
|----------------|----------------------------------------------------------------------------------------------|
| Next Hop       | IP address of the next hop.                                                                  |
| Status         | Status of the next hop.                                                                      |
| Metric         | IGP metric of the next hop.                                                                  |
| Notf           | Number of critical and noncritical notifications received.                                   |
| LastRIBEvent   | When the last notification was received from the RIB.                                        |
| RefCount       | The number of neighbors or prefixes that refer to the next hop in address family/all format. |
| Address Family | Name of the address family.                                                                  |

## show bgp nsr

To display Border Gateway Protocol (BGP) nonstop routing (NSR) information, use the **show bgp nsr** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast| all| tunnel| mdt}| ipv6 {unicast| multicast| all|
labeled-unicast}| all {unicast| multicast| all| labeled-unicast| mdt| tunnel}| vpnv4 unicast| vrf {vrf-name|
all} [ipv4 {unicast| labeled-unicast}| ipv6 unicast]| vpnv6 unicast] nsr [standby]
```

### Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>standby</b>                            | Displays information about the standby card.                                        |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp nsr** command:

```
RP/0/0/CPU0:router# show bgp nsr

Fri Jan 30 10:18:48.171 PST PDT

BGP Process Information:
BGP is operating in STANDALONE mode
Autonomous System: 100
Router ID: 10.1.0.1 (manually configured)
Default Cluster ID: 10.1.0.1
Active Cluster IDs: 10.1.0.1
Fast external fallover enabled
Neighbor logging is not enabled
Enforce first AS enabled
AS Path ignore is enabled
AS Path multipath-relax is enabled
Default local preference: 100
Default keepalive: 60
Graceful restart enabled
Restart time: 180
Stale path timeout time: 360
RIB purge timeout time: 600
Non-stop routing is enabled
Update delay: 120
Generic scan interval: 60

Address family: IPv4 Unicast
Dampening is not enabled
Client reflection is enabled in global config
Scan interval: 60
Main Table Version: 7034
IGP notification: IGP notified
RIB has converged: version 1
```

```

The following example shows sample output from the **show bgp nsr** command with the **standby** keyword:

```

RP/0/0/CPU0:router# show bgp nsr standby

Fri Jan 30 10:18:55.654 PST PDT

BGP Process Information:
BGP is operating in STANDALONE mode
Autonomous System: 100
Router ID: 10.1.0.1 (manually configured)
Default Cluster ID: 10.1.0.1
Active Cluster IDs: 10.1.0.1
Fast external fallover enabled
Neighbor logging is not enabled
Enforce first AS enabled
AS Path ignore is enabled
AS Path multipath-relax is enabled
Default local preference: 100
Default keepalive: 60
Graceful restart enabled
Restart time: 180

```

**show bgp nsr**

```

Stale path timeout time: 360
RIB purge timeout time: 600
Non-stop routing is enabled
Update delay: 120
Generic scan interval: 60

```

```

Address family: IPv4 Unicast
Dampening is not enabled
Client reflection is enabled in global config
Scan interval: 60
Main Table Version: 7034
IGP notification: IGP notified
RIB has converged: version 1

```

```

# show bgp paths

To display all the Border Gateway Protocol (BGP) paths in the database, use the **show bgp paths** command in EXEC mode.

**show bgp paths** [**detail**] [**debug**] [**regex** *regular-expression*]

## Syntax Description

|                                        |                                                                                                 |
|----------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>detail</b>                          | (Optional) Displays detailed attribute information.                                             |
| <b>debug</b>                           | (Optional) Displays attribute process ID, hash bucket, and hash chain ID attribute information. |
| <b>regex</b> <i>regular-expression</i> | (Optional) Specifies an autonomous system path that matches the regular expression.             |

## Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                         |
| Release 3.3.0 | The <b>regex</b> keyword was added.                                                                                                                                                                                                  |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show bgp paths** command to display information about AS paths and the associated attributes with which the paths were received.

If no options are specified, all stored AS paths are displayed with the number of routes using each path.

**Note**

The AS path information is stored independently of the address family, making it possible that routes from different address families could be using the same path.

Use the *regular-expression* argument to limit the output to only those paths that match the specified regular expression. See the *Cisco IOS XR Getting Started Guide for the Cisco XR 12000 Series Router* for information on regular expressions.

Use the **detail** keyword to display detailed information on the attributes stored with the AS path.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp paths** command:

```
RP/0/0/CPU0:router# show bgp paths detail
```

```

Proc  Attributes                      Refcount    Metric Path
Spk 0  ORG AS LOCAL                    7           0 i
Spk 0  ORG AS LOCAL COMM EXTCOMM      3           0 21 i
Spk 0  MET ORG AS                     3          55 2 i
Spk 0  ORG AS                         3           0 2 10 11 i
Spk 0  ORG AS COMM                     3           0 2 10 11 i

**Table 26: show bgp paths Field Descriptions**

| Field | Description                                                            |
|-------|------------------------------------------------------------------------|
| Proc  | ID of the process in which the path is stored. This is always "Spk 0." |

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attributes | <p>Attributes that are present. The following may appear:</p> <p>MET —Multi Exit Discriminator (MED) attribute is present.</p> <p>ORG—Origin attribute is present.</p> <p>AS—AS path attribute is present.</p> <p>LOCAL—Local preference attribute is present.</p> <p>AGG—Aggregator attribute is present.</p> <p>COMM—Communities attribute is present.</p> <p>ATOM—Atomic aggregate attribute is present.</p> <p>EXTCOMM—Extended communities attribute is present.</p> |
| NeighborAS | <p>Autonomous system number of the neighbor, or 0, if the path information originated locally.</p> <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul>                                            |
| Refcount   | Number of routes using a path.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Metric     | Value of the interautonomous system metric, otherwise known as the MED metric.                                                                                                                                                                                                                                                                                                                                                                                            |
| Path       | <p>Autonomous system path to the destination network. At the end of the path is the origin code for the path:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                         |

# show bgp policy

To display information about Border Gateway Protocol (BGP) advertisements under a proposed policy, use the **show bgp policy** command in EXEC mode.

## show bgp policy

### Syntax Description

|                                           |                                                                                                                                                 |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                                                                             |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                                                                                  |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                                                                                |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                                                                                          |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families.                                                             |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                                                                                   |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.                                                                        |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                                                                             |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.                                                                     |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                                                                            |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                                                                                 |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                                                                                 |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                                                                                       |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                                                                                         |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.                                                                 |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                                                                                    |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                                                                            |
| <b>neighbor</b>                           | (Optional) Previews advertisements for a single neighbor.                                                                                       |
| <i>ip-address</i>                         | (Optional) IP address of a single neighbor.                                                                                                     |
| <b>sent-advertisements</b>                | (Optional) Displays the routes that have been advertised to neighbors. If a route has not yet been advertised to the neighbor, it is not shown. |

|                          |                                                                |
|--------------------------|----------------------------------------------------------------|
| <b>route-policy</b>      | (Optional) Displays advertisements for an output route policy. |
| <b>route-policy-name</b> | (Optional) Name of the route policy.                           |
| <b>standby</b>           | (Optional) Displays information about the standby card.        |
| <b>summary</b>           | (Optional) Displays a summary of the BGP advertisements.       |

**Command Default**

Advertisements for all neighbors are displayed if the **neighbor** *ip-address* keyword and argument are not specified. If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.<br><br>The <b>unsuppress-map</b> <i>map</i> keyword and argument were removed and the <b>route-policy</b> <i>route-policy-name</i> keyword and argument were added.                                                                                                                                                                               |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4 unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul>                                                                                     |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                                                              |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br><br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br><br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br><br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                                          |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined in turn.

Use the **show bgp policy** command to display routes that would be advertised to neighbors under a proposed policy. Unlike in the **show bgp advertised** command, the information displayed reflects any modifications made to the routes when executing the specified policy.

Use the **neighbor** keyword to limit the output to routes advertised to a particular neighbor. Use the **sent-advertisements** keyword to change the output in two ways:

- If a policy is not specified explicitly, any policy configured on the neighbor (using the **route-policy (BGP)** command) is executed before displaying the routes.
- Only routes that have already been advertised to the neighbor (and not withdrawn) are displayed. Routes that have not yet been advertised are not displayed.

Use the **summary** keyword to display abbreviated output.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp policy** command with the **summary** keyword in EXEC mode:

```
RP/0/0/CPU0:router# show bgp policy summary
```

| Network       | Next Hop   | From       | Advertised to                          |
|---------------|------------|------------|----------------------------------------|
| 172.16.1.0/24 | 10.0.101.1 | 10.0.101.1 | 10.0.101.2<br>10.0.101.3               |
| 172.17.0.0/16 | 0.0.0.0    | Local      | 10.0.101.1<br>10.0.101.2<br>10.0.101.3 |

This table describes the significant fields shown in the display.

**Table 27: show bgp policy summary Field Descriptions**

| Field   | Description                                |
|---------|--------------------------------------------|
| Network | IP prefix and prefix length for a network. |

| Field           | Description                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Next Hop        | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network. |
| From            | IP address of the peer that advertised this route.                                                                                                                                   |
| Local           | Indicates the route originated on the local system.                                                                                                                                  |
| Local Aggregate | Indicates the route is an aggregate created on the local system.                                                                                                                     |
| Advertised to   | Indicates the neighbors to which this route was advertised.                                                                                                                          |

The following is sample output from the **show bgp policy** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp policy

11.0.0.0/24 is advertised to 10.4.101.1

This table describes the significant fields shown in the display.

**Table 28: show bgp policy Field Descriptions**

| Field                      | Description                                                                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Is advertised to           | IP address of the peer to which this route is advertised. If the route is advertised to multiple peers, information is shown separately for each peer.                                                   |
| neighbor                   | IP address of the peer that advertised this route, or one of the following:<br><br>Local—Route originated on the local system.<br><br>Local Aggregate—Route is an aggregate created on the local system. |
| neighbor router id         | BGP identifier for the peer, or the local system if the route originated on the local system.                                                                                                            |
| Not advertised to any peer | Indicates the no-advertise well-known community is associated with this route. Routes with this community are not advertised to any BGP peers.                                                           |

| Field                               | Description                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Not advertised to any EBGp peer     | Indicates the no-export well-known community is associated with this route. Routes with this community are not advertised to external BGP peers, even if those peers are in the same confederation as the local router.                                                                                                                                            |
| Not advertised outside the local AS | Indicates the local-AS well-known community is associated with this route. Routes with this community value are not advertised outside the local autonomous system or confederation boundary.                                                                                                                                                                      |
| (Received from a RR-client)         | Path was received from a route reflector client.                                                                                                                                                                                                                                                                                                                   |
| (received-only)                     | Path is not used for routing purposes. It is used to support soft reconfiguration, and records the path attributes before inbound policy was applied to a path received from a peer. A path marked "received-only" indicates that either the path was dropped by inbound policy, or that a copy of path information was created and then modified for routing use. |
| (received & used)                   | Indicates that the path is used both for soft reconfiguration and routing purposes. A path marked "(received & used)", implies the path information was not modified by inbound policy.                                                                                                                                                                            |
| valid                               | Path is valid.                                                                                                                                                                                                                                                                                                                                                     |
| redistributed                       | Path is locally sourced through redistribution.                                                                                                                                                                                                                                                                                                                    |
| aggregated                          | Path is locally sourced through aggregation.                                                                                                                                                                                                                                                                                                                       |
| local                               | Path is locally sourced through the <b>network</b> command.                                                                                                                                                                                                                                                                                                        |
| confed                              | Path was received from a confederation peer.                                                                                                                                                                                                                                                                                                                       |
| best                                | Path is selected as best.                                                                                                                                                                                                                                                                                                                                          |
| multipath                           | Path is one of multiple paths selected for load-sharing purposes.                                                                                                                                                                                                                                                                                                  |

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| metric             | Value of the interautonomous system metric, otherwise known as the MED metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| localpref          | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| aspath             | AS path associated with the route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| community          | <p>Community attributes associated with the path. Community values are displayed in AA:NN format, except for the following well-known communities:</p> <p>Local-AS—Community with value 4294967043 or hex 0xFFFFFFFF03. Routes with this community value are not advertised outside the local autonomous system or confederation boundary.</p> <p>no-advertise—Community with value 4294967042 or hex 0xFFFFFFFF02. Routes with this community value are not advertised to any BGP peers.</p> <p>no-export—Community with value 4294967041 or hex 0xFFFFFFFF01. Routes with this community are not advertised to external BGP peers, even if those peers are in the same confederation as the local router.</p> |
| Extended community | <p>Extended community attributes associated with the path. For known extended community types, the following codes may be displayed:</p> <p>RT—Route target community</p> <p>SoO—Site of Origin community</p> <p>LB—Link Bandwidth community</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Originator         | Router ID of the originating router when route reflection is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Cluster lists      | Router ID or cluster ID of all route reflectors through which the route has passed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Field                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attributes after outbound policy was applied | <p>Displays attributes associated with the received route, after any outbound policy has been applied.</p> <p>AGG—Aggregator attribute is present.</p> <p>AS—AS path attribute is present.</p> <p>ATOM—Atomic aggregate attribute is present.</p> <p>COMM—Communities attribute is present.</p> <p>EXTCOMM—Extended communities attribute is present.</p> <p>LOCAL—Local preference attribute is present.</p> <p>MET—Multi Exit Discriminator (MED) attribute is present.</p> <p>next hop—IP address of the next system used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.</p> <p>ORG—Origin attribute is present.</p> |

#### Related Commands

|-----------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">route-policy (BGP)</a> , on page 243    | Applies an inbound or outbound routing policy to a neighbor.                  |
| <b>set default-afi</b>                              | Sets the default Address Family Identifier (AFI) for the current session.     |
| <b>set default-safi</b>                             | Sets the default Subaddress Family Identifier (SAFI) for the current session. |
| <a href="#">show bgp advertised</a> , on page 291   | Displays routes advertised to neighbors.                                      |
| <a href="#">show bgp neighbors</a> , on page 346    | Displays information about the TCP and BGP connections to neighbors.          |
| <a href="#">show bgp route-policy</a> , on page 424 | Displays BGP information about networks that match an outbound route policy.  |

# show bgp process

To display Border Gateway Protocol (BGP) process information, use the **show bgp process** command in EXEC mode.

**show bgp** [**ipv4** {**unicast**|**multicast**|**labeled-unicast**|**all**|**tunnel**|**mdt**}|**ipv6** {**unicast**|**multicast**|**all**|**labeled-unicast**}|**all** {**unicast**|**multicast**|**all**|**labeled-unicast**|**mdt**|**tunnel**}|**vpn4 unicast**|**vpn6 unicast**] **process** [**performance-statistics**] [**detail**] [**standby**]

## Syntax Description

|                                |                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                    | (Optional) Specifies IP Version 4.                                                             |
| <b>unicast</b>                 | (Optional) Specifies the unicast subaddress family.                                            |
| <b>multicast</b>               | (Optional) Specifies the multicast subaddress family.                                          |
| <b>labeled-unicast</b>         | (Optional) Specifies labeled unicast address prefixes.                                         |
| <b>all</b>                     | (Optional) For subaddress families, specifies prefixes for all subaddress families.            |
| <b>tunnel</b>                  | (Optional) Specifies tunnel address prefixes.                                                  |
| <b>mdt</b>                     | (Optional) Specifies multicast distribution tree (MDT) address prefixes.                       |
| <b>ipv6</b>                    | (Optional) Specifies IP Version 6.                                                             |
| <b>all</b>                     | (Optional) For address family, specifies prefixes for all address families.                    |
| <b>vpn4 unicast</b>            | (Optional) Specifies VPNv4 unicast address families.                                           |
| <b>vpn6 unicast</b>            | (Optional) Specifies VPNv6 unicast address families.                                           |
| <b>performance- statistics</b> | (Optional) Displays performance statistics relative to the work done by the specified process. |
| <b>detail</b>                  | (Optional) Specifies detailed process information.                                             |
| <b>standby</b>                 | (Optional) Displays information about the standby card.                                        |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

## Command Modes

EXEC

|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                              |
| Release 3.4.0 | The <b>vpnv4 unicast</b> and the <b>labeled-unicast</b> keywords were supported.                                                                                                                                                                                                                                                          |
| Release 3.5.0 | <p>The <b>vpnv6 unicast</b> keywords were added.</p> <p>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.</p> <p>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.</p> <p>The <b>standby</b> keyword was removed.</p> |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                     |
| Release 3.9.0 | Asplain format for 4-byte autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations.                                                                                                      |
| Release 4.0   | The command output was modified to include information from BGP additional paths send and receive capability configurations.                                                                                                                                                                                                              |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Note

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

Use the **show bgp process** command to display status and summary information for the Border Gateway Protocol (BGP) process. The output shows various global and address family-specific BGP configurations. A summary of the number of neighbors, update messages, and notification messages sent and received by the process is also displayed.

Use the **detail** keyword to display detailed process information. The detailed process information shows the memory used by each of various internal structure types.

Use the **performance-statistics** keyword to display a summary or detail of work done by the BGP processes. The summary display shows the real time spent performing certain operations and the time stamps for state transitions during initial convergence.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp process** command:

```
RP/0/0/CPU0:router# show bgp process
```

```
BGP Process Information
BGP is operating in STANDALONE mode
Autonomous System: 1
Router ID: 10.0.0.5 (manually configured)
Cluster ID: 10.0.0.5
Fast external fallover enabled
Neighbor logging is enabled
Enforce first AS enabled
Default local preference: 100
Default keepalive: 60
Update delay: 120
Generic scan interval: 60
```

```
Address family: IPv4 Unicast
Dampening is enabled
Client reflection is enabled
Scan interval: 60
Main Table Version: 150
IGP notification: IGP notified
```

```
Node          Process      Nbrs Estab Rst Upd-Rcvd Upd-Sent Nfn-Rcvd Nfn-Sent
node0_0_CPU0 Speaker      3      2    1      20      10       0        0
```

This table describes the significant fields shown in the display.

**Table 29: show bgp process Field Descriptions**

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP is operating in | Indicates BGP is operating in standalone mode. This is the only supported mode.                                                                                                                                                                                                                                                                                            |
| Autonomous System   | Autonomous system number for the local system. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |

| Field                          | Description                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router ID                      | BGP identifier assigned to the local system. If this is explicitly configured using the <b>bgp router-id</b> command, “manually configured” is displayed. If the router ID is not manually configured, it is determined from a global router ID. If no global ID is available, the router ID is shown as 0.0.0.0. |
| Confederation ID               | Confederation identifier for the local system.                                                                                                                                                                                                                                                                    |
| Cluster ID                     | Cluster identifier for the local system. If this is manually configured using the <b>bgp cluster-id</b> command, “manually configured” is displayed.                                                                                                                                                              |
| Default metric                 | Default metric. This is controlled by the <b>default-metric</b> command.                                                                                                                                                                                                                                          |
| Fast external fallover enabled | Indicates whether fast external fallover is enabled. This is controlled by the <b>bgp fast-external-fallover disable</b> command.                                                                                                                                                                                 |
| Neighbor logging enabled       | Indicates whether logging of peer connection up and down transitions is enabled. This is controlled by the <b>bgp log neighbor changes disable</b> command.                                                                                                                                                       |
| Enforce first AS enabled       | Indicates that strict checking of the first AS number in paths received from external BGP peers is enabled. This is controlled by the <b>bgp enforce-first-as disable</b> command.                                                                                                                                |
| iBGP to IGP redistribution     | Indicates internal redistribution is enabled using the <b>bgp redistribution-internal</b> command.                                                                                                                                                                                                                |
| Treating missing MED as worst  | Indicates missing Multi Exit Discriminator (MED) metric values are treated as worst in the route selection algorithm. This is controlled by the <b>bgp bestpath med missing-as-worst</b> command.                                                                                                                 |
| Always compare MED is enabled  | Indicates that the MED is always used during the route selection algorithm, even when paths are received from external BGP neighbors in different autonomous systems. This is controlled by the <b>bgp bestpath med always</b> command.                                                                           |
| AS Path ignore is enabled      | Indicates that the AS path length is ignored by the route selection algorithm. This is controlled by the <b>bgp bestpath as-path ignore</b> command.                                                                                                                                                              |

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Comparing MED from confederation peers | Indicates that the MED values are used in the route selection algorithm when comparing routes received from confederation peers. This is controlled by the <b>bgp bestpath med confed</b> command.                                                                                                                                                                                                                               |
| Comparing router ID for eBGP paths     | Indicates that the router ID is used as a tiebreaker by the route selection algorithm when comparing identical routes received from different external BGP neighbors. This is controlled by the <b>bgp bestpath compare-routerid</b> command.                                                                                                                                                                                    |
| Default local preference               | Default local preference value used for BGP routes. This is controlled by the <b>bgp default local-preference</b> command.                                                                                                                                                                                                                                                                                                       |
| Default keepalive                      | Default keepalive interval. This is controlled by the <b>timers bgp</b> command.                                                                                                                                                                                                                                                                                                                                                 |
| Graceful restart enabled               | Indicates that the graceful restart capability is enabled. The configuration commands affecting graceful restart behavior are: <ul style="list-style-type: none"> <li>• <b>bgp graceful-restart</b></li> <li>• <b>bgp graceful-restart purge-time</b></li> <li>• <b>bgp graceful-restart stalepath-time</b></li> <li>• <b>bgp graceful-restart restart-time</b></li> <li>• <b>bgp graceful-restart graceful-reset</b></li> </ul> |
| Update delay                           | Maximum time that a BGP process stays in read-only mode.                                                                                                                                                                                                                                                                                                                                                                         |
| Generic scan interval                  | Interval (in seconds) between BGP scans for address family-independent tasks. This is controlled by the <b>bgp scan-time</b> command.                                                                                                                                                                                                                                                                                            |
| Dampening                              | Indicates whether dampening is enabled for the specified address family. This is controlled by the <b>dampening</b> command.                                                                                                                                                                                                                                                                                                     |
| Client reflection                      | Indicates whether client-to-client route reflection is enabled for the specified address family. This is controlled by the <b>bgp client-to-client reflection disable</b> command.                                                                                                                                                                                                                                               |

| Field              | Description                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan interval      | Interval (in seconds) between BGP scans for the given address family. This is controlled by the <b>bgp scan-time</b> command in address family configuration mode. |
| Main Table Version | Last version of the BGP database that was installed into the main routing table.                                                                                   |
| IGP notification   | Indicates whether Interior Gateway Protocols (IGP) have been notified of BGP convergence for the specified address family.                                         |
| Node               | Node on which the process is executing.                                                                                                                            |
| Process            | Type of BGP process.                                                                                                                                               |
| Speaker            | Speaker process. A speaker process is responsible for receiving, processing, and sending BGP messages to configured neighbors.                                     |
| Nbrs               | Number of neighbors for which the process is responsible.                                                                                                          |
| Estab              | Number of neighbors that have connections in the established state for this process.                                                                               |
| Rst                | Number of times this process was restarted.                                                                                                                        |
| Upd-Rcvd           | Number of update messages received by the process.                                                                                                                 |
| Upd-Sent           | Number of update messages sent by the process.                                                                                                                     |
| Nfn-Rcvd           | Number of notification messages received by the process.                                                                                                           |
| Nfn-Sent           | Number of notification messages sent by the process.                                                                                                               |

The following is sample output from the **show bgp process** command with the **detail** keyword:

```
RP/0/0/CPU0:router# show bgp all all process detail
```

```
BGP Process Information
BGP is operating in STANDALONE mode
Autonomous System: 1
Router ID: 10.0.0.5 (manually configured)
Cluster ID: 10.0.0.5
Fast external fallover enabled
Neighbor logging is enabled
Enforce first AS enabled
Default local preference: 100
Default keepalive: 60
```

```

Update delay: 120
Generic scan interval: 60

BGP Speaker process: 0, location node0_0_0
Neighbors: 3, established: 2

                Sent           Received
Updates:         3             15
Notifications:   0             0

                Number         Memory Used
Attributes:      12            1104
AS Paths:        10            400
Communities:     2             1080
Extended communities: 1         40
Route Reflector Entries: 0       0
Route-map Cache Entries: 0       0
Filter-list Cache Entries: 0     0
Next Hop Cache Entries: 2       80
Update messages queued: 0

Address family: IPv4 Unicast
Dampening is enabled
Client reflection is enabled
Main Table Version: 12
IGP notification: IGP notified

State: normal mode.
BGP Table Version: 12
Network Entries: 15, Soft Reconfig Entries: 0
Dampened Paths: 0, History Paths: 9

                Allocated      Freed
Prefixes:        15            0
Paths:           19            0

                Number         Memory Used
Prefixes:        15            1230
Paths:           19            760

```

This table describes the significant fields shown in the display.

**Table 30: show bgp process detail Field Descriptions**

| Field               | Description                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP is operating in | Indicates whether BGP is operating in standalone mode.                                                                                                                                                                                                                                                                 |
| Autonomous System   | Autonomous system number for the local system.                                                                                                                                                                                                                                                                         |
| Router ID           | BGP identifier assigned to the local system. If this is explicitly configured using the <b>bgp router-id</b> command, “manually configured” is displayed. If the router ID is not manually configured, it is determined from a global router ID. If the global ID is not available, the router ID is shown as 0.0.0.0. |
| Confederation ID    | Confederation identifier for the local system.                                                                                                                                                                                                                                                                         |
| Cluster ID          | Cluster identifier for the local system. If this is manually configured using the <b>bgp cluster-id</b> command, “manually configured” is displayed.                                                                                                                                                                   |

| Field                                  | Description                                                                                                                                                                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default metric                         | Default metric.                                                                                                                                                                                                                               |
| Fast external fallover enabled         | Indicates whether fast external fallover is enabled.                                                                                                                                                                                          |
| Neighbor logging enabled               | Indicates whether logging of peer connection up and down transitions is enabled.                                                                                                                                                              |
| Enforce first AS enabled               | Indicates that strict checking of the first autonomous system (AS) number in paths received from external BGP peers is enabled.                                                                                                               |
| iBGP to IGP redistribution             | Indicates internal redistribution is enabled using the <b>bgp redistribution-internal</b> command.                                                                                                                                            |
| Treating missing MED as worst          | Indicates missing MED metric values are treated as worst in the route selection algorithm. This is controlled by the <b>bgp bestpath med missing-as-worst</b> command.                                                                        |
| Always compare MED is enabled          | Indicates that the MED is always used during the route selection algorithm, even when paths are received from external BGP neighbors in different autonomous systems. This is controlled by the <b>bgp bestpath med always</b> command.       |
| AS Path ignore is enabled              | Indicates that the AS path length is ignored by the route selection algorithm. This is controlled by the <b>bgp bestpath as-path ignore</b> command.                                                                                          |
| Comparing MED from confederation peers | Indicates that the MED values are used in the route selection algorithm when comparing routes received from confederation peers. This is controlled by the <b>bgp bestpath med confed</b> command.                                            |
| Comparing router ID for eBGP paths     | Indicates that the router ID is used as a tiebreaker by the route selection algorithm when comparing identical routes received from different external BGP neighbors. This is controlled by the <b>bgp bestpath compare-routerid</b> command. |
| Default local preference               | Default local preference value used for BGP routes.                                                                                                                                                                                           |
| Default keepalive                      | Default keepalive interval. This is controlled by the <b>timers bgp</b> command.                                                                                                                                                              |

| Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Graceful restart enabled | Indicates that the graceful restart capability is enabled. The configuration commands affecting graceful restart behavior are: <ul style="list-style-type: none"> <li>• <b>bgp graceful-restart</b></li> <li>• <b>bgp graceful-restart purge-time</b></li> <li>• <b>bgp graceful-restart stalepath-time</b></li> <li>• <b>bgp graceful-restart restart-time</b></li> <li>• <b>bgp graceful-restart graceful-reset</b></li> </ul> |
| Update delay             | Maximum time that a BGP process stays in read-only mode.                                                                                                                                                                                                                                                                                                                                                                         |
| Generic scan interval    | Interval (in seconds) between BGP scans for address family-independent tasks. This is controlled by the <b>bgp scan-time</b> command.                                                                                                                                                                                                                                                                                            |
| BGP Speaker Process      | Speaker process responsible for receiving, processing and sending BGP messages.                                                                                                                                                                                                                                                                                                                                                  |
| Node                     | Node on which the specified process is executing.                                                                                                                                                                                                                                                                                                                                                                                |
| Neighbors                | Number of neighbors for which the specified process is responsible.                                                                                                                                                                                                                                                                                                                                                              |
| established              | Number of neighbors that have connections in the established state for the specified process.                                                                                                                                                                                                                                                                                                                                    |
| Updates                  | Number of update messages sent and received by the specified process.                                                                                                                                                                                                                                                                                                                                                            |
| Notifications            | Number of notification messages sent and received by the specified process.                                                                                                                                                                                                                                                                                                                                                      |
| Attributes               | Number of unique sets of attribute information stored in the specified process and the amount of memory used by the attribute information.                                                                                                                                                                                                                                                                                       |
| AS Paths                 | Number of unique autonomous system paths stored in the specified process and the amount of memory used by the AS path information.                                                                                                                                                                                                                                                                                               |
| Communities              | Number of unique sets of community information stored in the specified process and the amount of memory used by them.                                                                                                                                                                                                                                                                                                            |

| Field                   | Description                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extended communities    | Number of unique sets of extended community information stored in the specified process and the amount of memory used by them.                                                     |
| Route Reflector Entries | Number of unique sets of route reflector information stored in the specified process and the amount of memory used by them.                                                        |
| Nexthop Entries         | Number of entries and memory usage for cached next-hop information.                                                                                                                |
| Update messages queued  | Total number of update messages queued to be sent across all neighbors for which the specified process is responsible.                                                             |
| Address family          | Specified address family.                                                                                                                                                          |
| Dampening               | Indicates whether dampening is enabled for the specified address family.                                                                                                           |
| Client reflection       | Indicates whether client-to-client route reflection is enabled for the specified address family. This is controlled by the <b>bgp client-to-client reflection disable</b> command. |
| Scan interval           | Interval (in seconds) between BGP scans for the given address family. This is controlled by the <b>bgp scan-time</b> command.                                                      |
| Main Table Version      | Last version of the local BGP database for the specified address family that was injected into the main routing table.                                                             |
| IGP notification        | Indicates whether IGP have been notified of BGP convergence for the specified address family.                                                                                      |
| RIB has converged       | Indicates whether the main routing table version has converged and the version at which it converged.                                                                              |

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| State                 | <p>BGP system state for the specified address family and process. This may be one of the following:</p> <p>read-only mode—Initial set of updates is being recovered. In this mode, route selection is not performed, routes are not installed in the global RIB, and updates are not advertised to peers.</p> <p>best-path calculation mode—Route selection is being performed for the routes that were received while in read-only mode.</p> <p>import mode—Routes are imported from one VRF to another VRF once the best paths are calculated. This mode is supported in VPNv4 unicast address family mode.</p> <p>RIB update mode—Routes that were selected in best-path calculation mode are being installed in the global RIB.</p> <p>label allocation mode: Labels are allocated for the received prefixes based on the requirement.</p> <p>normal mode—Best paths are sent to the peers for routes that exist in the RIB. The route selection, import processing, RIB updates, and label allocation are performed as new updates are received.</p> |
| BGP Table Version     | Last version used in the BGP database for received routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Attribute download    | Indicates whether the RIB attribute download is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Network Entries       | Number of sets of prefix information held in the specified BGP process for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Soft Reconfig Entries | Number of sets of prefix information that are present only for the purpose of supporting soft reconfiguration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Dampened Paths        | Number of routes that are suppressed due to dampening for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| History Paths         | Number of routes that are currently withdrawn, but are being maintained to preserve dampening information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Field                         | Description                                                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Prefixes (Allocated/Freed)    | Number of sets of prefix information for the specified address family that have been allocated and freed during the lifetime of the process. |
| Paths (Allocated/Freed)       | Number of sets of route information for the specified address family that have been allocated and freed during the lifetime of the process.  |
| Prefixes (Number/Memory Used) | Number of sets of prefix information currently allocated for the specified address family, and the amount of memory used by them.            |
| Paths (Number/Memory Used)    | Number of sets of route information currently allocated for the specified address family, and the amount of memory used by them.             |

The following is sample output from the **show bgp process** command with the **performance-statistics** keyword:

```
RP/0/0/CPU0:router# show bgp process performance-statistics detail

BGP Speaker process: 0, Node: node0_0_CPU0
Restart count: 2
Neighbors: 3, established: 2

Updates:                Sent          Received
Notifications:         20             0

Attributes:             Number        Memory Used
AS Paths:               2          184

This table describes the significant fields shown in the display.

**Table 31: show bgp process performance-statistics Field Descriptions**

| Field                          | Description                                                                                                                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP is operating in            | Indicates whether BGP is operating in standalone mode.                                                                                                                                                                                                                                                                 |
| Autonomous system              | Autonomous system number for the local system.                                                                                                                                                                                                                                                                         |
| Router ID                      | BGP identifier assigned to the local system. If this is explicitly configured using the <b>bgp router-id</b> command, “manually configured” is displayed. If the router ID is not manually configured, it is determined from a global router ID. If the global ID is not available, the router ID is shown as 0.0.0.0. |
| Confederation ID               | Confederation identifier for the local system.                                                                                                                                                                                                                                                                         |
| Cluster ID                     | The cluster identifier for the local system. If this is manually configured using the <b>bgp cluster-id</b> command, “manually configured” is displayed.                                                                                                                                                               |
| Default metric                 | Default metric.                                                                                                                                                                                                                                                                                                        |
| Fast external fallover enabled | Indicates whether fast external fallover is enabled.                                                                                                                                                                                                                                                                   |
| Neighbor logging enabled       | Indicates whether logging of peer connection up and down transitions is enabled. This is controlled by the <b>bgp log neighbor changes disable</b> command.                                                                                                                                                            |
| Enforce first AS enabled       | Indicates that strict checking of the first AS number in paths received from external BGP peers is enabled.                                                                                                                                                                                                            |
| iBGP to IGP redistribution     | Indicates internal redistribution is enabled using the <b>bgp redistribution-internal</b> command.                                                                                                                                                                                                                     |

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Treating missing MED as worst          | Indicates missing MED metric values are treated as worst in the route selection algorithm. This is controlled using the <b>bgp bestpath med missing-as-worst</b> command.                                                                                                                                                                      |
| Always compare MED is enabled          | Indicates that the MED is always used during the route selection algorithm, even when paths are received from external BGP neighbors in different autonomous systems. This setting is controlled by the <b>bgp bestpath med always</b> command.                                                                                                |
| AS Path ignore is enabled              | Indicates that the AS path length is ignored by the route selection algorithm. This is controlled by the <b>bgp bestpath as-path ignore</b> command.                                                                                                                                                                                           |
| Comparing MED from confederation peers | Indicates that the MED values are used in the route selection algorithm when comparing routes received from confederation peers. This is controlled by the <b>bgp bestpath med confed</b> command.                                                                                                                                             |
| Comparing router ID for eBGP paths     | Indicates that the router ID is used as a tiebreaker by the route selection algorithm when comparing identical routes received from different external BGP neighbors. This is controlled by the <b>bgp bestpath compare-routerid</b> command.                                                                                                  |
| Default local preference               | Default local preference value used for BGP routes.                                                                                                                                                                                                                                                                                            |
| Default keepalive                      | Default keepalive interval. This setting is controlled by the <b>timers bgp</b> command.                                                                                                                                                                                                                                                       |
| Graceful restart enabled               | Indicates that the graceful restart capability is enabled. The configuration commands affecting graceful restart behavior are: <b>bgp graceful-restart</b> , <b>bgp graceful-restart purge-time</b> , <b>bgp graceful-restart stalepath-time</b> , <b>bgp graceful-restart restart-time</b> , and <b>bgp graceful-restart graceful-reset</b> . |
| Update delay                           | Maximum time that a BGP process stays in read-only mode.                                                                                                                                                                                                                                                                                       |
| Generic scan interval                  | Interval (in seconds) between BGP scans for address family-independent tasks. This setting is controlled by the <b>bgp scan-time</b> command in router configuration mode.                                                                                                                                                                     |
| Address family                         | Specified address family.                                                                                                                                                                                                                                                                                                                      |

| Field              | Description                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dampening          | Indicates whether dampening is enabled for the specified address family.                                                                                                           |
| Client reflection  | Indicates whether client-to-client route reflection is enabled for the specified address family. This is controlled by the <b>bgp client-to-client reflection disable</b> command. |
| Scan interval      | Interval (in seconds) between BGP scans for the given address family. This is controlled by the <b>bgp scan-time</b> command.                                                      |
| Main Table Version | Last version of the local BGP database for the specified address family that was injected into the main routing table.                                                             |
| IGP notification   | Indicates whether IGP has been notified of BGP convergence for the specified address family.                                                                                       |
| Node               | Node on which the process is executing.                                                                                                                                            |
| Process            | BGP process.                                                                                                                                                                       |
| Speaker            | Speaker process. The speaker process is responsible for receiving, processing and sending BGP messages.                                                                            |
| Read               | Real time (in seconds) spent reading messages from peers by this process.                                                                                                          |
| Write              | Real time (in seconds) spent writing messages to peers by this process.                                                                                                            |
| Inbound            | The real time (in seconds) spent processing messages read from peers by this process.                                                                                              |
| Config             | Real time (in seconds) spent processing configuration commands by this process.                                                                                                    |
| Data               | Real time (in seconds) spent providing operational data by this process.                                                                                                           |
| Conv               | Indicates whether the process has converged after the initial update.                                                                                                              |
| Nbr Estab          | Time stamp (in seconds) recording the time when the first neighbor became established.                                                                                             |
| Bestpath           | Time stamp (in seconds) recording the time the best-path calculation mode was entered.                                                                                             |

| Field                                                       | Description                                                                                                                        |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| RIB Inst                                                    | Time stamp (in seconds) recording the time RIB update mode was entered.                                                            |
| Read/Write                                                  | Time stamp (in seconds) recording the time normal mode was entered.                                                                |
| Last Upd                                                    | Time stamp (in seconds) recording the time the last update was sent to a neighbor.                                                 |
| Address Family IPv4 Unicast converged in <i>n</i> seconds   | Indicates that BGP has reached initial convergence for the IPv4 unicast address family. The time taken for convergence is shown.   |
| Address Family IPv6 Multicast converged in <i>n</i> seconds | Indicates that BGP has reached initial convergence for the IPv6 multicast address family. The time taken for convergence is shown. |

The following is sample output from the **show bgp process** command with the **performance-statistics** and **detail** keywords:

```
RP/0/0/CPU0:router# show bgp process performance-statistics detail

BGP Speaker process: 0, Node: node0_0_CPU0
Restart count: 2
Neighbors: 3, established: 2

Updates:                Sent      Received
Notifications:         0          0

Attributes:             Number     Memory Used
AS Paths:               2         184
Communities:            0          0
Extended communities:  0          0
Route Reflector Entries: 0          0
Route-map Cache Entries: 0          0
Filter-list Cache Entries: 0         0
Next Hop Cache Entries: 2          80
Update messages queued: 0

Read 14 messages (1142 bytes) in 12 calls (time spent: 0.024 secs)
Read throttled 0 times
Processed 14 inbound messages (time spent: 0.132 secs)
Wrote 2186 bytes in 24 calls (time spent: 0.024 secs)
Processing write list: wrote 18 messages in 4 calls (time spent: 0.000 secs)
Processing write queue: wrote 10 messages in 20 calls (time spent: 0.000 secs)
Socket setup (LPTS): 4 calls (time spent: 0.010 secs)
Configuration: 1 requests (time spent: 0.002 secs)
Operational data: 9 requests (time spent: 0.026 secs)

State: normal mode.
BGP Table Version: 150
Network Entries: 149, Soft Reconfig Entries: 0

This table describes the significant fields shown in the display.

**Table 32: show bgp process performance-statistics detail Field Descriptions**

| Field                | Description                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Process              | The specified process.                                                                                                                     |
| Location             | Node in which the specified process is executing.                                                                                          |
| Neighbors            | Number of neighbors for which the specified process is responsible.                                                                        |
| established          | Number of neighbors that have connections in the established state for the specified process.                                              |
| Updates              | Number of update messages sent and received by the specified process.                                                                      |
| Notifications        | Number of notification messages sent and received by the specified process.                                                                |
| Attributes           | Number of unique sets of attribute information stored in the specified process and the amount of memory used by the attribute information. |
| AS Paths             | Number of unique autonomous system paths stored in the specified process, and the amount of memory used by the AS path information.        |
| Communities          | Number of unique sets of community information stored in the specified process and the amount of memory used by them.                      |
| Extended communities | Number of unique sets of extended community information stored in the specified process and the amount of memory used by them.             |

| Field                     | Description                                                                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Route Reflector Entries   | Number of unique sets of route reflector information stored in the specified process and the amount of memory used by them.                                                                                                   |
| Route-map Cache Entries   | Number of entries and memory usage for cached results for applying a route map.                                                                                                                                               |
| Filter-list Cache Entries | Number of entries and memory usage for cached results for applying an AS path filter list.                                                                                                                                    |
| Next Hop Cache Entries    | Number of entries and memory usage for cached next-hop information.                                                                                                                                                           |
| Update messages queued    | Number of update messages queued to be sent across all neighbors for which the specified process is responsible.                                                                                                              |
| Read                      | Indicates the number of messages read by the process, the total size of read messages, the number of read operations performed, and the real time spent by the process performing read operations.                            |
| Read throttled            | Number of times that reading from TCP has been throttled due to a backlog of messages read but not processed.                                                                                                                 |
| inbound messages          | Number of read messages that have been processed and the real time spent processing inbound messages.                                                                                                                         |
| Wrote                     | Amount of data that has been written by the process, the number of write operations performed, and the real time spent by the process performing write operations.                                                            |
| Processing write list     | Number of messages written from write lists, the number of times the write list has been processed, and the real time spent processing the write list.<br><br><b>Note</b> Write lists typically contain only update messages. |
| Processing write queue    | Number of messages written from write queues, number of times the write queue has been processed, and the real time spent processing the write queue.                                                                         |
| Socket setup              | Number of socket setup operations performed and the real time spent during socket setup operations.                                                                                                                           |

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configuration         | Number of configuration requests received by the process and the real time spent processing configuration requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Operational data      | Number of requests for operational data (for <b>show</b> commands) received by the process and the real time spent processing operation data requests                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| State                 | <p>BGP system state for the specified address family and process. This may be one of the following:</p> <p>read-only mode—Initial set of updates is being recovered. In this mode, route selection is not performed, routes are not installed in the global RIB, and updates are not advertised to peers.</p> <p>best-path calculation mode—Route selection is being performed for the routes that were received while in read-only mode.</p> <p>import mode—Routes are imported from one VRF to another VRF once the best paths are calculated. This mode is supported in VPNv4 unicast address family mode.</p> <p>RIB update mode—Routes that were selected in best-path calculation mode are being installed in the global RIB.</p> <p>label allocation mode: Labels are allocated for the received prefixes based on the requirement.</p> <p>normal mode—Best paths are sent to the peers for routes that exist in the RIB. The route selection, import processing, RIB updates, and label allocation are performed as new updates are received.</p> |
| BGP Table Version     | Last version used in the BGP database for received routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Network Entries       | Number of sets of prefix information held in the specified BGP process for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Soft Reconfig Entries | Number of sets of prefix information that are present only for the purpose of supporting soft reconfiguration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Dampened Paths        | Number of routes that are suppressed due to dampening for the specified address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Field                         | Description                                                                                                                                                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| History Paths                 | Number of routes that are currently withdrawn, but are being maintained to preserve dampening information.                                                                                                                                   |
| Prefixes (Allocated/Freed)    | Number of sets of prefix information for the specified address family that have been allocated and freed during the lifetime of the process.                                                                                                 |
| Paths (Allocated/Freed)       | Number of sets of route information for the specified address family that have been allocated and freed during the lifetime of the process.                                                                                                  |
| Prefixes (Number/Memory Used) | Number of sets of prefix information currently allocated for the specified address family and amount of memory used by them.                                                                                                                 |
| Paths (Number/Memory Used)    | Number of sets of route information currently allocated for the specified address family and amount of memory used by them.                                                                                                                  |
| Updates generated             | Number of prefixes for which updates have been generated, the number of messages used to advertise the updates, the number of update generation runs performed, and the real time spent generating updates for the specified address family. |
| Scanner                       | Number of times the scanner has run for the specified address family and real time spent in scanner processing.                                                                                                                              |
| RIB Update                    | Number of global routing information base update runs performed for the specified address family, number of prefixes installed, withdrawn, or modified in the global RIB during these runs, and real time spent performing these runs.       |
| Process has converged         | Indicates whether the process has reached initial convergence for the specified address family.                                                                                                                                              |
| First neighbor established    | Time stamp (in seconds) recording the time the first neighbor in the process was established.                                                                                                                                                |
| Entered DO_BESTPATH mode      | Time stamp (in seconds) recording the time best-path calculation mode was entered.                                                                                                                                                           |
| Entered DO_RIBUPD mode        | Time stamp (in seconds) recording the time RIB update mode was entered.                                                                                                                                                                      |

| Field               | Description                                                                        |
|---------------------|------------------------------------------------------------------------------------|
| Entered Normal mode | Time stamp (in seconds) recording the time normal mode was entered.                |
| Last UPDATE sent    | Time stamp (in seconds) recording the time the last update was sent to a neighbor. |

The following is sample output from the **show bgp vpnv4 unicast process performance-statistics detail** command:

```
RP/0/0/CPU0:router# show bgp vpnv4 unicast process performance-statistics detail

# show bgp regexp

To display routes matching the autonomous system path regular expression, use the **show bgp regexp** command in EXEC mode.

**show bgp regexp** *regular-expression*

## Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpn6 unicast</b>                       | (Optional) Specifies VPNv6 unicast address families.                                |
| <i>regular-expression</i>                 | Regular expression to match the BGP autonomous system paths.                        |

## Command Default

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                                                                                                                                                                                                                                                                       |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                       |
| Release 3.3.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• <b>vpn4 unicast</b></li> </ul>                              |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                  |
| Release 3.5.0 | The <b>vpn6 unicast</b> keywords were added.<br><br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br><br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each configured address family and subaddress family combination. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined in turn.

Use the **show bgp regexp** command to display all routes in the specified BGP table whose autonomous system path is matched by the specified regular expression.

**Note**

If the regular expression contains spaces and parentheses, it must be specified and surrounded by quotation marks.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp regexp** command:

```
RP/0/0/CPU0:router# show bgp regexp "^3 "

BGP router identifier 10.0.0.5, local AS number 1
BGP main routing table version 64

Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop           Metric LocPrf Weight Path
*>i172.20.17.121   10.0.101.2             100      0 3 2000 3000 i
*>i10.0.0.0        10.0.101.2             100      0 3 100 1000 i
*>i172.5.23.0/24   10.0.101.2             100      0 3 4 60 4378 i
```

This table describes the significant fields shown in the display.

**Table 33: show bgp regexp Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| Dampening enabled              | Displayed if dampening has been enabled for the routes in this BGP routing table.                           |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is placed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Network      | IP address of a network entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

|----------------------------------------------------|-------------------------------------------------------------------------------|
| <b>set default-afi</b>                             | Sets the default Address Family Identifier (AFI) for the current session.     |
| <b>set default-safi</b>                            | Sets the default Subaddress Family Identifier (SAFI) for the current session. |
| <a href="#">show bgp, on page 265</a>              | Displays entries in the BGP routing table.                                    |
| <a href="#">show bgp route-policy, on page 424</a> | Displays BGP information about networks that match an outbound route policy.  |

# show bgp route-policy

To display Border Gateway Protocol (BGP) information about networks that match an outbound route policy, use the **show bgp route-policy** command in EXEC mode.

**show bgp route-policy** *route-policy-name* [**standby**]

## Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpn6 unicast</b>                       | (Optional) Specifies VPNv6 unicast address families.                                |
| <i>route-policy-name</i>                  | Name of a route policy.                                                             |
| <b>standby</b>                            | (Optional) Displays information about the standby card.                             |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.<br>The <b>count-only</b> keyword was removed.                                                                                                                                                                                                                                                                    |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                              |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each address family and subaddress family combination that has been configured. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined.

A route policy must be configured to use this command. When the **show bgp route-policy** command is entered, routes in the specified BGP table are compared with the specified route policy, and all routes passed by the route policy are displayed.

If a pass clause is encountered while the route policy is being applied to the route and the route policy processing completes without hitting a drop clause, the route is displayed. The route is not displayed if a drop clause is encountered, if the route policy processing completes without hitting a pass clause, or if the specified route policy does not exist.

The information displayed does not reflect modifications the policy might make to the route. To display such modifications, use the **show bgp policy** command.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp route-policy** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp route-policy p1

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 729
Dampening enabled
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop           Metric LocPrf Weight Path
*  10.13.0.0/16    192.168.40.24                      0 1878 704 701 200 ?
*  10.16.0.0/16    192.168.40.24                      0 1878 704 701 i
```

This table describes the significant fields shown in the display.

**Table 34: show bgp route-policy Field Descriptions**

| Field                          | Description                                                                      |
|--------------------------------|----------------------------------------------------------------------------------|
| BGP router identifier          | BGP identifier for the local system.                                             |
| local AS number                | Autonomous system number for the local system.                                   |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table. |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.      |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP scan interval | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Status codes      | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes      | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network           | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop          | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metric | Value of the interautonomous system metric, otherwise known as the Multi Exit discriminator (MED) metric.                                                             |
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

#### Related Commands

| Command                                         | Description                                                                                             |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">aggregate-address, on page 27</a>   | Configures an aggregate entry in a BGP routing table.                                                   |
| <a href="#">network (BGP), on page 191</a>      | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |
| <a href="#">route-policy (BGP), on page 243</a> | Applies a routing policy to updates advertised to or received from a BGP neighbor                       |
| <b>route-policy</b>                             | Configures a route policy.                                                                              |
| <b>set default-afi</b>                          | Sets the default Address Family Identifier (AFI) for the current session.                               |
| <b>set default-safi</b>                         | Sets the default Subaddress Family Identifier (SAFI) for the current session.                           |
| <a href="#">show bgp policy, on page 386</a>    | Displays advertisements under a proposed policy.                                                        |

# show bgp session-group

To display information about the Border Gateway Protocol (BGP) configuration for session groups, use the **show bgp session-group** command in EXEC mode.

**show bgp session-group** *group-name* {**configuration** [**defaults**] [**nvgen**]| **inheritance**| **users**}

## Syntax Description

|                      |                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group-name</i>    | Name of the session family group to display.                                                                                                                                                                         |
| <b>configuration</b> | (Optional) Displays the effective configuration for the session group, including any inherited configuration.                                                                                                        |
| <b>defaults</b>      | (Optional) Displays all configuration, including default configuration.                                                                                                                                              |
| <b>nvgen</b>         | (Optional) Displays output in the form of the <b>show running-config</b> command. If the <b>defaults</b> keyword also is specified, the output is not suitable for cutting and pasting into a configuration session. |
| <b>inheritance</b>   | (Optional) Displays the session groups from which this session group inherits configuration.                                                                                                                         |
| <b>users</b>         | (Optional) Display the session groups, neighbor groups, and neighbors that inherit configuration from this session group.                                                                                            |

## Command Default

No default behavior or value

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show bgp session-group** command with the *group-name* **configuration** argument and keyword to display the effective configuration of a session group, including any configuration inherited from other session groups through application of the **use** command. The source for each configured command is also displayed.

Use the **defaults** keyword to display the value of all configuration, including default configuration. Use the **nvgen** keyword to display configuration in the form of the **show running-config** command output. Output in this form is suitable for cutting and pasting into a configuration session.

Use the **show bgp session-group** command with the *group-name* **inheritance** argument and keyword to display the session groups from which the specified session group inherits configuration.

Use the **show bgp session-group** command with the *group-name* **users** argument and keyword to display the neighbors, neighbor groups, and session groups that inherit configuration from the specified session group.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

For the example shown here, the following configuration is used:

```
session-group group3
  advertisement-interval 5
  dmzlink-bw
  !
session-group group1
  use session-group group2
  update-source Loopback0
  !
session-group group2
  use session-group group3
  ebgp-multihop 2
```

The following example shows the **show bgp session-group** command with the **configuration** keyword:

```
RP/0/0/CPU0:router# show bgp session-group group1 configuration

session-group group1
  advertisement-interval 5[s:group2 s:group3]
  ebgp-multihop 2 [s:group2]
  update-source Loopback0 []
  dmzlink-bandwidth [s:group2 s:group3]
```

The source of each command is shown to the right of the command. For example, **update-source** is configured directly on session group group1. The **dmzlink-bandwidth** command is inherited from session group group2, which in turn inherits it from session group group3.

The following example shows the **show bgp session-group** command with the **users** keyword:

```
RP/0/0/CPU0:router# show bgp session-group group2 users

IPv4 Unicast:a:group1
```

The following example shows the **show bgp session-group** command with the **inheritance** keyword.

```
RP/0/0/CPU0:router# show bgp session-group group1 inheritance

Session:s:group2 s:group3
```

The command output shows that the session group group1 directly uses the group2 session group. The group2 session group uses the group3 session group.

This table describes the significant fields shown in the display.

**Table 35: show bgp session-group Field Descriptions**

| Field     | Description                                                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ ]       | Configures the command directly on the specified session group.                                                                                                                        |
| s:        | Indicates the name that follows is a session group.                                                                                                                                    |
| a:        | Indicates the name that follows is an address family group.                                                                                                                            |
| n:        | Indicates the name that follows is a neighbor group.                                                                                                                                   |
| [dflt]    | Indicates the command is not explicitly configured or inherited, and the default value for the command is used. This field may be shown when the <b>defaults</b> keyword is specified. |
| <not set> | Indicates that the default is for the command to be disabled. This field may be shown when the <b>defaults</b> keyword is specified.                                                   |

**Related Commands**

# show bgp sessions

To display brief information about BGP neighbors, use the **show bgp sessions** command in EXEC mode.

**show bgp sessions** [**not-established**] [**not-nsr-ready**]

## Syntax Description

|                        |                                                                                 |
|------------------------|---------------------------------------------------------------------------------|
| <b>not-established</b> | (Optional) Displays all the neighbors that are not in established state         |
| <b>not-nsr-ready</b>   | (Optional) Displays all the neighbors that are not nonstop routing (NSR) ready. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show bgp sessions** command without a keyword provides brief information about all the BGP neighbors configured irrespective of the address family or VRF.

The **show bgp sessions** command with the **not-established** keyword shows BGP peers which are yet to establish their peering relationship.

The **show bgp sessions** command with the and **not-nsr-ready** keyword shows BGP peers which are yet to reach the nsr ready state.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp sessions** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp sessions
Thu Jan 15 17:41:45.277 UTC
```

| Neighbor                       | VRF                     | Spk | AS  | InQ | OutQ | NBRState    | NSRState  |
|--------------------------------|-------------------------|-----|-----|-----|------|-------------|-----------|

This table describes the significant fields shown in the display.

**Table 36: show bgp sessions Field Descriptions**

| Field    | Description                                                       |
|----------|-------------------------------------------------------------------|
| Neighbor | Displays neighbor IP address.                                     |
| VRF      | Displays information about the VRF.                               |
| Spk      | Speaker process that is responsible for the neighbor. Always 0.   |
| AS       | Autonomous system.                                                |
| InQ      | Number of messages from a neighbor waiting to be processed.       |
| OutQ     | Number of messages waiting to be sent to a neighbor.              |
| NBRState | State of the Border Gateway Protocol (BGP) neighbor sessions.     |
| NSRState | State of the Border Gateway Protocol (BGP) nonstop routing (NSR). |

**Related Commands**

|-------------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">show bgp neighbors, on page 346</a> | Displays information about Border Gateway Protocol (BGP) connections to neighbors. |

# show bgp summary

To display the status of all Border Gateway Protocol (BGP) connections, use the **show bgp summary** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast| all| tunnel| mdt}| ipv6 {unicast| multicast| all|
labeled-unicast}| all {unicast| multicast| all| labeled-unicast| mdt| tunnel}| vpnv4 unicast| vrf {vrf-name|
all}| ipv4 {unicast| labeled-unicast}| ipv6 unicast| vpnv6 unicast] summary [standby]
```

## Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>standby</b>                            | (Optional) Displays information about the standby card.                             |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                          |
| Release 3.3.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• <b>vpn4 unicast</b></li> </ul>                                                                 |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                     |
| Release 3.5.0 | The <b>vpn6 unicast</b> keywords were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                 |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations.                                                                                  |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

Use the **show bgp summary** command to display a summary of the neighbors for which the specified address family and subaddress family are enabled. If the neighbor does not have the specified address family and subaddress family enabled, it is not included in the output of the **show** command. If the **all** keyword is specified for the address family or subaddress family, a summary for each combination of address family and subaddress family is displayed in turn.

The table versions shown in the output (RcvTblVer, bRIB/RIB, SendTblVer, and TblVer) are specific to the specified address family and subaddress family. All other information is global.

The table versions provide an indication of whether BGP is up to date with all work for the specified address family and subaddress family.

- bRIB/RIB < RcvTblVer—Some received routes have not yet been considered for installation in the global routing table.
- TblVer < SendTblVer—Some received routes have been installed in the global routing table but have not yet been considered for advertisement to this neighbor.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp summary** command:

```
RP/0/0/CPU0:router#show bgp summary
```

```
BGP router identifier 10.0.0.0, local AS number 2
BGP generic scan interval 60 secs
BGP table state: Active
Table ID: 0xe0000000
BGP main routing table version 1
BGP scan interval 60 secs
```

BGP is operating in STANDALONE mode.

|         |            |          |          |           |            |
|---------|------------|----------|----------|-----------|------------|
| Process | RecvTblVer | bRIB/RIB | LabelVer | ImportVer | SendTblVer |
| Speaker | 1          | 0        | 1        | 1         | 0          |

  

|            |     |    |         |         |        |     |      |          |           |
|------------|-----|----|---------|---------|--------|-----|------|----------|-----------|
| Neighbor   | Spk | AS | MsgRcvd | MsgSent | TblVer | InQ | OutQ | Up/Down  | St/PfxRcd |
| 10.0.101.0 | 0   | 2  | 0       | 0       | 0      | 0   | 0    | 00:00:00 | Idle      |
| 10.0.101.1 | 0   | 2  | 0       | 0       | 0      | 0   | 0    | 00:00:00 | Idle      |

This table describes the significant fields shown in the display.

**Table 37: show bgp summary Field Descriptions**

| Field                 | Description               |
|-----------------------|---------------------------|
| BGP router identifier | IP address of the router. |

| Field                          | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local AS number                | Autonomous system number set by the <a href="#">router bgp, on page 249</a> command. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| BGP generic scan interval      | Interval (in seconds) between scans of the BGP table by a generic scanner.                                                                                                                                                                                                                                                                                                                                       |
| BGP table state                | State of the BGP database.                                                                                                                                                                                                                                                                                                                                                                                       |
| Table ID                       | BGP database identifier.                                                                                                                                                                                                                                                                                                                                                                                         |
| BGP main routing table version | Last version of the BGP database that was injected into the main routing table.                                                                                                                                                                                                                                                                                                                                  |
| Dampening enabled              | Displayed if dampening has been enabled for the routes in this BGP routing table.                                                                                                                                                                                                                                                                                                                                |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family.                                                                                                                                                                                                                                                                                                      |
| BGP is operating in            | Specifies BGP is operating in standalone mode.                                                                                                                                                                                                                                                                                                                                                                   |
| Process                        | BGP process.                                                                                                                                                                                                                                                                                                                                                                                                     |
| RecvTblVer                     | Last version used in the BGP database for received routes.                                                                                                                                                                                                                                                                                                                                                       |
| bRIB/RIB                       | Last version of the local BGP database that was injected into the main routing table.                                                                                                                                                                                                                                                                                                                            |
| LabelVer                       | Label version used in the BGP database for label allocation.                                                                                                                                                                                                                                                                                                                                                     |
| ImportVer                      | Last version of the local BGP database for importing routes.                                                                                                                                                                                                                                                                                                                                                     |
| SendTblVer                     | Latest version of the local BGP database that is ready to be advertised to neighbors.                                                                                                                                                                                                                                                                                                                            |

| Some configured eBGP neighbors do not have any policy | Some external neighbors exist that do not have both an inbound and outbound policy configured for every address family, using the <b>route-policy (BGP)</b> command. In this case, no prefixes are accepted and advertised to those neighbors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Neighbor                                              | IP address of a neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## show bgp summary nsr

To display the summary of Border Gateway Protocol (BGP) neighbor state and nonstop routing (NSR) state information, use the **show bgp summary nsr** command in EXEC mode.

**show bgp summary** [**ipv4** {**unicast**|**multicast**|**labeled-unicast**|**all**|**tunnel**|**mdt**}|**ipv6** {**unicast**|**multicast**|**all**|**labeled-unicast**}|**all** {**unicast**|**multicast**|**all**|**labeled-unicast**|**mdt**|**tunnel**}|**vpn4** **unicast**|**vrf** {*vrf-name*|**all**} [**ipv4** {**unicast**|**labeled-unicast**}|**ipv6** **unicast**]|**vpn6** **unicast**] **nsr** [**standby**]

### Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpn6 unicast</b>                       | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>standby</b>                            | Displays information about the standby card.                                        |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

EXEC

**Command History**

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp summary nsr** command:

```
RP/0/0/CPU0:router# show bgp summary nsr

BGP router identifier 10.1.0.1, local AS number 100
BGP generic scan interval 60 secs
Non-stop routing is enabled
BGP table state: Active
Table ID: 0xe0000000
BGP main routing table version 13037
BGP NSR Initial initsync version 11034 (Reached)
BGP scan interval 60 secs

BGP is operating in STANDALONE mode.

This table describes the significant fields shown in the display.

**Table 38: show bgp summary nsr Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | IP address of the router.                                                                                   |
| BGP generic scan interval      | Interval (in seconds) between scans of the BGP table by a generic scanner.                                  |
| Non-stop routing               | State of the Nonstop routing.                                                                               |
| BGP table state                | State of the BGP database.                                                                                  |
| Table ID                       | BGP database identifier.                                                                                    |
| BGP main routing table version | Last version of the BGP database that was injected into the main routing table.                             |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |
| BGP is operating in            | Specifies BGP is operating in standalone mode.                                                              |

| Field        | Description                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entered mode | The successive transition of various states of TCP and BGP, leading to the NSR ready state.<br><b>Note</b> This is used for monitoring and debugging purposes. |
| SyncVer      | The version which has synced to standby for this neighbor.                                                                                                     |
| AckVer       | The version which the neighbor has acknowledge.                                                                                                                |
| NBRState     | State of the BGP neighbor.                                                                                                                                     |
| NSRState     | Neighbor NSR state.                                                                                                                                            |

# show bgp table

To display neighbors in the global table, use the **show bgp table** command in EXEC mode.

**show bgp table** [**ipv4** {**unicast**| **multicast**| **tunnel**| **mdt**}| **ipv6** {**unicast**| **multicast**}| **vpn4** **unicast**| **vpn6** **unicast**]

## Syntax Description

|                       |                                                                        |
|-----------------------|------------------------------------------------------------------------|
| <b>ipv4 unicast</b>   | (Optional) Specifies IP Version 4 (IPv4) unicast neighbors.            |
| <b>ipv4 multicast</b> | (Optional) Specifies IPv4 multicast neighbors.                         |
| <b>ipv4 tunnel</b>    | (Optional) Specifies IPv4 tunnel neighbors.                            |
| <b>ipv4 mdt</b>       | (Optional) Specifies IPv4 multicast distribution tree (MDT) neighbors. |
| <b>ipv6 unicast</b>   | (Optional) Specifies IP Version 6 (IPv6) unicast neighbors.            |
| <b>ipv6 multicast</b> | (Optional) Specifies IPv6 multicast neighbors.                         |
| <b>vpn4 unicast</b>   | (Optional) Specifies VPN Version 4 (VPNv4) unicast neighbors.          |
| <b>vpn6 unicast</b>   | (Optional) Specifies VPN Version 6 (VPNv6) unicast neighbors.          |

## Command Default

No default behavior or value

## Command Modes

|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show bgp table** command provides information about the BGP neighbors based on the global address family and independent of VRFs. Use the **show bgp table** command to get information about all BGP neighbors in different address families.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

## Examples

The following is sample output from the **show bgp table vpnv4 unicast** command in EXEC mode:

```
RP/0/0/CPU0:router# show bgp table vpnv4 unicast
Thu Jan 15 17:43:31.215 UTC

**Table 39: show bgp table Field Descriptions**

| Field    | Description                                                                        |
|----------|------------------------------------------------------------------------------------|
| Neighbor | IP address of a neighbor.                                                          |
| VRF      | The VRF which each neighbor belongs to; either the default VRF or a specified VRF. |
| Spk      | Speaker process that is responsible for the neighbor. Always 0.                    |
| AS       | Autonomous system.                                                                 |
| TblVer   | Last version of the BGP database that was sent to a neighbor.                      |
| InQ      | Number of messages from a neighbor waiting to be processed.                        |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OutQ      | Number of messages waiting to be sent to a neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| St/PfxRcd | <p>If the BGP session is not established, the current state of the session. If the session is established, the number of prefixes the router has received from the neighbor.</p> <p>If the number of prefixes received exceeds the maximum allowed (as set by the maximum-prefix command), "(PfxRcd)" appears.</p> <p>If the connection has been shut down using the shutdown command, "(Admin)" appears.</p> <p>If the neighbor is external and it does not have an inbound and outbound policy configured for every address family, an exclamation mark (!) is inserted at the end of the state when using the route-policy (BGP) command.</p> <p>If the connection has been shut down due to out of memory (OOM), "(OOM)" appears.</p> |

**Related Commands**

## show bgp truncated-communities

To display routes in the Border Gateway Protocol (BGP) routing table for which inbound policy or aggregation has exceeded the maximum number of communities that may be attached, use the **show bgp truncated-communities** command in EXEC mode.

**show bgptruncated-communities standby**

### Syntax Description

|                                           |                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 address prefixes.                                 |
| <b>unicast</b>                            | (Optional) Specifies unicast address prefixes.                                      |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                              |
| <b>all</b>                                | (Optional) For subaddress families, specifies prefixes for all subaddress families. |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                       |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.            |
| <b>multicast</b>                          | (Optional) Specifies multicast address prefixes.                                    |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 address prefixes.                                 |
| <b>all</b>                                | (Optional) For address family, specifies prefixes for all address families.         |
| <b>vpn4 unicast</b>                       | (Optional) Specifies VPNv4 unicast address families.                                |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                     |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                     |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                           |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                             |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families.     |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                        |
| <b>vpn6 unicast</b>                       | (Optional) Specifies VPNv6 unicast address families.                                |
| <b>standby</b>                            | (Optional) Displays information about the standby card.                             |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

| Release 3.2   | This command was introduced.<br>The <b>count-only</b> keyword was added.                                                                                                                                                                                                                                                                                           |
| Release 3.3.0 | The following keywords and arguments were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpn4</b> <b>unicast</b> ] [ <b>rd</b> <i>rd-address</i> ]</li> </ul>                                                                  |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.<br>The <b>count-only</b> keyword was removed.                                                                                                                                                                                                                                                                    |
| Release 3.5.0 | The <b>vpn6 unicast</b> [ <b>rd</b> <i>rd-address</i> ] keywords and argument were added.<br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                                                              |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

BGP contains a separate routing table for each address family and subaddress family combination that has been configured. The address family and subaddress family options specify the routing table to be examined. If the **all** keyword is specified for the address family or subaddress family, each matching routing table is examined.

Use the **show bgp truncated-communities** command to display those routes in the specified BGP routing table in which the buffers used to store communities or extended communities have overflowed. An overflow occurs if an attempt is made to associate more communities or extended communities with the route than fits in a BGP update message. This can happen due to modification of communities or extended communities during aggregation or when inbound policy is applied.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp truncated-communities** command:

```
RP/0/0/CPU0:router# show bgp truncated-communities

BGP router identifier 172.20.1.1, local AS number 1820
BGP main routing table version 3042
BGP scan interval 60 secs
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, S stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network        Next Hop           Metric LocPrf Weight Path
*  10.13.0.0/16    192.168.40.24             0 1878 704 701 200 ?
*> 10.16.0.0/16    192.168.40.24             0 1878 704 701 i
```

This table describes the significant fields shown in the display.

**Table 40: show bgp truncated-communities Field Descriptions**

| Field                          | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| BGP router identifier          | BGP Identifier for the local system.                                                                        |
| local AS number                | Autonomous system number for the local system.                                                              |
| BGP main routing table version | Last version of the BGP database that was installed into the main routing table.                            |
| Dampening enabled              | Displayed if dampening is enabled for the routes in this BGP routing table.                                 |
| BGP scan interval              | Interval (in seconds) between scans of the BGP table specified by the address family and subaddress family. |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status codes | <p>Status of the table entry. The status is displayed as a three-character field at the beginning of each line in the table. The first character may be (in order of precedence):</p> <p>S—Path is stale, indicating that a graceful restart is in progress with the peer from which the route was learned.</p> <p>s—Path is more specific than a locally sourced aggregate route and has been suppressed.</p> <p>*—Path is valid.</p> <p>The second character may be (in order of precedence):</p> <p>&gt;—Path is the best path to use for that network.</p> <p>d—Path is dampened.</p> <p>h—Path is a history entry, representing a route that is currently withdrawn, but that is being maintained to preserve dampening information. Such routes should never be marked as valid.</p> <p>The third character may be:</p> <p>i—Path was learned by an internal BGP (iBGP) session.</p> |
| Origin codes | <p>Origin of the path. The origin code is displayed at the end of each line in the table. It can be one of the following values:</p> <p>i—Path originated from an Interior Gateway Protocol (IGP) and was advertised with a <b>network</b> or <b>aggregate-address</b> command.</p> <p>e—Path originated from an Exterior Gateway Protocol (EGP).</p> <p>?—Origin of the path is not clear. Usually, this is a route that is redistributed into BGP from an IGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Network      | IP prefix and prefix length for a network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Next Hop     | IP address of the next system that is used when a packet is forwarded to the destination network. An entry of 0.0.0.0 indicates that the router has a non-BGP route to this network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Metric       | Value of the interautonomous system metric, otherwise known as the Multi Exit Discriminator (MED) metric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field  | Description                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LocPrf | Local preference value. This is used to determine the preferred exit point from the local autonomous system. It is propagated throughout the local autonomous system. |
| Weight | Path weight. Weight is used in choosing the preferred path to a route. It is not advertised to any neighbor.                                                          |
| Path   | Autonomous system path to the destination network. At the end of the path is the origin code for the path.                                                            |

### Related Commands

| Command                                         | Description                                                                                             |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">aggregate-address, on page 27</a>   | Creates an aggregate entry in a BGP routing table.                                                      |
| <a href="#">network (BGP), on page 191</a>      | Specifies a local network that the BGP routing process should originate and advertise to its neighbors. |
| <a href="#">route-policy (BGP), on page 243</a> | Applies a routing policy to updates advertised to or received from a BGP neighbor.                      |
| set default-afi                                 | Sets the default Address Family Identifier (AFI) for the current session.                               |
| set default-safi                                | Sets the default Subaddress Family Identifier (SAFI) for the current session.                           |
| <a href="#">show bgp, on page 265</a>           | Displays entries in the BGP routing table.                                                              |

# show bgp update-group

To display Border Gateway Protocol (BGP) information for update groups, use the **show bgp update-group** command in EXEC mode.

```
show bgp [ipv4 {unicast| multicast| labeled-unicast| all| tunnel| mdt}| ipv6 {unicast| multicast| all|
labeled-unicast}| all {unicast| multicast| all| labeled-unicast| mdt| tunnel}| vpnv4 unicast| vrf {vrf-name|
all}| [ipv4 {unicast| labeled-unicast}| ipv6 unicast]| vpnv6 unicast] update-group [neighbor ip-address|
process-id.index [summary| performance-statistics]] [standby]
```

## Syntax Description

|                                           |                                                                                 |
|-------------------------------------------|---------------------------------------------------------------------------------|
| <b>ipv4</b>                               | (Optional) Specifies IP Version 4 update groups.                                |
| <b>unicast</b>                            | (Optional) Specifies unicast update groups.                                     |
| <b>multicast</b>                          | (Optional) Specifies multicast update groups.                                   |
| <b>labeled-unicast</b>                    | (Optional) Specifies labeled unicast address prefixes.                          |
| <b>all</b>                                | (Optional) Displays both unicast and multicast update groups.                   |
| <b>tunnel</b>                             | (Optional) Specifies tunnel address prefixes.                                   |
| <b>mdt</b>                                | (Optional) Specifies multicast distribution tree (MDT) address prefixes.        |
| <b>ipv6</b>                               | (Optional) Specifies IP Version 6 update groups.                                |
| <b>all</b>                                | (Optional) Displays both IP Version 4 and IP Version 6 update groups.           |
| <b>vpnv4 unicast</b>                      | (Optional) Specifies VPNv4 unicast address families.                            |
| <b>rd</b> <i>rd-address</i>               | (Optional) Displays routes with a specific route distinguisher.                 |
| <b>vrf</b>                                | (Optional) Specifies VPN routing and forwarding (VRF) instance.                 |
| <i>vrf-name</i>                           | (Optional) Name of a VRF.                                                       |
| <b>all</b>                                | (Optional) For VRF, specifies all VRFs.                                         |
| <b>ipv4 { unicast   labeled-unicast }</b> | (Optional) For VRF, specifies IPv4 unicast or labeled-unicast address families. |
| <b>ipv6 unicast</b>                       | (Optional) For VRF, specifies IPv6 unicast address families.                    |
| <b>vpnv6 unicast</b>                      | (Optional) Specifies VPNv6 unicast address families.                            |
| <b>neighbor</b> <i>ip-address</i>         | (Optional) Specifies information on an update group for a specific neighbor.    |

|                               |                                                                                                                                                                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>process-id.index</i>       | (Optional) Update group index. Process ID range is 0 to 254. Index range is 0 to 4294967295.<br><br>The <i>process id.index</i> argument is specified as follows: process ID (dot) index. In standalone mode, the process ID is always 0. |
| <b>summary</b>                | (Optional) Specifies summary of update group members.                                                                                                                                                                                     |
| <b>performance-statistics</b> | (Optional) Specifies performance information about the updates generated for the update group.                                                                                                                                            |
| <b>standby</b>                | (Optional) Displays information about the standby card.                                                                                                                                                                                   |

**Command Default**

If no address family or subaddress family is specified, the default address family and subaddress family specified using the **set default-afi** and **set default-safi** commands are used.

**Command Modes**

| Release       | Modification                                                                                                                                                                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                                                                                                                        |
| Release 3.3.0 | The following keywords and argument were added: <ul style="list-style-type: none"> <li>• <b>vrf</b> { <i>vrf-name</i>   <b>all</b> }</li> <li>• [ <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } ]</li> <li>• [ <b>vpnvp4 unicast</b> ]</li> </ul>                                                                         |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                                                                                                                   |
| Release 3.5.0 | The <b>vpnvp6 unicast</b> keywords were added.<br><br>The <b>tunnel</b> and <b>mdt</b> keywords were supported under the <b>ipv4</b> and <b>all</b> address families.<br><br>The <b>labeled-unicast</b> keyword was supported under the <b>ipv6</b> and <b>all</b> address families.<br><br>The <b>standby</b> keyword was removed. |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                                                                                                               |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations.                                                                                                |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

The **set default-afi** command is used to specify the default address family for the session, and the **set default-safi** command is used to specify the default subaddress family for the session. See the *Cisco IOS XR System Management Command Reference for the Cisco XR 12000 Series Router* for detailed information and syntax for the **set default-afi** and **set default-safi** commands. If you do not specify a default address family, the default address family is IPv4. If you do not specify a default subaddress family, the default subaddress family is unicast.

Every BGP neighbor is automatically assigned to an update group for each address family that is enabled on the neighbor. Neighbors that have similar outbound policy, such that they are sent the same updates, are placed in the same update group.

Use the **show bgp update-group** command to display the update groups and a list of the neighbors that belong to the update group.

Use the **show bgp update-group neighbor** command to display details about the update group to which a neighbor belongs for the specified address family.

Use the **summary** keyword to display a summary of the neighbors belonging to the specified update group. The display format is the same as for the [show bgp summary, on page 435](#) command.

Use the **performance-statistics** keyword to display information about the number of prefixes processed and the time taken to generate updates for the specified update group.

**Note**

Update group indexes are not necessarily persistent over a process restart. If a BGP process restarts, the index of the update group to which a particular neighbor is assigned may be different, though the set of neighbors belonging to the update group is the same.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp update-group** command:

```
RP/0/0/CPU0:router# show bgp update-group

Update group for IPv4 Unicast, index 0.1:
  Attributes:
    Internal
    Common admin
    Send communities
    Send extended communities
    Minimum advertisement interval: 300
  Update group desynchronized: 0
  Sub-groups merged: 0
```

```

Messages formatted: 0, replicated: 0
Neighbors not in any sub-group:
10.0.101.1

```

This table describes the significant fields shown in the display.

**Table 41: show bgp update-group Field Descriptions**

| Field                        | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Update group for             | Address family to which updates in this update group apply.                                                                                |
| index                        | Update group index.                                                                                                                        |
| Attributes                   | Attributes common to all members of the update group.                                                                                      |
| Unsuppress map               | Unsuppress route map used to selectively unsuppress more specific routes of locally generated aggregates for members of this update group. |
| Outbound policy              | Route policy applied to outbound updates generated for members of this update group.                                                       |
| Internal                     | Members of the update group are internal peers.                                                                                            |
| ORF Receive enabled          | Members of this update group are capable of receiving an outbound route filter.                                                            |
| Route Reflector Client       | Local system is acting as a route reflector for members of this update group.                                                              |
| Remove private AS numbers    | Members of this update group have private AS numbers stripped from outbound updates.                                                       |
| Next-hop-self enabled        | Next- Next hop for members of the update group is set to the local router.                                                                 |
| Directly connected IPv6 EBGp | Members of this update group are directly connected external BGP IPv6-based peers.                                                         |
| Configured Local AS          | Local autonomous system (AS) used for members of this update group.                                                                        |
| Common admin                 | Peers in this update group are under common administration (internal or confederation peers).                                              |
| Send communities             | Communities are sent to neighbors in this update group.                                                                                    |

| Field                          | Description                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------|
| Send extended communities      | Extended communities is sent to neighbors in this update group.                                         |
| Minimum advertisement interval | Minimum advertisement interval for members of this update group.                                        |
| replicated                     | Number of update messages replicated for this update group.                                             |
| Messages formatted             | Number of update messages generated for this update group.                                              |
| Neighbors in this update group | List of neighbors that use this update group for the given address family.                              |
| Update group desynchronized    | Number of times an update group has been split to accommodate the slower peer. This option is disabled. |
| Sub-groups merged              | Number of times an update group has been split and merged.                                              |
| Neighbors not in any sub-group | BGP neighbor that does not belong to any subgroup.                                                      |

The following is sample output from the **show bgp update-group** command with the **ipv4** , **unicast** , and **summary** keywords and the *process id.index* argument:

```
RP/0/0/CPU0:router# show bgp ipv4 unicast update-group 0.1 summary

BGP router identifier 10.140.140.1, local AS number 1.1
BGP generic scan interval 60 secs
BGP table state: Active
Table ID: 0xe0000000
BGP main routing table version 1
BGP scan interval 60 secs

BGP is operating in STANDALONE mode.

# show bgp vrf imported-routes

To display Border Gateway Protocol (BGP) information for routes imported into specified VPN routing and forwarding (VRF) instances, use the **show bgp vrf imported-routes** command in EXEC mode.

**show bgp vrf**{vrf| *vrf-name*} **imported-routes**

## Syntax Description

|                                                         |                                                                               |
|---------------------------------------------------------|-------------------------------------------------------------------------------|
| <i>vrf-name</i>                                         | Displays imported routes for a specific VRF.                                  |
| <b>all</b>                                              | Displays imported routes for all VRFs.                                        |
| <b>ipv4</b> { <b>unicast</b>   <b>labeled-unicast</b> } | (Optional) Specifies IP Version 4 unicast or labeled-unicast imported routes. |
| <b>ipv6 unicast</b>                                     | (Optional) Specifies IP Version 6 unicast imported routes.                    |
| <b>vrf</b> <i>source-vrf-name</i>                       | (Optional) Displays routes imported from the specified source VRF.            |
| <b>neighbor</b> <i>neighbor-address</i>                 | (Optional) Displays preview advertisements for a specified neighbor.          |
| <b>standby</b>                                          | (Optional) Displays information about the standby card.                       |

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                         |
| Release 3.4.0 | The <b>labeled-unicast</b> keyword was supported.                                                                                                                                                                                    |
| Release 3.5.0 | The <b>ipv6 unicast</b> keywords were added.<br>The <b>standby</b> keyword was removed.                                                                                                                                              |
| Release 3.8.0 | The <b>standby</b> keyword was added.                                                                                                                                                                                                |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show bgp vrf imported-routes** command to display all paths imported into a specified VRF from the default VRF. Use the **neighbor** *neighbor-address* keyword and argument to display all imported paths and which paths were learned from the specified neighbor. Use the **vrf** *source-vrf-name* keyword and argument to display all imported routes that belong to the specified source VRF. The **neighbor** *neighbor-address* and **vrf** *source-vrf-name* cannot coexist.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |

**Examples**

The following is sample output from the **show bgp vrf imported-routes** command:

```
RP/0/0/CPU0:router# show bgp vrf vrf-1 ipv6 unicast imported-routes

BGP VRF one, state: Active BGP
BGP Route Distinguisher: 100:222
VRF ID: 0x60000001
BGP router identifier 10.2.0.1, local AS number 100
BGP table state: Active
Table ID: 0xe0800001

**Table 43: show bgp vrf imported-routes Field Descriptions**

| Field                    | Description                                     |
|--------------------------|-------------------------------------------------|
| BGP VRF                  | VRF name.                                       |
| state                    | State of the VRF.                               |
| BGP Route Distinguisher: | Unique identifier for the BGP routing instance. |
| VRF Id                   | VRF identifier.                                 |
| BGP router identifier    | IP address of the router.                       |

| Field                          | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| local AS number                | Autonomous system number set by the <a href="#">router bgp, on page 249</a> command. <ul style="list-style-type: none"><li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li><li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li><li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li></ul> |
| BGP table state                | State of the BGP database.                                                                                                                                                                                                                                                                                                                                                                                   |
| Table ID                       | Table identifier.                                                                                                                                                                                                                                                                                                                                                                                            |
| BGP main routing table version | Last version of the BGP database that was injected into the main routing table.                                                                                                                                                                                                                                                                                                                              |
| Network                        | Network address.                                                                                                                                                                                                                                                                                                                                                                                             |
| Neighbor                       | IP address of a neighbor.                                                                                                                                                                                                                                                                                                                                                                                    |
| Route Distinguisher            | Unique identifier for the routing instance.                                                                                                                                                                                                                                                                                                                                                                  |
| Source VRF                     | Source VRF for the imported route.                                                                                                                                                                                                                                                                                                                                                                           |

# show protocols (BGP)

To display information about the Border Gateway Protocol (BGP) instances running on the router, use the **show protocols** command in EXEC mode and specify either the **bgp** or **all** keyword.

**show protocols** [**ipv4**|**ipv6**|**afi-all**] [**all**|*protocol*]

## Syntax Description

|                 |                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>     | (Optional) Specifies the IP Version 4 address family.                                                                                                                                                                                                                           |
| <b>ipv6</b>     | (Optional) Specifies the IP Version 6 address family.                                                                                                                                                                                                                           |
| <b>afi-all</b>  | (Optional) Specifies all address families.                                                                                                                                                                                                                                      |
| <b>all</b>      | (Optional) Specifies all protocols for a given address family.                                                                                                                                                                                                                  |
| <i>protocol</i> | (Optional) Specifies a routing protocol.<br>For the IPv4 address family, the options are <b>bgp</b> , <b>isis</b> , <b>rip</b> , <b>eigrp</b> , and <b>ospf</b> .<br>For the IPv6 address family, the options are <b>bgp</b> , <b>eigrp</b> , <b>isis</b> , and <b>ospfv3</b> . |

## Command Default

Default is IPv4.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced..                                                                                                                                                                                                        |
| Release 3.3.0 | The <b>afi-all</b> keyword was added.                                                                                                                                                                                                |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show protocols** command to get information about the protocols running on the router and to quickly determine which protocols are active. The command is designed to summarize the important characteristics of the running protocol, and command output varies depending on the specific protocol selected. For BGP,

the command output lists the protocol ID, peers with elapsed time since last reset, and miscellaneous information, such as external and internal local distances and sourced routes.

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |
| rib     | read       |

### Examples

The following example shows the display for the **show protocols** command using the **bgp** keyword:

```
RP/0/0/CPU0:router# show protocols bgp
Routing Protocol "BGP 40"
Address Family IPv4 Unicast:
  Distance: external 20 internal 200 local 200
  Sourced Networks:
    10.100.0.0/16 backdoor
    10.100.1.0/24
    10.100.2.0/24
  Routing Information Sources:
    Neighbor      State/Last update received
    10.5.0.2       Idle
    10.9.0.3       Idle
```

This table describes the significant fields shown in the display.

**Table 44: show protocols (BGP) Field Descriptions**

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing Protocol:  | Identifies BGP as the running protocol and displays the BGP AS number. <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| Address Family     | Specifies the address family. This can be IPv4 Unicast, IPv4 Multicast, or IPv6 Unicast.                                                                                                                                                                                                                                                                                                           |
| Distance: external | Specifies the distance BGP sets when installing eBGP routes into the RIB. eBGP routes are routes received from eBGP peers. The RIB uses the distance as a tiebreaker when several protocols install a route for the same prefix.                                                                                                                                                                   |

| Field                       | Description                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------|
| Distance: internal          | Specifies the distance BGP sets for routes received from iBGP peers.                                           |
| Distance: local             | Specifies the distance BGP sets for locally generated aggregates and backdoor routes.                          |
| Sourced Networks            | List of locally sourced networks. These are networks sourced using the <b>network</b> command.                 |
| Routing information Sources | List of configured BGP neighbors.                                                                              |
| Neighbor                    | Address of a BGP neighbor.                                                                                     |
| State/Last update received  | State of each neighbor and the time since the last update was received from the neighbor if it is established. |

# show svd role

To display selective VRF download (SVD) role information, use the **show svd role** command in EXEC mode.

**show svd role**

**Syntax Description** This command has no keywords or arguments.

**Command Default** None.

**Command Modes** EXEC

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.1.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show svd role** command output displays name of the line card and role for each address-family in a table.

| Task ID | Task ID     | Operation |
|---------|-------------|-----------|
|         | ip-services | read      |

**Examples** This example displays the different nodes in a line card and corresponding IPv4, and IPv6 SVD role information:

```
RP/0/0/CPU0:router#show svd role
Thu Mar 10 10:45:17.886 PST
Node Name      IPv4 Role      IPv6 Role
-----
0/1/CPU0       Core Facing    Not Interested
0/2/CPU0       Core Facing    Core Facing
0/4/CPU0       Standard       Standard
0/5/CPU0       Standard       Standard
```

| Related Commands | Command                                                                      | Description                            |
|------------------|------------------------------------------------------------------------------|----------------------------------------|
|                  | <a href="#">selective-vrf-download disable</a> , <a href="#">on page 252</a> | Disables selective VRF Download (SVD). |

| Command                                     | Description                                              |
|---------------------------------------------|----------------------------------------------------------|
| <a href="#">show svd state, on page 469</a> | Displays Selective VRF Download (SVD) state information. |

# show svd state

To display selective VRF download (SVD) state information, use the **show svd state** command in EXEC mode.

**show svd state**

**Syntax Description** This command has no keywords or arguments.

**Command Default** None.

**Command Modes** EXEC

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.1.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID     | Operation |
|---------|-------------|-----------|
|         | ip-services | read      |

**Examples** This example shows the SVD configuration state and the SVD operational state in a line card:

```
RP/0/0/CPU0:router#show svd state
Thu Mar 10 10:45:32.184 PST
Selective VRF Download (SVD) Feature State:
SVD Configuration State      Enabled
SVD Operational State        Enabled
```

| Related Commands | Command                                                     | Description                                             |
|------------------|-------------------------------------------------------------|---------------------------------------------------------|
|                  | <a href="#">selective-vrf-download disable, on page 252</a> | Disables selective VRF Download (SVD).                  |
|                  | <a href="#">show svd role, on page 467</a>                  | Displays Selective VRF Download (SVD) role information. |

## shutdown (BGP)

To disable a neighbor without removing its configuration, use the **shutdown** command in an appropriate configuration mode. To re-enable the neighbor and reestablish a Border Gateway Protocol (BGP) session, use the **no** form of this command.

**shutdown [inheritance-disable]**

**no shutdown [inheritance-disable]**

### Syntax Description

|                            |                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Overrides the value of a <b>shutdown</b> command inherited from a neighbor group or session group. |
|----------------------------|---------------------------------------------------------------------------------------------------------------|

### Command Default

Neighbors are not shutdown.

### Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

### Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                         |
| Release 3.3.0 | This command was supported in the VRF neighbor configuration mode.                   |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **shutdown** command to terminate any active session for the specified neighbor and remove all associated routing information. Use of the **shutdown** command with a neighbor group or session group may suddenly terminate a large number of BGP neighbor sessions because all neighbors using the neighbor group or session group may be affected.

Use the **show bgp summary** command to display a summary of BGP neighbors. Neighbors that are idle due to the **shutdown** command are displayed with the "Idle (Admin)" state.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows that any active session for neighbor 192.168.40.24 is disabled:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# shutdown
RP/0/0/CPU0:router(config-bgp-nbr)# exit
```

In the following example, the session remains active for neighbor 192.168.40.24 because the inherited **shutdown** command has been overridden:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group group1
RP/0/0/CPU0:router(config-bgp-sngrp)# shutdown
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group group1
RP/0/0/CPU0:router(config-bgp-nbr)# shutdown inheritance-disable
RP/0/0/CPU0:router(config-bgp-nbr)# exit
```

**Related Commands**

| Command                                       | Description                                                            |
|-----------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a>   | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">session-group, on page 261</a>    | Creates a session group and enters session group configuration mode.   |
| <a href="#">show bgp summary, on page 435</a> | Displays the status of all BGP connections.                            |

## shutdown (rpki-server)

To shutdown RPKI cache-server, use the **shutdown** command in rpki-server configuration mode. To set that the RPKI cache be active, use the **no** form of this command.

**shutdown**

**no shutdown**

This command has no keywords or arguments.

### Command Default

RPKI cache is active.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This command shows how to configure no shutdown of the RPKi cache configuration after other RPKI cache parameters are configured:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
RP/0/0/CPU0:router(config-bgp-rpki-cache)#password rpki-ssh-pass
RP/0/0/CPU0:router(config-bgp-rpki-cache)#preference 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#purge-time 30
RP/0/0/CPU0:router(config-bgp-rpki-cache)#refresh-time 30
RP/0/0/CPU0:router(config-bgp-rpki-cache)#response-time 30
RP/0/0/CPU0:router(config-bgp-rpki-cache)#no shutdown
```

## site-of-origin (BGP)

To attach a site-of-origin extended community attribute to each route received from the specified peer, use the **site-of-origin** command in VRF neighbor address family configuration mode. To restore the system to its default condition, use the **no** form of this command.

**site-of-origin** [*as-number:nn*| *ip-address:nn*]

### Syntax Description

*as-number:nn*

- *as-number*— Autonomous system (AS) number.
  - Range for 2-byte Autonomous system number is 1 to 65535.
  - Range for 4-byte Autonomous system number in asplain format is 1 to 4294967295.
  - Range for 4-byte Autonomous system number in asdot format is 1.0 to 65535.6553.
- *nn* —32-bit number

*ip-address:nn*

IP address.

- *ip-address* —32-bit IP address
- *nn* —16-bit number

### Command Default

No default behavior or values

### Command Modes

VRF neighbor address family configuration

### Command History

| Release       | Modification                                                                |
|---------------|-----------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When routes are advertised to the peer, routes whose extended communities list contain the site of origin (SoO) are filtered out and not advertised to the peer. Site-of-origin uniquely identifies the site from which the provide edge (PE) router learned routes, thus filtering based on the extended community helps prevent transient routing loops from occurring in complex and mixed network topologies.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to configure SoO filtering:

```
RP/0/0/CPU0:router(config)# router bgp 6
RP/0/0/CPU0:router(config-bgp)# vrf vrf_A
RP/0/0/CPU0:router(config-bgp-vrf)# neighbor 192.168.70.24
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# remote-as 10
RP/0/0/CPU0:router(config-bgp-vrf-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-nbr-af)# site-of-origin 10.0.01:20
```

## socket receive-buffer-size

To set the size of the receive buffers for all Border Gateway Protocol (BGP) neighbors, use the **socket receive-buffer-size** command in an appropriate configuration mode. To set the size of the receive buffers to the default size, use the **no** form of this command.

**socket receive-buffer-size** *socket-size* [*bgp-size*]

**no socket receive-buffer-size** [*socket-size*] [*bgp-size*]

### Syntax Description

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <i>socket-size</i> | Size (in bytes) of the receive-side socket buffers. Range is 512 to 131072.       |
| <i>bgp-size</i>    | (Optional) Size (in bytes) of the receive buffers in BGP. Range is 512 to 131072. |

### Command Default

*socket-size* : 32,768 bytes  
*bgp-size* : 4,032 bytes

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                                              |
|---------------|-----------------------------------------------------------|
| Release 3.2   | This command was introduced.                              |
| Release 3.3.0 | This command was supported in the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **socket receive-buffer-size** command to increase the buffer size when receiving updates from a neighbor. Using larger buffers can improve convergence time because the software can process more packets simultaneously. However, allocating larger buffers uses more memory on your router.

#### Note

Increasing the socket buffer size uses more memory only when more messages are waiting to be processed by the software. In contrast, increasing the BGP buffer size uses extra memory indefinitely.

Use the **receive-buffer-size** command on individual neighbors to change the values set by the **socket receive-buffer-size** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the receive buffer sizes for all neighbors to 65,536 bytes for the socket buffer and 8192 bytes for the BGP buffer:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# socket receive-buffer-size 65536 8192
```

**Related Commands**

| Command                                              | Description                                              |
|------------------------------------------------------|----------------------------------------------------------|
| <a href="#">receive-buffer-size, on page 223</a>     | Sets the size of the receive buffers for a BGP neighbor. |
| <a href="#">socket send-buffer-size, on page 477</a> | Sets the size of the send buffers for all BGP neighbors. |

## socket send-buffer-size

To set the size of the send buffers for all Border Gateway Protocol (BGP) neighbors, use the **socket send-buffer-size** command in an appropriate configuration mode. To set the size of the send buffers to the default size, use the **no** form of this command.

**socket send-buffer-size** *socket-size* [*bgp-size*]

**no socket send-buffer-size** [*socket-size*] [*bgp-size*]

### Syntax Description

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <i>socket-size</i> | Size (in bytes) of the send-side socket buffers. Range is 4096 to 131072.       |
| <i>bgp-size</i>    | (Optional) Size (in bytes) of the send buffers in BGP. Range is 4096 to 131072. |

### Command Default

*socket-size* : 10240 bytes

*bgp-size* : 4096 bytes

### Command Modes

Router configuration

VRF configuration

### Command History

| Release       | Modification                                              |
|---------------|-----------------------------------------------------------|
| Release 3.2   | This command was introduced.                              |
| Release 3.3.0 | This command was supported in the VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **socket send-buffer-size** command to increase the buffer size when sending updates to neighbors. Using larger buffers can improve convergence time because the software can process more packets simultaneously. However, allocating larger buffers uses more memory on your router.

#### Note

Increasing the socket buffer size uses more memory only when more messages are waiting to be sent by the software. In contrast, increasing the BGP buffer size uses extra memory indefinitely.

Use the **send-buffer-size** command on individual neighbors to change the values set by the **socket send-buffer-size** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to set the send buffer sizes for all neighbors to 8192 bytes for the socket buffer and the BGP buffer:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# socket send-buffer-size 8192 8192
```

**Related Commands**

| Command                                                 | Description                                                 |
|---------------------------------------------------------|-------------------------------------------------------------|
| <a href="#">send-buffer-size, on page 253</a>           | Sets the size of the send buffers for a BGP neighbor.       |
| <a href="#">socket receive-buffer-size, on page 475</a> | Sets the size of the receive buffers for all BGP neighbors. |

# soft-reconfiguration inbound

To configure the software to store updates received from a neighbor, use the **soft-reconfiguration inbound** command in an appropriate configuration mode. To disable storing received updates, use the **no** form of this command.

**soft-reconfiguration inbound** [**always**| **inheritance-disable**]

**no soft-reconfiguration inbound** [**always**| **inheritance-disable**]

## Syntax Description

|                            |                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>always</b>              | (Optional) Always performs a soft inbound clear using stored updates, even if the neighbor supports the route refresh capability. |
| <b>inheritance-disable</b> | (Optional) Overrides configuration for this command that may be inherited from a neighbor group or address family group.          |

## Command Default

Soft reconfiguration is not enabled.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 VPNv4 address family group configuration  
 IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                                                                                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv4 address family group</li> <li>• VPNv4 neighbor address family</li> <li>• VRF IPv4 neighbor address family</li> <li>• VPNv4 neighbor group address family</li> </ul> |
| Release 3.5.0 | This command was supported in the following configuration modes: <ul style="list-style-type: none"> <li>• VPNv6 address family group</li> <li>• VPNv6 neighbor address family</li> <li>• VRF IPv6 neighbor address family</li> <li>• VPNv6 neighbor group address family</li> </ul> |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword.                                                                                                                                                                                                |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

To filter or modify some of the updates received from a neighbor, you configure an inbound policy using the **route-policy (BGP)** command. Configuring soft reconfiguration inbound causes the software to store the original unmodified route beside a route that is modified or filtered. This allows a “soft clear” to be performed after the inbound policy is changed. To perform a soft clear, use the **clear bgp soft** command with the **in** keyword specified. The unmodified routes are then passed through the new policy and installed in the BGP table.

#### Note

If an address family group, neighbor group, or session group is configured, the configuration inside these configuration groups will not be effective unless it is applied directly or indirectly to one or more neighbors.

#### Note

The **bgp auto-policy-soft-reset** is enabled by default. A soft clear is done automatically when the inbound policy configured with the **route-policy (BGP)** command is changed. This behavior can be changed by disabling the auto-policy-soft-reset using the **bgp auto-policy-soft-reset disable** command.

If the neighbor supports the route refresh capability, then the original routes are not stored because they can be retrieved from the neighbor through a route refresh request. However, if the **always** keyword is specified, the original routes are stored even when the neighbor supports the route refresh capability.

If the **soft-reconfiguration inbound** command is not configured and the neighbor does not support the route refresh capability, then an inbound soft clear is not possible. In that case, the only way to rerun the inbound policy is to use the **clear bgp ip-address** command to reset the neighbor BGP session.

**Note**

If there is an existing BGP session with a neighbor that does not support the route refresh capability, the session is terminated and a new one is initiated.

**Note**

The extra routes stored as a result of configuring this command use more memory on the router.

If you configure this command for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows inbound soft reconfiguration enabled for IP Version 4 (IPv4) unicast routes received from neighbor 10.108.1.1. The software stores all routes received in their unmodified form so that when an inbound soft clear is performed later, the stored information can then be used to generate a new set of modified routes.

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# neighbor 10.108.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# soft-reconfiguration inbound
RP/0/0/CPU0:router(config-bgp-nbr-af)# exit
```

The following example shows inbound soft reconfiguration disabled for neighbor 10.108.1.1, preventing this feature from being automatically inherited by address family group group1:

```
RP/0/0/CPU0:router(config)# router bgp 100
RP/0/0/CPU0:router(config-bgp)# af-group group1 address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-afgrp)# soft-reconfiguration inbound
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 10.108.1.1
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group group1
RP/0/0/CPU0:router(config-bgp-nbr-af)# soft-reconfiguration inbound inheritance-disable
RP/0/0/CPU0:router(config-bgp-nbr-af)# exit
```

**Related Commands**

# speaker-id

To allocate a speaker process to a neighbor, use the **speaker-id** command in the appropriate configuration mode. To remove the speaker process from a neighbor, use the **no** form of this command.

**speaker-id** *id*

**no speaker-id** [*id*]

## Syntax Description

|           |                                              |
|-----------|----------------------------------------------|
| <i>id</i> | ID of the speaker process. Range is 1 to 15. |
|-----------|----------------------------------------------|

## Command Default

Default is 0.

## Command Modes

Session group configuration

## Command History

| Release       | Modification                                                     |
|---------------|------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                     |
| Release 3.6.0 | The command was supported in session group configuration mode.   |
| Release 4.2.0 | Removed support for this command in neighbor configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to allocate speaker process 3 to neighbor 192.168.40.24:

```
RP/0/0/CPU0:router(config)# router bgp 109  
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.40.24  
RP/0/0/CPU0:router(config-bgp-nbr)# speaker-id 3
```

# table-policy

To apply a routing policy to routes being installed into the routing table, use the **table-policy** command in an appropriate configuration mode. To disable applying a routing policy when installing routes into the routing table, use the **no** form of this command.

**table-policy** *policy-name*

**no table-policy** [*policy-name*]

## Syntax Description

|                    |                                      |
|--------------------|--------------------------------------|
| <i>policy-name</i> | Name of the routing policy to apply. |
|--------------------|--------------------------------------|

## Command Default

No policy is applied when routes are installed into the routing table.

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 VRF IPv4 address family configuration  
 VRF IPv6 address family configuration

## Command History

| Release       | Modification                                                                  |
|---------------|-------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                  |
| Release 3.3.0 | This command was supported in the VRF IPv4 address family configuration mode. |
| Release 3.5.0 | This command was supported in the VRF IPv6 address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Note

Table policy provides users with the ability to drop routes from the RIB based on match criteria. This feature can be useful in certain applications and should be used with caution as it can easily create a routing 'black hole' where BGP advertises routes to neighbors that BGP does not install in its global routing table and forwarding table.

Use the **table-policy** command to modify route attributes as the routes are installed into the routing table by Border Gateway Protocol (BGP). Commonly, it is used to set the traffic index attribute.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to apply the set-traffic-index policy to IPv4 unicast routes being installed into the routing table:

```
RP/0/0/CPU0:router(config)# router bgp 1  
RP/0/0/CPU0:router(config-bgp)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-bgp-af)# table-policy set-traffic-index
```

**Related Commands**

| Command                   | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>route-policy (RPL)</b> | Defines a route policy and enters route policy configuration mode. |

## timers (BGP)

To set the timers for a specific Border Gateway Protocol (BGP) neighbor, use the **timers** command in an appropriate configuration mode. To set the timers to the default values, use the **no** form of this command.

**timers** *keepalive hold-time*

**no timers** [*keepalive hold-time*]

### Syntax Description

|                  |                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>keepalive</i> | Frequency (in seconds) with which the software sends keepalive messages to a neighbor. Range is 0 to 65535.                                                                                           |
| <i>hold-time</i> | Interval (in seconds) after not receiving a keepalive message from the neighbor that the software terminates the BGP session for the neighbor. Values are 0 or a number in the range from 3 to 65535. |

### Command Default

*keepalive* : 60 seconds

*hold-time* : 180 seconds

Use the **timers bgp** command to override the default values.

### Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

### Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The timers actually used in connection with the neighbor may not be the same as those configured with this command. The actual timers are negotiated with the neighbor when establishing the session. The negotiated hold time is the minimum of the configured time and the hold time received from the neighbor. If the negotiated hold time is 0, keepalives are disabled.

The configured value for the keepalive must not exceed one-third of the negotiated hold time. If it does, a value of one-third of the negotiated hold time is used.

If this command is configured for a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

In cases where mechanisms such as Bi-directional Forwarding Detection (BFD), BGP fast-external-failover or Next-hop Tracking cannot be employed to detect and react to changes in the network in a faster manner, BGP Keepalive and Hold-timer values can be configured to use smaller values than the default (60 and 180 seconds respectively). When using aggressive values, consider the router's profile and scale, particularly in respect to the number of BGP neighbours that will be using sessions with the non-default timers.

Sessions using very aggressive values will be more susceptible to flap during events that cause the Route-Processor's CPU utilization levels to increase. Such events include component OIR, Route-Processor Failover, network instability, excessive churn in routing protocols etc. It is therefore recommended that the desired scale and profile of the router be tested with the non-default timer values, subjecting the router to CPU-intensive events in order to determine the timer threshold values that are appropriate for the router before configuring the values in an operational network.

The BGP Non-Stop Routing (NSR) is able to sustain sessions with more aggressive timer values than BGP Graceful Restart (GR) since in the event of a Route-Processor Failover, Graceful Restart (GR) requires the re-establishment of the TCP session over which the BGP session takes place. When using Non-Stop Routing (NSR), both the underlying TCP session and BGP session are maintained during Route-Processor failover.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to change the keepalive timer to 70 seconds and the hold-time timer to 210 seconds for the BGP peer 192.168.40.24:

```
RP/0/0/CPU0:router(config)# router bgp 109
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# timers 70 210
```

## Related Commands

## timers bgp

To change the default timer values for Border Gateway Protocol (BGP) neighbors, use the **timers bgp** command in an appropriate configuration mode. To set the default timers to the default values, use the **no** form of this command.

**timers bgp** *keepalive hold-time*

**no timers bgp** [*keepalive hold-time*]

### Syntax Description

|                  |                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>keepalive</i> | Frequency (in seconds) with which the software sends keepalive messages to a neighbor. Range is 0 to 65535.                                                                                           |
| <i>hold-time</i> | Interval (in seconds) after not receiving a keepalive message from the neighbor that the software terminates the BGP session for the neighbor. Values are 0 or a number in the range from 3 to 65535. |

### Command Default

*keepalive* : 60 seconds

*hold-time* : 180 seconds

### Command Modes

Router configuration

VRF configuration

### Command History

| Release       | Modification                                          |
|---------------|-------------------------------------------------------|
| Release 3.2   | This command was introduced.                          |
| Release 3.3.0 | This command was supported in VRF configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers bgp** command to adjust the default timer times used by all BGP neighbors. The values can be overridden on particular neighbors using the **timers** command in the neighbor configuration mode.

The timers actually used in connection with the neighbor may not be the same as those configured with this command. The actual timers are negotiated with the neighbor when establishing the session. The negotiated hold time is the minimum of the configured time and the hold time received from the neighbor. If the negotiated hold time is 0, keepalives are disabled.

The configured value for the keepalive must not exceed one-third of the negotiated hold time. If it does, a value of one-third of the negotiated hold time is used.

In cases where mechanisms such as Bi-directional Forwarding Detection (BFD), BGP fast-external-failover or Next-hop Tracking cannot be employed to detect and react to changes in the network in a faster manner, BGP Keepalive and Hold-timer values can be configured to use smaller values than the default (60 and 180 seconds respectively). When using aggressive values, consider the router's profile and scale, particularly in respect to the number of BGP neighbors that will be using sessions with the non-default timers.

Sessions using very aggressive values will be more susceptible to flap during events that cause the Route-Processor's CPU utilization levels to increase. Such events include component OIR, Route-Processor Failover, network instability, excessive churn in routing protocols etc. It is therefore recommended that the desired scale and profile of the router be tested with the non-default timer values, subjecting the router to CPU-intensive events in order to determine the timer threshold values that are appropriate for the router before configuring the values in an operational network.

The BGP Non-Stop Routing (NSR) is able to sustain sessions with more aggressive timer values than BGP Graceful Restart (GR) since in the event of a Route-Processor Failover, Graceful Restart (GR) requires the re-establishment of the TCP session over which the BGP session takes place. When using Non-Stop Routing (NSR), both the underlying TCP session and BGP session are maintained during Route-Processor failover.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to configure a default keepalive time of 30 seconds and a default hold time of 90 seconds:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# timers bgp 30 90
```

|-------------------------------------------|------------------------------------------------|
| <a href="#">timers (BGP), on page 486</a> | Adjusts BGP network timers for a BGP neighbor. |

## transport (rpki-server)

To choose a transport mechanism for the RPKI cache-server configuration, establish and manage transport connections, and send or receive byte streams from the network, use the **transport** command in rpki-server configuration mode. To disable the transport connection, use the **no** form of this command.

**transport** {ssh| tcp} **port** *port-number*

**no transport** {ssh| tcp} **port** *port-number*

### Syntax Description

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>port</b>        | Specifies to choose a port number for the RPKI cache transport.              |
| <i>port-number</i> | Specifies the port number for the RPKI cache transport. Range is 1 to 65535. |

### Command Default

Transport mechanism is disabled.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The transport can be set to either TCP or SSH. An SSH transport session is the recommended transport between router and RPKI cache for security reasons.

The transport method (TCP or SSH) can be configured on a per-RPKI-server basis: once server can be TCP port 980, another can be SSH port 22, for example. This can be changed by configuration. Changing the transport method will cause the cache session to flap (cleanup its existing transport related data and initialize the new transport related data).

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to configure SSH as the transport mechanism and to use port 1 for SSH communication:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
```

# ttl-security

To configure a router to check the time-to-live (TTL) field in incoming IP packets for the specified external Border Gateway Protocol (eBGP) peer, use the **ttl-security** command in an appropriate configuration mode. To disable TTL verification, use the **no** form of this command.

**ttl-security [inheritance-disable]**

**no ttl-security [inheritance-disable]**

## Syntax Description

|                            |                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>inheritance-disable</b> | (Optional) Prevents the <b>ttl-security</b> command from being inherited from a session group or neighbor group. |
|----------------------------|------------------------------------------------------------------------------------------------------------------|

## Command Default

TTL verification is not enabled for eBGP peers.

## Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                                         |
|---------------|--------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                         |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode.                       |
| Release 3.9.0 | The <b>disable</b> keyword was replaced with the <b>inheritance-disable</b> keyword. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **ttl-security** command to enable a lightweight security mechanism to protect eBGP peering sessions from CPU utilization-based and other resource exhaustion-based attacks. These types of attacks are typically brute-force Denial of Service (DoS) attacks that attempt to disable the network by flooding devices in the network with IP packets that contain forged source and destination IP addresses in the packet headers.

This command leverages existing behavior in IP packets. For a given IP packet, the TTL count of the packet always is equal to or less than the TTL count when the packet originated, a behavior that is considered impossible to circumvent. Therefore, a packet received with a TTL count equal to the maximum TTL value of 255 can be sent only by a directly adjacent peer. When the **ttl-security** command is configured for an

eBGP neighbor that is directly adjacent, the router accepts only IP packets with a TTL count that is equal to the maximum TTL value.

The **ttl-security** command secures the eBGP session in the incoming direction only. In the outbound direction, it causes packets to be sent only with the maximum TTL value so that the BGP neighbor can also verify the TTL value of incoming packets. When this command is enabled, BGP establishes or maintains a session only if the TTL value in the IP packet header is equal to the maximum TTL value. If the value is less than the maximum TTL value, the packet is discarded and an Internet Control Message Protocol (ICMP) message is not generated. This behavior is designed because a response to a forged packet is not necessary.

**Note**

The **ttl-security** command must be configured on each participating router. Failure to configure this command on both ends of the BGP session results in the session progressing as far as the OpenSent or OpenConfirm state, remaining there until the hold time expires.

The following restrictions apply to the configuration of this command:

- The **ttl-security** command should not be configured for a peer that is already configured with the **neighbor ebgp-multihop** command. The simultaneous configuration of these commands is permitted; however, the **ttl-security** command overrides the **ebgp-multihop** command.
- This command is not supported for internal BGP (iBGP) peers.
- This command is not effective against attacks from a directly adjacent peer that has been compromised.

If you configure this command for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Note**

If the **ttl-security** command is configured on a neighbor to which the router has an established connection or the router is in the process of establishing a connection, the session must be cleared using the **clear bgp** command.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to enable TTL security for eBGP neighbor 192.168.223.7:

```
RP/0/0/CPU0:router(config)# router bgp 65534
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.223.7
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65507
RP/0/0/CPU0:router(config-bgp-nbr)# ttl-security
```

The following example shows how to enable TTL security for multiple eBGP neighbors using a session group:

```
RP/0/0/CPU0:router(config)# router bgp 65534
RP/0/0/CPU0:router(config-bgp)# session-group ebgp-nbrs
RP/0/0/CPU0:router(config-bgp-sngrp)# ttl-security
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.223.1
```

```

RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65501
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group ebgp-nbrs
RP/0/0/CPU0:router(config-bgp-nbr)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.223.2
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65502
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group ebgp-nbrs
RP/0/0/CPU0:router(config-bgp-nbr)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.223.3
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 65503
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group ebgp-nbrs
RP/0/0/CPU0:router(config-bgp-nbr)# exit

```

# update limit

To set upper bound on transient memory usage for update generation, use the **update limit** command in router configuration mode. To return the bounds to the default value, use the **no** form of this command.

**update limit** *update-limit-MB*

**no update limit**

## Syntax Description

|                        |                                                                  |
|------------------------|------------------------------------------------------------------|
| <i>update-limit-MB</i> | Sets the update limit in megabytes (MB). Range is 16 to 2048 MB. |
|------------------------|------------------------------------------------------------------|

## Command Default

Default update limit is 512 MB.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                                 |
|---------------|------------------------------------------------------------------------------|
| Release 4.2.0 | This command was introduced and replaced the <b>bgp write-limit</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **update limit** command to configure a global limit on the size of messages the software queues when updating peers. Increasing the limit can result in faster Border Gateway Protocol (BGP) convergence, but also may result in higher memory usage during convergence.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set the update limit as 1024 MB:

```
RP/0/0/CPU0:router(config)# router bgp 65000
RP/0/0/CPU0:router(config-bgp)#update limit 1024
```

**Related Commands**

# update limit address-family

To set upper bound on transient memory usage for update generation for an address family, use the **update limit address-family** command in an appropriate address-family configuration mode. To return the bounds to the default value, use the **no** form of this command.

**update limit address-family** *update-limit-MB*

**no update limit address-family**

## Syntax Description

|                        |                                                                    |
|------------------------|--------------------------------------------------------------------|
| <i>update-limit-MB</i> | Sets the update limit in megabytes (MB). Range is 4 MB to 2048 MB. |
|------------------------|--------------------------------------------------------------------|

## Command Default

Default update limit is 256 MB.

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 L2VPN address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration

## Command History

| Release       | Modification                                                                 |
|---------------|------------------------------------------------------------------------------|
| Release 4.2.0 | This command was introduced and replaced the <b>bgp write-limit</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **update limit address-family** command to configure a global limit on the size of messages the software queues when updating peers. Increasing the limit can result in faster Border Gateway Protocol (BGP) convergence, but also may result in higher memory usage during convergence.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set the update limit as *512 MB* for address family VPNv6 unicast:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family vpnv6 unicast
RP/0/0/CPU0:router(config-bgp-af)#update limit address-family 512
```

# update limit sub-group

To set upper bound on transient memory usage for update generation for eBGP or iBGP sub-groups, use the **update limit sub-group** command in an appropriate address-family configuration mode. To return the bounds to the default value, use the **no** form of this command.

**update limit sub-group** {ebgp| ibgp} *update-limit-MB*

**no update limit sub-group** {ebgp| ibgp}

## Syntax Description

|                        |                                                                   |
|------------------------|-------------------------------------------------------------------|
| <b>ebgp</b>            | Specifies the update limit for eBGP sub-groups.                   |
| <b>ibgp</b>            | Specifies the update limit for iBGP sub-groups.                   |
| <i>update-limit-MB</i> | Sets the update limit in megabytes (MB). Range is 1 MB to 512 MB. |

## Command Default

Default update limit is 32 MB.

## Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 L2VPN address family configuration  
 VPNv4 address family configuration  
 VPNv6 address family configuration

## Command History

| Release       | Modification                                                                 |
|---------------|------------------------------------------------------------------------------|
| Release 4.2.0 | This command was introduced and replaced the <b>bgp write-limit</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **update limit sub-group** command to configure a global limit on the size of messages the software queues when updating peers. Increasing the limit can result in faster Border Gateway Protocol (BGP) convergence, but also may result in higher memory usage during convergence.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to set the update limit as *256 MB* for eBGP sub-group under address family VPNv6 unicast:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family vpnv6 unicast
RP/0/0/CPU0:router(config-bgp-af)#update limit sub-group ebgp 256
```

This example shows how to set the update limit as *256 MB* for iBGP sub-group under address family IPv6 multicast:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#address-family ipv6 multicast
RP/0/0/CPU0:router(config-bgp-af)#update limit sub-group ibgp 256
```

## update in error-handling basic disable

To disable inbound update message basic error handling for eBGP or iBGP neighbors, use the **update in error-handling basis disable** command in router configuration mode. To enable inbound update message basic error handling, use the **no** form of this command.

**update in error-handling basic {ebgp| ibgp} disable**

**no update in error-handling basic {ebgp| ibgp} disable**

### Syntax Description

|             |                                                                           |
|-------------|---------------------------------------------------------------------------|
| <b>ebgp</b> | Specifies inbound update message basic error handling for eBGP neighbors. |
| <b>ibgp</b> | Specifies inbound update message basic error handling for iBGP neighbors. |

### Command Default

Inbound update message basic error handling is enabled.

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to disable inbound update message basic error handling for eBGP neighbors:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#update in error-handling basic ebgp disable
```

This example shows how to disable inbound update message basic error handling for iBGP neighbors:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
```

```
RP/0/0/CPU0:router(config-bgp)#update in error-handling basic ibgp disable
```

# update in error-handling extended

To enable inbound update message extended error handling for eBGP or iBGP neighbors, use the **update in error-handling extended** command in router configuration mode. To disable inbound update message error handling, use the **no** form of this command.

**update in error-handling extended** {ebgp|ibgp}

**no update in error-handling extended** {ebgp|ibgp}

## Syntax Description

|             |                                                                                        |
|-------------|----------------------------------------------------------------------------------------|
| <b>ebgp</b> | Specifies to enable inbound update message extended error handling for eBGP neighbors. |
| <b>ibgp</b> | specifies to enable inbound update message extended error handling for iBGP neighbors. |

## Command Default

Inbound update message extended error handling is disabled.

## Command Modes

Router configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

## Examples

This example shows how to enable inbound update message extended error handling for eBGP neighbors:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#update in error-handling extended ebgp
```

This example shows how to enable inbound update message extended error handling for iBGP neighbors:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#update in error-handling extended ibgp
```

# update out logging

To enable logging of update generation events, use the **update out logging** command in router configuration mode. To disable the logging of update generation events, use the **no** form of this command.

**update out logging**

**no update out logging**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Update generation event logging is disabled.

**Command Modes** Router configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

**Examples** This example shows how to enable logging of update generation events:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#update out logging
```

# update-source

To allow internal Border Gateway Protocol (iBGP) sessions to use the primary IP address from a particular interface as the local address when forming an iBGP session with a neighbor, use the **update-source** command in an appropriate configuration mode. To set the chosen local IP address to the nearest interface to the neighbor, use the **no** form of this command.

**update-source** *type interface-path-id*

**no update-source** [*type interface-path-id*]

## Syntax Description

|                          |                                                                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>              | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

## Command Default

Best local address

## Command Modes

Neighbor configuration  
VRF neighbor configuration  
Neighbor group configuration  
Session group configuration

## Command History

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                   |
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |
| Release 3.5.0 | No modification                                                |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **update-source** command is commonly used with the loopback interface feature for iBGP sessions. The loopback interface is defined, and the interface address is used as the endpoint for a BGP session through the

**update-source** command. This mechanism allows a BGP session to remain up even if the outbound interface goes down, provided there is another route to the neighbor.

If this command is configured for a neighbor group or session group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

### Examples

The following example shows how to configure this router to use the IP address from the Loopback0 interface when trying to open a session with neighbor 172.20.16.6:

```
RP/0/0/CPU0:router(config)# router bgp 110
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.16.6
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 110
RP/0/0/CPU0:router(config-bgp-nbr)# update-source Loopback0
```

### Related Commands

| Command                                     | Description                                                            |
|---------------------------------------------|------------------------------------------------------------------------|
| <a href="#">neighbor-group, on page 189</a> | Creates a neighbor group and enters neighbor group configuration mode. |
| <a href="#">session-group, on page 261</a>  | Creates a session group and enters session group configuration mode.   |

## use

To inherit configuration from a neighbor group, session group, or address family group, use the **use** command in an appropriate configuration mode. To discontinue inheritance from a group, use the **no** form of this command.

**use** {**af-group** *group-name*| **neighbor-group** *group-name*| **session-group** *group-name* **e**}

**no use** {**af-group** [*group-name*]| **neighbor-group** [*group-name*]| **session-group** [*group-name*]}

### Syntax Description

|                       |                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| <b>af-group</b>       | Specifies an address family group.                                                                               |
| <i>group-name</i>     | Name of the neighbor group, session group, or address family group from which you want to inherit configuration. |
| <b>neighbor-group</b> | Specifies a neighbor group.                                                                                      |
| <b>session-group</b>  | Specifies a session group.                                                                                       |

### Command Default

Inheritance of group characteristics does not occur.

### Command Modes

For **use af-group** version:  
 Address family group configuration  
 Neighbor address family configuration  
 Neighbor group address family configuration  
 For **use neighbor-group** version:  
 Neighbor group configuration  
 Neighbor configuration  
 VRF neighbor configuration  
 For **use session-group** version:  
 Neighbor group configuration  
 Neighbor configuration  
 VRF neighbor configuration  
 Session-group configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                   |
|---------------|----------------------------------------------------------------|
| Release 3.3.0 | This command was supported in VRF neighbor configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **use** command configures inheritance of configuration from an address family group, neighbor group, or session group, which means that any configuration for the group also takes effect for the user of the group.

The configuration inherited depends on the type of group that is specified. The group types are described in the following sections:

### Address Family Group

An address family group can specify a configuration for only a single address family. The address family specified when the address family group was defined (through the **af-group** command) must match the address family from which the group is used.

### Neighbor Group

A neighbor group (like a neighbor) can have address family-independent configuration and address family-specific configuration. All of these configurations could be inherited.

### Session Group

A session group can have only address family-independent configuration and thus only address family-independent configuration is inherited from it.

The following rules govern inheritance to resolve possible conflicting configuration:

- 1 If a command is configured directly on the neighbor that is using group configuration, the command overrides the value that would be normally inherited from the group.
- 2 If the neighbor is configured to use a session group (for address family-independent configuration) or an address family group (for address family-specific configuration) and the command is configured for the session group or address family group, that configuration is used.
- 3 The neighbor group configuration is used:
  - If the command is not configured directly on the neighbor and the neighbor is not using a session group (for address family-independent configuration) or an af-group (for address family-specific configuration).
  - The neighbor is using a neighbor group and the command is configured on the neighbor group.

Typically, all configuration for a neighbor group is inherited, but some characteristics may be masked by a session group or address family group. For an example of this configuration, see the “Examples” section.

If the neighbor is using both a session group and a neighbor group and a specific command is configured for the neighbor group but not for the session group, then the configuration for the neighbor group does not take effect. The session group “hides” all address family-independent configuration on the neighbor group and prevents it from being inherited. Similarly, the use of an address family group hides any address family-specific configuration that may otherwise be inherited from a neighbor group for that address family.

In addition to neighbors using groups, it is possible to build a hierarchy by having groups use other groups. The following hierarchical groups are permitted:

- Session groups may use other session groups.
- Address family groups may use other address family groups.
- Neighbor groups may use other neighbor groups.
- Neighbor groups may use session groups and address family groups.

**Note**

Within the Cisco IOS XR system configuration architecture, do not combine the **remote-as** command and the **no use neighbor-group** command in the same commit, or the **remote-as** command and the **no use session-group** command in the same commit.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to define a session group session1 and configure neighbor 172.168.40.24 to use session1. As a result, the session1 configuration takes effect on the neighbor also.

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group session1
RP/0/0/CPU0:router(config-bgp-sngrp)# advertisement-interval 40
RP/0/0/CPU0:router(config-bgp-sngrp)# timers 30 90
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group session1
RP/0/0/CPU0:router(config-bgp-nbr)# exit
```

The following example is similar to the previous example, but in this case the **timers** command on the session group does not take effect on the neighbor because it is overridden by a **timers** command directly configured for the neighbor.

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group session1
RP/0/0/CPU0:router(config-bgp-sngrp)# advertisement-interval 40
RP/0/0/CPU0:router(config-bgp-sngrp)# timers 30 90
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group session1
RP/0/0/CPU0:router(config-bgp-nbr)# timers 60 180
RP/0/0/CPU0:router(config-bgp-nbr)# exit
```

The following example shows an address family group, family1, for IPv4 multicast and a neighbor group, neighbor1, that have IPv4 unicast and IPv4 multicast enabled. In this case, the neighbor inherits IPv4 unicast (and address family-independent) configuration from the neighbor group, but inherits IPv4 multicast configuration from the address family group. In this example, the neighbor group also has a remote autonomous system configured, so there is no need to configure a remote autonomous system for the neighbor because it inherits the remote autonomous system from the neighbor group:

```
RP/0/0/CPU0:router(config)# router bgp 1
```

```

RP/0/0/CPU0:router(config-bgp)# af-group family1 address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-afgrp)# route-policy mcast-in in
RP/0/0/CPU0:router(config-bgp-afgrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor-group neighbor1
RP/0/0/CPU0:router(config-bgp-nbrgrp)# remote-as 2
RP/0/0/CPU0:router(config-bgp-nbrgrp)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# route-policy policy1 in
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# route-policy policy1 out
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# exit
RP/0/0/CPU0:router(config-bgp-nbrgrp)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# route-policy policy1 in
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# route-policy policy1 out
RP/0/0/CPU0:router(config-bgp-nbrgrp-af)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# use neighbor-group neighbor1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 multicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# use af-group family1
RP/0/0/CPU0:router(config-bgp-nbr-af)# exit

```

In the previous example, the neighbor uses the policy1 route policy for inbound and outbound IPv4 unicast routes, but uses the mcast-in route policy for inbound IPv4 multicast routes and no policy for outbound IPv4 multicast routes.

The following example shows a neighbor inheriting configuration from a session group that likewise inherits configuration from another session group. The configuration from both session groups take effect on the neighbor:

```

RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# session-group session1
RP/0/0/CPU0:router(config-bgp-sngrp)# advertisement-interval 40
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# session-group session2
RP/0/0/CPU0:router(config-bgp-sngrp)# use session-group session1
RP/0/0/CPU0:router(config-bgp-sngrp)# update-source Loopback0
RP/0/0/CPU0:router(config-bgp-sngrp)# exit
RP/0/0/CPU0:router(config-bgp)# neighbor 172.168.40.24
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# use session-group session2
RP/0/0/CPU0:router(config-bgp-nbr)# exit

```

## username (rpki-server)

To specify a SSH **username** for the RPKI cache-server, use the **username** command in rpki-server configuration mode. To remove the username, use the **no** form of this command.

**username** *user-name*

**no username** *user-name*

### Syntax Description

|                  |                                                               |
|------------------|---------------------------------------------------------------|
| <i>user-name</i> | Enters a username to be used for the SSH transport mechanism. |
|------------------|---------------------------------------------------------------|

### Command Default

Username is not configured.

### Command Modes

RPKI server configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The username configuration applies only if the SSH transport mechanism is active.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |

### Examples

This example shows how to configure a username (*rpki-user*) for the RPKI cache-server SSH transport mechanism:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router bgp 100
RP/0/0/CPU0:router(config-bgp)#rpki server 172.168.35.40
RP/0/0/CPU0:router(config-bgp-rpki-cache)# transport ssh port 1
RP/0/0/CPU0:router(config-bgp-rpki-cache)#username rpki-user
```

## vrf (BGP)

To configure a VPN routing and forwarding (VRF) instance and enter VRF configuration mode, use the **vrf** command in router configuration mode. To remove the VRF instance from the configuration file and restore the system to its default condition, use the **no** form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

### Syntax Description

|                 |                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------|
| <i>vrf-name</i> | Name of the VRF instance. The following names cannot be used: all, default, and global. |
|-----------------|-----------------------------------------------------------------------------------------|

### Command Default

No default behavior or values

### Command Modes

Router configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                                                      |
| Release 3.5.0 | The following restriction was removed:<br><br>If you remove a VRF configuration using the <b>no vrf</b> <i>vrf-name</i> command and want to reconfigure the VRF configuration using the <b>vrf</b> <i>vrf-name</i> command, you must wait at least three minutes. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vrf** command to configure a VRF instance. A VRF instance is a collection of VPN routing and forwarding tables maintained at the provider edge (PE) router.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

## Examples

The following example shows how to configure a VRF instance and enter VRF configuration mode:

```
RP/0/0/CPU0:router(config)# router bgp 1  
RP/0/0/CPU0:router(config-bgp)# vrf vrf-1  
RP/0/0/CPU0:router(config-bgp-vrf)#
```

# weight

To assign a weight to routes received from a neighbor, use the **weight** command in an appropriate configuration mode. To remove the **weight** command from the configuration file and restore the system to its default condition in which the software assigns the default weight to routes, use the **no** form of this command.

**weight** *weight-value*

**no weight** [ *weight-value* ]

## Syntax Description

*weight-value*

Weight to assign. Range is 0 to 65535.

## Command Default

Routes learned through another Border Gateway Protocol (BGP) peer have a default weight of 0 and routes sourced by the local router have a default weight of 32768.

## Command Modes

IPv4 address family group configuration  
 IPv6 address family group configuration  
 VPNv4 address family group configuration  
 IPv4 neighbor address family configuration  
 VPNv4 neighbor address family configuration  
 VRF IPv4 neighbor address family configuration  
 IPv4 neighbor group address family configuration  
 IPv6 neighbor group address family configuration  
 VPNv4 neighbor group address family configuration  
 VPNv6 address family group configuration  
 VPNv6 neighbor address family configuration  
 VRF IPv6 neighbor address family configuration  
 VPNv6 neighbor group address family configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

| Release       | Modification                                                                                                                                                                                                                                                                                                                                       |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | <p>This command was supported in the following configuration modes:</p> <ul style="list-style-type: none"> <li>• VPNv4 address family group</li> <li>• VPNv4 neighbor address family</li> <li>• VRF IPv4 neighbor address family</li> <li>• VPNv4 neighbor group address family</li> </ul>                                                         |
| Release 3.5.0 | <p>This command was supported in the following configuration modes:</p> <ul style="list-style-type: none"> <li>• VPNv6 address family group configuration</li> <li>• VPNv6 neighbor address family configuration</li> <li>• VRF IPv6 neighbor address family configuration</li> <li>• VPNv6 neighbor group address family configuration</li> </ul> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The weight of a route is a Cisco-specific attribute. It is used in the best-path selection process (as the strongest tie-breaker). See the *Implementing BGP on Cisco IOS XR Software* module of the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router* for information on best path. If there are two BGP routes with the same network layer reachability information (NLRI), the route with the higher weight is always chosen no matter what the value of other BGP attributes. Weight only has significance on the local router. Weight is assigned locally to the router, is a value that only makes sense to the specific router, is not propagated or carried through any route updates, and never is sent between BGP peers (even within the same AS).

#### Note

If an address family group, neighbor group, or session group is configured, the configuration inside these configuration groups will not be effective unless it is applied directly or indirectly to one or more neighbors.

The weight assigned to individual routes can be further manipulated in the inbound route policy of a neighbor using the **set weight** command. The **set weight** command sets the weight directly. If you have particular neighbors that you want to prefer for most of your outbound traffic, you can assign a higher weight to all routes learned from that neighbor.

The weight assigned to individual routes may be modified by using an inbound routing policy.

#### Note

For weight changes to take effect, you may need to use the [clear bgp soft](#), on page 135 command.

If this command configures a neighbor group or neighbor address family group, all neighbors using the group inherit the configuration. Values of commands configured specifically for a neighbor override inherited values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples**

The following example shows how to assign a weight of 50 to all IP Version 4 (IPv4) unicast routes learned through 172.20.16.6:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# neighbor 172.20.16.6
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 1
RP/0/0/CPU0:router(config-bgp-nbr)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-nbr-af)# weight 50
RP/0/0/CPU0:router(config-bgp-nbr-af)# exit
```

**Related Commands**

| Command                                     | Description                                                                                           |

| set weight                                  | Sets the weight for BGP routes.                                                                       |

# weight reset-on-import

To reset weight of paths on import, use the **weight reset-on-import** command in an appropriate configuration mode. To remove the **weight reset-on-import** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**weight reset-on-import**

**no weight reset-on-import**

**Syntax Description** This command has no arguments or keywords.

**Command Default** Reset weight on import is disabled.

**Command Modes**

- VRF IPv4 address family configuration
- VRF IPv6 address family configuration
- VPNv4 address family configuration
- VPNv6 address family configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | bgp     | read, write |

**Examples** The following example shows how to reset weight of paths on import under VRF IPv4 address family configuration:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# vrf vrf1
RP/0/0/CPU0:router(config-bgp-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)# weight reset-on-import
```

The following example shows how to reset weight of paths on import under VPNv6 address family configuration:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# address-family vpnv6 unicast
RP/0/0/CPU0:router(config-bgp-af)# weight reset-on-import
```

#### Related Commands

|-------------------------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">weight reset-on-import disable, on page 522</a> | Disables resetting weight of paths on import, if it is enabled globally. |

# weight reset-on-import disable

To disable resetting weight of paths on import, if it is enabled globally, use the **weight reset-on-import-disable** in appropriate configuration mode. To cancel the disable option and retain the weight reset-on-import option globally, use the **no** form of this command.

**weight reset-on-import disable**

**no weight reset-on-import disable**

**Syntax Description** This command has no arguments or keywords.

**Command Default** Reset weight of paths on import option is enabled globally.

**Command Modes**

- VRF IPv4 address family configuration
- VRF IPv6 address family configuration
- VPNv4 address family configuration
- VPNv6 address family configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |

**Examples** The following example shows how to disable reset weight of paths on import option under VPNv4 address family configuration:

```
RP/0/0/CPU0:router(config)# router bgp 1
RP/0/0/CPU0:router(config-bgp)# vrf vrf_A
RP/0/0/CPU0:router(config-bgp-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-bgp-vrf-af)# weight reset-on-import disable
```

## address-family ipv4 unicast (BFD)

To enable Bidirectional Forwarding Detection (BFD) fast-detection on a specific IPv4 unicast destination address prefix and on the forwarding next-hop address, use the **address-family ipv4 unicast** command in static route configuration mode. To return the router to the default setting, use the **no** form of this command.

**address-family ipv4 unicast** *address nexthop* **bfd fast-detect** [**minimum interval** *interval*] [**multiplier** *multiplier*]

**no address-family ipv4 unicast** *address nexthop* **bfd fast-detect** [**minimum interval** *interval*] [**multiplier** *multiplier*]

### Syntax Description

|                                         |                                                                                                                                                                                                   |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address</i>                          | Specifies the IPv4 unicast destination address and prefix on which to enable BFD fast-detection.                                                                                                  |
| <i>nexthop</i>                          | Specifies the next-hop address on which to enable BFD fast-detection.                                                                                                                             |
| <b>bfd fast-detect</b>                  | Enables BFD fast-detection on the specified IPV4 unicast destination address prefix and on the forwarding next-hop address.                                                                       |
| <b>minimum interval</b> <i>interval</i> | (Optional) Ensures that the next hop is assigned with the same hello interval. Replace <i>interval</i> with a number that specifies the interval in milliseconds. Range is from 10 through 10000. |
| <b>multiplier</b> <i>multiplier</i>     | (Optional) Ensures that the next hop is assigned with the same detect multiplier. Replace <i>multiplier</i> with a number that specifies the detect multiplier. Range is from 1 through 10.       |

### Command Default

*interval*: 100  
*multiplier*: 3

### Command Modes

Static route configuration mode

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If the multiplier is changed using the **bfd multiplier** command, the new parameter is used to update all existing BFD sessions for the protocol (BGP, IS-IS, MPLS-TE, or OSPF).

### Task ID

| Task ID | Operations  |
|---------|-------------|
| static  | read, write |

### Examples

The following example shows how to enable BFD on a static route. In this example, BFD sessions are established with the next-hop 3.3.3.3 when it becomes reachable.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router static
RP/0/0/CPU0:router (config-static)# address-family ipv4 unicast 2.2.2.0/24 3.3.3.3 bfd
fast-detection
```

### Related Commands

| Command                                      | Description                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">bfd fast-detect, on page 543</a> | Enables BFD to detect failures in the path between adjacent forwarding engines. |
| <a href="#">show bfd, on page 571</a>        | Displays BFD information for a specific location.                               |

# bfd

To enter Bidirectional Forwarding Detection (BFD) configuration mode, use the **bfd** command in global configuration mode. To exit BFD configuration mode and return to global configuration mode, use the **no** form of this command.

**bfd**

**no bfd**

**Syntax Description** This command has no keywords or arguments.

**Command Default** No default behavior or values

**Command Modes** Global configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When you issue the **bfd** command in global configuration mode, the CLI prompt changes to “config-bfd,” indicating that you have entered BFD configuration mode. In the following sample output, the question mark (?) online help function displays all the commands available under BFD configuration mode:

```
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# ?

commit      Commit the configuration changes to running
describe    Describe a command without taking real actions
do          Run an exec command
echo        Configure BFD echo parameters
exit        Exit from this submode
interface   Configure BFD on an interface
no          Negate a command or set its defaults
root        Exit to the global configuration mode
show        Show contents of configuration
```

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |
| mpls-te | read, write |

### Examples

The following example shows how to enter BFD configuration mode:

```
RP/0/0/CPU0:router # configure
RP/0/0/CPU0:router(config) # bfd
RP/0/0/CPU0:router(config-bfd) #
```

### Related Commands

| <a href="#">interface (BFD), on page 567</a> | Enters BFD interface configuration mode, where you can disable echo mode on an interface. |
| <a href="#">show bfd, on page 571</a>        | Displays BFD information for a specific location.                                         |

## bfd address-family ipv4 destination

To specify the destination address for BFD sessions on bundle member links, use the **bfd address-family ipv4 destination** command in interface configuration mode. To return to the default, use the **no** form of this command.

**bfd address-family ipv4 destination** *ip-address*

**no bfd address-family ipv4 destination** *ip-address*

### Syntax Description

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <i>ip-address</i> | 32-bit IPv4 address in dotted-decimal format (A.B.C.D). |
|-------------------|---------------------------------------------------------|

### Command Default

No destination IPv4 address is configured.

### Command Modes

Interface configuration (config-if)

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command is supported on bundle interfaces only.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bundle  | read, write |

### Examples

The following example specifies the IPv4 address of 10.20.20.1 as the destination address for the BFD session on an Ethernet bundle interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-Ether 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 destination 10.20.20.1
```

The following example specifies the IPv4 address of 10.20.20.1 as the destination address for the BFD session on a POS bundle interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-POS 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 destination 10.20.20.1
```

| <a href="#">bfd address-family ipv4 destination</a> , on page 531 | Specifies the destination address for BFD sessions on bundle member links. |

## bfd address-family ipv4 minimum-interval

To specify the minimum interval for asynchronous mode control packets on IPv4 BFD sessions on bundle member links, use the **bfd address-family ipv4 minimum-interval** command in interface configuration mode. To return to the default, use the **no** form of this command.

**bfd address-family ipv4 minimum-interval** *milliseconds*

**no bfd address-family ipv4 minimum-interval** [ *milliseconds* ]

### Syntax Description

*milliseconds*

Shortest interval between sending BFD control packets to a neighbor. The range is 15 to 30000 milliseconds.

#### Note

### Command Default

The default is 150 ms.

### Command Modes

Interface configuration (config-if)

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command is supported on bundle interfaces only.

The BFD minimum interval is used with a configurable multiplier (**bfd address-family ipv4 multiplier** command) to determine the intervals and failure detection times for both control and echo packets in asynchronous mode on bundle member links.

For example, with a session interval of  $I$  and a multiplier of  $M$ , the following packet intervals and failure detection times apply for BFD asynchronous mode:

- Value of  $I$ —Minimum period between sending of BFD control packets.
- Value of  $I \times M$ 
  - BFD control packet failure detection time. This is the maximum amount of time that can elapse without receipt of a BFD control packet before the session is declared down.
  - Minimum period between sending of BFD echo packets.

- Value of  $(I \times M) \times M$ —BFD echo packet failure detection time. This is the maximum amount of time that can elapse without receipt of a BFD echo packet before the session is declared down.

When used with bundled VLANs, the following restrictions apply:

- The command specifies control packet intervals only because echo packets are not supported.
- The minimum interval is 250 ms.

The **bfd address-family ipv4 minimum-interval** command in bundle interface configuration overrides the minimum intervals specified by the **bfd minimum-interval** command in other areas of BFD configuration.

#### Note

When multiple applications share the same BFD session, the application with the most aggressive timer is used locally. Then, the result is negotiated with the peer router.

Keep the following router-specific rules in mind when configuring the minimum BFD interval:

- The maximum rate in packets-per-second (pps) for BFD sessions is linecard-dependent. If you have multiple linecards supporting BFD, then the maximum rate for BFD sessions per system is the supported linecard rate multiplied by the number of linecards.
- The maximum number of all BFD sessions on the router is 1024.
- The maximum number of all BFD sessions on the router is 1440.

To calculate the rate for BFD sessions on bundle members running in asynchronous mode without echo:

- Divide 1000 by the value of the minimum interval (as specified by the **bfd address-family ipv4 minimum-interval** command). This is also the base rate used per member session with echo:  
Asynchronous rate per bundle member =  $(1000 / \text{Min-interval})$

To calculate the rate for BFD sessions on bundle members running in asynchronous mode with echo:

- Determine the echo interval, which is the value of the minimum interval (specified by the **bfd address-family ipv4 minimum-interval** command) multiplied by the multiplier value (specified by the **bfd address-family ipv4 multiplier** command).  
Echo interval =  $(\text{Min-interval} \times \text{Multiplier})$
- Calculate the overall rate supported for all members on the bundle:  
Ethernet bundle rate =  $(1000 / \text{Echo interval}) \times 64$   
POS bundle rate =  $(1000 / \text{Echo interval}) \times 253$
- Add the asynchronous base rate per bundle member to find the total rate for all bundle links:  
Total bundle rate = Ethernet or POS bundle rate +  $(\text{Base asynchronous rate} \times \text{Number of links})$

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| bundle  | read, write |

## Examples

The following example specifies that control packets will be sent at a minimum interval of 200 ms for IPv4 BFD sessions on member links of an Ethernet bundle:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-Ether 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 minimum-interval 200
```

The following example specifies that control packets will be sent at a minimum interval of 200 ms for IPv4 BFD sessions on member links of a POS bundle:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-POS 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 minimum-interval 200
```

## Related Commands

## bfd address-family ipv4 multiplier

To specify a number that is used as a multiplier with the minimum interval to determine BFD control and echo packet failure detection times and echo packet transmission intervals for IPv4 BFD sessions on bundle member links, use the **bfd address-family ipv4 multiplier** command in interface configuration mode. To return to the default, use the **no** form of this command.

**bfd address-family ipv4 multiplier** *multiplier*

**no bfd address-family ipv4 multiplier** [*multiplier*]

### Syntax Description

*multiplier*

Number from 2 to 50.

#### Note

Although the command allows you to configure a minimum of 2, the supported minimum is 3.

### Command Default

The default multiplier is 3.

### Command Modes

Interface configuration (config-if)

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command is supported on bundle interfaces only.

The BFD multiplier is used with a configurable minimum interval (**bfd address-family ipv4 minimum-interval** command) to determine the intervals and failure detection times for both control and echo packets in asynchronous mode on bundle member links.

For example, with a session interval of *I* and a multiplier of *M*, the following packet intervals and failure detection times apply for BFD asynchronous mode:

- Value of *I*—Minimum period between sending of BFD control packets.
- Value of *I* x *M*
  - BFD control packet failure detection time. This is the maximum amount of time that can elapse without receipt of a BFD control packet before the session is declared down.
  - Minimum period between sending of BFD echo packets.

**Note**

The maximum echo packet interval for BFD on bundle member links is the minimum of either 30 seconds or the asynchronous control packet failure detection time.

- Value of  $(I \times M) \times M$ —BFD echo packet failure detection time. This is the maximum amount of time that can elapse without receipt of a BFD echo packet before the session is declared down.

Keep the following router-specific rules in mind when configuring the minimum BFD interval:

- The maximum rate in packets-per-second (pps) for BFD sessions is linecard-dependent. If you have multiple linecards supporting BFD, then the maximum rate for BFD sessions per system is the supported linecard rate multiplied by the number of linecards.
- The maximum number of all BFD sessions per linecard is 1024.
- The maximum number of all BFD sessions per linecard is 1440.

To calculate the rate for BFD sessions on bundle members running in asynchronous mode without echo:

- Divide 1000 by the value of the minimum interval (as specified by the **bfd address-family ipv4 minimum-interval** command). This is also the base rate used per member session with echo:  
Asynchronous rate per bundle member =  $(1000 / \text{Min-interval})$

To calculate the rate for BFD sessions on bundle members running in asynchronous mode with echo:

- Determine the echo interval, which is the value of the minimum interval (specified by the **bfd address-family ipv4 minimum-interval** command) multiplied by the multiplier value (specified by the **bfd address-family ipv4 multiplier** command).  
Echo interval =  $(\text{Min-interval} \times \text{Multiplier})$
- Calculate the overall rate supported for all members on the bundle:  
Ethernet bundle rate =  $(1000 / \text{Echo interval}) \times 64$   
POS bundle rate =  $(1000 / \text{Echo interval}) \times 253$
- Add the asynchronous base rate per bundle member to find the total rate for all bundle links:  
Total bundle rate = Ethernet or POS bundle rate +  $(\text{Base asynchronous rate} \times \text{Number of links})$

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bundle  | read, write |

**Task ID****Examples**

The following example specifies the following packet intervals and failure detection times for IPv4 BFD sessions on member links with asynchronous echo mode on an Ethernet bundle:

- 200 ms control packet interval
- 600 ms control packet failure detection interval

- 600 ms echo packet interval
- 1800 ms echo packet failure detection interval

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-Ether 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 minimum-interval 200
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 multiplier 3
```

The following example specifies the same packet intervals and failure detection times for IPv4 BFD sessions on member links of a POS bundle:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-POS 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 minimum-interval 200
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 multiplier 3
```

## bfd address-family ipv4 timers

To configure timers to allow for delays in receipt of BFD state change notifications (SCNs) from peers before declaring a link bundle BFD session down for IPv4 BFD sessions on bundle member links, use the **bfd address-family ipv4 timers** command in interface configuration mode. To return to the default, use the **no** form of this command.

**bfd address-family ipv4 timers** [*start*| *nbr-unconfig*] *seconds*

**no bfd address-family ipv4 timers** [*start*| *nbr-unconfig*] *seconds*

### Syntax Description

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>start</b> <i>seconds</i>        | Number of seconds after startup of a BFD member link session to wait for the expected notification from the BFD peer to be received, so that the session can be declared up. If the SCN is not received after that period of time, the BFD session is declared down. The range is 60 to 3600.<br><br><b>Note</b> In Cisco IOS XR Releases 4.0 and 4.0.1, the available minimum is 30, but is not recommended.                                                       |
| <b>nbr-unconfig</b> <i>seconds</i> | Number of seconds to wait after receipt of notification that the BFD configuration has been removed by a BFD neighbor, so that any configuration inconsistency between the BFD peers can be fixed. If the BFD configuration issue is not resolved before the specified timer is reached, the BFD session is declared down. The range is 60 to 3600.<br><br><b>Note</b> In Cisco IOS XR Releases 4.0 and 4.0.1, the available minimum is 30, but is not recommended. |

### Command Default

No timers are configured.

### Command Modes

Interface configuration (config-if)

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command is supported on bundle interfaces only.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bundle  | read, write |

**Examples**

The following example configures a timer for members of the specified Ethernet bundle that allows up to 1 minute (60 seconds) after startup of a BFD member link session to wait for receipt of the expected notification from the BFD peer to declare the session up:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-Ether 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 timers start 60
```

The following example configures a timer for members of the specified Ethernet bundle that allows up to 1 minute (60 seconds) to wait after receipt of notification that the BFD configuration has been removed by a BFD neighbor, before declaring a BFD session down:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-Ether 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 timers nbr-unconfig 60
```

The following example specifies the same timers for member links of a POS bundle:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# interface Bundle-POS 1
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 timers start 30
RP/0/0/CPU0:router(config-if)# bfd address-family ipv4 timers nbr-unconfig 60
```

## bfd fast-detect

To enable Bidirectional Forwarding Detection (BFD) to detect failures in the path between adjacent forwarding engines, use the **bfd fast-detect** command in the appropriate configuration mode. To return the software to the default state in which BFD is not enabled, use the **no** form of this command.

**bfd fast-detect** [**disable**| **ipv4**]

**no bfd fast-detect**

### Syntax Description

|                |                                                                                                                                                                                                                                                                                                                                 |

Interface configuration

### Command History

| Release       | Modification                                                                                 |
|---------------|----------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                 |
| Release 3.4.0 | The <b>bfd fast-detect</b> command was supported in router PIM interface configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

BFD can support multihop for internal and external BGP peers.

Use the **bfd fast-detect** command to provide protocol- and media-independent, short-duration failure detection of the path between adjacent forwarding engines, including the interfaces and data links.

BFD must be configured on directly connected neighbors for a BFD session to be established between the neighbors.

When MPLS-TE tunnels are protected by backup tunnels, BFD failure triggers fast reroute on affected tunnels.

In OSPF environments, the setting of the **bfd fast-detect** command is inherited from the highest-level configuration mode in which the command was configured. From the lowest to the highest configuration modes, the inheritance rules are as follows:

- If you enable BFD in area interface configuration mode, it is enabled on the specified interface only.
- If you enable BFD in area configuration mode, it is enabled on all interfaces in the specified area.
- If you enable BFD in router configuration mode, it is enabled on all areas and all associated interfaces in the specified routing process.

The **disable** keyword is available in the following modes: BGP configuration, OSPF area configuration, and OSPF area interface configuration. In OSPF environments, the **disable** option enables you to override the inheritance rules described previously. For example, if you enable BFD in an OSPF area, BFD is enabled on all interfaces in that area. If you do not want BFD running on one of the interfaces in that area, you must specify the **bfd fast-detect disable** command for that interface only.

To disable BFD or return the software to the default state in which BFD is not enabled in IS-IS router configuration mode and MPLS-TE configuration mode, you must enter the **no bfd fast-detect** command.

**Task ID**

| Task ID   | Operations  |
|-----------|-------------|
| bgp       | read, write |
| isis      | read, write |
| mpls-te   | read, write |
| ospf      | read, write |
| multicast | read, write |

**Examples**

The following example shows how to configure BFD on a BGP router:

```
RP/0/0/CPU0:router# configure
```

```
RP/0/0/CPU0:router(config)# router bgp 65000  
RP/0/0/CPU0:router(config-bgp)# neighbor 192.168.70.24  
RP/0/0/CPU0:router(config-bgp-nbr)# remote-as 2  
RP/0/0/CPU0:router(config-bgp-nbr)# bfd fast-detect
```

**Related Commands**

## bfd minimum-interval

To specify the minimum control packet interval for BFD sessions for the corresponding BFD configuration scope, use the **bfd minimum-interval** command in the appropriate configuration mode. To return the router to the default setting, use the **no** form of this command.

**bfd minimum-interval** *milliseconds*

**no bfd minimum-interval** [ *milliseconds* ]

### Syntax Description

|                     |                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>milliseconds</i> | Interval between sending BFD hello packets to the neighbor. The range is 15 to 30000 milliseconds. For MPLS-TE, the range is 50 to 200 milliseconds. |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|

### Command Default

BGP *interval*: 50 milliseconds

IS-IS *interval*: 250 milliseconds

OSPF *interval*: 150 milliseconds

MPLS-TE *interval*: 50 milliseconds

PIM *interval*: 150 milliseconds

### Command Modes

### Command History

| Release       | Modification                                                                                      |
|---------------|---------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                      |
| Release 3.4.0 | The <b>bfd minimum-interval</b> command was supported in router PIM interface configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

In OSPF environments, the setting of the **bfd minimum-interval** command is inherited from the highest-level configuration mode in which the command was configured. From the lowest to the highest configuration modes, the inheritance rules are as follows:

- If you configure the minimum interval in area interface configuration mode, the updated interval affects the BFD sessions on the specified interface only.
- If you configure the minimum interval in area configuration mode, the updated interval affects the BFD sessions on all interfaces in the specified area.
- If you configure the minimum interval in router configuration mode, the updated interval affects the BFD sessions in all areas and all associated interfaces in the specified routing process.

If desired, you can override these inheritance rules by explicitly configuring the **bfd minimum-interval** command for a specific area interface or area.

**Note**

When multiple applications share the same BFD session, the application with the most aggressive timer wins locally. Then, the result is negotiated with the peer router.

Keep the following router-specific rules in mind when configuring the minimum BFD interval:

- The maximum rate in packets-per-second (pps) for BFD sessions is linecard-dependent. If you have multiple linecards supporting BFD, then the maximum rate for BFD sessions per system is the supported linecard rate multiplied by the number of linecards.
  - The maximum rate for BFD sessions per linecard is 1334 pps.
- If a session is running in asynchronous mode without echo, then PPS used for this session is  $(1000 / \text{asynchronous interval in milliseconds})$ .
- If a session is running in asynchronous mode with echo, then PPS used for this session is  $(1000 / \text{echo interval in milliseconds})$ .  
This is calculated as:  $1000 / \text{value of the } \textbf{bfd minimum-interval} \text{ command}$ .
- The maximum number of all BFD sessions per linecard is 1024.
- The maximum number of all BFD sessions per linecard is 1440.
- When asynchronous mode is available, the minimum interval must be greater than or equal to 15 milliseconds for up to 100 sessions on the line card. If you are running the maximum of 1024 sessions, the failure detection interval must be greater than or equal to 150 milliseconds.
- When asynchronous mode is available, the minimum interval must be greater than or equal to 250 milliseconds, with a multiplier of 3 for up to 100 sessions per line card.
- When asynchronous mode is available, the minimum interval must be greater than or equal to 15 milliseconds for up to 100 sessions on the line card. If you are running the maximum of 1440 sessions, the failure detection interval must be greater than or equal to 150 milliseconds.
- When echo mode is available, the minimum interval must be greater than or equal to 15 milliseconds for up to 100 sessions on the line card. If you are running the maximum of 1024 sessions, the failure detection interval must be less than or equal to 150 milliseconds.
- When echo mode is available, the minimum interval must be 50 milliseconds with a multiplier of 3.

- When echo mode is available, the minimum interval must be greater than or equal to 15 milliseconds for up to 100 sessions on the line card. If you are running the maximum of 1440 sessions, the failure detection interval must be less than or equal to 150 milliseconds.

**Task ID**

| Task ID   | Operations  |
|-----------|-------------|
| bgp       | read, write |
| isis      | read, write |
| mpls-te   | read, write |
| ospf      | read, write |
| multicast | read, write |

**Examples**

The following example shows how to set the BFD minimum interval for a BGP routing process:

```
RP/0/0/CPU0:router(config)# router bgp 6500
RP/0/0/CPU0:router(config-bgp)# bfd minimum-interval 275
```

| Release 3.3.0 | This command was introduced.                                                                |
| Release 3.4.0 | The <b>bfd multiplier</b> command was supported in router PIM interface configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

In OSPF environments, the setting of the **bfd multiplier** command is inherited from the highest-level configuration mode in which the command was configured. From the lowest to the highest configuration modes, the inheritance rules are as follows:

- If you configure a multiplier in area interface configuration mode, the updated multiplier affects the BFD sessions on the specified interface only.
- If you configure a multiplier in area configuration mode, the updated multiplier affects the BFD sessions on all interfaces in the specified area.
- If you configure a multiplier in router configuration mode, the updated multiplier affects the BFD sessions in all areas and all associated interfaces in the specified routing process.

If desired, you can override these inheritance rules by explicitly configuring the **bfd multiplier** command for a specific area interface or area.

If the multiplier is changed using the **bfd multiplier** command, the new value is used to update all existing BFD sessions for the protocol (BGP, IS-IS, MPLS-TE, or OSPF).

### Task ID

| Task ID   | Operations  |
|-----------|-------------|
| bgp       | read, write |
| isis      | read, write |
| mpls-te   | read, write |
| ospf      | read, write |
| multicast | read, write |

### Examples

The following example shows how to set the BFD multiplier in a BGP routing process:

```
RP/0/0/CPU0:router(config)# router bgp 65000
RP/0/0/CPU0:router(config-bgp)# bfd multiplier 2
```

### Related Commands

# clear bfd counters

To clear Bidirectional Forwarding Detection (BFD) counters, use the **clear bfd counters** command in EXEC mode.

**clear bfd counters** {**ipv4**| [**singlehop**] || [**singlehop**] || **all**| **label**} [**packet**] [**timing**] [**interface type interface-path-id**] **location node-id**

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>              | (Optional) Clears BFD over IPv4 information only.                                                                                                                                                                                                                                 |
| <b>all</b>               | (Optional) Clears BFD over IPv4 information.                                                                                                                                                                                                                                      |
| <b>packet</b>            | (Optional) Specifies that packet counters are cleared.                                                                                                                                                                                                                            |
| <b>timing</b>            | (Optional) Specifies that timing counters are cleared.                                                                                                                                                                                                                            |
| <b>interface</b>         | (Optional) Specifies the interface from which the BFD packet counters are cleared.                                                                                                                                                                                                |
| <i>type</i>              | Specifies the interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                             |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <b>location node-id</b>  | Clears BFD counters from the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation.                                                                                                                                                  |

## Command Default

The default is the default address family identifier (AFI) that is set by the **set default-afi** command.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                        |
|---------------|---------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                        |
| Release 3.7.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>all</b> keywords were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For the *interface-path-id* argument, use the following guidelines:

- If specifying a physical interface, the naming notation is *rack/slot/module/port*. The slash between values is required as part of the notation. An explanation of each component of the naming notation is as follows:
  - *rack*: Chassis number of the rack.
  - *slot*: Physical slot number of the line card.
  - *module*: Module number. A physical layer interface module (PLIM) is always 0.
  - *port*: Physical port number of the interface.
- If specifying a virtual interface, the number range varies, depending on interface type.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

### Examples

The following example shows how to clear the BFD IPv4 timing counters:

```
RP/0/0/CPU0:router# clear bfd counters ipv4 timing location 0/5/cpu0
```

### Related Commands

| <a href="#">show bfd, on page 571</a>             | Displays BFD information for a specific location.                                                             |

## dampening (BFD)

To specify delays for BFD session startup, use the **dampening** command in Bidirectional Forwarding Detection (BFD) configuration mode. To return to the default, use the **no** form of this command.

**dampening** [**bundle-member**] {**initial-wait**| **maximum-wait**| **secondary-wait**} *milliseconds*

**no dampening** [**bundle-member**] {**initial-wait**| **maximum-wait**| **secondary-wait**} *milliseconds*

### Syntax Description

|                       |                                                                                                                                                                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bundle-member</b>  | (Optional) Specifies initial, maximum, or secondary delays in milliseconds for BFD session startup on BFD bundle members.                                                                                                                           |
| <b>initial-wait</b>   | Specifies the initial delay in milliseconds before starting a BFD session. For bundle members, the default is 16000. For non-bundle interfaces, the default is 2000.                                                                                |
| <b>maximum-wait</b>   | Specifies the maximum delay in milliseconds before starting a BFD session. For bundle members, the default is 600000. For non-bundle interfaces, the default is 12000.<br><br><b>Note</b> The maximum delay must be greater than the initial delay. |
| <b>secondary-wait</b> | Specifies a secondary delay in milliseconds before starting a BFD session. For bundle members, the default is 20000. For non-bundle interfaces, the default is 5000.                                                                                |
| <i>milliseconds</i>   | Number from 1 to 3600000.                                                                                                                                                                                                                           |

### Command Default

BFD session startup delays are not configured and the default timer is indefinite.

### Command Modes

BFD configuration

### Command History

| Release       | Modification                                |
|---------------|---------------------------------------------|
| Release 3.9.0 | This command was introduced.                |
| Release 4.0.0 | The <b>bundle-member</b> keyword was added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You do not have to configure the BFD startup timers. If you do configure the initial wait startup timer (using the **initial-wait** keyword), then it must be less than the value of the maximum wait timer.

By default, BFD dampening is applied to all sessions in the following manner:

- If a session is brought down, then dampening is applied before a session is allowed to transition to initial/up states.
- Length of time a session is dampened grows exponentially with continuous session flap.
- If a session remains up for minimum two minutes, then the length of time a session dampens with the next session flap is reset to the initial dampening value.

BFD on bundle member applies dampening, only if the detected failure is specific to layer 3. BFD dampening is not invoked for L1 or L2 failures. BFD is started after Layer 1 and Layer 2 (LACP) is up to prevent a race condition and false triggers. BFD is notified to stop/ignore when L1 or L2 goes down and must be notified to start/resume when L1 or L2 recovers for a given/affected link/member.

BFD applies dampening till the session transitions from up to down state and the session is not removed. Whenever there is a failure detected at L1 or L2, the bundle manager removes BFD session on a member.

When dampening is removed a syslog message 'Exponential backoff dampening for BFD session has been cleared for specified BFD session. When/if same session gets created by application(s), only calculated initial wait time will be applied' is generated. If this is the desired behavior, then dampening can be enabled by configuring the BFD configuration, by using the command **bfd dampening bundle-member l3-failure-only**.

#### Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

#### Examples

The following example shows how to configure an initial and maximum delay for BFD session startup on BFD bundle members:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# dampening bundle-member initial-wait 8000
RP/0/0/CPU0:router(config-bfd)# dampening bundle-member maximum-wait 15000
```

The following example shows how to change the default initial-wait for BFD on a non-bundle interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# dampening initial-wait 30000
RP/0/0/CPU0:router(config-bfd)# dampening maximum-wait 35000
```

**Related Commands**

| Command                           | Description                    |
|-----------------------------------|--------------------------------|
| <a href="#">bfd</a> , on page 529 | Enters BFD configuration mode. |

# echo disable

To disable echo mode on a router or on an individual interface or bundle, use the **echo disable** command in Bidirectional Forwarding Detection (BFD) configuration mode. To return the router to the default configuration where echo mode is enabled, use the **no** form of this command.

**echo disable**

**no echo disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** No default behavior or values

**Command Modes** BFD configuration  
BFD interface configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you are using BFD with Unicast Reverse Path Forwarding (uRPF), you need to use the **echo disable** command to disable echo mode; otherwise, echo packets are rejected.

**Note** To enable or disable IPv4 uRPF checking on an IPv4 interface, use the **[no] ipv4 verify unicast source reachable-via** command in interface configuration mode.

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

## Examples

The following example shows how to disable echo mode on a router:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo disable
```

The following example shows how to disable echo mode on an individual interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# interface gigabitethernet 0/1/0/0
RP/0/0/CPU0:router(config-bfd-if)# echo disable
```

## Related Commands

|----------------------------------------------------------|---------------------------------------------------------------|
| <a href="#">bfd</a> , on page 529                        | Enters BFD configuration mode.                                |
| <a href="#">interface (BFD)</a> , on page 567            | Enters BFD interface configuration mode.                      |
| <a href="#">ipv4 verify unicast source reachable-via</a> | Enables and disables IPv4 uRPF checking on an IPv4 interface. |
| <a href="#">show bfd</a> , on page 571                   | Displays BFD information.                                     |

# echo ipv4 source

To specify the IP address that you want to use as the source address for BFD echo packets, use the **echo ipv4 source** command in BFD or BFD interface configuration mode. To return to the default, use the **no** form of this command.

**echo ipv4 source** *ip-address*

**no echo ipv4 source** *ip-address*

## Syntax Description

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <i>ip-address</i> | 32-bit IPv4 address in dotted-decimal format (A.B.C.D). |
|-------------------|---------------------------------------------------------|

## Command Default

The IP address of the output interface, or the IP address in the **router-id** command (if configured), is the default address used for an echo packet when the **echo ipv4 source** command is not configured.

## Command Modes

BFD configuration  
BFD interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If you do not configure the IPv4 source address for echo packets, then BFD uses the IP address of the output interface or the address in the **router-id** command if specified.

You can override the default address for BFD echo packets by specifying an IPv4 source address for echo packets globally for all BFD sessions on the router and at an individual interface. Specifying the IP address at an individual interface will override any value specified globally for BFD on the router.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

## Examples

The following example shows how to specify the IP address 10.10.10.1 as the source address for BFD echo packets for all BFD sessions on the router:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo ipv4 source 10.10.10.1
```

The following example shows how to specify the IP address 10.10.10.1 as the source address for BFD echo packets on an individual Gigabit Ethernet interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# interface gigabitethernet 0/1/0/0
RP/0/0/CPU0:router(config-bfd-if)# echo ipv4 source 10.10.10.1
```

The following example shows how to specify the IP address 10.10.10.1 as the source address for BFD echo packets on an individual Packet-over-SONET (POS) interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# interface pos 0/1/0/0
RP/0/0/CPU0:router(config-bfd-if)# echo ipv4 source 10.10.10.1
```

# echo latency detect

To enable latency detection for BFD echo packets, use the **echo latency detect** command in BFD configuration mode. To return to the default, use the **no** form of this command.

**echo latency detect** [**percentage** *percent-value* [**count** *packet-count*]]

**no echo latency detect** [**percentage** *percent-value* [**count** *packet-count*]]

## Syntax Description

|                                        |                                                                                                                                                            |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>percentage</b> <i>percent-value</i> | (Optional) Percentage of the echo failure detection time to be detected as bad latency. The range is 100 to 250. The default is 100.                       |
| <b>count</b> <i>packet-count</i>       | (Optional) Number of consecutive packets received with the detected bad latency that will take down a BFD session. The range is 1 to 10. The default is 1. |

## Command Default

Echo latency detection is disabled.

## Command Modes

BFD configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Note

Latency detection is only valid where echo mode is supported for BFD. However, it is not supported on bundle interfaces.

Without latency detection, standard BFD echo failure detection tracks only the absence of receipt of echo packets within a period of time based on a counter. However, this standard echo failure detection does not address latency between transmission and receipt of any specific echo packet, which can build beyond desired tolerances over the course of the BFD session.

When latency detection is enabled, a percentage is multiplied to the echo failure detection value ( $I \times M \times \%$ ), and the roundtrip delay is computed for the echo packet. If this delay is greater than ( $I \times M \times \%$ ), then the BFD session is taken down.

If you have specified a packet count, then the system tracks the number of packets received back-to-back with bad latency before taking down the session.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

**Examples**

In the following examples, consider that the BFD minimum interval is 50 ms, and the multiplier is 3 for the BFD session.

The following example shows how to enable echo latency detection using the default values of 100% of the echo failure period (I x M) for a packet count of 1. In this example, when one echo packet is detected with a roundtrip delay greater than 150 ms, the session is taken down:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo latency detect
```

The following example shows how to enable echo latency detection based on 200% (two times) of the echo failure period for a packet count of 1. In this example, when one packet is detected with a roundtrip delay greater than 300 ms, the session is taken down:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo latency detect percentage 200
```

The following example shows how to enable echo latency detection based on 100% of the echo failure period for a packet count of 3. In this example, when three consecutive echo packets are detected with a roundtrip delay greater than 150 ms, the session is taken down:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo latency detect percentage 100 count 3
```

**Related Commands**

|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">bfd</a> , on page 529                   | Enters BFD configuration mode.                                                                                |
| <a href="#">bfd minimum-interval</a> , on page 546  | Specifies the minimum control packet interval for BFD sessions for the corresponding BFD configuration scope. |
| <a href="#">bfd multiplier</a> , on page 551        | Sets the BFD multiplier.                                                                                      |
| <a href="#">echo startup validate</a> , on page 565 | Enables verification of the echo packet path before starting a BFD session.                                   |

# echo startup validate

To enable verification of the echo packet path before starting a BFD session, use the **echo startup validate** command in BFD configuration mode. To return to the default, use the **no** form of this command.

**echo startup [force]**

**no echo startup [force]**

## Syntax Description

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| <b>force</b> | (Optional) Ignores the remote 'Required Min Echo RX Interval' setting. |
|--------------|------------------------------------------------------------------------|

## Command Default

Echo startup validation is disabled.

## Command Modes

BFD configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Note

Echo validation is only valid where echo mode is supported for BFD. However, it is not supported on bundle interfaces.

When a BFD session is down and the **echo startup validate** command is configured, an echo packet is periodically transmitted on the link while it is down to verify successful transmission within the configured latency before allowing the BFD session to change state.

Without the **force** option, the echo validation test only runs if the last received control packet contains a non-zero "Required Min Echo RX Interval" value. When the **force** keyword is configured, the echo validation test runs regardless of this value.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |
| mpls-te | read, write |

## Examples

The following example shows how to enable echo startup validation for BFD sessions on non-bundle interfaces if the last received control packet contains a non-zero “Required Min Echo RX Interval” value:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo startup validate
```

The following example shows how to enable echo startup validation for BFD sessions on non-bundle interfaces regardless of the “Required Min Echo RX Interval” value in the last control packet:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# echo startup validate force
```

## Related Commands

| Command                                           | Description                                     |
|---------------------------------------------------|-------------------------------------------------|

| <a href="#">echo latency detect</a> , on page 563 | Enables latency detection for BFD echo packets. |

## interface (BFD)

To enter Bidirectional Forwarding Detection (BFD) interface configuration mode, where you can disable echo mode on an interface, use the **interface** command in BFD configuration mode. To return to BFD configuration mode, use the **no** form of this command.

**interface** *type interface-path-id*

**no interface** *type interface-path-id*

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                 |

| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |

### Command Default

No default behavior or values

### Command Modes

BFD configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For the *interface-path-id* argument, use the following guidelines:

- If specifying a physical interface, the naming notation is *rack/slot/module/port*. The slash between values is required as part of the notation. An explanation of each component of the naming notation is as follows:
  - *rack*: Chassis number of the rack.
  - *slot*: Physical slot number of the line card.
  - *module*: Module number. A physical layer interface module (PLIM) is always 0.
  - *port*: Physical port number of the interface.
- If specifying a virtual interface, the number range varies, depending on interface type.

If you are using BFD with Unicast Reverse Path Forwarding (uRPF) on a particular interface, then you need to use the **echo disable** command in BFD interface configuration mode to disable echo mode on that interface; otherwise, echo packets are rejected by the interface.

**Note**

To enable or disable IPv4 uRPF checking on an IPv4 interface, use the **[no] ipv4 verify unicast source reachable-via** command in interface configuration mode.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

**Examples**

The following example shows how to enter BFD interface configuration mode for a Gigabit Ethernet interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# interface gigabitethernet 0/1/0/0
RP/0/0/CPU0:router(config-bfd-if)#
```

The following example shows how to enter BFD interface configuration mode for a Packet-over-SONET/SDH (POS) interface:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# bfd
RP/0/0/CPU0:router(config-bfd)# interface pos 0/1/0/0
RP/0/0/CPU0:router(config-bfd-if)#
```

**Related Commands**

| Command                                                  | Description                                                            |

| <a href="#">show bfd</a> , on page 571                   | Displays BFD information.                                              |

# multihop ttl-drop-threshold

To specify the maximum time to live (TTL) value for multihop sessions per system, use the **multihop ttl-drop-threshold** command in the BFD configuration mode. To return to the default, use the **no** form of this command.

**multihop ttl-drop-threshold** *value*

**no multihop ttl-drop-threshold** *value*

## Syntax Description

|              |                                                                              |
|--------------|------------------------------------------------------------------------------|
| <i>value</i> | Specifies the configurable range of values for TTL. It ranges from 0 to 254. |
|--------------|------------------------------------------------------------------------------|

## Command Default

No default behavior or values

## Command Modes

BFD configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Note

This configuration command is only applicable for BFD multihop sessions.

## Task ID

| Task ID | Operation   |
|---------|-------------|
| bgp     | read, write |
| ospf    | read, write |
| isis    | read, write |
| mpls-te | read, write |

## Examples

This example shows how to set the maximum ttl value as 2 using the **multihop-ttl-drop-threshold** command:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router#bfd multihop ttl-drop threshold 2
```

## Related Commands

# show bfd

To display Bidirectional Forwarding Detection (BFD) information for a specific location, use the **show bfd** command in EXEC mode.

```
show bfd [ipv4| [singlehop| ]] all[label]interface[destination| ] [location node-id]
```

## Syntax Description

|                         |                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>             | (Optional) Displays BFD over IPv4 information only.                                                                                  |
| <b>all</b>              | (Optional) Displays BFD over IPv4 information.                                                                                       |
| <b>label</b>            | (Optional) Displays the BFD label information.                                                                                       |
| <b>interface</b>        | Specifies the BFD interface.                                                                                                         |
| <b>destination</b>      | (Optional) Specifies the destination IPv4 unicast address.                                                                           |
| <b>source</b>           | (Optional) Specifies the source IPv4 unicast address.                                                                                |
| <b>location node-id</b> | Displays BFD information for the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. |

## Command Default

The default is the default address family identifier (AFI) that is set by the **set default-afi** command.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |

## Examples

The following example shows the output from the **show bfd** command:

```
RP/0/0/CPU0:router# show bfd
IPV4 Sessions Up: 0, Down: 0, Total: 0
```

The following example shows the output from the **show bfd all** command:

```
RP/0/0/CPU0:router# show bfd all
IPv4:
-----
IPV4 Sessions Up: 20, Down: 0, Unknown/Retry: 2, Total: 22
IPv6:
-----
IPV6 Sessions Up: 128, Down: 2, Unknown/Retry: 1, Total: 131
Label:
-----
Label Sessions Up: 10, Down: 0, Unknown/Retry: 1, Total: 11
```

The following example shows the output from the **show bfd ipv4** command:

```
RP/0/0/CPU0:router# show bfd ipv4
IPV4 Sessions Up: 0, Down: 0, Total: 0
```

The following example shows the output from the **show bfd ipv4 location** command:

```
RP/0/0/CPU0:router# show bfd ipv4 location 0/3/cpu0
IPV4 Sessions Up: 0, Down: 1, Standby: 0, Total: 1
```

## Related Commands

## Examples

The following example shows the output from the **show bfd client** command:

```
RP/0/0/CPU0:router# show bfd client
Name           Node           Num sessions
-----
```

```

bgp          0/0/CPU0 0
isis         0/0/CPU0 0
isis         0/0/CPU0 0

```

**Table 45: show bfd client Field Descriptions**

| Field        | Description                                   |
|--------------|-----------------------------------------------|
| Name         | Name of the BFD client.                       |
| Node         | Location of the BFD client.                   |
| Num sessions | Number of active sessions for the BFD client. |

**Related Commands**

# show bfd counters

To display Bidirectional Forwarding Detection (BFD) counter information, use the **show bfd counters** command in EXEC mode.

**show bfd counters** [**ipv4** | [**singlehop** | ] | **all** | **label**] **packet** [**interface** *type interface-path-id*] **location** *node-id*

## Syntax Description

|                                |                                                                                                                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                    | (Optional) Displays BFD over IPv4 information only.                                                                                                                                                                                                                             |
| <b>all</b>                     | (Optional) Displays BFD over IPv4 information.                                                                                                                                                                                                                                  |
| <b>packet</b>                  | Specifies that packet counters are displayed.                                                                                                                                                                                                                                   |
| <b>interface</b>               | (Optional) Specifies the interface for which to show counters.                                                                                                                                                                                                                  |
| <i>type</i>                    | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i>       | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <b>location</b> <i>node-id</i> | Displays BFD counters from the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation.                                                                                                                                              |

## Command Default

The default is the default address family identifier (AFI) that is set by the **set default-afi** command.

## Command Modes

EXEC

|---------------|---------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                        |
| Release 3.7.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>all</b> keywords were added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For the *interface-path-id* argument, use the following guidelines:

- If specifying a physical interface, the naming notation is *rack/slot/module/port*. The slash between values is required as part of the notation. An explanation of each component of the naming notation is as follows:
  - *rack*: Chassis number of the rack.
  - *slot*: Physical slot number of the line card.
  - *module*: Module number. A physical layer interface module (PLIM) is always 0.
  - *port*: Physical port number of the interface.
- If specifying a virtual interface, the number range varies, depending on interface type.

**Task ID**

| Task ID | Operations |
|---------|------------|
| bgp     | read       |
| ospf    | read       |
| isis    | read       |
| mpls-te | read       |

**Examples**

The following example shows the output from the **show bfd counters packet** command for IPv4:

```
RP/0/0/CPU0:router# show bfd counters ipv4 packet

IPv4 Singlehop:
GigabitEthernet0/0/1/2          Recv      Xmit      Echo: (   Recv      Xmit
  Async:          4148      4137      Echo: (  47136)    80192
GigabitEthernet0/1/1/2          Recv      Xmit      Echo: (   Recv      Xmit
  Async:    116876    125756      Echo: ( 2268192)  2301312
Bundle-Ether10                  Recv      Xmit      Echo:      Recv      Xmit
  Async:           2         0      Echo:          0         0
Bundle-Ether20                  Recv      Xmit      Echo:      Recv      Xmit
  Async:          91         0      Echo:          0         0

IPv4 Multihop: (Src IP/Dst IP/Vrf Id)
33.15.151.4/33.16.151.4/0x12345678  Recv      Xmit
  Async:           0      570337
```

**Table 46: show bfd counters packet Field Descriptions**

| Field | Description                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------|
| Async | Number of asynchronous mode (control) packets that were received or transmitted on the specified interface. |
| Echo  | Number of echo packets that were received or transmitted on the specified interface.                        |

# show bfd mib session

To display IPv4 Bidirectional Forwarding Detection (BFD) MIB session information, use the **show bfd mib session** command in EXEC mode.

**show bfd mib session** [*location node-id*]

## Syntax Description

|                                |                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>location</b> <i>node-id</i> | (Optional) Displays all IPv4 BFD MIB session information stored on the specified node. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Command Default

When *node-id* is not specified, information for all IPv4 BFD MIB sessions, stored on the route processor node, is displayed.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When *node-id* is not specified, information for all IPv4 BFD MIB sessions, stored on the route processor node, is displayed, and this information is populated and updated only after SNMP operations for those BFD MIB sessions are performed.

When *node-id* is specified, information for all IPv4 BFD MIB sessions, stored on the specified node (linecard), is displayed, and this information is updated automatically without SNMP operations being performed.

## Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |
| ospf    | read       |
| isis    | read       |
| mpls-te | read       |

**Examples**

The following example displays all IPv4 BFD MIB session information stored on the RP node:

```
RP/0/0/CPU0:router# show bfd mib session

Tue Sep  9 07:49:30.828 PST DST
Local Discr: 327681(0x50001), Remote Discr: 0(0x0)
BFD session: GigabitEthernet0_1_5_2(0x11800c0), 10.27.4.7
  Current State: ADMIN DOWN, Number of Times UP: 0
  Running Version: 0, Last Down Diag: None
  Last Up Time (s.ns): 0.0
  Last Down Time (s.ns): 0.0
  Detection Multiplier: 0
  Desired Min TX Interval: 0
  Required Min RX Interval: 0
  Required Min RX Echo Interval: 0
  Packets in/out: 0/0
  Current Trap Bitmap: 0x0
  Last Time Cached: Not yet cached
```

The following example displays all IPv4 and IPv6 BFD MIB session information stored on 0/1/CPU0:

```
RP/0/0/CPU0:router# show bfd mib session location 0/1/CPU0

Tue Sep  9 07:44:49.190 PST DST
Local Discr: 327681(0x50001), Remote Discr: 0(0x0)
BFD session: GigabitEthernet0_1_5_2(0x11800c0), 10.27.4.7
  Number of times UP: 0
  Last Down Diag: None
  Last Up Time (s.ns): 0.0
  Last Down Time (s.ns): 0.0
  Packets in/out: 0/1140134
```

**Table 47: show bfd mib Field Descriptions**

| Field              | Description                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| date and timestamp | Date and time stamp during which a snapshot of the BFD MIB session information is taken.                                               |
| Local Discr        | Local discriminator (in decimal and hexadecimal) that uniquely identifies the BFD MIB session.                                         |
| Remote Discr       | Session discriminator (in decimal and hexadecimal) that was chosen by the remote system for the BFD MIB session.                       |
| BFD session        | Index of interface upon which the BFD MIB session is running. Also, neighboring IP address that is monitored with the BFD MIB session. |
| Current State      | Current state of the BFD MIB session.                                                                                                  |
| Number of Times UP | Number of times the BFD MIB session has gone into the up state since the router was last rebooted.                                     |

| Field                         | Description                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Running Version               | BFD protocol version number in which the BFD MIB session is running.                                                                                                  |
| Last Down Diag                | Diagnostic value associated with the last time the BFD MIB session went down.                                                                                         |
| Last Up Time (s.ns)           | Value of sysUpTime, in <i>seconds.nanoseconds</i> , during which the BFD MIB session last came up. If such an event does not exist, a zero is displayed.              |
| Last Down Time (s.ns)         | Value of sysUpTime, in <i>seconds.nanoseconds</i> , during which communication was last lost with the neighbor. If such an event does not exist, a zero is displayed. |
| Detection Multiplier          | Failure detection multiplier.                                                                                                                                         |
| Desired Min TX Interval       | Minimum interval, in microseconds, preferred by the local system when transmitting BFD control packets.                                                               |
| Required Min RX Interval      | Minimum interval, in microseconds, that the local system supports between received BFD control packets.                                                               |
| Required Min RX Echo Interval | Minimum interval, in microseconds, that the local system supports between received BFD echo packets.                                                                  |
| Packets in/out                | Total number of BFD messages received and transmitted for the BFD MIB session.                                                                                        |
| Current Trap Bitmap           | Bits that control the trap for the BFD MIB session. A nonzero value indicates that the trap is generated when the next trap event is triggered.                       |
| Last Time Cached              | When information for the BFD MIB session was last cached. Typically, the information is cached when SNMP operations for the BFD MIB session are performed.            |

## Related Commands

| Command                                        | Description |
|------------------------------------------------|-------------|
| <a href="#">show bfd session</a> , on page 583 |             |

# show bfd multipath

To display information concerning only BFD multipath sessions, use the **show bfd multipath** command in the EXEC mode.

**show bfd multipath** {**ipv4**| **ipv6**| **label**| **all**} **location** *node-id*

## Syntax Description

|                                |                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                    | Displays BFD over IPv4 information only.                                                                                           |
| <b>ipv6</b>                    | Displays BFD over IPv6 information only.                                                                                           |
| <b>label</b>                   | Displays BFD label information.                                                                                                    |
| <b>all</b>                     | Displays both BFD over IPv4 and BFD over IPv6 information.                                                                         |
| <b>location</b> <i>node-id</i> | Displays BFD counters from the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. |

## Command Default

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation |
|---------|-----------|
| bgp     | read      |
| ospf    | read      |
| isis    | read      |
| mpls-te | read      |

## Examples

This example shows the sample output for **show bfd multipath** command:

RP/0/0/CPU0:router#show bfd multipath location 0/5/cpu0

| Int/Src Addr | Label/Dest Addr | VRF ID     | Discr | Node     | State |
|--------------|-----------------|------------|-------|----------|-------|
| pw-ether 1   | 10.10.10.10     | 0x00000002 | 0x4   | 0/5/CPU0 | DOWN  |
| tunnel-ip 1  | 1.1.1.1         | 0x8        | 0x5   | 0/5/CPU0 | UP    |

# show bfd session

To display Bidirectional Forwarding Detection (BFD) session information, use the **show bfd session** command in EXEC mode.

**show bfd** [**ipv4** | [**singlehop** | ]] [**ipv6** | [**singlehop** | ]] **all** | **label**] **session** [**interface** *type interface-path-id* [**destination** *ip-address*] [**detail**][**in-label**]] **location** *node-id*

## Syntax Description

|                                      |                                                                                                                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                          | (Optional) Displays BFD over IPv4 information only.                                                                                                                                                                                                                             |
| <b>all</b>                           | (Optional) Displays BFD over IPv4 information.                                                                                                                                                                                                                                  |
| <b>label</b>                         | (Optional) Displays the MPLS Transport Profile (MPLS-TP) label BFD information only.                                                                                                                                                                                            |
| <b>interface</b>                     | (Optional) Specifies the interface for which to show information.                                                                                                                                                                                                               |
| <i>type</i>                          | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                           |
| <i>interface-path-id</i>             | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |
| <b>destination</b> <i>ip-address</i> | (Optional) Displays the BFD session destined for the specified IP address.                                                                                                                                                                                                      |
| <b>detail</b>                        | (Optional) Displays detailed session information, including statistics and number of state transitions.                                                                                                                                                                         |
| <b>in-label</b>                      | (Optional) Displays the BFD session with a specific incoming MPLS-TP label.                                                                                                                                                                                                     |
| <b>location</b> <i>node-id</i>       | (Optional) Displays BFD sessions hosted from the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation.                                                                                                                            |

## Command Default

The default is the default address family identifier (AFI) that is set by the **set default-afi** command.

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

| Release       | Modification                                                        |
|---------------|---------------------------------------------------------------------|
| Release 3.7.0 | The <b>ipv4</b> , <b>ipv6</b> , and <b>all</b> keywords were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For the *interface-path-id* argument, use the following guidelines:

- If specifying a physical interface, the naming notation is *rack/slot/module/port*. The slash between values is required as part of the notation. An explanation of each component of the naming notation is as follows:
  - *rack*: Chassis number of the rack.
  - *slot*: Physical slot number of the line card.
  - *module*: Module number. A physical layer interface module (PLIM) is always 0.
  - *port*: Physical port number of the interface.
- If specifying a virtual interface, the number range varies, depending on interface type.

#### Note

Only VRF ID is displayed in the summary CLI (such as **show bfd multiple-path**, **show bfd all session**, **show bfd counters**) and VRF name and VRF ID is displayed in the detailed CLI (such as **show bfd all session detail**, **show bfd all session status**).

### Task ID

| Task ID | Operations |
|---------|------------|
| bgp     | read       |
| ospf    | read       |
| isis    | read       |
| mpls-te | read       |

### Examples

The following example shows the output from the **show bfd session** command with the **detail** keyword and IPv4 as the default:

```
RP/0/0/CPU0:router# show bfd session detail
I/f:TenGigE0/2/0/0.6, Location:0/2/CPU0, dest:10.0.6.2, src:10.0.6.1
State:UP for 0d:0h:3m:4s, number of times UP:1
Received parameters:
Version:1, desired tx interval:2 s, required rx interval:2 s
Required echo rx interval:1 ms, multiplier:3, diag:None
My discr:589830, your discr:590028, state UP, D/F/P/C/A:0/0/0/1/0
```

```

Transmitted parameters:
  Version:1, desired tx interval:2 s, required rx interval:2 s
  Required echo rx interval:1 ms, multiplier:3, diag:None
  My discr:590028, your discr:589830, state UP, D/F/P/C/A:0/0/0/1/0
Timer Values:
  Local negotiated async tx interval:2 s
  Remote negotiated async tx interval:2 s
  Desired echo tx interval:250 ms, local negotiated echo tx interval:250 ms
  Echo detection time:750 ms(250 ms*3), async detection time:6 s(2 s*3)
Local Stats:
  Intervals between async packets:
    Tx:Number of intervals=100, min=952 ms, max=2001 ms, avg=1835 ms
      Last packet transmitted 606 ms ago
    Rx:Number of intervals=100, min=1665 ms, max=2001 ms, avg=1828 ms
      Last packet received 1302 ms ago
  Intervals between echo packets:
    Tx:Number of intervals=100, min=250 ms, max=252 ms, avg=250 ms
      Last packet transmitted 188 ms ago
    Rx:Number of intervals=100, min=250 ms, max=252 ms, avg=250 ms
      Last packet received 187 ms ago
  Latency of echo packets (time between tx and rx):
    Number of packets:100, min=1 ms, max=2 ms, avg=1 ms
Session owner information:
  Client          Desired interval      Multiplier
  -----
  bgp-            250 ms                      3

```

The following example shows the output from the **show bfd session** command with the **all** keyword, which displays both IPv4 and IPv6 information:

```

RP/0/0/CPU0:router# show bfd all session location 0/1/CPU0

Mon Nov  5 08:51:50.339 UTC
IPv4:
-----
Interface          Dest Addr          Local det time(int*mult)      State
                   Echo              Async
-----
PO0/1/0/0          10.0.0.2           300ms(100ms*3)      6s(2s*3)      UP

IPv6:
-----
Interface          Dest Addr          Local det time(int*mult)      State
                   Echo              Async
-----
PO0/1/0/0          abcd::2            0s(0s*0)            15s(5s*3)      UP

```

**Table 48: show bfd session detail command Field Descriptions**

| Field    | Description                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------|
| I/f      | Interface type.                                                                                               |
| Location | Location of the node that hosts the local endpoint of the connection, in the <i>rack/slot/module</i> notation |
| dest     | IP address of the destination endpoint.                                                                       |
| src      | IP address of the source endpoint.                                                                            |

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Command                                           | Description                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <a href="#">bfd fast-detect, on page 543</a>      | Enables BFD to detect failures in the path between adjacent forwarding engines.                               |
| <a href="#">bfd minimum-interval, on page 546</a> | Specifies the minimum control packet interval for BFD sessions for the corresponding BFD configuration scope. |
| <a href="#">bfd multiplier, on page 551</a>       | Sets the BFD multiplier.                                                                                      |
| <a href="#">show bfd mib session, on page 578</a> | Displays BFD MIB session information.                                                                         |

# show bfd summary

To display the percentage of PPS rate in use per line card, maximum usage of PPS, and total number of sessions, use the **show bfd summary** command in the EXEC mode.

**show bfd summary** [**private**]*location**node-id*

## Syntax Description

|                                |                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>private</b>                 | Displays the private information.                                                                                                  |
| <b>location</b> <i>node-id</i> | Displays BFD counters from the specified location. The <i>node-id</i> argument is entered in the <i>rack/slot/module</i> notation. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operation |
|---------|-----------|
| bgp     | read      |
| ospf    | read      |
| isis    | read      |
| mpls-te | read      |

## Examples

This example shows the sample output from the **show bfd summary** command for a specified location:

```
RP/0/0/CPU0:router#show bfd summary location 0/1/cpu0
```

## show bfd summary

| Node     | PPS<br>% | rate<br>Used | usage<br>Max | Session<br>Total | number<br>Max |
|----------|----------|--------------|--------------|------------------|---------------|
| 0/1/CPU0 | 0        | 80           | 9600         | 4                | 4000          |

This example shows the sample output from the **show bfd summary** command:

```
RP/0/0/CPU0:router#show bfd summary
```

| Node     | PPS<br>% | rate<br>Used | usage<br>Max | Session<br>Total | number<br>Max |
|----------|----------|--------------|--------------|------------------|---------------|
| 0/0/CPU0 | 0        | 0            | 9600         | 0                | 4000          |
| 0/1/CPU0 | 0        | 0            | 9600         | 0                | 4000          |
| 0/2/CPU0 | 0        | 0            | 9600         | 0                | 4000          |
| 0/5/CPU0 | 0        | 0            | 9600         | 0                | 4000          |
| 0/6/CPU0 | 0        | 0            | 9600         | 0                | 4000          |
| 0/7/CPU0 | 0        | 0            | 9600         | 0                | 4000          |

# Enhanced Interior Gateway Routing Protocol Commands

---

This module describes the commands used to configure and monitor the Enhanced Interior Gateway Routing Protocol (EIGRP).

For detailed information about EIGRP concepts, configuration tasks, and examples, see *Implementing EIGRP on Cisco IOS XR Software* module in *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

## address-family (EIGRP)

To enable an IPv4 or IPv6 address family under Enhanced Interior Gateway Routing Protocol (EIGRP), use the **address-family** command in the appropriate mode. To remove the address family from the EIGRP configuration, use the **no** form of this command.

**address-family** {ipv4| ipv6}

**no address-family** {ipv4| ipv6}

### Syntax Description

|             |                              |
|-------------|------------------------------|
| <b>ipv4</b> | Selects IPv4 address family. |
| <b>ipv6</b> | Selects IPv6 address family. |

### Command Default

No default behavior or values

### Command Modes

Router configuration  
VRF configuration

### Command History

| Release       | Modification                       |
|---------------|------------------------------------|
| Release 3.3.0 | This command was introduced.       |
| Release 3.5.0 | The <b>ipv6</b> keyword was added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address-family ipv4** command to configure IPv4 address family sessions in EIGRP and the **address-family ipv6** command to configure IPv6 address family sessions in EIGRP.

EIGRP Virtual Private Networks (VPNs) can be configured under IPv4 and IPv6 address family configuration modes after first entering VRF configuration mode. All commands in address family configuration mode can be configured in VRF address families except the **autonomous-system** and **maximum-prefix** commands.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to configure an IPv4 VRF address family session after defining the VRF named `vrf1`:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1  
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# default-metric 1000 100 255 1 1500
```

**Related Commands**

| Command                       | Description                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------|
| <b>autonomous-system</b>      | Configures an EIGRP routing process to run within a VRF.                          |
| <b>maximum-prefix (EIGRP)</b> | Limits the number of prefixes that are accepted under an address family by EIGRP. |

# authentication keychain

To authenticate all EIGRP protocol traffic on one or more interfaces based on the MD5 algorithm, use the **authentication keychain** command in an appropriate configuration mode. To disable authentication, use the **no** form of this command.

**authentication keychain** *key-chain-name*

**no authentication keychain** *key-chain-name*

## Syntax Description

|                       |                                     |
|-----------------------|-------------------------------------|
| <i>key-chain-name</i> | Name of the authentication keychain |
|-----------------------|-------------------------------------|

## Command Default

Authentication is disabled.

## Command Modes

IPv4 address family interface configuration  
IPv6 address family interface configuration  
IPv4 VRF address family interface configuration  
IPv6 VRF address family interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address-family ipv4** command to configure IPv4 address family sessions in EIGRP and the **address-family ipv6** command to configure IPv6 address family sessions in EIGRP.

EIGRP Virtual Private Networks (VPNs) can be configured under IPv4 and IPv6 address family configuration modes after first entering VRF configuration mode.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to enable an EIGRP authentication keychain:

```
RP/0/0/CPU0:router# configure eigrp 1  
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# interface POS 0/2/0/0  
RP/0/0/CPU0:router(config-eigrp-if)# authentication key chain key1
```

## Related Commands

| Command                                   | Description                                                                                                              |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router eigrp, on page 653</a> | Configures a routing process and enter router configuration mode for Enhanced Interior Gateway Routing Protocol (EIGRP). |

## auto-summary (EIGRP)

To allow automatic summarization of subnet routes into network-level routes for an Enhanced Interior Gateway Routing Protocol (EIGRP) process, use the **autosummary** command in the appropriate configuration mode. To disable this function and send subprefix routing information across classful network boundaries, use the **no** form of this command.

**auto-summary**

**no auto-summary**

**Syntax Description** This command has no keywords or arguments.

**Command Default** The behavior of this command is disabled by default. (The software sends subnet routing information across classful network boundaries.)

**Command Modes** IPv4 Address family configuration  
IPv4 VRF address family configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Route summarization reduces the amount of routing information in the routing tables. Use the **auto-summary** command to allow the software to create summary subprefixes to the classful network boundary when crossing classful network boundaries.

EIGRP summary routes are given an administrative distance value of 5. You cannot configure this value.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | eigrp   | read, write |

**Examples** The following example shows how to enable automatic summarization for EIGRP 1:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vpn-1
```

**auto-summary (EIGRP)**

```
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# auto-summary
```

**Related Commands**

| Command                                              | Description                                                       |
|------------------------------------------------------|-------------------------------------------------------------------|
| <a href="#">summary-address (EIGRP), on page 680</a> | Configures a summary aggregate address for a specified interface. |

## autonomous-system

To configure an Enhanced Interior Gateway Routing Protocol (EIGRP) routing process to run within a VPN routing and forwarding instance (VRF), use the **autonomous-system** command in IPv4 VRF address family configuration mode.

**autonomous-system** *as-number*

**no autonomous-system** *as-number*

### Syntax Description

|                  |                                                                                  |
|------------------|----------------------------------------------------------------------------------|
| <i>as-number</i> | Autonomous system number of the EIGRP routing process. Range is from 1 to 65535. |
|------------------|----------------------------------------------------------------------------------|

### Command Default

None

### Command Modes

IPv4 VRF address family configuration.

IPv6 VRF address family configuration.

### Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                              |
| Release 3.5.0 | This command was supported in IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **autonomous-system** command in IPv4 or IPv6 VRF address family configuration mode.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

The following example shows how to configure autonomous system 101 under VRF VPN-1:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp)# vrf vpn-1
```

```
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# autonomous-system 101
```

**Related Commands**

| Command                                  | Description                                                  |
|------------------------------------------|--------------------------------------------------------------|
| <a href="#">vrf (EIGRP), on page 688</a> | Defines a VRF instance and to enters VRF configuration mode. |

## bandwidth-percent (EIGRP)

To configure the percentage of bandwidth that may be used by EIGRP on an interface, use the **bandwidth-percent** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**bandwidth-percent** *percent*

**no bandwidth-percent**

| Syntax Description |                                             |
|--------------------|---------------------------------------------|
| <b>percent</b>     | Percentage of bandwidth that EIGRP may use. |

| Command Default | <i>percent</i> : 50 |
|-----------------|---------------------|
|-----------------|---------------------|

| Command Modes | Interface configuration |
|---------------|-------------------------|
|---------------|-------------------------|

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.3.0 | This command was introduced. |

| Usage Guidelines | <p>To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.</p> <p>EIGRP uses up to 50 percent of the bandwidth of a link, as defined by the bandwidth interface configuration command. This command may be used if some other fraction of the bandwidth is desired. Values greater than 100 percent may be configured. The configuration option may be useful if the bandwidth is set artificially low for other reasons.</p> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | eigrp   | read, write |

| Examples | <p>The following example shows how to configure EIGRP to use up to 75 percent (42 kbps) of an interface in autonomous system 209:</p> |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
|----------|---------------------------------------------------------------------------------------------------------------------------------------|

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
```

**bandwidth-percent (EIGRP)**

```
RP/0/0/CPU0:router(config-eigrp-af-if)# bandwidth-percent 75
```

**Related Commands**

| Command               | Description                              |
|-----------------------|------------------------------------------|
| bandwidth (interface) | Sets a bandwidth value for an interface. |

# clear eigrp neighbors

To remove and re-establish Enhanced Interior Gateway Routing Protocol (EIGRP) neighbor entries from the appropriate table, use the **clear eigrp neighbors** command in EXEC mode.

**clear eigrp** [*as-number*] [**vrf** {*vrf* | *all*}] [**ipv4**| **ipv6**] **neighbors** [*ip-address*| *type interface-path-id*] [**soft**]

## Syntax Description

|                                        |                                                                                                                                                                                                                                                                           |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>                       | (Optional) Autonomous system number. Range is from 1 to 65535.                                                                                                                                                                                                            |
| <b>vrf</b> { <i>vrf</i>   <i>all</i> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                                                                                                                                         |
| <b>ipv4</b>                            | (Optional) Specifies the IPv4 address family.                                                                                                                                                                                                                             |
| <b>ipv6</b>                            | (Optional) Specifies the IPv6 address family.                                                                                                                                                                                                                             |
| <i>ip-address</i>                      | (Optional) Address of the neighbor.                                                                                                                                                                                                                                       |
| <i>type</i>                            | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                   |
| <i>interface-path-id</i>               | Physical interface or virtual interface.<br><br>Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <b>soft</b>                            | (Optional) Specifies a soft reset.                                                                                                                                                                                                                                        |

## Command Default

When no autonomous system number or VRF instance is specified, all EIGRP neighbor entries are cleared from the table.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                                                                                 |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                 |
| Release 3.5.0 | The <b>ipv4</b> and <b>ipv6</b> keywords were added.<br><br>The <i>as-number</i> and <b>vrf</b> argument and keyword were changed from required to optional. |
| Release 3.6.0 | The <b>soft</b> keyword was added.                                                                                                                           |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to clear all EIGRP VRF entries for neighbor Gigabit Ethernet interface 0/5/0/0:

```
RP/0/0/CPU0:router# clear eigrp vrf customer_1 neighbors GigabitEthernet 0/5/0/0
```

**Related Commands**

|----------------------------------------------------|-------------------------------------------------------------|
| <a href="#">show eigrp interfaces, on page 659</a> | Displays information about interfaces configured for EIGRP. |
| <a href="#">show eigrp neighbors, on page 663</a>  | Displays the neighbors discovered by EIGRP.                 |

# clear eigrp topology

To remove and relearn Enhanced Interior Gateway Routing Protocol (EIGRP) topology entries from the appropriate table, use the **clear eigrp topology** command in EXEC mode.

**clear eigrp** [*as-number*] [**vrf**{**vrf** | **all**}] [**ipv4** | **ipv6**] **topology** [*prefix mask* | *prefix/length*]

## Syntax Description

|                                        |                                                                                                                                                                                                          |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>as-number</b>                       | (Optional) Autonomous system number. Range is from 1 to 65535.                                                                                                                                           |
| <b>vrf</b> { <i>vrf</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                                                                        |
| <b>ipv4</b>                            | (Optional) Specifies the IPv4 address family.                                                                                                                                                            |
| <b>ipv6</b>                            | (Optional) Specifies the IPv6 address family.                                                                                                                                                            |
| <i>prefix</i>                          | IP prefix, which limits output to a specific route.                                                                                                                                                      |
| <i>mask</i>                            | IP address mask.                                                                                                                                                                                         |
| <i>/ length</i>                        | Prefix length, which can be indicated as a slash (/) and number. For example, /8 indicates that the first eight bits in the IP prefix are network bits. If <i>length</i> is used, the slash is required. |

## Command Default

No EIGRP topology entries are cleared.

## Command Modes

EXEC

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to clear EIGRP topology entries for a specific route:

```
RP/0/0/CPU0:router# clear eigrp topology 10.1.0.0/8
```

**Related Commands**

| Command                                          | Description                                        |
|--------------------------------------------------|----------------------------------------------------|
| <a href="#">show eigrp topology, on page 666</a> | Displays information for the EIGRP topology table. |

# default-information

To control the candidate default routing information for an Enhanced Interior Gateway Routing Protocol (EIGRP), use the **default-information** command in the appropriate configuration mode. To suppress EIGRP candidate default information in incoming or outgoing updates, use the **no** form of this command.

**default-information allowed** {in|out} [*route-policy name*]

**no default-information allowed** {in|out} [*route-policy name*]

## Syntax Description

|                                 |                                                                |
|---------------------------------|----------------------------------------------------------------|
| <b>allowed</b>                  | Specifies EIGRP to allow default routing information.          |
| <b>in</b>                       | Specifies EIGRP to allow inbound default routing information.  |
| <b>out</b>                      | Specifies EIGRP to allow outbound default routing information. |
| <b>route-policy</b> <i>name</i> | (Optional) Specifies a route policy.                           |

## Command Default

Default routing information is not accepted or flagged.

## Command Modes

Address family configuration  
IPv4 VRF address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure inbound default routes specified with route policy acme to be accepted by an EIGRP peer in autonomous system 1:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1  
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# default-information accept in route-policy acme
```

## default-metric (EIGRP)

To set metrics for an Enhanced Interior Gateway Routing Protocol (EIGRP), use the **defaultmetric** command in the appropriate configuration mode. To remove the metric values and restore the default state, use the **no** form of this command.

**default-metric** *bandwidth delay reliability loading mtu*  
**no default-metric**

### Syntax Description

|                    |                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bandwidth</i>   | Minimum bandwidth of the route in kilobits per second. Range is 1 to 4294967295.                                                                                     |
| <i>delay</i>       | Route delay in ten microsecond units. Range is 1 to 4294967295.                                                                                                      |
| <i>reliability</i> | Likelihood of successful packet transmission expressed as a number between 0 and 255. The value 255 means 100-percent reliability; 0 means the link is not reliable. |
| <i>loading</i>     | Effective bandwidth of the route expressed as a number from 1 to 255 (255 is 100-percent loading).                                                                   |
| <i>mtu</i>         | Minimum maximum transmission unit (MTU) size of the route in bytes. Range is from 1 to 65535.                                                                        |

### Command Default

No default values

### Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **default-metric** command to provide default metric values while redistributing a protocol into EIGRP. Metric defaults have been carefully set to work for a wide variety of networks. Take great care when changing these values.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to take redistributed Routing Information Protocol (RIP) metrics and translate them into EIGRP metrics with values as follows: bandwidth = 1000, delay = 100, reliability = 250, loading = 100, and MTU = 1500.

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# redistribute rip
RP/0/0/CPU0:router(config-eigrp-vrf-af)# default-metric 1000 100 250 100 1500
```

**Related Commands**

| Command      | Description                                                               |
|--------------|---------------------------------------------------------------------------|
| redistribute | Redistributes routes from one routing domain into another routing domain. |

## distance (EIGRP)

To allow the use of one of two administrative distances—internal and external—that could provide a better route to a node, use the **distance** command in the appropriate configuration mode. To reset these values to their defaults, use the **no** form of this command.

**distance** *internal-distance external-distance*

**no distance**

### Syntax Description

|                          |                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>internal-distance</i> | Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system (AS). The distance can be a value from 1 to 255. |
| <i>external-distance</i> | Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a source external to the AS. The distance can be a value from 1 to 255.         |

### Command Default

*internal-distance* : 90  
*external-distance* : 170

### Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An administrative distance is a rating of the trustworthiness of a routing information source, such as an individual router or a group of routers. Numerically, an administrative distance is an integer from 0 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored.

Use the **distance** command if another protocol is known to provide a better route to a node than was actually learned through the external Enhanced Interior Gateway Routing Protocol (EIGRP) or some internal routes should be preferred by EIGRP.

To display the default administrative distance for a specified routing process, use the **show protocols EXEC** command.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

The following example shows how to set the administrative distance of all EIGRP 1 internal routes (within vrf vpn-1) to 80 and all EIGRP external routes to 130:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# distance 80 130
```

### Related Commands

|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">show protocols (EIGRP), on page 671</a> | Displays information about the Enhanced Interior Gateway Routing Protocol (EIGRP) running on the router. |

## hello-interval (EIGRP)

To configure the hello interval for an interface, use the **hello-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**hello-interval** *seconds*

**no hello-interval**

### Syntax Description

|                |                                                        |
|----------------|--------------------------------------------------------|
| <i>seconds</i> | Hello interval (in seconds). Range is from 1 to 65535. |
|----------------|--------------------------------------------------------|

### Command Default

For low-speed, nonbroadcast multiaccess (NBMA) networks: 60 seconds

For all other networks: 5 seconds

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

The following example shows how to set the hello interval to 0 to 10 seconds for the interface:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp-af-if)# hello-interval 10
```

## hold-time (EIGRP)

To configure the hold time for an interface, use the **hold-time** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**hold-time** *seconds*

**no hold-time**

### Syntax Description

|                |                                                   |
|----------------|---------------------------------------------------|
| <i>seconds</i> | Hold time (in seconds). Range is from 1 to 65535. |
|----------------|---------------------------------------------------|

### Command Default

Three times the default hello interval time of 15 seconds.

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

On very congested and large networks, the default hold time might not be sufficient time for all routers to receive hello packets from their neighbors. In this case, you may want to increase the hold time.

We recommend that the hold time be at least three times the hello interval. If a router does not receive a hello packet within the specified hold time, routes through this router are considered unavailable.

Increasing the hold time delays route convergence across the network.

To ensure nonstop forwarding during RP failovers, we recommend that the hold time be increased to 30 seconds.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

The following example shows how to set the hold time to 0 to 40 seconds for the interface:

```
RP/0/0/CPU0:router(config)# router eigrp 1
```

```
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp-af-if)# hold-time 40
```

# interface (EIGRP)

To define the interfaces on which the Enhanced Interior Gateway Routing Protocol (EIGRP) routing protocol runs, use the **interface** command in the appropriate configuration mode. To disable EIGRP routing for interfaces, use the **no** form of this command.

**interface** *type interface-path-id*

**no interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                   |

## Command Default

When you do not specify this command in configuration mode, EIGRP routing for interfaces is not enabled.

## Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

## Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **interface** command to associate a specific interface with an EIGRP process. The interface remains associated with the process even when the IPv4 address of the interface changes.

This command places the router in interface configuration mode, from which you can configure interface-specific settings. Commands configured under this mode (such as the **hello-interval** command) are automatically bound to that interface.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to enter interface configuration mode for EIGRP process 1 and set the hello interval to 10 seconds for GigabitEthernet interface 0/1/0/0:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp)# router-id 10.1.1.1
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp-af-if)# hello-interval 10
```

# log-neighbor-changes

To enable the logging of changes in Enhanced Interior Gateway Routing Protocol (EIGRP) neighbor adjacencies, use the **log-neighbor-changes** command in the appropriate configuration mode. To disable the logging of changes in EIGRP neighbor adjacencies, use the **no** form of this command.

**log-neighbor-changes**

**no log-neighbor-changes**

## Command Default

This command has no keywords or arguments.  
Adjacency changes are not logged.

## Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

## Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **log-neighbor-changes** command to log neighbor adjacency changes, monitor the stability of the routing system, and help detect problems. Logging is disabled by default. To disable the logging of neighbor adjacency changes, use the **no** form of this command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to enable logging of neighbor changes for EIGRP 1:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
```

```
RP/0/0/CPU0:router(config-eigrp-af)# log-neighbor-changes
```

# log-neighbor-warnings

To enable the logging of Enhanced Interior Gateway Routing Protocol (EIGRP) neighbor warning messages, use the **log-neighbor-warnings** command in the appropriate configuration mode. To disable the logging of EIGRP neighbor warning messages, use the **no** form of this command.

**log-neighbor-warnings**

**no log-neighbor-warnings**

## Syntax Description

This command has no keywords or arguments.

## Command Default

Neighbor warning messages are not logged.

## Command Modes

IPv4 address family configuration

IPv6 address family configuration

IPv4 VRF address family configuration

IPv6 VRF address family configuration

## Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **log-neighbor-warnings** command to disable and enable neighbor warning messages. When neighbor warning messages occur, they are not logged by default.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure log neighbor warning messages for EIGRP process 20:

```
RP/0/0/CPU0:router(config)# router eigrp 20
```

```
RP/0/0/CPU0:router(config-eigrp) vrf vrf1  
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# log-neighbor-warnings
```

## maximum-paths (EIGRP)

To control the maximum number of parallel routes that the Enhanced Interior Gateway Routing Protocol (EIGRP) can support, use the **maximum-paths** command in the appropriate configuration mode. To remove the **maximum-paths** command from the configuration file and restore the system to its default condition with respect to the routing protocol, use the **no** form of this command.

**maximum-paths** *maximum*

**no maximum-paths**

### Syntax Description

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <i>maximum</i> | Maximum number of parallel routes that EIGRP can install in a routing table. Range is from 1 to 16 routes . |
|----------------|-------------------------------------------------------------------------------------------------------------|

### Command Default

*maximum* : 4

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum-paths** command to allow the EIGRP protocol to install multiple paths into the routing table for each prefix. Multiple paths are installed for both internal and external routes, providing these routes are learned in the same autonomous system and that they are equal cost (according to the EIGRP best path algorithm).

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to allow a maximum of 10 paths to a destination:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) vrf vrfl  
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-vrf-af)# maximum-paths 10
```

## maximum-prefix (EIGRP)

To limit the number of prefixes that are accepted under a VRF address family by Enhanced Interior Gateway Routing Protocol (EIGRP), use the **maximum-prefix** command in IPv4 VRF address family configuration mode. To disable this function, use the **no** form of this command.

**maximum-prefix** *maximum* [*threshold*] [**dampened**] [**reset-time** *minutes*] [**restart** *minutes*] [**restart-count** *number*] [**warning-only**]

**no maximum-prefix** *maximum* [*threshold*] [**dampened**] [**reset-time** *minutes*] [**restart** *minutes*] [**restart-count** *number*] [**warning-only**]

### Syntax Description

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>maximum</i>                     | Maximum number of prefixes allowed under an address family. Range is from 1 to 4294967295.<br><br>The number of prefixes that can be configured is limited only by the available system resources on the router.                                                                                                                                                                                                                               |
| <i>threshold</i>                   | (Optional) Syslog warning messages are specified as a percentage of the maximum prefix limit that was exceeded. The prefix percentage number range is from 1 to 100. The default is 75 percent.                                                                                                                                                                                                                                                |
| <b>dampened</b>                    | (Optional) A decay penalty is applied to the restart time period each time the maximum prefix limit is exceeded. The half-life for the decay penalty is 150 percent of the default or user-defined restart time value in minutes. This keyword is disabled by default.                                                                                                                                                                         |
| <b>reset-time</b> <i>minutes</i>   | (Optional) The restart count is reset to 0 after the default or user-defined reset time period has expired. The range of values that can be applied with the <i>minutes</i> argument is from 1 to 65535 minutes. The default reset-time period is 15 minutes.                                                                                                                                                                                  |
| <b>restart</b> <i>minutes</i>      | (Optional) A time period when router adjacencies are not formed or when redistributed routes are not accepted from the RIB after the maximum prefix limit has been exceeded. The value for the <i>minutes</i> argument is from 1 to 65535 minutes. The default restart time period is 5 minutes.                                                                                                                                               |
| <b>restart-count</b> <i>number</i> | (Optional) Number of times a peering session is automatically reestablished after the peering session is torn down or after the redistribute route is cleared and relearned when the maximum prefix exceeds limits. The default restart count limit is 3.<br><br>Once the restart count threshold is crossed, you need to use the <b>clear route</b> or <b>clear eigrp neighbors</b> command to reestablish normal peering and redistribution. |
| <b>warning-only</b>                | (Optional) Configures the router to generate syslog messages only when the maximum prefix limit is reached, instead of terminating the peering session.                                                                                                                                                                                                                                                                                        |

### Command Default

*threshold*: 75 percent

**dampened** : False**reset-time** : 15 minutes**restart** : 5 minutes**restart-count** : 3**warning-only** : False**Command Modes**

IPv4 VRF address family configuration

IPv6 VRF address family configuration

**Command History**

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced .                                             |
| Release 3.5.0 | This command was supported in IPv6 VRF address family configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum-prefix** command to limit the number of prefixes that are accepted from all sources. When the maximum prefix limit is exceeded, sessions with remote peers are torn down, all routes learned from remote peers and through redistribution are removed from the topology and routing tables, and redistribution and peering are suspended for the default or user-defined time period.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to configure the maximum prefix limit for an EIGRP process, which includes routes learned through redistribution and routes learned through EIGRP peering sessions. The maximum limit is set to 50,000 prefixes. When the number of prefixes learned through redistribution reaches 37,500 (75 percent of 50,000), warning messages are displayed in the console. When the maximum prefix limit is exceeded, all peering sessions are reset, the topology and routing tables are cleared and redistributed routes and all peering sessions are placed in a penalty state.

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# maximum-prefix 50000
```

**Related Commands**

## metric (EIGRP)

To set metrics for an Enhanced Interior Gateway Routing Protocol (EIGRP) interface, use the **metric** command in interface configuration mode. To remove the metric values and restore the default state, use the **no** form of this command.

**metric** {**bandwidth** | **delay** | **load** | **reliability**}

**no metric**

### Syntax Description

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bandwidth</b>   | Minimum interface bandwidth of the route in kilobits per second. Range is 1 to 4294967295.                                                                 |
| <b>delay</b>       | Interface route delay in tens of microseconds. Delay is 1 or any positive number that is a multiple of 39.1 nanoseconds. Range is 1 to 4294967295.         |
| <b>load</b>        | Effective bandwidth of the route expressed as a number from 1 to 255 (255 is 100-percent loaded).                                                          |
| <b>reliability</b> | Likelihood of successful packet transmission expressed as a number between 0 and 255. The value 255 means 100-percent reliability; 0 means no reliability. |

### Command Default

Metric values are not set.

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.6.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **metric** command to provide metric values while redistributing a protocol into an EIGRP interface. Metric defaults have been carefully set to work for a wide variety of networks. Take great care when changing these values.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| eigrp   | read, write |

## Examples

This example shows how to configure metric values for interface POS 0/1/0/1 with values as bandwidth = 100, delay = 7, reliability = 250, and load = 100.

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router eigrp 100
RP/0/0/CPU0:router(config-eigrp)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# interface POS 0/1/0/1
RP/0/0/CPU0:router(config-eigrp-af-if)# metric bandwidth 100 delay 7 reliability 250 load 100
```

## Related Commands

|------------------------------------------------------|-------------------------------------------------------------------------|
| <a href="#">default-metric (EIGRP)</a> , on page 611 | Sets metrics for an Enhanced Interior Gateway Routing Protocol (EIGRP). |

## metric maximum-hops

To advertise as unreachable those Enhanced Interior Gateway Routing Protocol (EIGRP) routes with a hop count higher than is specified by the command, use the **metric maximum-hops** command in the appropriate configuration mode. To reset the value to the default, use the **no** form of this command.

**metric maximum-hops** *hops-number*

**no metric maximum-hops**

### Syntax Description

|                    |                                                 |
|--------------------|-------------------------------------------------|
| <b>hops-number</b> | Maximum hop count. Range is from 1 to 255 hops. |
|--------------------|-------------------------------------------------|

### Command Default

*hops-number* : 100

### Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.4.0 | The maximum hop count range was changed from 0 through 255 to 1 through 255.                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **metric maximum-hops** command to provide a safety mechanism that breaks any potential *count-to-infinity* problems. This command causes the EIGRP routing protocol to advertise as unreachable routes with a hop count greater than the value assigned to the *hops-number* argument.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure a hop count to 200 for a router that has a complex WAN generating a large hop count under normal (nonlooping) operations.

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# metric maximum-hops 200
```

## Related Commands

|---------------------------------------------|-----------------------------------------------------|
| <a href="#">metric weights, on page 633</a> | Allows the tuning of the EIGRP metric calculations. |

## metric weights

To allow the tuning of the Enhanced Interior Gateway Routing Protocol (EIGRP) metric calculations, use the **metric weights** command in the appropriate configuration mode. To reset the values to their defaults, use the **no** form of this command.

**metric weights** *tos k1 k2 k3 k4 k5*

**no metric weights**

### Syntax Description

|                       |                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------|
| <i>tos</i>            | Type of service (ToS) which must always be 0.                                                       |
| <i>k1 k2 k3 k4 k5</i> | Constants that convert an EIGRP metric vector into a scalar quantity. The range is 0 to 4294967295. |

### Command Default

*tos*: 0  
*k1*: 1  
*k2*: 0  
*k3*: 1  
*k4*: 0  
*k5*: 0

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **metric weights** command to alter the default behavior of EIGRP routing and metric computation and allow the tuning of the EIGRP metric calculation for a particular ToS.

If k5 equals 0, the composite EIGRP metric is computed according to the following formula:

$$\text{metric} = [k1 * \text{bandwidth} + (k2 * \text{bandwidth}) / (256 - \text{load}) + k3 * \text{delay}]$$

If k5 does not equal zero, an additional operation is performed:

$$\text{metric} = \text{metric} * [k5 / (\text{reliability} + k4)]$$

Bandwidth is inverse minimum bandwidth of the path in BPS scaled by a factor of  $2.56 * 10^{12}$ . The range is from a 1200-bps line to 10 terabits per second.

Delay is in units of 10 microseconds. The range of delay is from 10 microseconds to 168 seconds. A delay of all 1s indicates that the network is unreachable.

The delay parameter is stored in a 32-bit field, in increments of 39.1 nanoseconds. The range of delay is from 1 (39.1 nanoseconds) to hexadecimal FFFFFFFF (decimal 4,294,967,040 nanoseconds). A delay of all 1s (that is, a delay of hexadecimal FFFFFFFF) indicates that the network is unreachable.

This table lists the default values used for several common media.

**Table 49: Bandwidth Values by Media Type**

| Media Type | Delay                       | Bandwidth            |
|------------|-----------------------------|----------------------|
| Satellite  | 5120 (2 seconds)            | 5120 (500 megabits)  |
| Ethernet   | 25600 (1 milliseconds [ms]) | 256000 (10 megabits) |
| 1.544 Mbps | 512000 (20,000 ms)          | 1,657,856 bits       |
| 64 kbps    | 512000 (20,000 ms)          | 40,000,000 bits      |
| 56 kbps    | 512000 (20,000 ms)          | 45,714,176 bits      |
| 10 kbps    | 512000 (20,000 ms)          | 256,000,000 bits     |
| 1 kbps     | 512000 (20,000 ms)          | 2,560,000,000 bits   |

Reliability is given as a fraction of 255. That is, 255 is a reliability of 100 percent or a perfectly stable link. Load is given as a fraction of 255. A load of 255 indicates a completely saturated link.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to set the metric weights to change the default values:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
```

```
RP/0/0/CPU0:router(config-eigrp-af)# metric weights 0 2 0 2 0 0
```

**Related Commands**

| Command                                          | Description                                                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">metric maximum-hops, on page 631</a> | Advertises as unreachable those EIGRP VPN routes with a hop count higher than is specified by the command. |

## neighbor (EIGRP)

To define a neighboring router with which to exchange Enhanced Interior Gateway Routing Protocol (EIGRP) information, use the **neighbor** command in interface configuration mode. To remove an entry, use the **no** form of this command.

**neighbor** *ip-address*

**no neighbor** *ip-address*

### Syntax Description

|                   |                                                                          |
|-------------------|--------------------------------------------------------------------------|
| <i>ip-address</i> | IP address of a peer router with which routing information is exchanged. |
|-------------------|--------------------------------------------------------------------------|

### Command Default

No neighboring routers are defined.

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **neighbor** command to permit the point-to-point (nonbroadcast) exchange of routing information.

If a neighbor is configured on an interface using the **neighbor** command, the interface stops sending or receiving multicast hello messages. However, the interface can send or receive unicast hello messages. So each neighbor on a LAN must be configured individually. Multiple **neighbor** commands can be used to specify additional neighbors or peers.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

This example shows how to permit the sending of EIGRP updates to specific neighbors. One copy of the update is generated for each neighbor:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv6
```

```
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-eigrp-af-if)# neighbor 172.20.1.2
```

**Related Commands**

| Command                                                | Description                                                           |
|--------------------------------------------------------|-----------------------------------------------------------------------|
| <a href="#">passive-interface (EIGRP), on page 644</a> | Disables sending and receiving "hello" messages on (EIGRP) interface. |

## neighbor maximum-prefix

To limit the number of prefixes that are accepted from a single Enhanced Interior Gateway Routing Protocol (EIGRP) neighbor or all EIGRP VPN neighbors, use the **neighbor maximum-prefix** command in IPv4 VRF address family configuration mode. To disable this function, use the **no** form of this command.

### Single-Neighbor Configuration CLI

**neighbor** *ip-address* **maximum-prefix** *maximum* [ *threshold* ] [ **warning-only** ]

**no neighbor** *ip-address* **maximum-prefix**

### All-Neighbor Configuration CLI

**neighbor maximum-prefix** *maximum* [ *threshold* ] [ **dampened** ] [ **reset-time** *minutes* ] [ **restart** *minutes* ] [ **restart-count** *number* ] [ **warning-only** ]

**no neighbor maximum-prefix**

### Syntax Description

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>                  | (Optional) IP address of a single peer.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>maximum</i>                     | Maximum number of prefixes accepted. The range is from 1 to 4294967295.<br>The number of prefixes that can be configured is limited only by the available system resources on the router.                                                                                                                                                                                                                                                   |
| <i>threshold</i>                   | (Optional) Syslog warning messages are specified as a percentage of the maximum prefix limit that was exceeded. The prefix percentage number range is from 1 to 100. The default is 75 percent.                                                                                                                                                                                                                                             |
| <b>dampened</b>                    | (Optional) Configures a decay penalty to be applied to the restart time period each time the maximum prefix limit is exceeded. The half-life for the decay penalty is 150 percent of the default or user-defined restart time value in minutes. This keyword is disabled by default.                                                                                                                                                        |
| <b>reset-time</b> <i>minutes</i>   | (Optional) Configures the router to reset the restart count to 0 after the default or configured reset time period has expired. The range is from 1 to 65535 minutes.                                                                                                                                                                                                                                                                       |
| <b>restart</b> <i>minutes</i>      | (Optional) Configures a time period in which the router does not form adjacencies or accept redistributed routes from the RIB after the maximum prefix limit has been exceeded. The range is from 1 to 65535 minutes.                                                                                                                                                                                                                       |
| <b>restart-count</b> <i>number</i> | (Optional) Configures the number of times a peering session can be automatically reestablished after the peering session has been torn down or a redistribute route has been cleared and relearned because the maximum prefix limit has been exceeded.<br><br><b>Caution</b> After the restart count threshold is crossed, you need to use the <b>clear eigrp neighbors</b> command to reestablish normal peering, redistribution, or both. |
| <b>warning-only</b>                | (Optional) Configures the router to generate syslog messages only when the maximum prefix limit is reached, instead of terminating the peering session.                                                                                                                                                                                                                                                                                     |

**Command Default**

*threshold*: 75 percent  
**dampened** : disabled  
**warning-only** : disabled  
**reset-time** : 15 minutes  
**restart** : 5 minutes  
**restart-count** : 3

**Command Modes**

IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

**Command History**

| Release       | Modification                                                                            |
|---------------|-----------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                            |
| Release 3.4.0 | The <i>maximum</i> range was changed from 1 through 4294967295 to 0 through 4294967295. |
| Release 3.5.0 | This command was supported in IPv6 VRF address family configuration mode.               |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **neighbor maximum-prefix** command is configured to protect an individual peering session or all peering sessions. When this feature is enabled and the maximum prefix limit is exceeded, the router tears down the peering session, clears all routes that are learned from the peer, and then places the peer in a penalty state for the default or user-defined time period. After the penalty time period expires, normal peering is reestablished.

**Note**

In EIGRP, **neighbor** commands have been used traditionally to configure static neighbors. In the context of this feature, however, the **neighbor maximum-prefix** command can be used to configure the maximum prefix limit for both statically configured and dynamically discovered neighbors.

When configuring the **neighbor maximum-prefix** command to protect a single peering session, just the maximum prefix limit, percentage threshold, and warning only configuration options can be configured. Session dampening, restart, and reset timers are configured on a global basis.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure the maximum prefix limit for a single peer. The maximum limit is set to 1000 prefixes, and the warning threshold is set to 80 percent. When the maximum prefix limit is exceeded, the session with this peer is torn down, all routes learned from this peer are removed from the topology and routing tables, and this peer is placed in a penalty state for 5 minutes (default penalty value).

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# neighbor 10.0.0.1 maximum-prefix 1000 80
```

The following example shows how to configure the maximum prefix limit for all peers. The maximum limit is set to 10,000 prefixes, the warning threshold is set to 90 percent, the restart timer is set to 4 minutes, a decay penalty is configured for the restart timer with the **dampened** keyword, and all timers are configured to be reset to 0 every 60 minutes. When the maximum prefix limit is exceeded, all peering sessions are torn down, all routes learned from all peers are removed from the topology and routing tables, and all peers are placed in a penalty state for 4 minutes (user-defined penalty value). A dampening exponential decay penalty is also applied.

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vrf1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# neighbor maximum-prefix 10000 90 dampened
reset-time 60 restart4
```

| <a href="#">clear eigrp neighbors</a> , <a href="#">on page 605</a> | Deletes EIGRP and VRF neighbor entries from the appropriate tables. |

# next-hop-self disable

To instruct the Enhanced Interior Gateway Routing Protocol (EIGRP) process to use the received next-hop value when advertising the routes, use the **next-hop-self disable** command in interface configuration mode. To revert to the default, use the **no** form of this command.

**next-hop-self disable**

**no next-hop-self disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** EIGRP always sets the IP next-hop value to be itself.

**Command Modes** Interface configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

EIGRP, by default, sets the IP next-hop value to be itself for routes that it is advertising, even when advertising those routes on the same interface from which learned them. To change this default, you must use the **next-hop-self disable** interface configuration command to instruct EIGRP to use the received next-hop value when advertising these routes.

The **next-hop-self disable** feature is not available for redistributed routes.

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples** The following example shows how to change the default IP next-hop value and instruct EIGRP to use the received next-hop value:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp-af-if)# next-hop-self disable
```

## nsf disable (EIGRP)

To disable Enhanced Interior Gateway Routing Protocol (EIGRP) nonstop forwarding (NSF), use the **nsf disable** command in appropriate configuration mode. To re-enable the EIGRP NSF from a disabled state, use the **no** form of this command.

**nsf disable**

**no nsf disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** NSF in EIGRP is enabled.

**Command Modes**

- Router Configuration
- IPv4 address family configuration
- IPv6 address family configuration
- IPv4 VRF address family configuration
- IPv6 VRF address family configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.1.1 | This command was introduced. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If NSF is to be disabled for both IPv4 and IPv6 address families of all VRFs, use the **nsf disable** command at router configuration mode.

If NSF is to be disabled for a specific address family under a specific VRF, use the **nsf disable** command at address family configuration mode.

If NSF is disabled, EIGRP will not be able to retain the routes learnt from its peers and may result in traffic loss during ISSU.

| Task ID | Operation   |
|---------|-------------|
| eigrp   | read, write |

## Examples

This example shows how to disable NSF for all address families under all VRF's:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router eigrp 1
RP/0/0/CPU0:router(config-eigrp)#nsf disable
```

This example shows how to disable NSF for IPv4 address family of VRF v1:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router eigrp 1
RP/0/0/CPU0:router(config-eigrp)#vrf v1
RP/0/0/CPU0:router(config-eigrp-vrf)#address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)#nsf disable
```

## Related Commands

|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <a href="#">router eigrp</a> , on page 653 | Configures a routing process and enters router configuration mode for Enhanced Interior Gateway Routing Protocol (EIGRP). |

## passive-interface (EIGRP)

To disable sending and receiving "hello" messages on an Enhanced Interior Gateway Routing Protocol (EIGRP) interface and to disable formation of neighbors on the interface, use the **passive-interface** command in interface configuration mode. To reenale sending and receiving "hello messages", use the **no** form of this command.

**passive-interface**

**no passive-interface**

### Syntax Description

This command has no keywords or arguments.

### Command Default

**passive-interface** command is disabled on an interface.

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **passive-interface** command to disable sending of "hello" messages. The particular subnet on that interface will continue to be advertised by EIGRP to neighbors on other interfaces.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

This example shows how to configure **passive-interface** command on GigabitEthernet interface 0/6/5/0:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv6
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/6/5/0
RP/0/0/CPU0:router(config-eigrp-af-if)# passive-interface
```

## redistribute (EIGRP)

To inject routes from one routing domain into Enhanced Interior Gateway Routing Protocol (EIGRP), use the **redistribute** command in the appropriate configuration mode. To remove the **redistribute** command from the configuration file and restore the system to its default condition in which the software does not redistribute routes, use the **no** form of this command.

**redistribute** {{**bgp**|**connected**|**isis**|**ospf**|**ospfv3** | **rip**|**static** | **eigrp**}} [*as-number*| *instance-name*]][  
**route-policy** *name*]

**no redistribute** {{**bgp**|**connected**|**isis**|**ospf**|**ospfv3** | **rip**|**static** | **eigrp**}} [*as-number*| *instance-name*]]

### Syntax Description

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgp</b>                                 | Distributes routes from the BGP protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>connected</b>                           | Distributes routes that are established automatically by virtue of having enabled IP on an interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>isis</b>                                | Distributes routes from the IS-IS protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ospf</b>                                | Distributes routes from the OSPF protocol. This protocol is supported in the IPv4 address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ospfv3</b>                              | Distributes routes from the OSPFv3 protocol. This protocol is supported in the IPv6 address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>static</b>                              | Redistributes IP static routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>as-number</i>  <br><i>instance-name</i> | Represents one of the following three options:<br><br>For the <b>bgp</b> keyword:<br><br>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.<br><br>For the <b>isis</b> keyword, an IS-IS instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.<br><br>For the <b>ospf</b> keyword, an OSPF instance name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string. |
| <b>route-policy</b> <i>name</i>            | (Optional) Specifies the identifier of a configured policy. A policy is used to filter the importation of routes from this source routing protocol to EIGRP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Command Default**

Route redistribution is disabled.

**Command Modes**

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

**Command History**

| Release       | Modification                                                                                                                                              |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                              |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported.                                                                                |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. The <b>ospfv3</b> keyword was added. |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.                                                                               |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Redistributed routing information should always be filtered by the **route-policy name** keyword and argument. This filtering ensures that only those routes intended by the administrator are redistributed by EIGRP.

A default metric is usually required to redistribute routes from another protocol into EIGRP. The metric is configured through the **default-metric** command or under the route policy configured with the **redistribute** command. The one exception to this requirement is when EIGRP redistributes BGP routes on a provider edge (PE) router in an MPLS-VPN scenario. If the originating protocol of the route is EIGRP with the same autonomous system (as in MPLS-VPN), the metric would be learned automatically from the extended communities of the BGP route.

For information about routing policies, see the *Routing Policy Commands on Cisco IOS XR Software* module of the *Cisco IOS XR Routing Command Reference*.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to cause BGP routes to be redistributed into an EIGRP autonomous system:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# redistribute bgp 100
```

The following example shows how to redistribute the specified IS-IS process routes into an EIGRP autonomous system within a VPN routing and forwarding instance (VRF). The IS-IS routes are redistributed using route policy 3.

```
RP/0/0/CPU0:router(config)# router eigrp 109
RP/0/0/CPU0:router(config-eigrp)# vrf vpn-1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# redistribute isis 108 route-policy 3
```

## redistribute maximum-prefix

To limit the number of prefixes redistributed into an Enhanced Interior Gateway Routing Protocol (EIGRP) process, use the **redistribute maximum-prefix** command in IPv4 VRF address family configuration mode. To disable this function, use the **no** form of this command.

**redistribute maximum-prefix** *maximum* [ *threshold* ] [[**dampened**] [**reset-time** *minutes*] [**restart** *minutes*] [**restart-count** *number*]] [**warning-only**]

**no redistribute maximum-prefix**

### Syntax Description

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maximum                            | Maximum number of prefixes that are redistributed into EIGRP under an address-family. The range is from 1 to 4294967295.<br><br>The number of prefixes that can be configured is limited only by the available system resources on the router.                                                                                                                                                                                                    |
| threshold                          | (Optional) Syslog warning messages are specified as a percentage of the maximum prefix limit that was exceeded. The prefix percentage number range is from 1 to 100. The default is 75 percent.                                                                                                                                                                                                                                                   |
| <b>restart</b> <i>minutes</i>      | (Optional) Configures a time period in which the router will not form adjacencies or accept redistributed routes from the RIB after the <i>maximum-prefix</i> limit has been exceeded. The value for the minutes argument is from 1 to 65535 minutes.                                                                                                                                                                                             |
| <b>restart-count</b> <i>number</i> | (Optional) Configures the number of times a peering session can be automatically reestablished after the peering session has been torn down or after the redistribute route has been cleared and relearned because the maximum prefix limit has been exceeded.<br><br>After the restart count threshold has been crossed, you will need to enter the <b>process restart eigrp</b> command to reestablish normal peering, redistribution, or both. |
| <b>reset-time</b> <i>minutes</i>   | (Optional) Configures the router to reset the restart count to 0 after the default or configured reset time period has expired. The value for the minutes argument is from 1 to 65535 minutes.                                                                                                                                                                                                                                                    |
| dampened                           | (Optional) Configures a decay penalty to be applied to the restart time period each time the maximum prefix limit is exceeded. The half-life for the decay penalty is 150 percent of the default or user-defined restart time value in minutes.                                                                                                                                                                                                   |
| warning-only                       | (Optional) Configures the router to only generate syslog messages when the maximum prefix limit is reached, instead of suspending redistribution.                                                                                                                                                                                                                                                                                                 |

### Command Default

*threshold*: 75 percent  
**warning-only** : disabled  
**reset-time** : 15 minutes

**restart** : 5 minutes  
**restart-count** : 3  
**dampened**: disabled

**Command Modes**

IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

| Command History | Release       | Modification                                                              |
|-----------------|---------------|---------------------------------------------------------------------------|
|                 | Release 3.3.0 | This command was introduced.                                              |
|                 | Release 3.5.0 | This command was supported in IPv6 VRF address family configuration mode. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **redistribute maximum-prefix** command to configure limit prefixes learned through redistribution. When the maximum prefix limit is exceeded, all routes learned from the Routing Information Base (RIB) are discarded and redistribution is suspended for the default or user-defined time period. The maximum prefix limit that can be configured for redistributed prefixes is limited only by the available system resources on the router.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | eigrp   | read, write |

**Examples**

The following example shows how to configure the maximum prefix limit for routes learned through redistribution. The maximum limit is set to 5000 prefixes, and the warning threshold is set to 95 percent. When the number of prefixes learned through redistribution reaches 4750 (95 percent of 5000), warning messages are displayed in the console. Because the **warning-only** keyword is configured, the topology and routing tables are not cleared and route redistribution is not placed in a penalty state.

```
RP/0/0/CPU0:router(config)# router eigrp 100
RP/0/0/CPU0:router(config-eigrp)# vrf vpn-1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# redistribute maximum-prefix 5000 95 warning-only
```

**Related Commands**

| Command | Description                                |
|---------|--------------------------------------------|
| process | To start, terminate, or restart a process. |

## route-policy (EIGRP)

To apply a routing policy to updates advertised to or received from an Enhanced Interior Gateway Routing Protocol (EIGRP) neighbor, use the **route-policy** command in the appropriate configuration mode. To disable applying routing policy to updates, use the **no** form of this command.

**route-policy** *route-policy-name* {**in**|**out**}

**no route-policy** *route-policy-name* {**in**|**out**}

### Syntax Description

|                          |                                    |
|--------------------------|------------------------------------|
| <i>route-policy-name</i> | Name of route policy.              |
| <b>in</b>                | Applies policy to inbound routes.  |
| <b>out</b>               | Applies policy to outbound routes. |

### Command Default

No policy is applied.

### Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration  
Interface configuration

### Command History

|               |                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |
|---------------|----------------------------------------------------------------------------------------------------------------------|

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **route-policy** command to specify a routing policy for an inbound or outbound route. The policy can be used to filter routes or modify route attributes.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to apply the IN-Ipv4 policy to inbound IP Version 4 (IPv4) routes:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# route-policy IN-IPv4 in
```

# router eigrp

To configure a routing process and enter router configuration mode for Enhanced Interior Gateway Routing Protocol (EIGRP), use the **router eigrp** command in global configuration mode. To turn off the EIGRP routing process, use the **no** form of this command.

**router eigrp** { *instance-autonomous-system-number* | *virtual-instance-name* }

**no router eigrp** { *instance-autonomous-system-number* | *virtual-instance-name* }

## Syntax Description

*instance-autonomous-system-number* EIGRP instance autonomous-system number. This is used as the autonomous-system number for the default/global VRF. Valid range is 1 to 65535.

## Command Default

No routing process is defined.

## Command Modes

Global configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

- Only one instance of EIGRP is supported.
- 

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example configures EIGRP routing process 109 (109 is the autonomous-system number of default/global VRF):

```
RP/0/0/CPU0:router(config)# router eigrp 109
RP/0/0/CPU0:router(config-eigrp)#
```

## router-id (EIGRP)

To configure a router ID for an Enhanced Interior Gateway Routing Protocol (EIGRP) process, use the **router-id** command in the appropriate configuration mode. To cause the software to use the default method of determining the router ID, use the **no** form of this command.

**router-id** *router-id*

**no router-id**

### Syntax Description

|                  |                                                                         |
|------------------|-------------------------------------------------------------------------|
| <i>router-id</i> | 32-bit router ID value specified in four-part, dotted-decimal notation. |
|------------------|-------------------------------------------------------------------------|

### Command Default

If this command is not configured, EIGRP chooses an IPv4 address as the router ID from one of its interfaces.

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

It is good practice to use the **router-id** command to explicitly specify a unique 32-bit numeric value for the router ID. This action ensures that EIGRP can function regardless of the interface address configuration.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to assign the IP address of 172.20.1.1 to the EIGRP process 1:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# router-id 172.20.1.1
```

# show eigrp accounting

To display prefix accounting information for Enhanced Interior Gateway Routing Protocol (EIGRP) processes, use the **show eigrp accounting** command in EXEC mode.

**show eigrp** [*as-number*] [**vrf** {*vrf-name* | **all**}] [**ipv4** | **ipv6**] **accounting**

## Syntax Description

|                                             |                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>                            | (Optional) Autonomous system number. This option is available when a VPN routing and forwarding (VRF) instance is not specified. Range is from 1 to 65535. |
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                          |
| [ <b>ipv4</b>   <b>ipv6</b> ]               | (Optional) Specifies the IPv4 or IPv6 address family.                                                                                                      |

## Command Default

This command has no arguments or keywords.

## Command Modes

EXEC

## Command History

| Release       | Modification                                           |
|---------------|--------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                           |
| Release 3.5.0 | The [ <b>ipv4</b>   <b>ipv6</b> ] keywords were added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| EIGRP   | read       |

## Examples

The following is sample output from the **show eigrp accounting** command:

```
RP/0/0/CPU0:router# show eigrp accounting
IP-EIGRP accounting for AS(100)/ID(10.0.2.1) Routing Table: RED
```

Total Prefix Count: 4 States: A-Adjacency, P-Pending, D-Down

| State | Address/Source | Interface  | Prefix Count | Restart Count | Restart/Reset (s) |
|-------|----------------|------------|--------------|---------------|-------------------|
| P     | Redistributed  | ----       | 0            | 3             | 211               |
| A     | 10.0.1.2       | Gi0/6/0/0/ | 2            | 0             | 84                |
| P     | 10.0.2.4       | Gi00/2/0/3 | 0            | 2             | 114               |
| D     | 10.0.1.3       | Gi0/6/0/0  | 0            | 3             | 0                 |

**Note**

Connected and summary routes are not listed individually in the output of this command but are counted in the total aggregate count for each process.

This table describes the significant fields shown in the display.

**Table 50: show eigrp accounting Field Descriptions**

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EIGRP accounting for AS                | Identifies the EIGRP instance along with the AS number, router ID and table ID.                                                                                                                                                                                                                                                                                                                     |
| Total Prefix Count:                    | Shows the aggregate sum of the prefixes in an EIGRP instance topology table. The count includes prefixes learned from all neighbors or from redistribution.                                                                                                                                                                                                                                         |
| States: A-Adjacency, P-Pending, D-Down | <p>A-Adjacency: Indicates a stable adjacency with the neighbor or a normal redistribution state.</p> <p>P-Pending: Neighbor adjacency or redistribution is suspended or in a penalized state because the maximum prefix limit was exceeded.</p> <p>D-Down: Neighbor adjacency or redistribution is suspended permanently until a manual reset is performed with the <b>clear route</b> command.</p> |
| Address/Source                         | Shows the peer IP address of the redistribution source.                                                                                                                                                                                                                                                                                                                                             |
| Prefix Count                           | <p>Displays the total number of learned prefixes by source.</p> <p><b>Note</b> Routes can be learned for the same prefix from multiple sources, and the sum of all prefix counts in this column may be greater than the figure displayed in the “Prefix Count” field.</p>                                                                                                                           |
| Restart Count                          | Number of times a route source exceeded the maximum prefix limit.                                                                                                                                                                                                                                                                                                                                   |

| Field            | Description                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Restart Reset(s) | Displays the time, in seconds, that a route source is in a P (penalized) state. If the route source is in an A (stable or normal) state, the displayed time, in seconds, is the time period until penalization history is reset. |

# show eigrp interfaces

To display information about interfaces configured for Enhanced Interior Gateway Routing Protocol (EIGRP), use the **show eigrp interfaces** command in EXEC mode.

**show eigrp** [*as-number*] [**vrf**{*vrf-name*| **all**}] [**ipv4**| **ipv6**] **interfaces** [*type interface-path-id*] [**detail**]

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>as-number</b>                            | (Optional) Autonomous system number. This option is available when a VPN routing and forwarding (VRF) instance is not specified.<br><br>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535. |
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                                                                                                                                                                                                                                                                       |
| [ <b>ipv4</b>   <b>ipv6</b> ]               | (Optional) Specifies the IPv4 or IPv6 address family.                                                                                                                                                                                                                                                                                                                                                   |
| <b>type</b>                                 | (Optional) Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                                                                                                                                      |
| <b>interface-path-id</b>                    | Physical interface or virtual interface.<br><br>Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark ( ? ) online help function.                                                                                                                               |
| <b>detail</b>                               | (Optional) Displays detailed EIGRP interface information.                                                                                                                                                                                                                                                                                                                                               |

## Command Default

This command has no arguments or keywords.

## Command Modes

EXEC

## Command History

| Release       | Modification                                           |
|---------------|--------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                           |
| Release 3.5.0 | The [ <b>ipv4</b>   <b>ipv6</b> ] keywords were added. |

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.8.0 | The command output was modified with information on authentication keychain configuration.                                                                                                                                           |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show eigrp interfaces** command to determine on which interfaces EIGRP is active and learn information about EIGRP related to those interfaces.

If an interface is specified, only that interface is displayed. Otherwise, all interfaces on which EIGRP is running are displayed.

If an autonomous system is specified, only the routing process for the specified autonomous system is displayed. Otherwise, all EIGRP processes are displayed.

**Task ID**

| Task ID | Operations |
|---------|------------|
| EIGRP   | read       |

**Examples**

The following is sample output from the **show eigrp interfaces** command:

```
RP/0/0/CPU0:router# show eigrp interfaces
IP EIGRP interfaces for process 1
```

| Interface     | Peers | Xmit Queue<br>Un/Reliable | Mean<br>SRTT | Pacing Time<br>Un/Reliable | Multicast<br>Flow Timer | Pending<br>Routes |
|---------------|-------|---------------------------|--------------|----------------------------|-------------------------|-------------------|
| Gi0/6/0/2.212 | 0     | 0/0                       | 0            | 11/434                     | 0                       | 0                 |
| Gi0/6/0/0     | 1     | 0/0                       | 337          | 0/10                       | 0                       | 0                 |
| Gi0/2/0/3     | 1     | 0/0                       | 10           | 1/63                       | 103                     | 0                 |
| Gi0/6/2/5     | 1     | 0/0                       | 330          | 0/16                       | 0                       | 0                 |

This table describes the significant fields shown in the display.

**Table 51: show eigrp interfaces Field Descriptions**

| Field     | Description                               |
|-----------|-------------------------------------------|
| Interface | Interface over which EIGRP is configured. |

| Field                   | Description                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| Peers                   | Number of directly connected EIGRP neighbors.                                                                        |
| Xmit Queue Un/Reliable  | Number of packets remaining in the unreliable and reliable transmit queues.                                          |
| Mean SRTT               | Mean smoothed round-trip time (SRTT) internal (in milliseconds).                                                     |
| Pacing Time Un/Reliable | Pacing time used to determine when EIGRP packets should be sent out the interface (unreliable and reliable packets). |
| Multicast Flow Timer    | Maximum number of seconds in which the router sends multicast EIGRP packets.                                         |
| Pending Routes          | Number of routes in the packets in the transmit queue waiting to be sent.                                            |

The following is sample output from the **show eigrp interfaces** command when issued with the **detail** keyword:

```
RP/0/0/CPU0:router# show eigrp interfaces detail
```

```
IPv4-EIGRP interfaces for AS(100)
```

| Interface | Peers | Xmit Queue Un/Reliable | Mean SRTT | Pacing Time Un/Reliable | Multicast Flow Timer | Pending Routes |
|-----------|-------|------------------------|-----------|-------------------------|----------------------|----------------|
| Lo0       | 0     | 0/0                    | 0         | 640/640                 | 0                    | 0              |

This table describes the significant fields shown in the display.

**Table 52: show eigrp interfaces detail Field Descriptions**

| Field          | Description                         |
|----------------|-------------------------------------|
| Hello interval | Hello packet transmission interval. |

| Field                                         | Description                                                                                                                                                        |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hold time                                     | Hold time announced to neighbors. If neighbors do not get hello packets from the router for this period, neighbors declare that the neighbor relationship is down. |
| Next xmit serial                              | Next transmission serial number.                                                                                                                                   |
| Un/reliable mcasts                            | Number of unreliable and reliable multicast packets sent on this interface.                                                                                        |
| Un/reliable ucasts                            | Number of unreliable and reliable unicast packets sent on this interface.                                                                                          |
| Mcast exceptions                              | Number of multicast exceptions (sequence TLVs).                                                                                                                    |
| CR packets                                    | Number of packets sent with the conditional receive bit set.                                                                                                       |
| ACKs suppresses                               | Number of ACK packets suppressed.                                                                                                                                  |
| Retransmissions                               | Number of retransmissions sent on this interface.                                                                                                                  |
| Out-of-sequence rcvd                          | Number of packets received out of sequence.                                                                                                                        |
| Bandwidth percent                             | Configured percent of bandwidth.                                                                                                                                   |
| Authentication                                | Mode of authentication.                                                                                                                                            |
| Valid authenticated packets received          | Number of valid authentication packets.                                                                                                                            |
| Packets dropped due to wrong keychain config  | Number of packets dropped due to wrong keychain configuration.                                                                                                     |
| Packets dropped due to missing authentication | Number of packets dropped due to missing authentication.                                                                                                           |
| Packets dropped due to invalid authentication | Number of packets dropped due to invalid authentication.                                                                                                           |

**Related Commands**

| <a href="#">show eigrp neighbors</a> , on page 663 | Displays the neighbors discovered by EIGRP. |

# show eigrp neighbors

To display information about neighbors discovered by Enhanced Interior Gateway Routing Protocol (EIGRP), use the **show eigrp neighbors** command in EXEC mode.

**show eigrp** *as-number* *vrf {vrf-name | all}* **ipv4** **ipv6**

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                           |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>                            | (Optional) Autonomous system number. This option is available when a VPN routing and forwarding (VRF) instance is not specified. Range is from 1 to 65535.                                                                                                                |
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                                                                                                                                         |
| [ <b>ipv4</b>   <b>ipv6</b> ]               | (Optional) Specifies the IPv4 or IPv6 address family.                                                                                                                                                                                                                     |
| <b>detail</b>                               | (Optional) Displays detailed EIGRP neighbor information.                                                                                                                                                                                                                  |
| <b>type</b>                                 | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                   |
| <i>interface-path-id</i>                    | Physical interface or virtual interface.<br><br>Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |
| <b>static</b>                               | (Optional) Displays static routes.                                                                                                                                                                                                                                        |

## Command History

| Release       | Modification                                           |
|---------------|--------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                           |
| Release 3.5.0 | The [ <b>ipv4</b>   <b>ipv6</b> ] keywords were added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show eigrp neighbors** command to determine when neighbors become active and inactive. This command is also useful for debugging certain types of transport problems.

**Task ID**

| Task ID | Operations |
|---------|------------|
| EIGRP   | read       |

**Examples**

The following is sample output from the **show eigrp neighbors** command:

```
RP/0/0/CPU0:router# show eigrp neighbors
IP-EIGRP Neighbors for process 77

```

| Address      | Interface | Holdtime<br>(secs) | Uptime<br>(h:m:s) | Q<br>Count | Seq<br>Num | SRTT<br>(ms) | RTO<br>(ms) |
|--------------|-----------|--------------------|-------------------|------------|------------|--------------|-------------|
| 172.16.81.28 | Gi0/2/0/3 | 13                 | 0:00:41           | 0          | 11         | 4            | 20          |
| 172.16.80.28 | Gi0/6/0/0 | 14                 | 0:02:01           | 0          | 10         | 12           | 24          |
| 172.16.80.31 | Gi0/6/2/5 | 12                 | 0:02:02           | 0          | 4          | 5            | 20          |

```
RP/0/0/CPU0:router#
```

This table describes the significant fields shown in the display.

**Table 53: show eigrp neighbors Field Descriptions**

| Field     | Description                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| process   | Autonomous system number specified in the router configuration command.                                                        |
| Address   | IP address of the EIGRP peer.                                                                                                  |
| Interface | Interface on which the router is receiving hello packets from the peer.                                                        |
| Holdtime  | Length of time (in seconds) that the Cisco IOS XR software waits to hear from the peer before declaring that the peer is down. |
| Uptime    | Elapsed time (in hours, minutes, and seconds) since the local router first heard from this neighbor.                           |

| Field   | Description                                                                                                                                                                                 |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Q Count | Number of EIGRP packets (update, query, and reply) that the software waits to send.                                                                                                         |
| Seq Num | Sequence number of the last update, query, or reply packet that was received from this neighbor.                                                                                            |
| SRTT    | Smoothed round-trip time. This is the number of milliseconds required for an EIGRP packet to be sent to this neighbor and for the local router to receive an acknowledgment of that packet. |
| RTO     | Retransmission timeout (in milliseconds). This is the amount of time the software waits before resending a packet from the retransmission queue to a neighbor.                              |

The following is sample output from the **show eigrp neighbors** command when issued with the **detail** keyword:

```
RP/0/0/CPU0:router# show eigrp neighbors detail
IP-EIGRP neighbors for AS 1
H   Address                Interface      Hold Uptime   SRTT   RTO   Q   Seq
                   (sec)          (ms)
0   11.0.0.10              Gi0/6/0/0     14 01:00:52   3     200   0   10
Version 12.4/1.2, Retrans: 0, Retries: 0, Prefixes: 3
```

This table describes the significant fields shown in the display.

**Table 54: show eigrp neighbors detail Field Descriptions**

| Field    | Description                                                                           |
|----------|---------------------------------------------------------------------------------------|
| Version  | Version of EIGRP software (major.minor) running on the node and neighbor.             |
| Retrans  | Number of retransmissions sent to this neighbor.                                      |
| Retries  | Number of retransmissions sent to this neighbor since the last acknowledgement (ACK). |
| Prefixes | Number of prefixes learned from this neighbor.                                        |

# show eigrp topology

To display the Enhanced Interior Gateway Routing Protocol (EIGRP) topology table, use the **show eigrp topology** command in EXEC mode.

**show eigrp** [*as-number*] [*vrf*{*vrf-name*| **all**}] [**ipv4**| **ipv6**] **topology** [*ip-address mask*] {**active**| **all-links**| **detail-links**| **pending**| **summary**| **zero-successors**}

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>                            | (Optional) Autonomous system number. This option is available when a VPN routing and forwarding (VRF) instance is not specified.<br><br>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.                                             |
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                                                                                                                                                                                                                                                                                                                   |
| [ <b>ipv4</b>   <b>ipv6</b> ]               | (Optional) Specifies the IPv4 or IPv6 address family.                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>ip-address</i>                           | (Optional) IP address in four-part, dotted-decimal notation.                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>mask</i>                                 | (Optional) Network mask specified in either of two ways:<br><br>Network mask can be a four-part, dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit is a network address.<br><br>Network mask can be indicated as a slash (/) and number. For example, /8 indicates that the first 8 bits of the mask are 1s, and the corresponding bits of the address are the network address. |
| <b>active</b>                               | (Optional) Displays only active entries in the EIGRP topology table.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>all-links</b>                            | (Optional) Displays all entries in the EIGRP topology table.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>detail-links</b>                         | (Optional) Displays detailed information for all entries in the EIGRP topology table.                                                                                                                                                                                                                                                                                                                                                               |
| <b>pending</b>                              | (Optional) Displays all entries in the EIGRP topology table that are waiting for an update from a neighbor or are waiting to reply to a neighbor.                                                                                                                                                                                                                                                                                                   |
| <b>summary</b>                              | (Optional) Displays a summary of the EIGRP topology table.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>zero-successors</b>                      | (Optional) Displays available routes in the EIGRP topology table.                                                                                                                                                                                                                                                                                                                                                                                   |

|-----------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | Release 3.3.0 | This command was introduced.                                                                                                                                                                                                         |
|                 | Release 3.5.0 | The [ <b>ipv4</b>   <b>ipv6</b> ] keywords were added.                                                                                                                                                                               |
|                 | Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the **show eigrp topology** command is used without any keywords or arguments, only routes that are feasible successors are displayed.

The **show eigrp topology** command can be used to determine Diffusing Update Algorithm (DUAL) states and to debug possible DUAL problems.

| Task ID | Task ID | Operations |
|---------|---------|------------|
|         | EIGRP   | read       |

**Examples** The following is sample output from the **show eigrp topology** command. The EIGRP metrics for specified internal routes and external routes are displayed.

```
RP/0/0/CPU0:router# show eigrp topology 10.2.1.0/24

IP-EIGRP (AS 1): Topology entry for 10.2.1.0/24
  State is Passive, Query origin flag is 1, 1 Successor(s), FD is 281600
  Routing Descriptor Blocks:
    0.0.0.0 (GigabitEthernet0/6/0/0), from Connected, Send flag is 0x0
      Composite metric is (281600/0), Route is Internal !This is the internal route.
  Vector metric:
    Minimum bandwidth is 10000 Kbit
    Total delay is 1000 microseconds
    Reliability is 255/255
    Load is 1/255
    Minimum MTU is 1500
    Hop count is 0

RP/0/0/CPU0:router# show eigrp topology 10.4.80.0/20

IP-EIGRP (AS 1): Topology entry for 10.4.80.0/20
  State is Passive, Query origin flag is 1, 1 Successor(s), FD is 409600
```

```

Routing Descriptor Blocks:
10.2.1.1 (GigabitEthernet0/6/0/0), from 10.2.1.1, Send flag is 0x0
  Composite metric is (409600/128256), Route is External
    Vector metric:
      Minimum bandwidth is 10000 Kbit
      Total delay is 6000 microseconds
      Reliability is 255/255
      Load is 1/255
      Minimum MTU is 1500
      Hop count is 1
    External data:
      Originating router is 10.89.245.1
      AS number of route is 0
      External protocol is Connected, external metric is 0
      Administrator tag is 0 (0x00000000)

```

This table describes the significant fields shown in the display.

**Table 55: show eigrp topology Field Descriptions**

| Field                               | Description                                                                                                                                        |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Query origin                        | Query origin state.                                                                                                                                |
| Successors                          | Number of feasible successors for this prefix.                                                                                                     |
| FD                                  | Feasible distance for this prefix.                                                                                                                 |
| 10.2.1.1 (Gi0/0)                    | Next hop and interface from which this path was learned.                                                                                           |
| from 10.2.1.1                       | Information source for this path.                                                                                                                  |
| Send flag                           | Indicates if the sending of this prefix is pending to this neighbor.                                                                               |
| Composite Metric<br>(409600/128256) | The first number is the EIGRP metric that represents the cost to the destination. The second number is the EIGRP metric that this peer advertised. |
| Route is                            | Type of route (internal or external).                                                                                                              |
| Vector Metric                       | Shows the metric (bandwidth, delay, reliability, load, MTU, and hop count) advertised by the neighbor.                                             |
| External Data                       | Shows the external information (originating router ID, AS number, external protocol, metric, and tag) advertised by the neighbor.                  |

# show eigrp traffic

To display the number of Enhanced Interior Gateway Routing Protocol (EIGRP) packets sent and received, use the **show eigrp traffic** command in EXEC mode.

**show eigrp** [*as-number*] [**vrf**{*vrf-name*| **all**}][**ipv4**| **ipv6**] **traffic**

## Syntax Description

|                                             |                                                                                                                                                            |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i>                            | (Optional) Autonomous system number. This option is available when a VPN routing and forwarding (VRF) instance is not specified. Range is from 1 to 65535. |
| <b>vrf</b> { <i>vrf-name</i>   <b>all</b> } | (Optional) Specifies a particular VPN routing and forwarding instance (VRF) or all VRF instances.                                                          |
| [ <b>ipv4</b>   <b>ipv6</b> ]               | (Optional) Specifies the IPv4 or IPv6 address family.                                                                                                      |

## Command Modes

EXEC

## Command History

| Release       | Modification                                           |
|---------------|--------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                           |
| Release 3.5.0 | The [ <b>ipv4</b>   <b>ipv6</b> ] keywords were added. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show eigrp traffic** command to find the number of packets sent and received.

In addition, this command is useful in determining whether packets from one node are not reaching the neighboring node due to connectivity or configuration problems.

## Task ID

| Task ID | Operations |
|---------|------------|
| EIGRP   | read       |

## Examples

The following is sample output from the **show eigrp traffic** command:

```
RP/0/0/CPU0:router# show eigrp traffic
```

```

This table describes the significant fields shown in the display.

**Table 56: show eigrp traffic Field Descriptions**

| Field                       | Description                                                            |
|-----------------------------|------------------------------------------------------------------------|
| AS                          | Autonomous system number specified in the <b>router eigrp</b> command. |
| Hellos sent/received:       | Number of hello packets sent and received.                             |
| Updates sent/received:      | Number of update packets sent and received.                            |
| Queries sent/received:      | Number of query packets sent and received.                             |
| Replies sent/received:      | Number of reply packets sent and received.                             |
| Acks sent/received:         | Number of acknowledgment packets sent and received.                    |
| Input queue high water mark | Maximum number of packets in the input queue and number of drops.      |
| SIA-Queries sent/received   | Number of Stuck-in-Active query packets sent and received.             |
| SIA-Replies sent/received:  | Number of Stuck-in-Active reply packets sent and received.             |

## show protocols (EIGRP)

To display information about the Enhanced Interior Gateway Routing Protocol (EIGRP) process configuration, use the **show protocols** command in EXEC mode.

**show protocols** [**ipv4** | **ipv6** | **afi-all**] [**all** | *protocol*] [**default-context** | **vrf** *vrf-name*] [**private**]

### Syntax Description

|                            |                                                                                                                                                                                                                                                                  |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ipv4</b>                | (Optional) Specifies an IPv4 address family.                                                                                                                                                                                                                     |
| <b>ipv6</b>                | (Optional) Specifies an IPv6 address family.                                                                                                                                                                                                                     |
| <b>afi-all</b>             | (Optional) Specifies all address families.                                                                                                                                                                                                                       |
| <b>all</b>                 | (Optional) Specifies all protocols for a given address family.                                                                                                                                                                                                   |
| <i>protocol</i>            | (Optional) Specifies a routing protocol.<br>For the IPv4 address family, the options are <b>eigrp</b> , <b>bgp</b> , <b>isis</b> , <b>ospf</b> , and <b>rip</b> .<br>For the IPv6 address family, the options are <b>bgp</b> , <b>isis</b> , and <b>ospfv3</b> . |
| <b>default-context</b>     | (Optional) Displays default context information. This keyword is available when the <b>eigrp</b> or <b>rip</b> protocol is specified.                                                                                                                            |
| <b>vrf</b> <i>vrf-name</i> | (Optional) Displays VPN routing and forwarding (VRF) information for the specified process. This keyword is available when the <b>eigrp</b> or <b>rip</b> protocol is specified.                                                                                 |
| <b>private</b>             | (Optional) Displays private EIGRP data. This keyword is available when the <b>eigrp</b> is specified.                                                                                                                                                            |

### Command Modes

EXEC

### Command History

| Release       | Modification                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                                                                                         |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported. The input parameters and output were modified to display 4-byte autonomous system numbers and extended communities in either asplain or asdot notations. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show protocols** command to get information about the protocols running on the router and to quickly determine which protocols are active. The command is designed to summarize the important characteristics of the running protocol, and command output varies depending on the specific protocol selected.

For EIGRP, the command output lists the instance number, default AS context, router ID, default networks, distance, maximum paths, and so on.

**Task ID**

| Task ID | Operations |
|---------|------------|
| EIGRP   | read       |

**Examples**

The following is sample output from the **show protocols eigrp** command:

```
RP/0/0/CPU0:router# show protocols eigrp

Routing Protocol: EIGRP, instance 1
Default context AS: 1, Router ID: 192.168.0.22
Address Family: IPv4
  Default networks not flagged in outgoing updates
  Default networks not accepted from incoming updates
  Distance: internal 90, external 170
  Maximum paths: 4
  EIGRP metric weight K1=1, K2=0, K3=1, K4=0, K5=0
  EIGRP maximum hopcount 100
  EIGRP maximum metric variance 1
  EIGRP NSF: enabled
  NSF-aware route hold timer is 240s
  NSF signal timer is 20s
  NSF converge timer is 120s
  Time since last restart is 01:01:21
  SIA Active timer is 180s
  Interfaces:
    GigabitEthernet0/6/0/0
```

This table describes the significant fields shown in the display.

**Table 57: show protocols Field Descriptions**

| Field    | Descriptions                                                                                                                                                                                                                                                                                                                                                  |

| Field                      | Descriptions                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AS                         | <p>AS number of this context.</p> <ul style="list-style-type: none"> <li>• Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.</li> <li>• Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.</li> </ul> |
| Address Family             | Address family for which the configuration status is shown.                                                                                                                                                                                                                                                                                                   |
| Default Networks Candidate | Default network acceptance and announcement behavior.                                                                                                                                                                                                                                                                                                         |
| Distance                   | Administrative distance of EIGRP routes.                                                                                                                                                                                                                                                                                                                      |
| Maximum paths              | Maximum paths installed in RIB for a route.                                                                                                                                                                                                                                                                                                                   |
| Metric Weight              | Current metric weights used by EIGRP.                                                                                                                                                                                                                                                                                                                         |
| Maximum hopcount           | Maximum hop count accepted by EIGRP.                                                                                                                                                                                                                                                                                                                          |
| Variance                   | Metric variance used to find feasible paths for a route.                                                                                                                                                                                                                                                                                                      |
| Route hold time            | Time duration for which routes learned from a neighbor are held without deletion while the neighbor is undergoing a graceful restart.                                                                                                                                                                                                                         |
| signal time                | Nonstop forwarding signal time.                                                                                                                                                                                                                                                                                                                               |
| converge time              | Nonstop forwarding convergence time.                                                                                                                                                                                                                                                                                                                          |
| SIA Active time            | Active time period for SIA.                                                                                                                                                                                                                                                                                                                                   |
| Interfaces                 | List of interfaces configured for EIGRP.                                                                                                                                                                                                                                                                                                                      |

## site-of-origin (EIGRP)

To configure the Site of Origin (SoO) filtering on an Enhanced Interior Gateway Routing Protocol (EIGRP) interface, use the **site-of-origin** command in interface configuration mode. To disable SoO filtering on an interface, use the **no** form of this command.

**site-of-origin** {*as-number* : *number* | *ip-address* : *number*}

**no site-of-origin**

### Syntax Description

|                     |                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-number</i> :  | Autonomous system number.<br><br>Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.<br><br>Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.<br><br>The colon is used to separate the autonomous system number and network number. |
| <i>number</i>       | Network number. Range is from 0 to 4294967295 when a 2-byte AS number is used.<br>Range is from 0 to 65535 when a 4-byte AS number is used.                                                                                                                                                                                                                                            |
| <i>ip-address</i> : | IP address in four-part, dotted-decimal notation.<br><br>The colon is used to separate the IP address and network number.                                                                                                                                                                                                                                                              |

### Command Default

No default behavior or values

### Command Modes

Interface configuration

### Command History

| Release       | Modification                                                                                                                                                            |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                                                                            |
| Release 3.4.0 | The <i>as-number</i> 4-byte number range 1.0 to 65535.65535 was supported. The <i>number</i> range was changed from 1-4294967295 to 0-4294967295 for 2-byte AS numbers. |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.                                                                                             |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An EIGRP process must be capable of retrieving the SoO attribute on routes redistributed from the Border Gateway Protocol (BGP) when required to support complex topologies that include MPLS VPN links between sites with backdoor links.

Use the **site-of-origin** command to set an SoO BGP extended community attribute that is used to identify routes that have originated from a site so that the readvertisement of that prefix back to the source site can be prevented. The SoO extended community uniquely identifies the site from which a provider edge (PE) router has learned a route.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

### Examples

The following example shows how to configure SoO filtering on an EIGRP interface:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) vrf customer1
RP/0/0/CPU0:router(config-eigrp-vrf) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af) # interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp--vrf-af-if) # site-of-origin 10.0.0.1:20
```

## split-horizon disable (EIGRP)

To disable split horizon for an Enhanced Interior Gateway Routing Protocol (EIGRP) process, use the **split-horizon disable** command in interface configuration mode. To enable split horizon, use the **no** form of this command.

**split-horizon disable**

**no split-horizon disable**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Split horizon is enabled for an EIGRP process.

**Command Modes** Interface configuration

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples** The following example shows how to disable split horizon on a GigabitEthernet link:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-eigrp-af-if)# split-horizon disable
```

## stub (EIGRP)

To configure a router as a stub for Enhanced Interior Gateway Routing Protocol (EIGRP), use the **stub** command in the appropriate configuration mode. To disable this function, use the **no** form of this command.

**stub** [**receive-only**] [**connected**] [**redistributed**] [**static**] [**summary**]

**no stub** [**receive-only**] [**connected**] [**redistributed**] [**static**] [**summary**]

### Syntax Description

|                      |                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------|
| <b>receive-only</b>  | (Optional) Sets the router as a receive-only neighbor.                                  |
| <b>connected</b>     | (Optional) Advertises connected routes.                                                 |
| <b>redistributed</b> | (Optional) Advertises redistributed routes from other protocols and autonomous systems. |
| <b>static</b>        | (Optional) Advertises static routes.                                                    |
| <b>summary</b>       | (Optional) Advertises summary routes.                                                   |

### Command Default

Stub routing is disabled.

When stub routing is specified, connected and summary routes are advertised by default.

### Command Modes

IPv4 address family configuration  
IPv6 address family configuration  
IPv4 VRF address family configuration  
IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **stub** command to configure a router as a stub in which the router directs all IP traffic to a distribution router.

The **stub** command can be modified with several options, and these options can be used in any combination except for the **receive-only** keyword.

The **receive-only** keyword restricts the router from sharing any of its routes with any other router in that EIGRP autonomous system and does not permit any other option to be specified because it prevents any type of route from being sent. The four other optional keywords ( **connected** , **static** , **summary** , and **redistributed** ) can be used in any combination but cannot be used with the **receive-only** keyword. If any of these four keywords is used with the **stub** command, only the route types specified by the particular keyword or keywords are sent. Route types specified by the nonused keyword or keywords are not sent.

The **connected** keyword permits EIGRP stub routing to send connected routes. If all the connected routes are not covered by EIGRP interfaces, it may be necessary to redistribute connected routes with the **redistribute connected** command under the EIGRP process. This option is enabled by default.

The **static** keyword permits EIGRP stub routing to send static routes. Without the configuration of this option, EIGRP does not send any static routes. You may still need to redistribute static routes with the **redistribute static** command.

The **summary** keyword permits EIGRP stub routing to send summary routes. Summary routes can be created manually with the **summary address** command or automatically at a major network border router with the **auto-summary** command enabled. This option is enabled by default.

The **redistributed** keyword permits EIGRP stub routing to send other routing protocols and autonomous systems. Without the configuration of this option, EIGRP does not advertise redistributed routes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure, as a stub, the router that advertises connected and summary routes:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# stub
```

The following example shows how to configure the router as a receive-only neighbor (connected, summary, and static routes are not sent):

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# stub receive-only
```

## Related Commands

|----------------------------------------------------|----------------------------------------------------------|
| <a href="#">redistribute (EIGRP)</a> , on page 645 | Redistributes routes from one routing domain into EIGRP. |

| Command                                              | Description                                                                                     |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">summary-address (EIGRP), on page 680</a> | Configures a summary aggregate address for the specified EIGRP interface.                       |
| <a href="#">auto-summary (EIGRP), on page 599</a>    | Allows automatic summarization of subnet routes into network-level routes for an EIGRP process. |

## summary-address (EIGRP)

To configure a summary aggregate address for the specified Enhanced Interior Gateway Routing Protocol (EIGRP) interface, use the **summary-address** command in interface configuration mode. To disable a configuration, use the **no** form of this command.

**summary-address** *ip-address* {*/length*|*mask*} [*admin-distance*]

**no summary-address** *ip-address* {*/length*|*mask*}

### Syntax Description

|                       |                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>     | The IP address argument specifies the summary IP address to apply to an interface in four-part, dotted-decimal notation.                                                                                 |
| <i>/ length</i>       | Prefix length, which can be indicated as a slash (/) and number. For example, /8 indicates that the first eight bits in the IP prefix are network bits. If <i>length</i> is used, the slash is required. |
| <i>mask</i>           | IP address mask.                                                                                                                                                                                         |
| <i>admin-distance</i> | (Optional) Administrative distance. A value from 1 to 255.                                                                                                                                               |

### Command Default

An administrative distance of 5 is applied to EIGRP summary routes.  
No summary addresses are predefined.

### Command Modes

Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **summary-address** command is used to configure interface-level address summarization. EIGRP summary routes are given an administrative distance of 5. The administrative distance is used to advertise a summary without installing it in the routing table.

By default, EIGRP summarizes subnet routes to the network level. The **no auto-summary** command can be entered to configure subnet level summarization.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to configure an administrative distance of 95 on an EIGRP interface for the 192.168.0.0/16 summary address:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# interface GigabitEthernet 0/1/0/0  
RP/0/0/CPU0:router(config-eigrp-af-if)# summary-address 192.168.0.0/16 95
```

**Related Commands**

|---------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">auto-summary (EIGRP), on page 599</a> | Allows automatic summarization of subnet routes into network-level routes for an EIGRP process. |

## timers active-time

To adjust the Enhanced Interior Gateway Routing Protocol (EIGRP) routing wait time, use the **timers active-time** command in the appropriate configuration mode. To disable this function, use the **timers active-time no** form of the command.

**timers active-time** [*time-limit*] **disabled**

**no timers active-time**

### Syntax Description

|                   |                                                                                      |
|-------------------|--------------------------------------------------------------------------------------|
| <i>time-limit</i> | Active time limit (in minutes). Range is from 1 to 4294967295 minutes.               |
| <b>disabled</b>   | Disables the timers and permits the routing wait time to remain active indefinitely. |

### Command Default

Disabled

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers active-time** command to control the time the router waits (after query is sent) before declaring the route to be in the stuck in active (SIA) state.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

## Examples

The following example shows how to configure an indefinite routing wait time on the specified EIGRP route:

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp) address-family ipv4
RP/0/0/CPU0:router(config-eigrp-af)# timers active-time disabled
```

## Related Commands

| Command                                          | Description                                   |
|--------------------------------------------------|-----------------------------------------------|
| <a href="#">show eigrp topology, on page 666</a> | Displays entries in the EIGRP topology table. |

## timers nsf route-hold (EIGRP)

To set the timer that determines how long an NSF-aware Enhanced Interior Gateway Routing Protocol (EIGRP) router holds routes for an inactive peer, use the **timers nsf route-hold** command in the appropriate configuration mode. To return the route hold timer to the default value, use the **no** form of this command.

**timers nsf route-hold** *seconds*

**no timers nsf route-hold**

### Syntax Description

|                |                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Time, in seconds, that EIGRP holds routes for an inactive peer. Range is from 20 to 6000 seconds. |
|----------------|---------------------------------------------------------------------------------------------------|

### Command Default

EIGRP NSF awareness is enabled.

*seconds* :480

### Command Modes

IPv4 address family configuration

IPv6 address family configuration

IPv4 VRF address family configuration

IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |
| Release 4.1.1 | The default route hold time was changed from 240 seconds to 480 seconds.                                             |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **timers nsf route-hold** command to set the maximum period of time that the NSF-aware router holds known routes for an NSF-capable neighbor during a switchover operation or a well-known failure condition. The route hold timer is configurable so that you can tune network performance and avoid undesired effects, such as packet loss on routes if the switchover operation takes too much time. When this timer expires, the NSF-aware router scans the topology table and discards any stale routes, allowing EIGRP peers to find alternate routes instead of waiting during a long switchover operation.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to set the route hold timer value for an NSF-aware router to 2 minutes (120 seconds):

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# timers nsf route-hold 120
```

## variance

To control load balancing in an Enhanced Interior Gateway Routing Protocol (EIGRP)-based internetwork, use the **variance** command in the appropriate configuration mode. To reset the variance to the default value, use the **no** form of this command.

**variance** *multiplier*

**no variance**

### Syntax Description

|                   |                                                               |
|-------------------|---------------------------------------------------------------|
| <i>multiplier</i> | Metric value used for load balancing. Range is from 1 to 128. |
|-------------------|---------------------------------------------------------------|

### Command Default

*multiplier* : 1 (equal-cost load balancing)

### Command Modes

IPv4 address family configuration  
 IPv6 address family configuration  
 IPv4 VRF address family configuration  
 IPv6 VRF address family configuration

### Command History

| Release       | Modification                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| Release 3.3.0 | This command was introduced.                                                                                         |
| Release 3.5.0 | This command was supported in IPv6 address family configuration mode and IPv6 VRF address family configuration mode. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **variance** command to set a variance on the EIGRP router so that the router can determine the feasibility of a potential route. A route is feasible if the next router in the path is closer to the destination than the current router and the metric for the entire path is within the variance. Only paths that are feasible can be used for load balancing and included in the routing table.

If the following two conditions are met, the route is considered feasible and can be added to the routing table:

- 1 The local best metric must be greater than the metric learned from the next router.
- 2 The multiplier times the local best metric for the destination must be greater than or equal to the metric through the next router.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to set a variance of 4:

```
RP/0/0/CPU0:router(config)# router eigrp 1  
RP/0/0/CPU0:router(config-eigrp) address-family ipv4  
RP/0/0/CPU0:router(config-eigrp-af)# variance 4
```

## vrf (EIGRP)

To define a VPN routing and forwarding (VRF) instance and enter VRF configuration mode, use the **vrf** command in router configuration mode. To remove a VRF instance, use the **no** form of this command.

**vrf** *vrf-name*

**no vrf** *vrf-name*

### Syntax Description

|                 |                                      |
|-----------------|--------------------------------------|
| <i>vrf-name</i> | VPN routing and forwarding instance. |
|-----------------|--------------------------------------|

### Command Default

No VRFs are defined.

### Command Modes

Router configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **vrf** command to configure a VRF instance. A VRF instance is a collection of VPN routing and forwarding tables maintained at the provider edge (PE) router.

From VRF configuration mode, you must enter address family configuration mode and then issue commands, such as the **auto-summary** command.

A single EIGRP routing process can support multiple VRFs. The number of VRFs that can be configured is limited by available system resources on the router, which is determined by the number of VRFs, running processes, and available memory. However, only a single VRF can be supported by each VPN. Redistribution between different VRFs is not supported.

MPLS VPN support between PE and customer edge (CE) routers is configured only on PE routers that provide VPN services over the service provider backbone. The customer site does not require any changes to equipment or configurations to support the EIGRP VPN. Typically, a metric must be configured for routes to be advertised to the CE router. The metric can be configured under the route-policy for the **redistribute** protocol command or configured with the **default-metric** command.

You must remove IPv4/IPv6 addresses from an interface prior to assigning, removing, or changing a VRF on an IP interface. If this is not done in advance, any attempt to change the VRF on an IP interface is rejected.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| eigrp   | read, write |

**Examples**

The following example shows how to enter IPv4 VRF address family configuration mode and identify EIGRP commands that can be issued from that mode.

```
RP/0/0/CPU0:router(config)# router eigrp 1
RP/0/0/CPU0:router(config-eigrp)# vrf vpn-1
RP/0/0/CPU0:router(config-eigrp-vrf)# address-family ipv4
RP/0/0/CPU0:router(config-eigrp-vrf-af)# ?
```

|                       |                                                       |
|-----------------------|-------------------------------------------------------|
| auto-summary          | Auto summarisation                                    |
| autonomous-system     | Set the autonomous system of VRF                      |
| commit                | Commit the configuration changes to running           |
| default-information   | Handling of default route                             |
| default-metric        | Set metric of redistributed routes                    |
| describe              | Describe a command without taking real actions        |
| distance              | Set distance for EIGRP routes                         |
| do                    | Run an exec command                                   |
| exit                  | Exit from this submode                                |
| interface             | EIGRP interface configuration submode                 |
| log-neighbor-changes  | Enable/Disable EIGRP neighbor logging                 |
| log-neighbor-warnings | Enable/Disable EIGRP neighbor warnings                |
| maximum-paths         | Maximum paths                                         |
| maximum-prefix        | Maximum number of IP prefixes acceptable in aggregate |
| metric                | Modify EIGRP routing metrics and parameters           |
| neighbor              | Neighbor prefix limits configuration                  |
| no                    | Negate a command or set its defaults                  |
| redistribute          | Redistribute another protocol                         |
| route-policy          | Configure inbound/outbound policies                   |
| router-id             | Set router ID                                         |
| show                  | Show contents of configuration                        |
| stub                  | EIGRP stub                                            |
| timers                | Configure EIGRP timers                                |
| variance              | Control load balancing variance                       |

**Related Commands**

## IS-IS Commands

---

This module describes the commands used to configure and monitor the Intermediate System-to-Intermediate System (IS-IS) protocol.

For detailed information about IS-IS concepts, configuration tasks, and examples, see the *Implementing IS-IS on Cisco IOS XR Software* module in the *Cisco IOS XR Routing Configuration Guide for the Cisco XR 12000 Series Router*.

## address-family (IS-IS)

To enter address family configuration mode for configuring Intermediate System-to-Intermediate System (IS-IS) routing that use standard IP Version 4 (IPv4) and IP Version 6 (IPv6) address prefixes, use the **address-family** command in router configuration or interface configuration mode. To disable support for an address family, use the **no** form of this command.

**address-family** {ipv4| ipv6} {unicast| multicast}

**no address-family** {ipv4| ipv6} {unicast| multicast}

### Syntax Description

|                  |                                       |
|------------------|---------------------------------------|
| <b>ipv4</b>      | Specifies IPv4 address prefixes.      |
| <b>ipv6</b>      | Specifies IPv6 address prefixes.      |
| <b>unicast</b>   | Specifies unicast address prefixes.   |
| <b>multicast</b> | Specifies multicast address prefixes. |

### Command Default

An address family is not specified. The default subaddress family (SAFI) is unicast.

### Command Modes

Router configuration  
Interface configuration

### Command History

| Release       | Modification                            |
|---------------|-----------------------------------------|
| Release 3.2   | This command was introduced.            |
| Release 3.4.0 | The <b>multicast</b> keyword was added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address family** command to place the router or interface in address family configuration mode. In router address family configuration mode, you can configure routing that uses standard IPv4 or IPv6 address prefixes. An address family must be specified in interface configuration mode. In interface address family configuration mode, you can alter interface parameters for IPv4 or IPv6.

You must specify an address family in order to configure parameters that pertain to a single address family.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure the IS-IS router process with IPv4 unicast address prefixes:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface gigabitEthernet 0/1/0/0  
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-if-af)#
```

## address-family multicast topology (IS-IS)

To enable a multicast topology when configuring Intermediate System-to-Intermediate System (IS-IS) routing (or to place a given topology within the IS-IS interface), use the **address-family multicast topology** command with either IPv4 or IPv6 address prefix in the appropriate configuration mode. To disable a multicast topology in IS-IS, use the **no** form of this command.

**address-family** {ipv4| ipv6} **multicast topology** *topo-name* [**maximum prefix** *prefix-limit*]

**no address-family** {ipv4| ipv6} **multicast topology** *topo-name*

### Syntax Description

|                                  |                                                                     |
|----------------------------------|---------------------------------------------------------------------|
| <b>ipv4</b>                      | Specifies IPv4 address prefixes.                                    |
| <b>ipv6</b>                      | Specifies IPv6 address prefixes.                                    |
| <b>multicast</b>                 | Specifies multicast address prefixes.                               |
| <b>topology</b> <i>topo-name</i> | Specifies the name of the topology.                                 |
| <b>maximum prefix</b>            | Specifies maximum number of prefixes that a routing table can have. |
| <i>prefix-limit</i>              | Maximum number of prefixes. Range is from 32 to 2,000,000.          |

### Command Default

An address family for multicast topology is not specified. The default subaddress family (SAFI) is unicast.

### Command Modes

Router configuration  
Interface configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.7.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **address family multicast topology** command to place the router or interface in address family configuration mode. In router address family configuration mode, you can associate an IS-IS topology ID with the topology you have created to add connected and local routes to a specific routing table.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure the IS-IS router topology with an IPv4 multicast address prefix:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv6 multicast topology green
RP/0/0/CPU0:router(config-isis-af)#
```

or

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface gigabitethernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 multicast topology green
RP/0/0/CPU0:router(config-isis-if-af)#
```

# adjacency-check disable

To suppress Intermediate System-to-Intermediate System (IS-IS) IP Version 4 (IPv4) or IP Version 6 (IPv6) protocol-support consistency checks that are performed prior to forming adjacencies on hello packets, use the **adjacency-check disable** command in address family configuration mode. To remove this function, use the **no** form of this command.

**adjacency-check disable**

**no adjacency-check disable**

**Command Default** Adjacency check is enabled

**Command Modes** Address family configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

IS-IS performs consistency checks on hello packets and forms an adjacency only with a neighboring router that supports the same set of protocols. A router running IS-IS for both IPv4 and IPv6 does not form an adjacency with a router running IS-IS for IPv4 only.

Use the **adjacency-check disable** command to suppress the consistency checks for IPv6 IS-IS and allow an IPv4 IS-IS router to form an adjacency with a router running IPv4 IS-IS and IPv6. IS-IS never forms an adjacency between a router running IPv4 IS-IS only and a router running IPv6 only.

In addition, the **adjacency-check disable** command suppresses the IPv4 or IPv6 subnet consistency check and allows IS-IS to form an adjacency with other routers regardless of whether they have an IPv4 or IPv6 subnet in common.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The command in the following example disables the adjacency checks:

The following example shows how the network administrator introduces IPv6 into an existing IPv4 IS-IS network and ensures that the checking of hello packet checks from adjacent neighbors is disabled until all neighbor routers are configured to use IPv6:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv6 |ipv4  
RP/0/0/CPU0:router(config-isis-af)# adjacency-check disable
```

# advertise passive-only

To configure IS-IS to advertise only prefixes that belong to passive interfaces, use the **advertise-passive-only** command in ISIS address family configuration mode. To disable advertisement only prefixes that belong to passive interfaces, use the **no** form of this command.

**advertise passive-only**

**no advertise passive-only**

```

# attached-bit receive ignore

To ignore the attached bit in a received Level 1 link-state packet (LSP), use the **attached-bit receive ignore** command in address family configuration mode. To remove the **attached-bit receive ignore** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**attached-bit receive ignore**

**no attached-bit receive ignore**

## Command Default

The attached bit is set in the LSP.

## Command Modes

Address family configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure to ignore the attached bit in a received LSP:

```
RP/0/0/CPU0:router(config)# router isis ispl
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# attached-bit receive ignore
```

# attached-bit send

To configure an Intermediate System-to-Intermediate System (IS-IS) instance with an attached bit in the Level 1 link-state packet (LSP), use the **attached-bit send** command in address family configuration mode. To remove the **attached-bit send** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**attached-bit send** {always-set| never-set}

**no attached-bit send** {always-set| never-set}

## Syntax Description

|                   |                                                      |
|-------------------|------------------------------------------------------|
| <b>always-set</b> | Specifies to always set the attached bit in the LSP. |
| <b>never-set</b>  | Specifies to never set the attached bit in the LSP.  |

## Command Default

The attached bit is not forced to be set or unset in the LSP.

## Command Modes

Address family configuration

## Command History

| Release       | Modification                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------|
| Release 3.8.0 | This command was introduced and replaces the <a href="#">set-attached-bit, on page 829</a> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **attached-bit send** command to set an IS-IS instance with an attached bit in the Level 1 LSP that allows another IS-IS instance to redistribute Level 2 topology. The attached bit is used when the Level 2 connectivity from another IS-IS instance is advertised by the Level 1 attached bit.

Cisco IOS XR software does not support multiple Level 1 areas in a single IS-IS routing instance; however the equivalent functionality is achieved by redistribution of routes between two IS-IS instances by using the [redistribute \(IS-IS\), on page 818](#) command.

The attached bit is configured for a specific address family only if the **single-topology** command is not configured.

### Note

If connectivity for the Level 2 instance is lost, the attached bit in the Level 1 instance LSP continues sending traffic to the Level 2 instance and causes the traffic to be dropped.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure an Intermediate System-to-Intermediate System (IS-IS) instance with an attached bit:

```
RP/0/0/CPU0:router(config)# router isis ispl
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# attached-bit send always-set
```

**Related Commands**

|---------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">redistribute (IS-IS), on page 818</a> | Redistribute routes from one routing protocol into Intermediate System-to-Intermediate System (IS-IS). |
| <a href="#">single-topology, on page 907</a>      | Configures the link topology for IPv4 when IPv6 is configured.                                         |

# circuit-type

To configure the type of adjacency used for the Intermediate System-to-Intermediate System (IS-IS) protocol, use the **circuit-type** command in interface configuration mode. To reset the circuit type to Level 1 and Level 2, use the **no** form of this command.

**circuit-type** {level-1| level-1-2| level-2-only}

**no circuit-type**

## Syntax Description

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| <b>level-1</b>      | Establishes only Level 1 adjacencies over an interface.        |
| <b>level-1-2</b>    | Establishes both Level 1 and Level 2 adjacencies, if possible. |
| <b>level-2-only</b> | Establishes only Level 2 adjacencies over an interface.        |

## Command Default

Default adjacency types are Level 1 and Level 2 adjacencies.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Adjacencies may not be established even if allowed by the **circuit-type** command. The proper way to establish adjacencies is to configure a router as a Level 1, Level 1 and Level 2, or Level 2-only system using the [is-type, on page 753](#) command. Only on networking devices that are between areas (Level 1 and Level 2 networking devices) should you configure some interfaces to be Level 2-only to prevent wasting bandwidth by sending out unused Level 1 hello packets. Remember that on point-to-point interfaces, the Level 1 and Level 2 hello packets are in the same packet.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure a Level 1 adjacency with its neighbor on GigabitEthernetinterface 0/2/0/0 and Level 2 adjacencies with all Level 2-capable routers on GigabitEthernet interface 0/5/0/2:

```
RP/0/RP0/CPU0:router(config)# router isis isp
RP/0/RP0/CPU0:router(config-isis)# is-type level-1-2
RP/0/RP0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/0
RP/0/RP0/CPU0:router(config-isis-if)# circuit-type level-1
RP/0/RP0/CPU0:router(config-isis-if)# exit
RP/0/RP0/CPU0:router(config-isis)# interface GigabitEthernet 0/5/0/2
RP/0/RP0/CPU0:router(config-isis-if)# circuit-type level-2-only
```

In this example, only Level 2 adjacencies are established because the **is-type** command is configured:

```
RP/0/RP0/CPU0:router(config)# router isis isp
RP/0/RP0/CPU0:router(config-isis)# is-type level-2-only
RP/0/RP0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/0
RP/0/RP0/CPU0:router(config-isis-if)# circuit-type level-1-2
```

## Related Commands

# clear isis process

To clear the link-state packet (LSP) database and adjacency database sessions for an Intermediate System-to-Intermediate System (IS-IS) instance or all IS-IS instances, use the **clear isis process** command in EXEC mode.

**clear isis** [**instance** *instance-id*] **process**

## Syntax Description

**instance** *instance-id* (Optional) Specifies IS-IS sessions for the specified IS-IS instance only.

- The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear isis process** command without any keyword to clear all the IS-IS instances. Add the **instance** *instance-id* keyword and argument to clear the specified IS-IS instance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows the IS-IS LSP database and adjacency sessions being cleared for instance 1:

```
RP/0/0/CPU0:router# clear isis instance 1 process
```

EXEC

## Command History

| Release       | Modification                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                   |
| Release 3.4.0 | The following keywords were added: <ul style="list-style-type: none"> <li><b>multicast</b></li> <li><b>safi-all</b></li> </ul> |
| Release 3.7.0 | The <b>topology</b> <i>topo-name</i> keyword and argument were added.                                                          |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **clear isis route** command to clear the routes from the specified topology or all routes in all topologies if no topology is specified.

**Task ID**

| Task ID        | Operations  |
|----------------|-------------|
| isis           | execute     |
| rib            | read, write |
| basic-services | read, write |

**Examples**

The following example shows how to clear the routes with IPv4 unicast address prefixes:

```
RP/0/0/CPU0:router# clear isis ipv4 unicast route
```

**Related Commands**

| <a href="#">show isis neighbors, on page 877</a> | Displays information about IS-IS neighbors. |

# clear isis statistics

To clear the Intermediate System-to-Intermediate System (IS-IS) statistics, use the **clear isis statistics** command in EXEC mode.

**clear isis** [**instance** *instance-id*] **statistics** [*type interface-path-id*]

## Syntax Description

|                                    |                                                                                                                                                                                                                                                                                 |

# csnp-interval

To configure the interval at which periodic complete sequence number PDU (CSNP) packets are sent on broadcast interfaces, use the **csnp-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**csnp-interval** *seconds* [**level** {**1** | **2**}]

**no csnp-interval** *seconds* [**level** {**1** | **2**}]

## Syntax Description

|                                      |                                                                                                                                                                         |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i>                       | Interval (in seconds) of time between transmission of CSNPs on multiaccess networks. This interval applies only for the designated router. Range is 0 to 65535 seconds. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the interval of time between transmission of CSNPs for Level 1 or Level 2 independently.                                                           |

## Command Default

*seconds* : 10 seconds

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 2.0 | This command was introduced. |

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **csnp-interval** command applies only to the designated router (DR) for a specified interface. Only DRs send CSNP packets to maintain database synchronization. The CSNP interval can be configured independently for Level 1 and Level 2.

Use of the **csnp-interval** command on point-to-point subinterfaces makes sense only in combination with the IS-IS mesh-group feature.

**Task ID**

| Task ID        | Operations  |
|----------------|-------------|
| isis           | execute     |
| rib            | read, write |
| basic-services | read, write |

**Examples**

The following example shows how to set the CSNP interval for Level 1 to 30 seconds:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/0/2/0  
RP/0/0/CPU0:router(config-isis-if)# csnp-interval 30 level 1
```

## default-information originate (IS-IS)

To generate a default route into an Intermediate System-to-Intermediate System (IS-IS) routing domain, use the **default-information originate** command in address family configuration mode. To remove the **default-information originate** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**default-information originate** [**external**| **route-policy** *route-policy-name*]

**no default-information originate** [**external**| **route-policy** *route-policy-name*]

### Syntax Description

|                          |                                                                         |
|--------------------------|-------------------------------------------------------------------------|
| <b>external</b>          | (Optional) Enables default route to be originated as an external route. |
| <b>route-policy</b>      | (Optional) Defines the conditions for the default route.                |
| <i>route-policy-name</i> | (Optional) Name for the route policy.                                   |

### Command Default

A default route is not generated into an IS-IS routing domain.

### Command Modes

Address family configuration

### Command History

| Release       | Modification                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                             |
| Release 3.3.0 | The <b>route-map</b> <i>map-name</i> keyword and argument were changed to <b>route-policy</b> <i>route-policy-name</i> . |
| Release 4.2.0 | The <b>external</b> keyword was added.                                                                                   |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If a router configured with the **default-information originate** command has a route to 0.0.0.0 in the routing table, IS-IS originates an advertisement for 0.0.0.0 in its link-state packets (LSPs).

Without a route policy, the default is advertised only in Level 2 LSPs. For Level 1 routing, there is another process to find the default route, which is to look for the closest Level 1 and Level 2 router. The closest Level 1 and Level 2 router can be found by looking at the attached-bit (ATT) in Level 1 LSPs.

A route policy can be used for two purposes:

- To make the router generate the default route in its Level 1 LSPs.
- To advertise 0.0.0.0/0 conditionally.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to generate a default external route into an IS-IS domain:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# default-information originate
```

### Related Commands

| Command                                           | Description                                                                                             |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <a href="#">redistribute (IS-IS), on page 818</a> | Redistributes routes from one routing protocol into Intermediate System-to-Intermediate System (IS-IS). |
| <a href="#">show isis database, on page 847</a>   | Displays the IS-IS link-state database.                                                                 |

## disable (IS-IS)

To disable the Intermediate System-to-Intermediate System (IS-IS) topology on a specified interface, use the **disable** command in interface address family configuration mode. To remove this function, use the **no** form of this command.

**disable**

**no disable**

**Command Default** IS-IS protocol is enabled.

**Command Modes** Interface address family configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The following example shows how to disable the IS-IS protocol for IPv4 unicast on GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# disable
```

## distance (IS-IS)

To define the administrative distance assigned to routes discovered by the Intermediate System-to-Intermediate System (IS-IS) protocol, use the **distance** command in address family configuration mode. To remove the **distance** command from the configuration file and restore the system to its default condition in which the software removes a distance definition, use the **no** form of this command.

**distance** *weight* [*prefix mask* | *prefix/length* | [*prefix-list-name*]]

**no distance** [*weight*] [*prefix mask* | *prefix/length* | [*prefix-list-name*]]

### Syntax Description

|                         |                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>weight</i>           | Administrative distance to be assigned to IS-IS routes. Range is 1 to 255.                                                                                                                                                                                                                             |
| <i>prefix</i>           | (Optional) The <i>prefix</i> argument specifies the IP address in four-part, dotted-decimal notation.                                                                                                                                                                                                  |
| <i>mask</i>             | (Optional) IP address mask.                                                                                                                                                                                                                                                                            |
| <i>/length</i>          | (Optional) The length of the IP prefix. A decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value. Range is 0 to 32 for IPv4 addresses and 0 to 128 for IPv6 addresses. |
| <i>prefix-list-name</i> | (Optional) List of routes to which administrative distance applies.                                                                                                                                                                                                                                    |

### Command Default

*weight* : 115

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An administrative distance is an integer from 1 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means that the routing information source cannot be trusted at all and should be ignored. Weight values are subjective; no quantitative method exists for choosing weight values.

Use the **distance** command to configure the administrative distances applied to IS-IS routes when they are inserted into the Routing Information Base (RIB), and influence the likelihood of these routes being preferred over routes to the same destination addresses discovered by other protocols.

The *address/prefix-length* argument defines to which source router the distance applies. In other words, each IS-IS route is advertised by another router, and that router advertises an address that identifies it. This source address is displayed in the output of the **show isis route detail** command.

The **distance** command applies to the routes advertised by routers whose address matches the specified prefix. The *prefix-list-name* argument can then be used to refine this further so that the **distance** command affects only specific routes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

In the following example, a distance of 10 is assigned to all routes to 2.0.0.0/8 and 3.0.0.0/8 (or more specific prefixes) that are advertised by routers whose ID is contained in 1.0.0.0/8. A distance of 80 is assigned to all other routes.

```
RP/0/RP0/CPU0:router(config)# ipv4 prefix-list target_routes
RP/0/RP0/CPU0:router(config-ipv4_pfx)# permit 2.0.0.0/8
RP/0/RP0/CPU0:router(config-ipv4_pfx)# permit 3.0.0.0/8
RP/0/RP0/CPU0:router(config-ipv4_pfx)# deny 0.0.0.0/0
RP/0/RP0/CPU0:router(config-ipv4_pfx)# exit
RP/0/RP0/CPU0:router(config)# router isis isp
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# distance 10 1.0.0.0/8 target_routes
RP/0/RP0/CPU0:router(config-isis-af)# distance 80
```

## Related Commands

| Command                                                     | Description                                                            |
|-------------------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">router isis</a> , on page 827                   | Configures the IS-IS routing protocol and specifies an IS-IS instance. |

## fast-reroute per-link (IS-IS)

To enable IP fast reroute (IPFRR) loop-free alternate (LFA) prefix independent per-link computation, use the **fast-reroute per-link** command in interface address family configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-link** [**exclude interface** *type interface-path-id*] **level** {1| 2}| **lfa-candidate interface** *type interface-path-id*]

**no fast-reroute per-link**

### Syntax Description

|                          |                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>exclude</b>           | Specifies fast-reroute (FRR ) loop-free alternate (LFA) computation exclusion information                                                                                                                                                                                  |
| <b>level</b> {1   2}     | Configures FRR LFA computation for one level only.                                                                                                                                                                                                                         |
| <b>lfa-candidate</b>     | Specifies FRR LFA computation candidate information                                                                                                                                                                                                                        |
| <b>interface</b>         | Specifies an interface that needs to be either excluded from FRR LFA computation (when used with <b>exclude</b> keyword) or to be included to LFA candidate list in FRR LFA computation (when used with the <b>lfa-candidate</b> keyword).                                 |
| <i>type</i>              | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                    |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the show interfaces command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

### Command Default

IP fast-reroute LFA per-link computation is disabled.

### Command Modes

Interface address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| isis    | read, write |

**Examples**

This example shows how to configure per-link fast-reroute LFA computation for the IPv4 unicast topology at Level 1:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface POS0/3/0/0  
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-if-af)# fast-reroute per-link level 1
```

**Related Commands**

|--------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">fast-reroute per-prefix (IS-IS), on page 722</a> | Enables IP fast reroute (IPFRR) loop-free alternate (LFA) prefix dependent computation. |

## fast-reroute per-prefix (IS-IS)

To enable IP fast reroute (IPFRR) loop-free alternate (LFA) prefix dependent computation, use the **fast-reroute per-prefix** command in interface address family configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix** [**exclude interface type** *interface-path-id*] **level** {1| 2} [**lfa-candidate interface type** *interface-path-id*] [**remote-lfa** {**maximum-metric** *metric-value*} **tunnel mpls-ldp** {**level** {1| 1}}]

**no fast-reroute per-prefix**

### Syntax Description

|                          |                                                                                                                                                                                                                                                                            |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>exclude</b>           | Specifies fast-reroute (FRR ) loop-free alternate (LFA) computation exclusion information                                                                                                                                                                                  |
| <b>level</b> {1   2}     | Configures FRR LFA computation for one level only.                                                                                                                                                                                                                         |
| <b>lfa-candidate</b>     | Specifies FRR LFA computation candidate information                                                                                                                                                                                                                        |
| <b>interface</b>         | Specifies an interface that needs to be either excluded from FRR LFA computation (when used with <b>exclude</b> keyword) or to be included to LFA candidate list in FRR LFA computation (when used with the <b>lfa-candidate</b> keyword).                                 |
| <i>type</i>              | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                    |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the show interfaces command to see a list of all interfaces currently configured on the router.<br><br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

### Command Default

IP fast-reroute LFA per-prefix computation is disabled.

### Command Modes

Interface address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operation   |
|---------|-------------|
| isis    | read, write |

**Examples**

This example shows how to configure per-prefix fast-reroute LFA computation for the IPv4 unicast topology at Level 1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface POS0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix level 1
```

**Related Commands**

| Command                                                    | Description                                                                                        |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">fast-reroute per-link (IS-IS), on page 720</a> | Enables IP fast reroute (IPFRR) loop-free alternate (LFA) prefix independent per-link computation. |

## fast-reroute per-link priority-limit (IS-IS)

To enable the IP fast reroute (IPFRR) loop-free alternate (LFA) prefix independent per-link computation, use the **fast-reroute per-link priority-limit** command in address family configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-link priority-limit** {critical| high| medium} level {1| 2}

**no fast-reroute per-link priority-limit**

### Syntax Description

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>critical</b>    | Enables LFA omputation for critical priority prefixes only.                   |
| <b>high</b>        | Enables LFA computation for for criticaland high priority prefixes.           |
| <b>medium</b>      | Enables LFA computation for for critical, high, and medium priority prefixes. |
| <b>level {1 2}</b> | Sets priority-limit for routing Level 1 or Level 2 independently.             |

### Command Default

Fast-reroute per link priority limit LFA computation is disabled.

### Command Modes

IPv4 unicast address family configuration  
 IPv4 multicast address family configuration  
 IPv6 unicast address family configuration  
 IPv6 multicast address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

This example shows how to configure fast-reroute prefix independent per-link computation for critical priority prefixes for level 1 only:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router isis isp_lfa
RP/0/0/CPU0:router(config-isis)#address-family ipv4
RP/0/0/CPU0:router(config-isis-af)#fast-reroute per-link priority-limit critical level 1
```

## fast-reroute per-link use-candidate-only (IS-IS)

To exclude all interfaces by default from prefix independent per-link fast-reroute computation, use the **fast-reroute per-link use-candidate-only** command ISIS address family configuration mode. To include all interfaces by default, use the no form of this command.

**fast-reroute per-link use-candidate-only** [**level** {1| 2}]

**no fast-reroute per-link use-candidate-only**

### Syntax Description

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| <b>level</b> {1  2} | [Optional] Sets priority-limit for routing Level 1 or Level 2 independently. |
|---------------------|------------------------------------------------------------------------------|

### Command Default

None

### Command Modes

IPv4 unicast address family configuration  
 IPv4 multicast address family configuration  
 IPv6 unicast address family configuration  
 IPv6 multicast address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.2.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command can be configured for a specific level. If no level is given it is applicable for both level 1 and level 2.

### Task ID

| Task ID | Operation   |
|---------|-------------|
| isis    | read, write |

### Examples

This example shows how to configure the **fast-reroute per-link use-candidate-only** command for Level 1.

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router isis isp
```

```
RP/0/0/CPU0:router(config-isis)#address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-af)#fast-reroute use-candidate-only per-link level 1
```

## fast-reroute per-prefix load-sharing disable (IS-IS)

To disable load sharing prefixes across multiple backups, use the **fast-reroute per-prefix load-sharing disable** command in IPv4 address family configuration mode. To disable this feature, use the **no** form of this command.

**fast-reroute per-prefix load-sharingdisable**

**no fast-reroute per-prefix load-sharingdisable**

### Syntax Description

|                    |                                                             |
|--------------------|-------------------------------------------------------------|
| <b>level {1 2}</b> | Disables load-sharing for Level 1 or Level 2 independently. |
|--------------------|-------------------------------------------------------------|

### Command Default

Load sharing is enabled.

### Command Modes

IPv4 unicast address family configuration

IPv4 multicast address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.1 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

This example shows how to disable loadsharing prefixes across multiple backups for level 1 routes:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router isis isp_lfa
RP/0/0/CPU0:router(config-isis)#address-family ipv4
RP/0/0/CPU0:router(config-isis-af)#fast-reroute per-prefix load-sharing disable level 1
```

## fast-reroute per-prefix tiebreaker (IS-IS)

To configure tie-breaker for multiple backups, use the **fast-reroute per-prefix tiebreaker** command in IPv4 address family configuration mode. To disable tie-breaker configuration, use the **no** form of this command.

**fast-reroute per-prefix tiebreaker** [**downstream** | **lc-disjoint** | **lowest-backup-metric** | **node-protecting** | **primary-path** | **secondary-path**] **index** *index\_number* **level** {**1** | **2**}

**no fast-reroute per-prefix tiebreaker**

| Syntax Description          |  |                                                                               |
|-----------------------------|--|-------------------------------------------------------------------------------|
| <b>downstream</b>           |  | Configures to prefer backup path via downstream node, in case of tie-breaker. |
| <b>lc-disjoint</b>          |  | Configures to prefer Prefer line card disjoint backup path.                   |
| <b>lowest-backup-metric</b> |  | Configures to prefer backup path with lowest total metric.                    |
| <b>node-protecting</b>      |  | Configures to prefer node protecting backup path.                             |
| <b>primary-path</b>         |  | Configures to prefer backup path from ECMP set.                               |
| <b>secondary-path</b>       |  | Configures to prefer non-ECMP backup path.                                    |
| <b>index</b>                |  | Sets preference order among tie-breakers.                                     |
| <i>index_number</i>         |  | Value for the index. Range is 1-255.                                          |
| <b>level {1   2}</b>        |  | Configures tiebreaker for Level 1 or Level 2 independently.                   |

**Command Default** Tie-breaker for multiple backups is not configured.

**Command Modes** IPv4 unicast address family configuration  
IPv4 multicast address family configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 4.0.1 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

This example shows how to configure preference of backup path via downstream node in case of a tie-breaker for selection of backup path from multiple backup paths:

```
RP/0/0/CPU0:router#configure
RP/0/0/CPU0:router(config)#router isis isp_lfa
RP/0/0/CPU0:router(config-isis)#address-family ipv4
RP/0/0/CPU0:router(config-isis-af)#fast-reroute per-prefix tiebreaker downstream index 255
```

## fast-reroute per-prefix use-candidate-only (IS-IS)

To exclude all interfaces by default from prefix dependent fast-reroute computation, use the **fast-reroute per-prefix use-candidate-only** command ISIS address family configuration mode. To include all interfaces by default, use the **no** form of this command.

**fast-reroute per-prefix use-candidate-only** [level {1| 2}]

**no fast-reroute per-prefix use-candidate-only**

| Syntax Description | <b>level {1   2}</b> [Optional] Sets priority-limit for routing Level 1 or Level 2 independently. |
|--------------------|---------------------------------------------------------------------------------------------------|
|--------------------|---------------------------------------------------------------------------------------------------|

| Command Default | None |
|-----------------|------|
|-----------------|------|

| Command Modes | IPv4 unicast address family configuration<br>IPv4 multicast address family configuration<br>IPv6 unicast address family configuration<br>IPv6 multicast address family configuration |

| Task ID | Task ID | Operation   |
|---------|---------|-------------|
|         | isis    | read, write |

| Examples | This example shows how to configure the <b>fast-reroute per-prefix use-candidate-only</b> command for Level 1.<br><br>RP/0/0/CPU0:router# <b>configure</b><br>RP/0/0/CPU0:router(config)# <b>router isis isp</b> |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
RP/0/0/CPU0:router(config-isis)#address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)#fast-reroute use-candidate-only per-link level 1
```

## hello-interval (IS-IS)

To specify the length of time between consecutive hello packets sent by the Intermediate System-to-Intermediate System (IS-IS) protocol software, use the **hello-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**hello-interval** *seconds* [**level** {**1** | **2**}]

**no hello-interval** [*seconds*] [**level** {**1** | **2**}]

### Syntax Description

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i>                       | Integer value (in seconds) for the length of time between consecutive hello packets. By default, a value three times the hello interval <i>seconds</i> is advertised as the <i>hold time</i> in the hello packets sent. (That multiplier of three can be changed by using the <b>hello-multiplier</b> command.) With smaller hello intervals, topological changes are detected more quickly, but there is more routing traffic. Range is 1 to 65535 seconds. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the hello interval for Level 1 and Level 2 independently. For broadcast interfaces only.                                                                                                                                                                                                                                                                                                                                                |

### Command Default

*seconds* : 10 seconds

Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The hello interval can be configured independently for Level 1 and Level 2, except on serial point-to-point interfaces. (Because only a single type of hello packet is sent on serial links, it is independent of Level 1 or Level 2.) Configuring Level 1 and Level 2 independently is used on LAN interfaces.

#### Note

A shorter hello interval gives quicker convergence, but increases bandwidth and CPU usage. It might also add to instability in the network.

A slower hello interval saves bandwidth and CPU. Especially when used in combination with a higher hello multiplier, this strategy may increase overall network stability.

For point-to-point links, IS-IS sends only a single hello for Level 1 and Level 2, making the **level** keyword meaningless on point-to-point links. To modify hello parameters for a point-to-point interface, omit the **level** keyword.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to configure TenGigE interface 0/6/0/0 to advertise hello packets every 5 seconds for Level 1 topology routes. This situation causes more traffic than configuring a longer interval, but topological changes are detected more quickly.

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface TenGigE 0/6/0/0
RP/0/0/CPU0:router(config-isis-if)# hello-interval 5 level 1
```

### Related Commands

| Command                                        | Description                                                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">hello-multiplier</a> , on page 735 | Specifies the number of IS-IS hello packets a neighbor must miss before the router should declare the adjacency as down. |

# hello-multiplier

To specify the number of Intermediate System-to-Intermediate System (IS-IS) hello packets a neighbor must miss before the router should declare the adjacency as down, use the **hello-multiplier** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**hello-multiplier** *multiplier* [**level** {**1** | **2**}]

**no hello-multiplier** [*multiplier*] [**level** {**1** | **2**}]

## Syntax Description

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>multiplier</i>                    | Advertised hold time in IS-IS hello packets is set to the hello multiplier times the hello interval. Range is 3 to 1000. Neighbors declare an adjacency to this down router after not having received any IS-IS hello packets during the advertised hold time. The hold time (and thus the hello multiplier and the hello interval) can be set on an individual interface basis, and can be different between different networking devices in one area.<br><br>Using a smaller hello multiplier gives faster convergence, but can result in more routing instability. Increase the hello multiplier to a larger value to help network stability when needed. Never configure a hello multiplier to a value lower than the default value of 3. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the hello multiplier independently for Level 1 or Level 2 adjacencies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Command Default

*multiplier* : 3  
Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The “holding time” carried in an IS-IS hello packet determines how long a neighbor waits for another hello packet before declaring the neighbor to be down. This time determines how quickly a failed link or neighbor is detected so that routes can be recalculated.

Use the **hello-multiplier** command in circumstances where hello packets are lost frequently and IS-IS adjacencies are failing unnecessarily. You can raise the hello multiplier and lower the hello interval ([hello-interval \(IS-IS\)](#), on page 733 command) correspondingly to make the hello protocol more reliable without increasing the time required to detect a link failure.

On point-to-point links, there is only one hello for both Level 1 and Level 2. Separate Level 1 and Level 2 hello packets are also sent over nonbroadcast multiaccess (NBMA) networks in multipoint mode, such as X.25, Frame Relay, and ATM.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how the network administrator wants to increase network stability by making sure an adjacency goes down only when many (ten) hello packets are missed. The total time to detect link failure is 60 seconds. This strategy ensures that the network remains stable, even when the link is fully congested.

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-isis-if)# hello-interval 6
RP/0/0/CPU0:router(config-isis-if)# hello-multiplier 10
```

**Related Commands**

| Command                                             | Description                                                                 |
|-----------------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">hello-interval (IS-IS), on page 733</a> | Specifies the length of time between hello packets that the software sends. |

# hello-padding

To configure padding on Intermediate System-to-Intermediate System (IS-IS) hello protocol data units (IIH PDUs) for all IS-IS interfaces on the router, use the **hello-padding** command in interface configuration mode. To suppress padding, use the **no** form of this command.

**hello-padding** {disable| sometimes} [level {1| 2}]

**no hello-padding** {disable| sometimes} [level {1| 2}]

## Syntax Description

|                        |                                                                          |
|------------------------|--------------------------------------------------------------------------|
| <b>disable</b>         | Suppresses hello padding.                                                |
| <b>sometimes</b>       | Enables hello padding during adjacency formation only.                   |
| <b>level</b> { 1   2 } | (Optional) Specifies hello padding for Level 1 or Level 2 independently. |

## Command Default

Hello padding is enabled.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You might want to suppress hello padding to conserve network resources. The lower the circuit speed, the higher the percentage of padding overhead. Before suppressing the hello padding, you should know your physical and data link layer configurations and have control over them, and also know your router configuration at the network layer.

For point-to-point links, IS-IS sends only a single hello for Level 1 and Level 2, making the **level** keyword meaningless on point-to-point links. To modify hello parameters for a point-to-point interface, omit the **level** keyword.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to suppress IS-IS hello padding over local area network (LAN) circuits for interface GigabitEthernet 0/2/0/1:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1  
RP/0/0/CPU0:router(config-isis-if)# hello-padding disable
```

## Related Commands

# hello-password

To configure the authentication password for an Intermediate System-to-Intermediate System (IS-IS) interface, use the **hello-password** command in interface configuration mode. To disable authentication, use the **no** form of this command.

**hello-password** [**hmac-md5** | **text**] [**clear** | **encrypted**] *password* [**level** {**1** | **2**}] [**send-only**]

**no hello-password** [**hmac-md5** | **text**] [**clear** | **encrypted**] *password* [**level** {**1** | **2**}] [**send-only**]

## Syntax Description

|                                      |                                                                                                                                                           |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hmac-md5</b>                      | (Optional) Specifies that the password use HMAC-MD5 authentication.                                                                                       |
| <b>text</b>                          | (Optional) Specifies that the password use clear text password authentication.                                                                            |
| <b>clear</b>                         | (Optional) Specifies that the password be unencrypted.                                                                                                    |
| <b>encrypted</b>                     | (Optional) Specifies that the password be encrypted using a two-way algorithm.                                                                            |
| <i>password</i>                      | Authentication password you assign for an interface.                                                                                                      |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies whether the password is for a Level 1 or a Level 2 protocol data unit (PDU).                                                         |
| <b>send-only</b>                     | (Optional) Specifies that the password applies only to protocol data units (PDUs) that are being sent and does not apply to PDUs that are being received. |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

*password*: encrypted text

## Command Modes

Interface configuration

## Command History

| Release       | Modification                                                                                                                                                                                                    |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                    |
| Release 3.5.0 | The <b>keychain</b> <i>keychain-name</i> keyword and argument were added.                                                                                                                                       |
| Release 3.7.0 | Removed the <b>keychain</b> keyword and added the <b>hello-password keychain</b> command as a separate command from the <b>hello-password</b> command. Updated the syntax of the <b>hello-password</b> command. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a **text** password is configured, it is exchanged as clear text. Therefore, the **hello-password** command provides limited security.

When an **hmac-md5** password is configured, the password is never sent over the network and is instead used to calculate a cryptographic checksum to ensure the integrity of the exchanged data.

For point-to-point links, IS-IS sends only a single hello for Level 1 and Level 2, making the **level** keyword meaningless on point-to-point links. To modify hello parameters for a point-to-point interface, omit the **level** keyword.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure a password with HMAC-MD5 authentication for hello packets running on GigabitEthernet 0/2/0/3 interface:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/3
RP/0/0/CPU0:router(config-isis-if)# hello-password hmac-md5 clear mypassword
```

# hello-password keychain

To configure the authentication password keychain for an Intermediate System-to-Intermediate System (IS-IS) interface, use the **hello-password keychain** command in interface configuration mode. To disable the authentication password keychain, use the **no** form of this command.

**hello-password keychain** *keychain-name* [**level** {1| 2}] [**send-only**]

**no hello-password keychain** *keychain-name* [**level** {1| 2}] [**send-only**]

## Syntax Description

|                        |                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>keychain</b>        | Keyword that specifies the keychain to be configured. An authentication password keychain is a sequence of keys that are collectively managed and used for authenticating a peer-to-peer group. |
| <i>keychain-name</i>   | Specifies the name of the keychain.                                                                                                                                                             |
| <b>level</b> { 1   2 } | (Optional) Specifies whether the keychain is for a Level 1 or a Level 2 protocol data unit (PDU).                                                                                               |
| <b>send-only</b>       | (Optional) Specifies that the keychain applies only to protocol data units (PDUs) that are being sent and does not apply to PDUs that are being received.                                       |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

*password*: encrypted text

## Command Modes

Interface configuration

## Command History

| Release       | Modification                                                                                                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                    |
| Release 3.5.0 | The <b>keychain</b> <i>keychain-name</i> keyword and argument were added.                                                                                                       |
| Release 3.7.0 | Separated the <b>hello-password keychain</b> command as a separate command from the <b>hello-password</b> command, and updated the syntax of the <b>hello-password</b> command. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Specify a keychain to enable keychain authentication between two IS-IS peers. Use the **keychain** *keychain-name* keyword and argument to implement hitless key rollover for authentication.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure a password keychain for level 1, send only authentication on a GigabitEthernet interface:

```
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config-isis-if)# hello-password keychain mykeychain
level 1 send-only
```

## Related Commands

|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">hello-password, on page 739</a>        | Configures the authentication password for an Intermediate System-to-Intermediate System (IS-IS) interface. |
| <a href="#">hello-password accept, on page 743</a> | Configures an additional authentication password for an IS-IS interface.                                    |

# hello-password accept

To configure an additional authentication password for an Intermediate System-to-Intermediate System (IS-IS) interface, use the **hello-password accept** command in interface configuration mode. To disable authentication, use the **no** form of this command.

**hello-password accept** {clear| encrypted} *password* [level {1| 2}]

**no hello-password accept** {clear| encrypted} *password* [level {1| 2}]

## Syntax Description

|                        |                                                                         |
|------------------------|-------------------------------------------------------------------------|
| <b>clear</b>           | Specifies that the password be unencrypted.                             |
| <b>encrypted</b>       | Specifies that the password be encrypted using a two-way algorithm.     |
| <i>password</i>        | Authentication password you assign.                                     |
| <b>level</b> { 1   2 } | (Optional) Specifies the password for Level 1 or Level 2 independently. |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **hello-password accept** command to add an additional password for an IS-IS interface. An authentication password must be configured using the **hello-password** command before an accept password can be configured for the corresponding level.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure a password:

```
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/3
RP/0/0/CPU0:routerRP/0/0/CPU0:router(config-isis)# hello-password accept encrypted
11D1C1603
```

## Related Commands

| <a href="#">hello-password</a> , on page 739 | Configures an authentication password for an IS-IS interface. |

# hostname dynamic disable

To disable Intermediate System-to-Intermediate System (IS-IS) routing protocol dynamic hostname mapping, use the **hostname dynamic** command in router configuration mode. To remove the specified command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**hostname dynamic disable**

**no hostname dynamic disable**

## Syntax Description

|                |                               |
|----------------|-------------------------------|
| <b>disable</b> | Disables dynamic host naming. |
|----------------|-------------------------------|

## Command Default

Router names are dynamically mapped to system IDs.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

In an IS-IS routing domain, each router is represented by a 6-byte hexadecimal system ID. When network administrators maintain and troubleshoot networking devices, they must know the router name and corresponding system ID.

Link-state packets (LSPs) include the dynamic hostname in the type, length, and value (TLV) which carries the mapping information across the entire domain. Every router in the network, upon receiving the TLV from an LSP, tries to install it in a mapping table. The router then uses the mapping table when it wants to convert a system ID to a router name.

To display the entries in the mapping tables, use the **show isis hostname** command.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to disable dynamic mapping of hostnames to system IDs:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# hostname dynamic disable
```

**Related Commands**

| Command                                         | Description                                          |
|-------------------------------------------------|------------------------------------------------------|
| hostname                                        | Specifies the name of the local router.              |
| <a href="#">show isis hostname, on page 858</a> | Displays the router name-to-system ID mapping table. |

# ignore-lsp-errors

To override the default setting of a router to ignore Intermediate System-to-Intermediate System (IS-IS) link-state packets (LSPs) that are received with internal checksum errors, use the **ignore-lsp-errors disable** command in router configuration mode. To enable ignoring IS-IS LSP errors, use the **no** form of this command.

**ignore-lsp-errors disable**

**no ignore-lsp-errors disable**

## Syntax Description

|                |                                            |
|----------------|--------------------------------------------|
| <b>disable</b> | Disables the functionality of the command. |
|----------------|--------------------------------------------|

## Command Default

The system purges corrupt LSPs that cause the initiator to regenerate LSPs.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The IS-IS protocol definition requires that a received LSP with an incorrect data-link checksum be purged by the receiver, which causes the initiator of the packet to regenerate it. However, if a network has a link that causes data corruption and at the same time is delivering LSPs with correct data-link checksums, a continuous cycle of purging and regenerating large numbers of packets can occur. Because this situation could render the network nonfunctional, use this command to ignore these LSPs rather than purge the packets.

The receiving network devices use link-state packets to maintain their routing tables.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to instruct the router to ignore LSPs that have internal checksum errors:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# ignore-lsp-errors disable
```

# interface (IS-IS)

To configure the Intermediate System-to-Intermediate System (IS-IS) protocol on an interface, use the **interface** command in router configuration mode. To disable IS-IS routing for interfaces, use the **no** form of this command.

**interface** *type interface-path-id*

**no interface** *type interface-path-id*

## Syntax Description

|                          |                                                                                                                                                                                                                                                                                   |

| <i>interface-path-id</i> | Physical interface or virtual interface.<br><br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark ( ? ) online help function. |

## Command Default

No interfaces are specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

An address family must be established on the IS-IS interface before the interface is enabled for IS-IS protocol operation.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to enable an IS-IS multitopology configuration for IPv4 on GigabitEthernet interface 0/3/0/0:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# net 49.0000.0000.0001.00
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# metric-style wide level 1
!
RP/0/0/CPU0:router(config)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-if)# ipv4 address 2001::1/64
```

## Related Commands

| <a href="#">router isis</a> , on page 827                   | Enables the IS-IS routing protocol.                                        |

# ispf

To configure the incremental shortest path first (iSPF) algorithm to calculate network topology, use the **ispf** command in address family configuration mode. To disable this algorithm function, use the **no** form of this command.

**ispf** [**level** {**1** | **2**}]

**no ispf** [**level** {**1** | **2**}]

## Syntax Description

|                                      |                                                                                |
|--------------------------------------|--------------------------------------------------------------------------------|
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Configures the iSPF algorithm for Level 1 or Level 2 independently. |
|--------------------------------------|--------------------------------------------------------------------------------|

## Command Default

The iSPF algorithm is not configured.

## Command Modes

Address family configuration

## Command History

| Release       | Modification                                                               |
|---------------|----------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                               |
| Release 3.3.0 | The <b>startup-delay</b> <i>seconds</i> keyword and argument were removed. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The iSPF algorithm may be used to reduce the processor load when IS-IS needs to recalculate its topology after minor changes.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure iSPF for the IPv4 unicast topology at Level 1:

```
RP/0/0/CPU0:router(config)# router isis ispf
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# ispf level 1
```

# is-type

To configure the routing level for an Intermediate System-to-Intermediate System (IS-IS) area, use the **is-type** command in router configuration mode. To set the routing level to the default level, use the **no** form of this command.

**is-type** {level-1| level-1-2| level-2-only}

**no is-type** [level-1| level-1-2| level-2-only]

## Syntax Description

|                     |                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>level-1</b>      | Specifies that the router perform only Level 1 (intra-area) routing. This router learns only about destinations inside its area. Level 2 (interarea) routing is performed by the closest Level 1-2 router. |
| <b>level-1-2</b>    | Specifies that the router perform both Level 1 and Level 2 routing.                                                                                                                                        |
| <b>level-2-only</b> | Specifies that the routing process acts as a Level 2 (interarea) router only. This router is part of the backbone, and does not communicate with Level 1-only routers in its own area.                     |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the router is configured with Level 1 routing only, this router learns about destinations only inside its area. Level 2 (interarea) routing is performed by the closest Level 1-2 router.

When the router is configured with Level 2 routing only, this router is part of the backbone, and does not communicate with Level 1 routers in its own area.

The router has one link-state packet database (LSDB) for destinations inside the area (Level 1 routing) and runs a shortest path first (SPF) calculation to discover the area topology. It also has another LSDB with link-state packets (LSPs) of all other backbone (Level 2) routers, and runs another SPF calculation to discover the topology of the backbone and the existence of all other areas.

We highly recommend that you configure the type of an IS-IS routing process to establish the proper level of adjacencies. If there is only one area in the network, there is no need to run both Level 1 and Level 2 routing algorithms.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to specify that the router is part of the backbone and that it does not communicate with Level 1-only routers:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# is-type level-2-only
```

### Related Commands

| Command                                           | Description                                 |
|---------------------------------------------------|---------------------------------------------|
| <a href="#">circuit-type</a> , on page 705        | Configures the type of adjacency.           |
| <a href="#">show isis neighbors</a> , on page 877 | Displays information about IS-IS neighbors. |

# log adjacency changes (IS-IS)

To cause an IS-IS instance to generate a log message when an Intermediate System-to-Intermediate System (IS-IS) adjacency changes state (up or down), use the **log adjacency changes** command in router configuration mode. To restore the default value, use the **no** form of this command.

**log adjacency changes**

**no log adjacency changes**

**Command Default** No IS-IS instance log messages are generated.

**Command Modes** Router configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **log adjacency changes** command to monitor IS-IS adjacency state changes; it may be very useful when you are monitoring large networks. Messages are logged using the system error message facility. Messages can be in either of two forms:

```
%ISIS-4-ADJCHANGE: Adjacency to 0001.0000.0008 (Gi 0/2/1/0) (L2) Up, new adjacency
%ISIS-4-ADJCHANGE: Adjacency to router-gsr8 (Gi 0/2/1/0) (L1) Down, Holdtime expired
```

Using the **no** form of the command removes the specified command from the configuration file and restores the system to its default condition with respect to the command.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The following example shows how to configure the router to log adjacency changes:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# log adjacency changes
```

**Related Commands**

| Command | Description                            |
|---------|----------------------------------------|
| logging | Logs messages to a syslog server host. |

# log pdu drops

To log Intermediate System-to-Intermediate System (IS-IS) protocol data units (PDUs) that are dropped, use the **log pdu drops** command in router configuration mode. To disable this function, use the **no** form of this command.

**log pdu drops**

**no log pdu drops**

**Command Default** PDU logging is disabled.

**Command Modes** Router configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **log pdu drops** command to monitor a network when IS-IS PDUs are suspected of being dropped. The reason for the PDU being dropped and current PDU drop statistics are recorded.

The following are examples of PDU logging output:

```
%ISIS-4-ERR_IIH_INPUT_Q_OVERFLOW: IIH input queue overflow: 86 total drops; 19 IIH drops,
44 LSP drops, 23 SNP drops
%ISIS-4-ERR_LSP_INPUT_Q_OVERFLOW: LSP input queue overflow: 17 total drops; 9 IIH drops,
3 LSP drops, 5 SNP drops
```

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The following example shows how to enable PDU logging:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# log pdu drops
```

# lsp fast-flood threshold

To configure the link-state packet (LSP) fast-flood threshold, use the **lsp fast-flood threshold** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**lsp fast-flood threshold** *lsp-number* [**level** {**1** | **2**}]

**no lsp fast-flood threshold** [*lsp-number*] [**level** {**1** | **2**}]

## Syntax Description

|                                      |                                                                              |
|--------------------------------------|------------------------------------------------------------------------------|
| <i>lsp-number</i>                    | Number of LSPs to send back to back. Range is 1 to 4294967295.               |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the LSP threshold for Level 1 or Level 2 independently. |

## Command Default

10 LSPs are allowed in a back-to-back window

## Command Modes

Interface configuration

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.4.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **lsp fast-flood threshold** command to accelerate convergence of LSP database. LSPs are sent back-to-back over an interface up to the specified limit. Past the limit, LSPs are sent out in the next batch window as determined by LSP pacing interval.

Duration of back-to-back window = LSP interval \* LSP fast-flood threshold limit.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure the LSP threshold:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/0
```

```
RP/0/0/CPU0:router(config-isis-if)# lsp fast-flood threshold 234 level 1
```

**Related Commands**

|--------------------------------------------|------------------------------------------------------------------------------------|
| <a href="#">lsp-interval</a> , on page 762 | Configures the amount of time between consecutive LSPs sent on an IS-IS interface. |

# lsp-gen-interval

To customize IS-IS throttling of link-state packet (LSP) generation, use the **lsp-gen-interval** command in router configuration mode. To restore the default value, use the **no** form of this command.

**lsp-gen-interval** [**initial-wait** *initial*] [**secondary-wait** *secondary*] [**maximum-wait** *maximum*] [**level** {**1** | **2**}]  
**no lsp-gen-interval** [[**initial-wait** *initial*] [**secondary-wait** *secondary*] [**maximum-wait** *maximum*]] [**level** {**1** | **2**}]

## Syntax Description

|                                        |                                                                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>initial-wait</b> <i>initial</i>     | Specifies the initial LSP generation delay (in milliseconds). Range is 0 to 120000 milliseconds.                                                   |
| <b>secondary-wait</b> <i>secondary</i> | Specifies the hold time between the first and second LSP generation (in milliseconds). Range is 1 to 120000 milliseconds.                          |
| <b>maximum-wait</b> <i>maximum</i>     | Specifies the maximum interval (in milliseconds) between two consecutive occurrences of an LSP being generated. Range is 1 to 120000 milliseconds. |
| <b>level</b> { <b>1</b>   <b>2</b> }   | (Optional) Specifies the LSP time interval for Level 1 or Level 2 independently.                                                                   |

## Command Default

**initial-wait** *initial* : 50 milliseconds  
**secondary-wait** *secondary* : 200 milliseconds  
**maximum-wait** *maximum* : 5000 milliseconds

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

During prolonged periods of network instability, repeated recalculation of LSPs can cause increased CPU load on the local router. Further, the flooding of these recalculated LSPs to the other Intermediate Systems in the network causes increased traffic and can result in other routers having to spend more time running route calculations.

Use the **lsp-gen-interval** command to reduce the rate of LSP generation during periods of instability in the network. This command can help to reduce CPU load on the router and to reduce the number of LSP transmissions to its IS-IS neighbors.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to set the maximum interval between two consecutive occurrences of an LSP to 15 milliseconds and the initial LSP generation delta to 5 milliseconds:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# lsp-gen-interval maximum-wait 15 initial-wait 5
```

**Related Commands**

| Command                                                  | Description                                                                                      |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">retransmit-interval (IS-IS), on page 823</a> | Configures the amount of time between retransmission of each IS-IS LSP on a point-to-point link. |

# lsp-interval

To configure the amount of time between consecutive link-state packets (LSPs) sent on an Intermediate System-to-Intermediate System (IS-IS) interface, use the **lsp-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**lsp-interval** *milliseconds* [**level** {**1** | **2**}]

**no lsp-interval** [*milliseconds*] [**level** {**1** | **2**}]

## Syntax Description

*milliseconds* Time delay (in milliseconds) between successive LSPs. Range is 1 to 4294967295.

**level** { **1** | **2** } (Optional) Configures the LSP time delay for Level 1 or Level 2 independently.

## Command Default

*milliseconds* : 33 milliseconds

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to cause the system to send LSPs every 100 milliseconds (10 packets per second) on Level 1 and Level 2:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-isis-if)# lsp-interval 100
```

**Related Commands**

| <a href="#">retransmit-interval (IS-IS)</a> , on page 823 | Configures the amount of time between retransmission of each IS-IS LSP on a point-to-point link. |

# lsp-mtu

To set the maximum transmission unit (MTU) size of Intermediate System-to-Intermediate System (IS-IS) link-state packets (LSPs), use the **lsp-mtu** command in router configuration mode. To restore the default, use the **no** form of this command.

**lsp-mtu** *bytes* [**level** {**1** | **2**}]

**no lsp-mtu** [ *bytes* ] [**level** {**1** | **2**}]

## Syntax Description

|                                      |                                                                                                                                                          |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>bytes</i>                         | Maximum packet size in bytes. The number of bytes must be less than or equal to the smallest MTU of any link in the network. Range is 128 to 4352 bytes. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently.                                                                                           |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Under normal conditions, the default MTU size should be sufficient. However, if the MTU size of a link is less than 1500 bytes, the LSP MTU size must be lowered accordingly on each router in the network. If this action is not taken, routing becomes unpredictable.

This guideline applies to all Cisco networking devices in a network. If any link in the network has a reduced MTU size, all devices must be changed, not just the devices directly connected to the link.

### Note

Do not set the **lsp-mtu** command (network layer) to a value greater than the link MTU size that is set with the **mtu** command (physical layer).

To be certain about a link MTU size, use the [show isis interface](#), on page 860 command to display the value.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to set the MTU size to 1300 bytes:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# lsp-mtu 1300
```

**Related Commands**

| Command                                          | Description                                     |
|--------------------------------------------------|-------------------------------------------------|
| <b>mtu</b>                                       | Adjusts the maximum packet size or MTU size.    |
| <a href="#">show isis interface, on page 860</a> | Displays information about the IS-IS interface. |

# lsp-password

To configure the link-state packet (LSP) authentication password, use the **lsp-password** command in router configuration mode. To remove the **lsp-password** command from the configuration file and disable link-state packet authentication, use the **no** form of this command.

**lsp-password** [[**hmac-md5** | **text**] [**clear** | **encrypted**] *password* | **keychain** *keychain-name*] [**level** {**1** | **2**}] [**send-only**] [**snp send-only**]

**no lsp-password** [[**hmac-md5** | **text**] [**clear** | **encrypted**] *password* | **keychain** *keychain-name*] [**level** {**1** | **2**}] [**send-only**] [**snp send-only**]

## Syntax Description

|                                      |                                                                                                                                                                                         |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hmac-md5</b>                      | Specifies that the password uses HMAC-MD5 authentication.                                                                                                                               |
| <b>text</b>                          | Specifies that the password uses clear text password authentication.                                                                                                                    |
| <b>clear</b>                         | Specifies that the password be unencrypted.                                                                                                                                             |
| <b>encrypted</b>                     | Specifies that the password be encrypted using a two-way algorithm.                                                                                                                     |
| <i>password</i>                      | Authentication password you assign.                                                                                                                                                     |
| <b>keychain</b>                      | (Optional) Specifies a keychain.                                                                                                                                                        |
| <i>keychain-name</i>                 | Name of the keychain.                                                                                                                                                                   |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the password for Level 1 or Level 2 independently.                                                                                                                 |
| <b>send-only</b>                     | (Optional) Adds passwords to LSP and sequence number protocol (SNP) data units when they are sent. Does not check for authentication in received LSPs or sequence number PDUs (SNPs).   |
| <b>snp send-only</b>                 | (Optional) Adds passwords to SNP data units when they are sent. Does not check for authentication in received SNPs. This option is available when the <b>text</b> keyword is specified. |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release       | Modification                                                              |
|---------------|---------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                              |
| Release 3.5.0 | The <b>keychain</b> <i>keychain-name</i> keyword and argument were added. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a **text** password is configured, it is exchanged as clear text. Therefore, the **lsp-password** command provides limited security.

When an **HMAC-MD5** password is configured, the password is never sent over the network and is instead used to calculate a cryptographic checksum to ensure the integrity of the exchanged data.

The recommended password configuration is that both incoming and outgoing SNPs be authenticated.

**Note**

To disable SNP password checking, the **snp send-only** keywords must be specified in the **lsp-password** command.

To configure an additional password, use the **lsp-password accept** command.

Specify a key chain to enable key chain authentication between two IS-IS peers. Use the **keychain** *keychain-name* keyword and argument to implement hitless key rollover for authentication.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure separate Level 1 and Level 2 LSP and SNP passwords, one with HMAC-MD5 authentication and encryption and one with clear text password authentication and no encryption:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# lsp-password hmac-md5 clear password1 level 1
RP/0/0/CPU0:router(config-isis)# lsp-password text clear password2 level 2
```

**Related Commands**

|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| <a href="#">lsp-password accept</a> , <a href="#">on page 768</a> | Configures an additional LSP password when one LSP password is already configured for a level. |

# lsp-password accept

To configure an additional link-state packet (LSP) authentication password, use the **lsp-password accept** command in router configuration mode. To remove the **lsp-password accept** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**lsp-password accept** {clear| encrypted} *password* [level {1| 2}]

**no lsp-password accept** [{clear| encrypted} *password* [level {1| 2}]]

## Syntax Description

|                        |                                                                         |
|------------------------|-------------------------------------------------------------------------|
| <b>clear</b>           | Specifies that the password be unencrypted.                             |
| <b>encrypted</b>       | Specifies that the password be encrypted using a two-way algorithm.     |
| <i>password</i>        | Authentication password you assign.                                     |
| <b>level { 1   2 }</b> | (Optional) Specifies the password for Level 1 or Level 2 independently. |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **lsp-password accept** command adds an additional password for use when the system validates incoming LSPs and sequence number PDUs (SNPs). An LSP password must be configured using the **lsp-password** command before an accept password can be configured for the corresponding level.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure an accept Level 1 LSP and SNP password:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# lsp-password accept encrypted password1 level 1
```

## Related Commands

| <a href="#">lsp-password</a> , on page 766 | Configures an authentication LSP password. |

# lsp-refresh-interval

To set the time between regeneration of link-state packets (LSPs) that contain different sequence numbers, use the **lsp-refresh-interval** command in router configuration mode. To restore the default refresh interval, use the **no** form of this command.

**lsp-refresh-interval** *seconds* [**level** {**1** | **2**}]

**no lsp-refresh-interval** [*seconds* [**level** {**1** | **2**}]]

## Syntax Description

|                                      |                                                                |
|--------------------------------------|----------------------------------------------------------------|
| <i>seconds</i>                       | Refresh interval (in seconds). Range is 1 to 65535 seconds.    |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently. |

## Command Default

*seconds* : 900 seconds (15 minutes)

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The refresh interval determines the rate at which the software periodically sends the route topology information that it originates. This behavior is done to keep the information from becoming too old. By default, the refresh interval is 900 seconds (15 minutes).

LSPs must be refreshed periodically before their lifetimes expire. The refresh interval must be less than the LSP lifetime specified with this router command. Reducing the refresh interval reduces the amount of time that undetected link-state database corruption can persist at the cost of increased link utilization. (This event is extremely unlikely, however, because there are other safeguards against corruption.) Increasing the interval reduces the link utilization caused by the flooding of refreshed packets (although this utilization is very small).

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to change the LSP refresh interval to 10,800 seconds (3 hours):

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# lsp-refresh-interval 10800
```

## Related Commands

| Command                                                        | Description                                                      |
|----------------------------------------------------------------|------------------------------------------------------------------|
| <a href="#">max-lsp-lifetime</a> , <a href="#">on page 775</a> | Sets the maximum time that LSPs persist without being refreshed. |

## maximum-paths (IS-IS)

To configure the maximum number of parallel routes that an IP routing protocol will install into the routing table, use the **maximum-paths** command in address family configuration mode. To remove the **maximum-paths** command from the configuration file and restore the system to its default condition with respect to the routing protocol, use the **no** form of this command.

**maximum-paths** *maximum*

**no maximum-paths**

### Syntax Description

|                |                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------|
| <i>maximum</i> | Maximum number of parallel routes that IS-IS can install in a routing table.<br>Range is 1 to 16 |
|----------------|--------------------------------------------------------------------------------------------------|

### Command Default

*maximum* : 8 routes

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to allow a maximum of 16 paths to a destination:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# maximum-paths 8
```

## maximum-redistributed-prefixes (IS-IS)

To specify an upper limit on the number of redistributed prefixes (subject to summarization) that the Intermediate System-to-Intermediate System (IS-IS) protocol advertises, use the **maximum-redistributed-prefixes** command in address family mode. To disable this feature, use the **no** form of this command.

**maximum-redistributed-prefixes** *maximum* [**level** {1| 2}]

**no maximum-redistributed-prefixes** [*maximum* [**level** {1| 2}]]

### Syntax Description

|                |                                                                           |
|----------------|---------------------------------------------------------------------------|
| <i>maximum</i> | Maximum number of redistributed prefixes advertised. Range is 1 to 28000. |
|----------------|---------------------------------------------------------------------------|

|                        |                                                               |
|------------------------|---------------------------------------------------------------|
| <b>level</b> { 1   2 } | (Optional) Specifies maximum prefixes for Level 1 or Level 2. |
|------------------------|---------------------------------------------------------------|

### Command Default

*maximum*: 10000

**level** : 1-2

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **maximum-redistributed-prefixes** command to prevent a misconfiguration from resulting in redistribution of excess prefixes. If IS-IS encounters more than the maximum number of prefixes, it sets a bi-state alarm. If the number of to-be-redistributed prefixes drops back to the maximum or lower—either through reconfiguration or a change in the redistribution source—IS-IS clears the alarm.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to specify the number of redistributed prefixes at 5000 for Level 2:

```
RP/0/RP0/CPU0:router(config)# router isis isp
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# maximum-redistributed-prefixes 5000 level 2
```

# max-lsp-lifetime

To set the maximum time that link-state packets (LSPs) persist without being refreshed, use the **max-lsp-lifetime** command in router configuration mode. To restore the default time, use the **no** form of this command.

**max-lsp-lifetime** *seconds* [**level** {**1** | **2**}]

**no max-lsp-lifetime** [*seconds* [**level** {**1** | **2**}]]

## Syntax Description

|                                      |                                                                  |
|--------------------------------------|------------------------------------------------------------------|
| <i>seconds</i>                       | Lifetime (in seconds) of the LSP. Range from 1 to 65535 seconds. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently.   |

## Command Default

*seconds* : 1200 seconds (20 minutes)

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

You might need to adjust the maximum LSP lifetime if you change the LSP refresh interval with the **lsp-refresh-interval** command. The maximum LSP lifetime must be greater than the LSP refresh interval.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to set the maximum time that the LSP persists to 11,000 seconds (more than 3 hours):

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# max-lsp-lifetime 11000
```

**Related Commands**

| Command                                            | Description                    |
|----------------------------------------------------|--------------------------------|
| <a href="#">lsp-refresh-interval</a> , on page 770 | Sets the LSP refresh interval. |

## mesh-group (IS-IS)

To optimize link-state packet (LSP) flooding in highly meshed networks, use the **mesh-group** command in interface configuration mode. To remove a subinterface from a mesh group, use the **no** form of this command.

**mesh-group** {*number*| **blocked**}

**no mesh-group**

### Syntax Description

|                |                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------|
| <i>number</i>  | Number identifying the mesh group of which this interface is a member. Range is 1 to 4294967295. |
| <b>blocked</b> | Specifies that no LSP flooding takes place on this interface.                                    |

### Command Default

There is no mesh group configuration (normal LSP flooding).

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

LSPs first received on subinterfaces that are not part of a mesh group are flooded to all other subinterfaces in the usual way.

LSPs first received on subinterfaces that are part of a mesh group are flooded to all interfaces except those in the same mesh group. If the **blocked** keyword is configured on a subinterface, then a newly received LSP is not flooded out over that interface.

To minimize the possibility of incomplete flooding, you should allow unrestricted flooding over at least a minimal set of links in the mesh. Selecting the smallest set of logical links that covers all physical paths results in very low flooding, but less robustness. Ideally you should select only enough links to ensure that LSP flooding is not detrimental to scaling performance, but enough links to ensure that under most failure scenarios, no router is logically disconnected from the rest of the network. In other words, blocking flooding on all links permits the best scaling performance, but there is no flooding. Permitting flooding on all links results in very poor scaling performance.

**Note**

See RFC 2973 for details about the mesh group specification.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

In the following example, six interfaces are configured in three mesh groups. LSPs received are handled as follows:

- LSPs first received by GigabitEthernet interface 0/1/0/0 are flooded to all interfaces except GigabitEthernet 0/1/0/1 (which is part of the same mesh group) and GigabitEthernet 0/3/0/0 (which is blocked).
- LSPs first received by GigabitEthernet 0/2/0/1 are flooded to all interfaces except GigabitEthernet 0/2/0/0 (which is part of the same mesh group) and GigabitEthernet 0/3/0/0 (which is blocked).
- LSPs first received by GigabitEthernet 0/3/0/0 are not ignored, but flooded as usual to all interfaces.
- LSPs received first through GigabitEthernet 0/3/0/1 are flooded to all interfaces, except GigabitEthernet 0/3/0/0 (which is blocked).

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-isis-if)# mesh-group 10
RP/0/0/CPU0:router(config-isis-if)# exit
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# mesh-group 10
RP/0/0/CPU0:router(config-isis-if)# exit
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/0
RP/0/0/CPU0:router(config-isis-if)# mesh-group 11
RP/0/0/CPU0:router(config-isis-if)# exit
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1
RP/0/0/CPU0:router(config-isis-if)# mesh-group 11
RP/0/0/CPU0:router(config-isis-if)# exit
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/1
RP/0/0/CPU0:router(config-isis-if)# mesh-group 12
RP/0/0/CPU0:router(config-isis-if)# exit
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# mesh-group blocked
```

## metric (IS-IS)

To configure the metric for an Intermediate System-to-Intermediate System (IS-IS) interface, use the **metric** command in address family or interface address family configuration mode. To restore the default metric value, use the **no** form of this command.

**metric** {*default-metric*| **maximum**} [**level** {**1**| **2**}]

**no metric** [{*default-metric*| **maximum**} [**level** {**1**| **2**}]]

### Syntax Description

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>default-metric</i>                | Metric assigned to the link and used to calculate the cost from each other router using the links in the network to other destinations. Range is 1 to 63 for narrow metric and 1 to 16777214 for wide metric.<br><b>Note</b> Setting the default metric under address family results in setting the same metric for all interfaces that is associated with the address family. Setting a metric value under an interface overrides the default metric |
| <b>maximum</b>                       | Specifies maximum wide metric. All routers exclude this link from their shortest path first (SPF).                                                                                                                                                                                                                                                                                                                                                    |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies the SPF calculation for Level 1 or Level 2 independently.                                                                                                                                                                                                                                                                                                                                                                        |

### Command Default

*default-metric* : Default is 10.

Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Address family configuration  
Interface address family configuration

### Command History

| Release       | Modification                        |
|---------------|-------------------------------------|
| Release 3.2   | This command was introduced.        |
| Release 3.8.0 | Default metric value was set to 10. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Specifying the **level** keyword resets the metric only for the specified level. We highly recommend that you configure metrics on all interfaces.

Set the default metric under address family to set the same metric for all interfaces that is associated with the address family. Set a metric value under an interface to override the default metric.

We highly recommend that you configure metrics on all interfaces.

Metrics of more than 63 cannot be used with narrow metric style.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure Packet-over-SONET/SDH 0/1/0/1 interface with a default link-state metric cost of 15 for Level 1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# metric 15 level 1
```

The following example shows how to configure a metric cost of 15 for all interfaces under address family IPv4 unicast for level 2:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# metric 15 level 2
```

## Related Commands

| Command                                              | Description                                                                               |
|------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">metric-style narrow, on page 781</a>     | Configures a router running IS-IS so that it generates and accepts old-style TLV objects. |
| <a href="#">metric-style transition, on page 783</a> | Configures the software to generate and accept both old-style and new-style TLV objects.  |
| <a href="#">metric-style wide, on page 785</a>       | Configures the software to generate and accept only new-style TLV objects objects.        |

## metric-style narrow

To configure the Intermediate System-to-Intermediate System (IS-IS) software to generate and accept old-style type, length, and value (TLV) objects, use the **metric-style narrow** command in address family configuration mode. To remove the **metric-style narrow** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**metric-style narrow** [**transition**] [**level** {**1** | **2**}]

**no metric-style narrow** [**transition**] [**level** {**1** | **2**}]

### Syntax Description

|                                      |                                                                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>transition</b>                    | (Optional) Instructs the router to generate and accept both old-style and new-style TLV objects. It generates only old-style TLV objects. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently.                                                                            |

### Command Default

Old-style TLVs are generated.

Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

IS-IS traffic engineering extensions include new-style TLV objects with wider metric fields than old-style TLV objects. By default, the router generates old-style TLV objects only. To perform Multiprotocol Label Switching traffic engineering (MPLS TE), a router must generate new-style TLV objects.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure the router to generate and accept only old-style TLV objects on router Level 1:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-af)# metric-style narrow level 1
```

## Related Commands

| Command                                              | Description                                                                          |
|------------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">metric-style transition, on page 783</a> | Configures a router to generate and accept both old-style and new-style TLV objects. |
| <a href="#">metric-style wide, on page 785</a>       | Configures a router to generate and accept only new-style TLV objects.               |

## metric-style transition

To configure the Intermediate System-to-Intermediate System (IS-IS) software to generate and accept both old-style and new-style type, length, and value (TLV) objects, use the **metric-style transition** command in address family configuration mode. To remove the **metric-style transition** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**metric-style transition** [level {1| 2}]

**no metric-style transition** [level {1| 2}]

### Syntax Description

|                        |                                                                                       |
|------------------------|---------------------------------------------------------------------------------------|
| <b>transition</b>      | Instructs the router to generate and accept both old-style and new-style TLV objects. |
| <b>level { 1   2 }</b> | (Optional) Specifies routing Level 1 or Level 2 independently.                        |

### Command Default

Old-style TLVs are generated, if this command is not configured.  
Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

IS-IS traffic engineering extensions include new-style TLV objects which have wider metric fields than old-style TLV objects. By default, the router generates old-style TLV objects only. To perform Multiprotocol Label Switching traffic engineering (MPLS TE), a router needs to generate new-style TLV objects.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure the router to generate and accept both old-style and new-style TLV objects on Level 2:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-af)# metric-style transition level 2
```

## Related Commands

| Command                                          | Description                                                            |
|--------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">metric-style narrow, on page 781</a> | Configures a router to generate and accept only old-style TLV objects. |
| <a href="#">metric-style wide, on page 785</a>   | Configures a router to generate and accept only new-style TLV objects. |

## metric-style wide

To configure the Intermediate System-to-Intermediate System (IS-IS) software to generate and accept only new-style type, length, and value (TLV) objects, use the **metric-style wide** command in address family configuration mode. To remove the **metric-style wide** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**metric-style wide** [**transition**] [**level** {**1** | **2**}]

**no metric-style wide** [**transition**] [**level** {**1** | **2**}]

### Syntax Description

|                 |                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| transition      | (Optional) Instructs the router to generate and accept both old-style and new-style TLV objects. It generates only new-style TLV objects. |
| level { 1   2 } | (Optional) Specifies routing Level 1 or Level 2 independently.                                                                            |

### Command Default

Old-style TLV lengths are generated, if this command is not configured.  
Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

IS-IS traffic engineering extensions include new-style TLV objects with wider metric fields than old-style TLV objects. If you enter the **metric-style wide** command, a router generates and accepts only new-style TLV objects. Therefore, the router uses less memory and fewer other resources rather than generating both old-style and new-style TLV objects.

To perform MPLS traffic engineering, a router needs to generate new-style TLV objects.

#### Note

This discussion of metric styles and transition strategies is oriented toward traffic engineering deployment. Other commands and models might be appropriate if the new-style TLV objects are desired for other reasons. For example, a network may require wider metrics, but might not use traffic engineering.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure a router to generate and accept only new-style TLV objects on Level 1:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast  
RP/0/RP0/CPU0:router(config-isis-af)# metric-style wide level 1
```

**Related Commands**

|--------------------------------------------------|------------------------------------------------------------------------|
| <a href="#">metric-style narrow, on page 781</a> | Configures a router to generate and accept only old-style TLV objects. |

# min-lsp-arrivaltime

To control the rate of incoming LSPs (link-state packets) LSPs, use the **min-lsp-arrivaltime** command in router configuration mode. To remove this function use the **no** form of this command.

**min-lsp-arrivaltime** [*initial-wait initial*] [*secondary-wait secondary*] [*maximum-wait maximum*] [*level {1|2}*]

**no min-lsp-arrivaltime** [*initial-wait initial*] [*secondary-wait secondary*] [*maximum-wait maximum*] [*level {1|2}*]

## Syntax Description

|                                        |                                                                                                    |
|----------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>initial-wait</b> <i>initial</i>     | Initial LSP calculation delay (in milliseconds). Range is 0 to 120000.                             |
| <b>secondary-wait</b> <i>secondary</i> | Hold time between the first and second LSP calculations (in milliseconds). Range is 0 to 120000.   |
| <b>maximum-wait</b> <i>maximum</i>     | Maximum interval (in milliseconds) between two consecutive LSP calculations. Range is 0 to 120000. |
| <b>level</b> { <b>1</b>   <b>2</b> }   | (Optional) Enables the LSP interval configuration for Level 1 or Level 2 independently.            |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Router configuration mode

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.9.0 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

This command can be used to protect a router against the possible instability of its neighbor's LSPs.

The command parameters are similar to **lsp-gen-interval** command and neighbors **lsp-gen-interval** values can be used to set the **min-lsp-arrivaltime**

### Note

The initial-wait of minimum-lsp-arrival has no use in computing maximum counts and maximum window sizes of the LSP arrival time parameter.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure min-lsp-arrival time commands:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config)# router isis isp min-lsp-arrivaltime  
RP/0/0/CPU0:router(config)# router isis 1 min- lsp-arrivaltime initial-wait  
RP/0/0/CPU0:router(config)#router isis 1 min-lsp-arrivaltime maximum-wait  
RP/0/0/CPU0:router(config)#router isis 1 min-lsp-arrivaltime secondary-wait
```

# **mpls ldp auto-config**

To enable Label Distribution Protocol (LDP) Interior Gateway Protocol (IGP) interface auto-configuration, use the **mpls ldp auto-config** command in IPv4 address family configuration mode. To disable LDP IGP auto-configuration, use the **no** form of this command.

**mpls ldp auto-config**

**no mpls ldp auto-config**

**Syntax Description** This command has no keywords or arguments.

**Command Default** LDP IGP auto-configuration is disabled.

**Command Modes** IPv4 address family configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.5.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **mpls ldp auto-config** command to automatically configure LDP on a set of interfaces associated with a specified IGP instance. Further, LDP IGP auto-configuration provides a means to block LDP from being enabled on a specified interface. If you do not want an IS-IS interface to have LDP enabled, use the **igp auto-config disable** command.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

**Examples** The following example shows how to enable LDP IGP auto-configuration:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# mpls ldp auto-config
```

**Related Commands**

| Command                        | Description                                                   |
|--------------------------------|---------------------------------------------------------------|
| <b>igp auto-config disable</b> | Disables LDP IGP auto-configuration for a specific interface. |

## mpls ldp sync (IS-IS)

To configure Label Distribution Protocol (LDP) IS-IS synchronization, use the **mpls ldp sync** command in interface address family configuration mode. To disable LDP synchronization, use the **no** form of this command.

**mpls ldp sync** [level {1| 2}]

**no mpls ldp sync** [level {1| 2}]

### Syntax Description

|                        |                                                              |
|------------------------|--------------------------------------------------------------|
| <b>level</b> { 1   2 } | (Optional) Sets LDP synchronization for the specified level. |
|------------------------|--------------------------------------------------------------|

### Command Default

If a level is not specified, LDP synchronization is set for both levels.

### Command Modes

Interface address family configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.3.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

MPLS VPN traffic forwarded using LDP labels can be dropped in the following instances:

- A new link is introduced in the network and IS-IS has converged before LDP establishes labels.
- An existing LDP session goes down while IS-IS adjacency is intact over the link.

In both instances, outbound LDP labels are not available for forwarding MPLS traffic. LDP IS-IS synchronization addresses the traffic drop. When the **mpls ldp sync** command is configured, IS-IS advertises the maximum possible link metric until LDP has converged over the link. The link is less preferred and least used in forwarding MPLS traffic. When LDP establishes the session and exchanges labels, IS-IS advertises the regular metric over the link.

#### Note

IS-IS advertises the maximum metric –1 (16777214) if wide metrics are configured since the maximum wide metric is specifically used for link exclusion from the shortest path first algorithm (SPF) (RFC 3784). However, the maximum narrow metric is unaffected by this definition.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to enable LDP IS-IS synchronization:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-if-af)# mpls ldp sync
```

**Related Commands**

| Command                                          | Description                                     |
|--------------------------------------------------|-------------------------------------------------|
| <a href="#">show isis interface, on page 860</a> | Displays information about the IS-IS interfaces |

## mpls traffic-eng (IS-IS)

To configure a router running the Intermediate System-to-Intermediate System (IS-IS) protocol to flood Multiprotocol Label Switching traffic engineering (MPLS TE) link information into the indicated IS-IS level, use the **mpls traffic-eng** command in IPv4 address family configuration mode. To disable this feature, use the **no** form of this command.

**mpls traffic-eng** {level-1| level-1-2| level-2-only}

**no mpls traffic-eng** [level-1| level-1-2| level-2-only]

### Syntax Description

|                     |                                   |
|---------------------|-----------------------------------|
| <b>level-1</b>      | Specifies routing level 1.        |
| <b>level-1-2</b>    | Specifies routing levels 1 and 2. |
| <b>level-2-only</b> | Specifies routing level 2.        |

### Command Default

Flooding is disabled.

### Command Modes

IPv4 address family configuration

### Command History

| Release       | Modification                                                                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                                                                                                                 |
| Release 3.4.0 | The <b>level</b> { <b>1</b>   <b>2</b> } keywords were removed. The following keywords were added: <ul style="list-style-type: none"><li>• <b>level-1</b></li><li>• <b>level-1-2</b></li><li>• <b>level-2-only</b></li></ul> |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **mpls traffic-eng** command, which is part of the routing protocol tree, to flood link resource information (such as available bandwidth) for appropriately configured links in the link-state packet (LSP) of the router.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to turn on MPLS traffic engineering for IS-IS level 1:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast  
RP/0/0/CPU0:router(config-isis-af)# mpls traffic-eng level-1
```

**Related Commands**

| Command                                                         | Description                                                                                                                |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">mpls traffic-eng router-id (IS-IS), on page 799</a> | Specifies that the traffic engineering router identifier for the node is the IP address associated with a given interface. |

## mpls traffic-eng multicast-intact (IS-IS)

To enable multicast-intact for Intermediate System-to-Intermediate System (IS-IS) routes with Protocol-Independent Multicast (PIM) and Multiprotocol Label Switching (MPLS) traffic engineering, use the **mpls traffic-eng multicast-intact** command in IPv4 address family configuration mode. To disable this feature, use the **no** form of this command.

**mpls traffic-eng multicast-intact**  
**no mpls traffic-eng [multicast-intact]**

**Syntax Description** This command has no keywords or arguments.

**Command Default** Multicast-intact is disabled.

**Command Modes** IPv4 address family configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | Release 3.2 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

If Multiprotocol Label Switching Traffic Engineering (MPLS-TE) is configured through the IS-IS routing domain and multicast protocols (like Protocol Independent Multicast [PIM]) are also enabled, then use the **mpls traffic-eng multicast-intact** command to install nontraffic engineering next hops in the Routing Information Base (RIB) for use by multicast. The installation of IP-only next hops is in addition to the installation of the standard set of paths for a prefix, which might be through traffic engineered tunnels.

The **mpls traffic-eng multicast-intact** command allows PIM to use the native hop-by-hop neighbors even though the unicast routing is using MPLS TE tunnels.

**Examples** The following example shows how to enable the multicast-intact feature:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# mpls traffic-engmulticast-intact
```

**Related Commands**

| Command                                         | Description                                                                                  |
|-------------------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">show isis route, on page 884</a>    | Displays IP reachability information for an IS-IS instance, optionally for multicast-intact. |
| <a href="#">show isis topology, on page 899</a> | Displays a list of connected IS-IS routers in all areas, optionally for multicast-intact.    |

# **mpls traffic-eng path-selection ignore overload**

To ensure that label switched paths (LSPs) are not disabled when routers have the Intermediate System-to-Intermediate System (IS-IS) overload bit set, use the **mpls traffic-eng path-selection ignore overload** command in global configuration mode. To disable this override, use the **no** form of this command.

**mpls traffic-eng path-selection ignore overload**

**no mpls traffic-eng path-selection ignore overload**

**Command Default** No default behavior or values

**Command Modes** Global configuration

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | Release 3.7.0 | This command was introduced. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the IS-IS overload bit avoidance feature is activated, which means that they are still available for use label switched paths (LSPs), all nodes with the overload bit set, including the following nodes, are ignored:

- head nodes
- mid nodes
- tail nodes

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | mpls-te | read, write |

**Examples** The following example shows how to activate IS-IS overload bit avoidance:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# mpls traffic-eng path-selection ignore overload
```

The following example shows how to deactivate IS-IS overload bit avoidance:

```
RP/0/0/CPU0:router# configure
RP/0/0/CPU0:router(config)# no mpls traffic-eng path-selection ignore overload
```

#### Related Commands

| Command                                       | Description                                                                                                                       |

| <a href="#">set-overload-bit, on page 831</a> | Configures a router to signal other routers not to use it as an intermediate hop in their shortest path first (SPF) calculations. |

## mpls traffic-eng router-id (IS-IS)

To specify the Multiprotocol Label Switching traffic engineering (MPLS TE) router identifier for the node, use the **mpls traffic-eng router-id** command in IPv4 address family configuration mode. To disable this feature, use the **no** form of this command.

**mpls traffic-eng router-id** *{ip-address| type interface-path-id}*

**no mpls traffic-eng** [*router-id*]

### Syntax Description

|                          |                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ip-address</i>        | IP address in four-part, dotted-decimal notation.                                                                                                                                                                                                                           |
| <i>type</i>              | Interface type. For more information, use the question mark (?) online help function.                                                                                                                                                                                       |
| <i>interface-path-id</i> | Physical interface or virtual interface.<br><b>Note</b> Use the <b>show interfaces</b> command to see a list of all interfaces currently configured on the router.<br>For more information about the syntax for the router, use the question mark (?) online help function. |

### Command Default

Global router identifier is used.

### Command Modes

IPv4 address family configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The identifier of the router acts as a stable IP address for the traffic engineering configuration. This IP address is flooded to all nodes. For all traffic engineering tunnels originating at other nodes and ending at this node, you must set the tunnel destination to the traffic engineering router ID of the destination node, because that is the address used by the traffic engineering topology database at the tunnel head for its path calculation.

#### Note

We recommend that loopback interfaces be used for MPLS TE, because they are more stable than physical interfaces.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to specify the traffic engineering router identifier as the IP address associated with loopback interface 0:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# mpls traffic-eng router-id Loopback0
```

**Related Commands**

|-------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">mpls traffic-eng (IS-IS), on page 793</a> | Turns on flooding of MPLS traffic engineering link information in the indicated IGP level or area. |

## mpls traffic-eng srlg (IS-IS)

To configure Shared Risk Link Group (SRLG) membership of a link, use the **mpls traffic-eng srlg** command in global configuration mode. To disable this feature, use the **no** form of this command.

**mpls traffic-eng** [*type interface-path-id*] **srlg** *number*

**no mpls traffic-eng** [*type interface-path-id*] **srlg** *number*

### Syntax Description

|                   |                                                                                                                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number            | SRLG membership number. Range is 0 to 4294967295.                                                                                                                                                                                                                         |
| type              | Interface type. For more information, use the question mark ( ? ) online help function.                                                                                                                                                                                   |

### Command Default

Shared Risk Link Group memberships are not configured.

### Command Modes

Global configuration

### Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 3.8.0 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |
| mpls-te | read, write |

## Examples

The following example shows how to configure an SRLG with 10 member links:

```
RP/0/0/CPU0:router(config)#mpls traffic-eng interface gigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-mpls-te-if)#srlg 10
```

## Related Commands

| Command                                                | Description                                                                                        |

| <a href="#">mpls traffic-eng (IS-IS)</a> , on page 793 | Turns on flooding of MPLS traffic engineering link information in the indicated IGP level or area. |

# net

To configure an Intermediate System-to-Intermediate System (IS-IS) network entity title (NET) for the routing instance, use the **net** command in router configuration mode. To remove the **net** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**net** *network-entity-title*

**no net** *network-entity-title*

## Syntax Description

|                      |                                                                                    |
|----------------------|------------------------------------------------------------------------------------|
| network-entity-title | NET that specifies the area address and the system ID for an ISIS routing process. |
|----------------------|------------------------------------------------------------------------------------|

## Command Default

No NET is configured. The IS-IS instance is not operational, because a NET is mandatory.

## Command Modes

Router configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Under most circumstances, one and only one NET should be configured.

A NET is a network service access point (NSAP) where the last byte is always 0. On a Cisco router running IS-IS, a NET can be 8 to 20 bytes in length. The last byte is always the n-selector and must be 0. The n-selector indicates to which transport entity the packet is sent. An n-selector of 0 indicates no transport entity and means that the packet is for the routing software of the system.

The six bytes directly preceding the n-selector are the system ID. The system ID length is a fixed size and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2).

All bytes preceding the system ID are the area ID.

A maximum of three NETs for each router is allowed. In rare circumstances, it is possible to configure two or three NETs. In such a case, the area this router is in has three area addresses. Only one area still exists, but it has more area addresses.

Configuring multiple NETs can be temporarily useful in network reconfiguration in which multiple areas are merged, or in which one area is split into more areas. Multiple area addresses enable you to renumber an area individually as needed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to configure a router with NET area ID 47.0004.004d.0001 and system ID 0001.0c11.1110:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# net 47.0004.004d.0001.0001.0c11.1110.00
```

**Related Commands**

| Command                                                    | Description                                                                |
|------------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">log adjacency changes (IS-IS), on page 755</a> | Configures the routing level for an instance of the IS-IS routing process. |
| <a href="#">router isis, on page 827</a>                   | Enables the IS-IS routing protocol and specifies an IS-IS instance.        |

## nsf (IS-IS)

To enable nonstop forwarding (NSF) on the next restart, use the **nsf** command in router configuration mode. To restore the default setting, use the **no** form of this command.

**nsf** {**cisco**|**ietf**}

**no nsf** {**cisco**|**ietf**}

### Syntax Description

|              |                                                               |
|--------------|---------------------------------------------------------------|
| <b>cisco</b> | Specifies Cisco-proprietary NSF restart.                      |
| <b>ietf</b>  | Specifies Internet Engineering Task Force (IETF) NSF restart. |

### Command Default

NSF is disabled.

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

NSF allows an Intermediate System-to-Intermediate System (IS-IS) instance to restart using checkpointed adjacency and link-state packet (LSP) information, and to perform restart with no impact on its neighbor routers. In other words, there is no impact on other routers in the network due to the destruction and recreation of adjacencies and the system LSP.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to enable Cisco proprietary NSF:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# nsf cisco
```

**Related Commands**

| Command                                            | Description                                                                                      |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">nsf interface-expires, on page 807</a> | Configures the number of resends of an acknowledged NSF-restart acknowledgment.                  |
| <a href="#">nsf interface-timer, on page 809</a>   | Configures the time interval after which an unacknowledged IETF NSF restart attempt is repeated. |
| <a href="#">nsf lifetime (IS-IS), on page 811</a>  | Configures the maximum route lifetime following an NSF restart.                                  |

## nsf interface-expires

To configure the number of resends of an acknowledged nonstop forwarding (NSF)-restart acknowledgment, use the **nsf interface-expires** command in router configuration mode. To restore the default value, use the **no** form of this command.

**nsf interface-expires** *number*

**no nsf interface-expires**

### Syntax Description

|        |                                     |
|--------|-------------------------------------|
| number | Number of resends. Range is 1 to 3. |
|--------|-------------------------------------|

### Command Default

*number* : 3 resends

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When a hello packet sent with the NSF restart flag set is not acknowledged, it is re-sent. Use the **nsf interface-expires** command to control the number of times the NSF hello is re-sent. When this limit is reached on an interface, any neighbor previously known on that interface is assumed to be down and the initial shortest path first (SPF) calculation is permitted, provided that all other necessary conditions are met.

The total time period available for adjacency reestablishment (interface-timer \* interface-expires) should be greater than the expected total NSF restart time.

The **nsf interface-expires** command applies only to Internet Engineering Task Force (IETF)-style NSF. It has no effect if Cisco-proprietary NSF is configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to allow only one retry attempt on each interface if an IETF NSF restart signal is not acknowledged:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# nsf ietf  
RP/0/0/CPU0:router(config-isis)# nsf interface-expires 1
```

## Related Commands

| Command                                           | Description                                                                                                              |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <a href="#">hello-multiplier</a> , on page 735    | Specifies the number of IS-IS hello packets a neighbor must miss before the router should declare the adjacency as down. |
| <a href="#">nsf interface-timer</a> , on page 809 | Configures the time interval after which an unacknowledged IETF NSF restart attempt is repeated.                         |

## nsf interface-timer

To configure the time interval after which an unacknowledged Internet Engineering Task Force (IETF) nonstop forwarding (NSF) restart attempt is repeated, use the **nsf interface-timer** command in router configuration mode. To restore the default value, use the **no** form of this command.

**nsf interface-timer** *seconds*

**no nsf interface-timer**

### Syntax Description

|         |                                                                   |
|---------|-------------------------------------------------------------------|
| seconds | NSF restart time interval (in seconds). Range is 3 to 20 seconds. |
|---------|-------------------------------------------------------------------|

### Command Default

*seconds* : 10 seconds

### Command Modes

Router configuration

### Command History

| Release     | Modification                |
|-------------|-----------------------------|
| Release 3.2 | This command was introduced |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

When the IETF NSF restart process begins, hello packets send an NSF restart flag that must be acknowledged by the neighbors of the router. Use the **nsf interface-timer** command to control the restart time interval after the hello packet is re-sent. The restart time interval need not match the hello interval.

The **nsf interface-timer** command applies only to IETF-style NSF. It has no effect if Cisco proprietary NSF is configured.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to ensure that a hello packet with the NSF restart flag set is sent again every 5 seconds until the flag is acknowledged:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# nsf ietf
```

```
RP/0/0/CPU0:router(config-isis)# nsf interface-timer 5
```

**Related Commands**

| Command                                              | Description                                                                     |
|------------------------------------------------------|---------------------------------------------------------------------------------|
| <a href="#">nsf interface-expires</a> , on page 807  | Configures the number of resends of an acknowledged NSF-restart acknowledgment. |
| <a href="#">hello-interval (IS-IS)</a> , on page 733 | Specifies the length of time between hello packets that the software sends.     |

## nsf lifetime (IS-IS)

To configure the maximum route lifetime following a nonstop forwarding (NSF) restart, use the **nsf lifetime** command in router configuration mode. To restore the default value, use the **no** form of this command.

**nsf lifetime** *seconds*

**no nsf lifetime**

### Syntax Description

|         |                                                                                          |
|---------|------------------------------------------------------------------------------------------|
| seconds | Maximum route lifetime (in seconds) following an NSF restart. Range is 5 to 300 seconds. |
|---------|------------------------------------------------------------------------------------------|

### Command Default

*seconds* : 60 seconds (1 minute)

### Command Modes

Router configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **nsf lifetime** command to set the maximum available time for the reacquisition of checkpointed adjacencies and link-state packets (LSPs) during a Cisco proprietary NSF restart. LSPs and adjacencies not recovered during this time period are abandoned, thus causing changes to the network topology.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to configure the router to allow only 20 seconds for the entire NSF process:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# nsf cisco
RP/0/0/CPU0:router(config-isis)# nsf lifetime 20
```

## passive (IS-IS)

To suppress Intermediate System-to-Intermediate System (IS-IS) packets from being transmitted to the interface and received packets from being processed on the interface, use the **passive** command in interface configuration mode. To restore IS-IS packets coming to an interface, use the **no** form of this command.

**passive**

**no passive**

### Command Default

Interface is active.

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to configure the router to suppress IS-IS packets on GigabitEthernet interface 0/1/0/1:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/1/0/1
RP/0/0/CPU0:router(config-isis-if)# passive
```

### Related Commands

| Command                                                  | Description                                                                                                          |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <a href="#">suppressed</a> , <a href="#">on page 917</a> | Allows the IS-IS interface to participate in forming adjacencies without advertising connected prefixes in the LSPs. |

# point-to-point

To configure a network of only two networking devices that use broadcast media and the integrated Intermediate System-to-Intermediate System (IS-IS) routing protocol to function as a point-to-point link instead of a broadcast link, use the **point-to-point** command in interface configuration mode. To disable the point-to-point usage, use the **no** form of this command.

**point-to-point**

**no point-to-point**

## Syntax Description

This command has no keywords or arguments.

## Command Default

Interface is treated as broadcast if connected to broadcast media.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **point-to-point** command only on broadcast media in a network with two networking devices. The command causes the system to issue packets point-to-point rather than as broadcasts. Configure the command on both networking devices in the network.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure a 10-Gb Ethernet interface to act as a point-to-point interface:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# interface TenGigE 0/6/0/0
RP/0/0/CPU0:router(config-isis-if)# point-to-point
```

# priority (IS-IS)

To configure the priority of designated routers, use the **priority** command in interface configuration mode. To reset the default priority, use the **no** form of this command.

**priority** *value* [**level** {1| 2}]

**no priority** [ *value* ] [**level** {1| 2}]

## Syntax Description

|                        |                                                                |
|------------------------|----------------------------------------------------------------|
| <i>value</i>           | Priority of a router. Range is 0 to 127.                       |
| <b>level</b> { 1   2 } | (Optional) Specifies routing Level 1 or Level 2 independently. |

## Command Default

*value* : 64

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                |
|-------------|-----------------------------|
| Release 3.2 | This command was introduced |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Priorities can be configured for Level 1 and Level 2 independently. Specifying Level 1 or Level 2 resets priority only for Level 1 or Level 2 routing, respectively. Specifying no level allows you to configure all levels.

The priority is used to determine which router on a LAN is the designated router or Designated Intermediate System (DIS). The priorities are advertised in the hello packets. The router with the highest priority becomes the DIS.

In the Intermediate System-to-Intermediate System (IS-IS) protocol, there is no backup designated router. Setting the priority to 0 lowers the chance of this system becoming the DIS, but does not prevent it. If a router with a higher priority comes online, it takes over the role from the current DIS. For equal priorities, the higher MAC address breaks the tie.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to give Level 1 routing priority by setting the priority level to 80. This router is now more likely to become the DIS.

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface TenGigE0/6/0/0  
RP/0/0/CPU0:router(config-isis-if)# priority 80 level 1
```

# propagate level

To propagate routes from one Intermediate System-to-Intermediate System (IS-IS) level into another level, use the **propagate level** command in address family configuration mode. To disable propagation, use the **no** form of this command.

**propagate level** {1| 2} **into level** {1| 2} **route-policy** *route-policy-name*

**no propagate level** {1| 2} **into level** {1| 2}

## Syntax Description

|                                              |                                                                           |
|----------------------------------------------|---------------------------------------------------------------------------|
| <b>level</b> { 1   2 }                       | Propagates from routing Level 1 or Level 2 routes.                        |
| <b>into</b>                                  | Propagates from Level 1 or Level 2 routes into Level 1 or Level 2 routes. |
| <b>route-policy</b> <i>route-policy-name</i> | Specifies a configured route policy.                                      |

## Command Default

Route leaking (Level 2 to Level 1) is disabled.

## Command Modes

Address family configuration

## Command History

| Release       | Modification                                                                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                                           |
| Release 3.5.0 | The <b>distribute-list</b> <i>access-list-name</i> keyword and argument were changed to <b>route-policy</b> <i>route-policy-name</i> . |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

In general, route propagation from Level 1 to Level 2 is automatic. You might want to use this command to better control which Level 1 routes can be propagated into Level 2.

Propagating Level 2 routes into Level 1 is called *route leaking*. Route leaking is disabled by default. That is, Level 2 routes are not automatically included in Level 1 link-state packets (LSPs). If you want to leak Level 2 routes into Level 1, you must enable that behavior by using this command.

Propagation from Level 1 into Level 1 and from Level 2 into Level 2 is not allowed.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

The following example shows how to redistribute Level 2 routes to Level 1:

```
RP/0/0/CPU0:router(config)# ipv4 access-list 101 permit ip 10.0.0.0 255.0.0.0 10.1.0.1
0.255.255.255
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# net 49.1234.2222.2222.00
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# propagate level 2 into level 1 route-policy policy_a
```

|---------------------------------------------------|-------------------------------------------------------------------------------|
| <a href="#">redistribute (IS-IS), on page 818</a> | Redistributes routes from one routing domain into a specified IS-IS instance. |

## redistribute (IS-IS)

To redistribute routes from one routing protocol into Intermediate System-to-Intermediate System (IS-IS), use the **redistribute** command in address family configuration mode. To remove the **redistribute** command from the configuration file and restore the system to its default condition in which the software does not redistribute routes, use the **no** form of this command.

### Border Gateway Protocol (BGP)

**redistribute bgp** *process-id* [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute bgp** *process-id* [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

### Connected Routes

**redistribute connected** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute connected** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

### Intermediate System-to-Intermediate System (IS-IS)

**redistribute isis** *process-id* [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute isis** *process-id* [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

### Open Shortest Path First (OSPF)

**redistribute ospf** *process-id* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* [*1* | *2*] | *internal* | *nssa-external* [*1* | *2*]}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute ospf** *process-id* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* [*1* | *2*] | *internal* | *nssa-external* [*1* | *2*]}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

### Open Shortest Path First Version 3 (OSPFv3)

**redistribute ospfv3** *process-id* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* [*1* | *2*] | *internal* | *nssa-external* [*1* | *2*]}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute ospfv3** *process-id* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* [*1* | *2*] | *internal* | *nssa-external* [*1* | *2*]}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

### Static Routes

**redistribute static** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute static** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

## EIGRP

**redistribute eigrp** *as-number* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* | *internal*}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute eigrp** *as-number* [*level-1* | *level-2* | *level-1-2*] [*match* {*external* | *internal*}] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

## RIP

**redistribute rip** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute rip** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

## Subscriber Routes

**redistribute subscriber** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

**no redistribute subscriber** [*level-1* | *level-2* | *level-1-2*] [*metric metric-value*] [*metric-type* {*internal* | *external* | *rib-metric-as-external* | *rib-metric-as-internal*}] [*route-policy route-policy-name*]

## Syntax Description

*process-id*

For the **bgp** keyword, an autonomous system number has the following ranges:

- Range for 2-byte Autonomous system numbers (ASNs) is 1 to 65535.
- Range for 4-byte Autonomous system numbers (ASNs) in asplain format is 1 to 4294967295.
- Range for 4-byte Autonomous system numbers (ASNs) in asdot format is 1.0 to 65535.65535.

For the **isis** keyword, an IS-IS instance identifier from which routes are to be redistributed.

For the **ospf** keyword, an OSPF process name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.

For the **ospfv3** keyword, an OSPFv3 process name from which routes are to be redistributed. The value takes the form of a string. A decimal number can be entered, but it is stored internally as a string.

**level-1**

(Optional) Specifies that redistributed routes are advertised in the Level-1 LSP of the router.

**level-1-2**

(Optional) Specifies that redistributed routes are advertised in the Level-1-2 LSP of the router.

|                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>level-2</b>                                                                                                                          | (Optional) Specifies that redistributed routes are advertised in the Level-2 LSP of the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>metric</b> <i>metric-value</i>                                                                                                       | (Optional) Specifies the metric used for the redistributed route. Range is 0 to 16777215. The <i>metric-value</i> must be consistent with the IS-IS metric style of the area and topology into which the routes are being redistributed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>metric-type</b> { <b>internal</b><br>  <b>external</b>  <br><b>rib-metric-as-external</b><br> <br><b>rib-metric-as-internal</b><br>} | <p>(Optional) Specifies the external link type associated with the route advertised into the ISIS routing domain. It can be one of four values:</p> <ul style="list-style-type: none"> <li>• <b>external</b></li> <li>• <b>internal</b>—Use the <b>internal</b> keyword to set IS-IS internal metric-type</li> <li>• <b>external</b>—Use the <b>external</b> keyword to set IS-IS external metric-type</li> <li>• <b>rib-metric-as-external</b>—Use the <b>rib-metric-as-external</b> keyword to use RIB metric and set IS-IS external metric-type</li> <li>• <b>rib-metric-as-internal</b>—Use the <b>rib-metric-as-internal</b> keyword to use RIB metric and set IS-IS internal metric-type</li> </ul> <p>Any route with an internal metric (however large the metric is) is preferred over a route with external metric (however small the metric is).</p> <p>Use the <b>rib-metric-as-external</b> and <b>rib-metric-as-internal</b> keywords to preserve RIB metrics when redistributing routes from another IS-IS router instance or another protocol.</p> |
| <b>route-policy</b><br><i>route-policy-name</i>                                                                                         | (Optional) Specifies the identifier of a configured policy. A policy is used to filter the importation of routes from this source routing protocol to IS-IS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>match</b> { <b>internal</b>  <br><b>external</b> [ <b>1</b>   <b>2</b> ]  <br><b>nssa-external</b> [ <b>1</b>   <b>2</b> ]<br>}      | <p>(Optional) Specifies the criteria by which OSPF routes are redistributed into other routing domains. It can be one or more of the following:</p> <ul style="list-style-type: none"> <li>• <b>internal</b>—Routes that are internal to a specific autonomous system (intra- and interarea OSPF routes).</li> <li>• <b>external</b> [ <b>1</b>   <b>2</b> ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 external routes.</li> <li>• <b>nssa-external</b> [ <b>1</b>   <b>2</b> ]—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 or Type 2 not-so-stubby area (NSSA) external routes.</li> </ul> <p>For the <b>external</b> and <b>nssa-external</b> options, if a type is not specified, then both Type 1 and Type 2 are assumed.</p>                                                                                                                                                                                                                             |

**Command Default**

Level 2 is configured if no level is specified.

**metric-type:** **internal**

**match** : If no match keyword is specified, all OSPF routes are redistributed.

**Command Modes**

Address family configuration

**Command History**

| Release       | Modification                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                                                             |
| Release 3.3.0 | The <b>policy</b> <i>policy-name</i> keyword and argument were changed to <b>route-policy</b> <i>route-policy-name</i> . |
| Release 3.8.0 | The <b>rib-metric-as-external</b> and <b>rib-metric-as-internal</b> keywords were added.                                 |
| Release 3.9.0 | Asplain format for 4-byte Autonomous system numbers notation was supported.                                              |
| Release 4.2.0 | Redistribute routes from EIGRP, RIP, and Subscriber Routes into IS-IS was supported.                                     |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Note**

When redistributing routes (into IS-IS) using both command keywords for setting or matching of attributes and a route policy, the routes are run through the route policy first, followed by the keyword matching and setting.

Use the **redistribute** command to control the redistribution of routes between separate IS-IS instances. To control the propagation of routes between the levels of a single IS-IS instance, use the [propagate level, on page 816](#) command.

Only IPv4 OSPF addresses can be redistributed into IS-IS IPv4 address families and only IPv6 OSPFv3 prefixes can be distributed into IS-IS IPv6 address families.

**Task ID**

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

**Examples**

In this example, IS-IS instance `isp_A` readadvertises all of the routes of IS-IS instance `isp_B` in Level 2 LSP. Note that the **level-2** keyword affects which levels instance `isp_A` advertises the routes in and has no impact

on which routes from instance `isp_B` are advertised. (Any Level 1 routes from IS-IS instance `isp_B` are included in the redistribution.

```
RP/0/RP0/CPU0:router(config)# router isis isp_A
RP/0/RP0/CPU0:router(config-isis)# net 49.1234.2222.2222.00
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# redistribute isis isp_B level-2
!
RP/0/RP0/CPU0:router(config)# router isis isp_B
RP/0/RP0/CPU0:router(config-isis)# is-type level 1
RP/0/RP0/CPU0:router(config-isis)# net 49.4567.2222.2222.00
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
```

## retransmit-interval (IS-IS)

To configure the amount of time between retransmission of each Intermediate System-to-Intermediate System (IS-IS) link-state packet (LSP) on a point-to-point link, use the **retransmit-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

**retransmit-interval** *seconds* [**level** {**1** | **2**}]

**no retransmit-interval** [*seconds* [**level** {**1** | **2**}]]

### Syntax Description

|                                      |                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>seconds</i>                       | Time (in seconds) between consecutive retransmissions of each LSP. It is an integer that should be greater than the expected round-trip delay between any two networking devices on the attached network. Range is 0 to 65535 seconds. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently.                                                                                                                                                                         |

### Command Default

*seconds* : 5 seconds

### Command Modes

Interface configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

To prevent needless transmission results, the *seconds* argument should be conservative.

The **retransmit-interval** command has no effect on LAN (multipoint) interfaces. On point-to-point links, the value can be increased to enhance network stability.

Because retransmissions occur only when LSPs are dropped, setting this command to a higher value has little effect on reconvergence. The more neighbors networking devices have, and the more paths over which LSPs can be flooded, the higher this value can be made.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure GigabitEthernet interface 0/2/0/1 for retransmission of IS-IS LSPs every 60 seconds for a large serial line:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1  
RP/0/0/CPU0:router(config-isis-if)# retransmit-interval 60
```

## Related Commands

# retransmit-throttle-interval

To configure minimum interval between retransmissions of different Intermediate System-to-Intermediate System (IS-IS) link-state packets (LSPs) on a point-to-point interface, use the **retransmit-throttle-interval** command in interface configuration mode. To remove the command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**retransmit-throttle-interval** *milliseconds* [**level** {**1** | **2**}]

**no retransmit-throttle-interval** [*milliseconds* [**level** {**1** | **2**}]]

## Syntax Description

|                                      |                                                                                                    |
|--------------------------------------|----------------------------------------------------------------------------------------------------|
| <i>milliseconds</i>                  | Minimum delay (in milliseconds) between LSP retransmissions on the interface. Range is 0 to 65535. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Specifies routing Level 1 or Level 2 independently.                                     |

## Command Default

Default is 0.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **retransmit-throttle-interval** command to define the minimum period of time that must elapse between retransmitting any two consecutive LSPs on an interface. The **retransmit-throttle-interval** command may be useful in very large networks with many LSPs and many interfaces as a way of controlling LSP retransmission traffic. This command controls the rate at which LSPs can be re-sent on the interface.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure GigabitEthernet interface 0/2/0/1 to limit the rate of LSP retransmissions to one every 300 milliseconds:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# interface GigabitEthernet 0/2/0/1  
RP/0/0/CPU0:router(config-isis-if)# retransmit-throttle-interval 300
```

# router isis

To enable the Intermediate System-to-Intermediate System (IS-IS) routing protocol and to specify an IS-IS instance, use the **router isis** command in global configuration mode. To disable IS-IS routing, use the **no** form of this command.

**router isis** *instance-id*

**no router isis** *instance-id*

## Syntax Description

|             |                                                                  |
|-------------|------------------------------------------------------------------|
| instance-id | Name of the routing process. Maximum number of characters is 40. |
|-------------|------------------------------------------------------------------|

## Command Default

An IS-IS routing protocol is not enabled.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **router isis** command to create an IS-IS routing process. An appropriate network entity title (NET) must be configured to specify the address of the area (Level 1) and system ID of the router. Routing must be enabled on one or more interfaces before adjacencies may be established and dynamic routing is possible.

Multiple IS-IS processes can be configured. Up to eight processes are configurable. A maximum of five IS-IS instances on a system are supported.

## Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

## Examples

The following example shows how to configure IS-IS for IP routing:

```
RP/0/0/CPU0:router(config)# router isis isp
RP/0/0/CPU0:router(config-isis)# net 49.0001.0000.0001.00
```

**Related Commands**

|----------------------------------|--------------------------------------------------|
| <a href="#">net, on page 803</a> | Configures an IS-IS NET for the routing process. |

# set-attached-bit

To configure an Intermediate System-to-Intermediate System (IS-IS) instance with an attached bit in the Level 1 link-state packet (LSP), use the **set-attached-bit** command in address family configuration mode. To remove the **set-attached-bit** command from the configuration file and restore the system to its default condition, use the **no** form of this command.

**set-attached-bit**

**no set-attached-bit**

**Command Default** Attached bit is not set in the LSP.

**Command Modes** Address family configuration

| Command History | Release       | Modification                                                                             |
|-----------------|---------------|------------------------------------------------------------------------------------------|
|                 | Release 3.2   | This command was introduced.                                                             |
|                 | Release 3.8.0 | This command was replaced by the <a href="#">attached-bit send, on page 703</a> command. |

**Usage Guidelines** To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set-attached bit** command to set an IS-IS instance with an attached bit in the Level 1 LSP that allows another IS-IS instance to redistribute Level 2 topology. The attached bit is used when the Level 2 connectivity from another IS-IS instance is advertised by the Level 1 attached bit.

Cisco IOS XR software does not support multiple Level 1 areas in a single IS-IS routing instance. But the equivalent functionality is achieved by redistribution of routes between two IS-IS instances by using the [redistribute \(IS-IS\), on page 818](#) command.

The attached bit is configured for a specific address family only if the **single-topology** command is not configured.

**Note**

If connectivity for the Level 2 instance is lost, the attached bit in the Level 1 instance LSP continues sending traffic to the Level 2 instance and causes the traffic to be dropped.

| Task ID | Task ID | Operations  |
|---------|---------|-------------|
|         | isis    | read, write |

## Examples

The following example shows how to set the attached bit for a Level 1 instance that allows the Level 2 instance to redistribute routes from the Level 1 instance:

```
RP/0/0/CPU0:router(config)# router isis 1
RP/0/0/CPU0:router(config-isis)# net 49.0001.0001.0001.0001.00
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# redistribute isis 2 level 2
!
RP/0/0/CPU0:router(config-isis-af)# interface GigabitEthernet 0/3/0/0
RP/0/0/CPU0:router(config-isis-af-if)# address-family ipv4 unicast
!
!
RP/0/0/CPU0:router(config)# router isis 2
RP/0/0/CPU0:router(config-isis)# is-type level-1
RP/0/0/CPU0:router(config-isis)# net 49.0002.0001.0001.0002.00
RP/0/0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/0/CPU0:router(config-isis-af)# -attachedbit send always-set
!
RP/0/0/CPU0:router(config-isis-af)# interface GigabitEthernet 0/1/0/0
RP/0/0/CPU0:router(config-isis-af-if)# address-family ipv4 unicast
```

## set-overload-bit

To configure the router to signal other routers not to use it as an intermediate hop in their shortest path first (SPF) calculations, use the **set-overload-bit** command in router configuration mode. To remove the designation, use the **no** form of this command.

**set-overload-bit** [**on-startup** {*delay*| **wait-for-bgp**}] [**level** {**1**| **2**}] [**advertise** {**external**| **interlevel**}]

**no set-overload-bit** [**on-startup** {*delay*| **wait-for-bgp**}] [**level** {**1**| **2**}] [**advertise** {**external**| **interlevel**}]

### Syntax Description

|                                                          |                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>on-startup</b>                                        | (Optional) Sets the overload bit only temporarily after reboot.                                                                                                                                                                                                                                                                                        |
| <i>delay</i>                                             | (Optional) Time (in seconds) to advertise when the router is overloaded after reboot. Range is 5 to 86400 seconds (86400 seconds = 1 day).                                                                                                                                                                                                             |
| <b>wait-for-bgp</b>                                      | (Optional) Sets the overload bit on startup until the Border Gateway Protocol (BGP) signals converge or time out.                                                                                                                                                                                                                                      |
| <b>level</b> { <b>1</b>   <b>2</b> }                     | (Optional) Specifies the overload bit for Level 1 or Level 2 independently.                                                                                                                                                                                                                                                                            |
| <b>advertise</b> { <b>external</b>   <b>interlevel</b> } | (Optional) Sets the overload bit set if the router advertises the following types of IP prefixes: <ul style="list-style-type: none"> <li>• <b>external</b>—If overload-bit set advertises IP prefixes learned from other protocols</li> <li>• <b>interlevel</b>— If overload-bit set advertise IP prefixes learned from another ISI S level</li> </ul> |

### Command Default

The overload bit is not set.  
Both Level 1 and Level 2 are configured if no level is specified.

### Command Modes

Router configuration

### Command History

| Release       | Modification                                                                    |
|---------------|---------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced.                                                    |
| Release 4.2.0 | The <b>advertise</b> { <b>external</b>   <b>interlevel</b> keywords were added. |

### Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **set-overload-bit** command to force the router to set the overload bit in its nonpseudonode link-state packets (LSPs). Normally the setting of the overload bit is allowed only when a router experiences problems. For example, when a router is experiencing a memory shortage, the reason might be that the link-state database is not complete, resulting in an incomplete or inaccurate routing table. If the overload bit is set in the LSPs of the unreliable router, other routers can ignore the router in their SPF calculations until it has recovered from its problems. The result is that no paths through the unreliable router are seen by other routers in the Intermediate System-to-Intermediate System (IS-IS) area. However, IP prefixes directly connected to this router are still reachable.

The **set-overload-bit** command can be useful when you want to connect a router to an IS-IS network, but do not want real traffic flowing through it under any circumstances.

Routers with overload bit set are:

- A test router in the lab, connected to a production network.
- A router configured as an LSP flooding server, for example, on a nonbroadcast multiaccess (NBMA) network, in combination with the mesh group feature.

### Task ID

| Task ID | Operations  |
|---------|-------------|
| isis    | read, write |

### Examples

The following example shows how to configure the overload bit:

```
RP/0/0/CPU0:router(config)# router isis isp  
RP/0/0/CPU0:router(config-isis)# set-overload-bit
```

# show isis

The **show isis** command displays general information about an IS-IS instance and protocol operation. If the instance ID is not specified, the command shows information about all IS-IS instances.

**show isis** [**instance** *instance-id*]

## Syntax Description

|                                    |                                                                                                               |
|------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the IS-IS adjacencies for the specified IS-IS instance only.                              |
| <b>Note</b>                        | The instance-id argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command. |

## Command Default

No instance ID specified displays IS-IS adjacencies for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

For each instance, the first line of output lists the IS-IS instance ID with the following lines identifying the IS-IS system ID, supported levels (level 1, level 2, or level-1-2), configured area addresses, active area addresses, status (enabled or not) and type (Cisco or IETF) of nonstop forwarding (NSF), and the mode in which the last IS-IS process startup occurred.

Next, the status of each configured address family (or just IPv4 unicast if none are configured) is summarized. For each level (level 1 or level 2), the metric style (narrow or wide) generated and accepted is listed along with the status of incremental shortest path first (iSPF) computation (enabled or not). Then redistributed protocols are listed, followed by the administrative distance applied to the redistributed routes.

Finally, the running state (active, passive, or disabled) and configuration state (active or disabled) of each IS-IS interface is listed.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis** command:

```
RP/0/0/CPU0:router# show isis
Wed Aug 20 23:54:55.043 PST DST

IS-IS Router: lab
System Id: 0000.0000.0002
IS Levels: level-2-only
Manual area address(es):
  49.1122
Routing for area address(es):
  49.1122
Non-stop forwarding: Disabled
Most recent startup mode: Cold Restart
Topologies supported by IS-IS:
  IPv4 Unicast
  Level-2
    Metric style (generate/accept): Narrow/Narrow
    Metric: 10
    ISPF status: Disabled
    No protocols redistributed
    Distance: 115
Interfaces supported by IS-IS:
  Loopback0 is running passively (passive in configuration)
  POS0/1/0/2 is running actively (active in configuration)
  POS0/1/0/3 is running actively (active in configuration)
```

This table describes the significant fields shown in the display.

**Table 58: show isis Field Descriptions**

| Field                         | Description                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| IS-IS Router                  | IS-IS instance ID.                                                                                            |
| System Id                     | IS-IS system ID.                                                                                              |
| IS Levels                     | Supported levels for the instance.                                                                            |
| Manual area address(es)       | Domain and area.                                                                                              |
| Routing for area address(es): | Configured area addresses and active area addresses.                                                          |
| Non-stop forwarding           | Status (enabled or not) and type (Cisco or IETF) of nonstop forwarding (NSF).                                 |
| Most recent startup mode      | The mode in which the last IS-IS process startup occurred.                                                    |
| Topologies supported by IS-IS | The summary of the status of each configured address family (or just IPv4 unicast if none are configured).    |
| Redistributed protocols       | List of redistributed protocols, followed by the administrative distance applied to the redistributed routes. |

| Field                          | Description                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Metric style (generate/accept) | The status of each configured address family (or just IPv4 unicast if none are configured) is summarized. For each level (level 1 or level 2), the metric style (narrow or wide) generated and accepted is listed along with the status of incremental shortest path first (iSPF) computation (enabled or not). |
| Interfaces supported by IS-IS  | The running state (active, passive, or disabled) and configuration state (active or disabled) of each IS-IS interface.                                                                                                                                                                                          |

# show isis adjacency

To display Intermediate System-to-Intermediate System (IS-IS) adjacencies, use the **show isis adjacency** command in EXEC mode.

**show isis** [**instance** *instance-id*] **adjacency** [**level** {**1** | **2**}] [*type interface-path-id*] [**detail**] [**systemid** *system-id*]

## Syntax Description

| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

**Task ID**

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis adjacency** command:

```
RP/0/0/CPU0:router# show isis adjacency

IS-IS p Level-1 adjacencies:
System Id      Interface      SNPA              State Hold    Changed NSF      BFD
12a4           PO0/1/0/1      *PtoP*           Up    23      00:00:06 Capable Init
12a4           Gi0/6/0/2      0004.2893.f2f6   Up    56      00:04:01 Capable Up

Total adjacency count: 2

IS-IS p Level-2 adjacencies:
System Id      Interface      SNPA              State Hold    Changed NSF      BFD
12a4           PO0/1/0/1      *PtoP*           Up    23      00:00:06 Capable None
12a4           Gi0/6/0/2      0004.2893.f2f6   Up    26      00:00:13 Capable Init

Total adjacency count: 2
```

This table describes the significant fields shown in the display.

**Table 59: show isis adjacency Field Descriptions**

| Field     | Description                                                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level-1   | Level 1 adjacencies.                                                                                                                                                                                                               |
| Level-2   | Level 2 adjacencies.                                                                                                                                                                                                               |
| System ID | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or the <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| Interface | Interface used to reach the neighbor.                                                                                                                                                                                              |
| SNPA      | Data-link address (also known as the Subnetwork Point of Attachment [SNPA]) of the neighbor.                                                                                                                                       |
| State     | Adjacency state of the neighboring interface. Valid states are Down, Init, and Up.                                                                                                                                                 |
| Holdtime  | Hold time of the neighbor.                                                                                                                                                                                                         |
| Changed   | Time the neighbor has been up (in hours:minutes:seconds).                                                                                                                                                                          |

| Field | Description                                                                                                                                                                                                                                                                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NSF   | Specifies whether the neighbor can adhere to the IETF-NSF restart mechanism.                                                                                                                                                                                                                                                                                         |
| BFD   | Specifies the Bidirectional Forwarding Detection (BFD) status for the interface. Valid status are: <ul style="list-style-type: none"><li>• None—BFD is not configured.</li><li>• Init—BFD session is not up. One reason is that other side is not yet enabled.</li><li>• Up—BFD session has been established.</li><li>• Down—BFD session holdtime expired.</li></ul> |

# show isis adjacency-log

To display the Intermediate System-to-Intermediate System (IS-IS) adjacency log, use the **show isis adjacency-log** command in EXEC mode.

**show isis adjacency-log** [**level** {**1** | **2**}] [**last number** | **first number**]

## Syntax Description

|                                      |                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Displays the IS-IS adjacency log for Level 1 or Level 2 independently.                            |
| <b>last number</b>                   | (Optional) Specifies that the output is restricted to the last <i>number</i> of entries. Range is 1 to 100.  |
| <b>first number</b>                  | (Optional) Specifies that the output is restricted to the first <i>number</i> of entries. Range is 1 to 100. |

## Command Default

No default behavior or values

## Command Modes

EXEC

## Command History

| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis adjacency-log** command:

```
RP/0/0/CPU0:router# show isis adjacency-log

IS-IS 10 Level 1 Adjacency log
When      System      Interface      State  Details
4d00h     12a1              PO0/5/0/0     d -> i
4d00h     12a1              PO0/5/0/0     i -> u  New adjacency
```

## show isis adjacency-log

```

4d00h      12a1      Gi0/6/0/0      d -> u      IPv4 Unicast Up
4d00h      12a1      Gi0/6/0/0      u -> d      New adjacency
down                               Interface state
3d17h      12a1      Gi0/6/0/0      d -> u      New adjacency
3d17h      12a1      Gi0/6/0/0      u -> d      Interface state
down
01:44:07   12a1      Gi0/6/0/0      d -> u      New adjacency

IS-IS 10 Level 2 Adjacency log
When      System      Interface      State      Details
4d00h     12a1      PO0/5/0/0     d -> i
4d00h     12a1      PO0/5/0/0     i -> u      New adjacency
4d00h     12a1      Gi0/6/0/0     d -> u      IPv4 Unicast Up
4d00h     12a1      Gi0/6/0/0     u -> d      New adjacency
down                               Interface state
3d17h     12a1      Gi0/6/0/0     d -> u      New adjacency
3d17h     12a1      Gi0/6/0/0     u -> d      Interface state
down
01:44:07   12a1      Gi0/6/0/0     d -> u      New adjacency

```

| Field     | Description                                            |
|-----------|--------------------------------------------------------|
| When      | Elapsed time (in hh:mm:ss) since the event was logged. |
| System    | System ID of the adjacent router.                      |
| Interface | Specific interface involved in the adjacency change.   |
| State     | State transition for the logged event.                 |
| Details   | Description of the adjacency change.                   |

# show isis checkpoint adjacency

To display the Intermediate System-to-Intermediate System (IS-IS) checkpoint adjacency database, use the **show isis checkpoint adjacency** command in EXEC mode.

**show isis** [*instance instance-id*] **checkpoint adjacency**

## Syntax Description

|                                    |                                                                                                                                                                      |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i> | (Optional) Displays the IS-IS checkpoint adjacencies for the specified IS-IS instance only.                                                                          |
|                                    | <ul style="list-style-type: none"><li>The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command.</li></ul> |

## Command Default

No instance ID specified displays IS-IS checkpoint adjacencies for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Use the **show isis checkpoint adjacency** command to display the checkpointed adjacencies. With this information you can restore the adjacency database during a Cisco proprietary nonstop forwarding (NSF) restart. This command, with the **show isis adjacency** command, can be used to verify the consistency of the two databases.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis checkpoint adjacency** command:

```
RP/0/0/CPU0:router# show
isis
checkpoint
```

**show isis checkpoint adjacency****adjacency**

| Interface | Level | System ID   | State | Circuit ID        | Chkpt ID |
|-----------|-------|-------------|-------|-------------------|----------|
| Gi3/0/0/1 | 1     | router-gsr8 | Up    | 0001.0000.0008.04 | 80011fec |
| Gi0/4/0/1 | 1     | router-gsr9 | Up    | 0001.0000.0006.01 | 80011fd8 |
| Gi3/0/0/1 | 2     | router-gsr8 | Up    | 0001.0000.0008.04 | 80011fc4 |

This table describes the significant fields shown in the display.

**Table 61: show isis checkpoint adjacency Field Descriptions**

| Field      | Description                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface  | Interface used to reach the neighbor.                                                                                                                                                                                          |
| Level      | Lists either routers with Level 1 or Level 2 adjacency configured.                                                                                                                                                             |
| System ID  | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| State      | State of the neighboring interface.                                                                                                                                                                                            |
| Circuit ID | Unique ID issued to a circuit at its creation.                                                                                                                                                                                 |
| Chkpt ID   | Unique ID issued to the checkpoint at its creation.                                                                                                                                                                            |

| Field     | Description                           |
|-----------|---------------------------------------|
| Interface | Interface used to reach the neighbor. |

| Field     | Description                                                 |
|-----------|-------------------------------------------------------------|
| Index     | Interface index assigned to an interface upon its creation. |
| CircNum   | Unique ID issued to a circuit internally.                   |
| DIS Areas | Designated Intermediate System area.                        |
| Chkpt ID  | Unique ID issued to the checkpoint at its creation.         |

# show isis checkpoint lsp

To display the Intermediate System-to-Intermediate System (IS-IS) checkpoint link-state packet (LSP) protocol data unit (PDU) identifier database, use the **show isis checkpoint lsp** command in EXEC mode.

**show isis** [**instance** *instance-id*] **checkpoint lsp**

## Syntax Description

**instance** *instance-id* (Optional) Displays the IS-IS checkpoint LSPs for the specified instance only.

- The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No instance ID specified displays IS-IS checkpoint LSPs for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The checkpointed LSPs displayed by this command are used to restore the LSP database during a Cisco-proprietary nonstop forwarding (NSF) restart. The **show isis checkpoint lsp** command, with the **show isis database** command, may be used to verify the consistency of the two databases.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis checkpoint lsp** command:

```
RP/0/0/CPU0:router#
      show isis checkpoint lsp
```

```
Level  LSPID          Chkpt ID
1      router-gsr6.00-00  80011f9c
```

**show isis checkpoint lsp**

```

1      router-gsr6.01-00  80011f88
1      router-gsr8.00-00  80011f74
1      router-gsr9.00-00  80011f60
2      router-gsr6.00-00  80011f4c
2      router-gsr6.01-00  80011f38
2      router-gsr8.00-00  80011f24
2      router-gsr9.00-00  80011f10
Total LSP count: 8 (L1: 4, L2 4, local L1: 2, local L2 2)

```

This table describes the significant fields shown in the display.

**Table 63: show isis checkpoint lsp Field Descriptions**

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level    | Routers with Level 1 or Level 2 adjacency configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LSPID    | <p>LSP identifier. The first six octets form the system ID of the router that originated the LSP.</p> <p>The next octet is the pseudonode ID. When this byte is zero, the LSP describes links from the system. When it is nonzero, the LSP is a so-called nonpseudonode LSP. This is similar to a router link-state advertisement (LSA) in the Open Shortest Path First (OSPF) protocol. The LSP describes the state of the originating router.</p> <p>For each LAN, the designated router for that LAN creates and floods a pseudonode LSP, describing all systems attached to that LAN.</p> <p>The last octet is the LSP number. If there is more data than can fit in a single LSP, the LSP is divided into multiple LSP fragments. Each fragment has a different LSP number. An asterisk (*) indicates that the LSP was originated by the system on which this command is issued.</p> |
| Chkpt ID | Unique ID issued to the checkpoint at its creation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# show isis database

To display the Intermediate System-to-Intermediate System (IS-IS) link-state packet (LSP) database, use the **show isis database** command in EXEC mode.

**show isis** [**instance** *instance-id*] **database** [**level** {**1** | **2**}] [**update**] [**summary**] [**detail**] [**verbose**] [**\*** | *lsp-id*]

## Syntax Description

|                                      |                                                                                                                                                                                                           |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b> <i>instance-id</i>   | (Optional) Displays the IS-IS LSP database for the specified instance only.<br><br>• The <i>instance-id</i> argument is the instance identifier (alphanumeric) defined by the <b>router isis</b> command. |
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Displays the IS-IS LSP database for Level 1 or Level 2 independently.                                                                                                                          |
| <b>update</b>                        | (Optional) Displays contents of LSP database managed by update thread.                                                                                                                                    |
| <b>summary</b>                       | (Optional) Displays the LSP ID number, sequence number, checksum, hold time, and bit information.                                                                                                         |
| <b>detail</b>                        | (Optional) Displays the contents of each LSP.                                                                                                                                                             |
| <b>verbose</b>                       | (Optional) Displays the contents of each LSP.                                                                                                                                                             |
| <b>*</b>   <i>lsp-id</i>             | (Optional) LSP protocol data units (PDUs) identifier. Displays the contents of a single LSP by its ID number or may contain an * as a wildcard character.                                                 |

## Command Default

No instance ID specified displays the IS-IS LSP database for all the IS-IS instances.  
Both Level 1 and Level 2 is configured if no level is specified.

## Command Modes

EXEC

## Command History

| Release       | Modification                                                                                   |
|---------------|------------------------------------------------------------------------------------------------|
| Release 3.2   | This command was introduced                                                                    |
| Release 3.8.0 | This command was modified to include MPLS Shared Risk Link Groups (SRLG) specific information. |

**Usage Guidelines**

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

Each of the options for the **show isis database** command can be entered in an arbitrary string within the same command entry. For example, the following are both valid command specifications and provide the same output: **show isis database detail level 2** and **show isis database level 2 detail**.

The **summary** keyword used with this command allows you to filter through a large IS-IS database and quickly identify problematic areas.

**Task ID**

| Task ID | Operations |
|---------|------------|
| isis    | read       |

**Examples**

The following is sample output from the **show isis database** command with the **summary** keyword:

```
RP/0/0/CPU0:router# show isis database summary
```

```
IS-IS 10 Database Summary for all LSPs
              Active
              L1  L2  Total  L1  L2  Total  L1  L2  Total
              ----  ---  ----  ---  ---  ----  ---  ---  ---
Fragment 0 Counts
  Router LSPs:      1   1   2     0   0   0     1   1   2
  Pseudo-node LSPs: 0   0   0     0   0   0     0   0   0
  All LSPs:         1   1   2     0   0   0     1   1   2
Per Topology
  IPv4 Unicast
    ATT bit set LSPs: 0   0   0     0   0   0     0   0   0
    OVL bit set LSPs: 0   0   0     0   0   0     0   0   0
All Fragment Counts
  Router LSPs:      1   1   2     0   0   0     1   1   2
  Pseudo-node LSPs: 0   0   0     0   0   0     0   0   0
  All LSPs:         1   1   2     0   0   0     1   1   2
```

This table describes the significant fields shown in the display.

**Table 64: show isis database summary Field Descriptions**

| Field             | Description                                                 |
|-------------------|-------------------------------------------------------------|
| Router LSPs:      | Active, purged, and total LSPs associated with routers.     |
| Pseudo-node LSPs: | Active, purged, and total LSPs associated with pseudonodes. |
| All LSPs:         | Total active and purged LSPs.                               |

| Field            | Description                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ATT bit set LSPs | Attach bit (ATT). Indicates that the router is also a Level 2 router, and it can reach other areas. Level 1-only routers and Level 1-2 routers that have lost connection to other Level 2 routers use the Attach bit to find the closest Level 2 router. They point to a default route to the closest Level 2 router. |
| OVL bit set LSPs | Overload bit. Indicates if the IS is congested. If the Overload bit is set, other routers do not use this system as a transit router when calculating routers. Only packets for destinations directly connected to the overloaded router are sent to this router.                                                     |

The following is sample output from the **show isis database** command with the keyword specified:

```

As the output shows, besides the information displayed with the **show isis database** command, the command with the keyword displays the contents of each LSP.

**Table 65: show isis database verbose Field Descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSPID        | <p>LSP identifier. The first six octets form the system ID of the router that originated the LSP.</p> <p>The next octet is the pseudonode ID. When this byte is zero, the LSP describes links from the system. When it is nonzero, the LSP is a so-called nonpseudonode LSP. This is similar to a router link-state advertisement (LSA) in the Open Shortest Path First (OSPF) protocol. The LSP describes the state of the originating router.</p> <p>For each LAN, the designated router for that LAN creates and floods a pseudonode LSP, describing all systems attached to that LAN.</p> <p>The last octet is the LSP number. If there is more data than can fit in a single LSP, the LSP is divided into multiple LSP fragments. Each fragment has a different LSP number. An asterisk (*) indicates that the LSP was originated by the system on which this command is issued.</p> |
| LSP Seq Num  | Sequence number for the LSP that allows other systems to determine if they have received the latest information from the source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| LSP Checksum | Checksum of the entire LSP packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Field                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSP Holdtime         | Time the LSP remains valid (in seconds). An LSP hold time of zero indicates that this LSP was purged and is being removed from the link-state database (LSDB) of all routers. The value indicates how long the purged LSP stays in the LSDB before being completely removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ATT/P/OL             | <p>ATT—Attach bit. This bit indicates that the router is also a Level 2 router, and it can reach other areas. Level 1-only routers and Level 1-2 routers that have lost connection to other Level 2 routers use the Attach bit to find the closest Level 2 router. They point to a default route to the closest Level 2 router.</p> <p>P—P bit. Detects if the intermediate system is area partition repair capable. Cisco and other vendors do not support area partition repair.</p> <p>OL—Overload bit. Determines if the IS is congested. If the Overload bit is set, other routers do not use this system as a transit router when calculating routes. Only packets for destinations directly connected to the overloaded router are sent to this router.</p> |
| Area Address         | Reachable area addresses from the router. For Level 1 LSPs, these are the area addresses configured manually on the originating router. For Level 2 LSPs, these are all the area addresses for the area to which this route belongs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NLPID                | Network Layer Protocol Identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Hostname             | Hostname of the node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IP Address           | IP address of the node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Metric               | IS-IS metric for the cost of the adjacency between the originating router and the advertised neighbor, or the metric of the cost to get from the advertising router to the advertised destination (which can be an IP address, an end system (ES), or a Connectionless Network Service (CLNS) prefix).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| MPLS SRLG            | MPLS SRLG TLV information per neighbor, identified by hostname or system ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Interface IP Address | Local interface IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Neighbor IP Address  | Remote interface IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Field | Description                                                                                     |
|-------|-------------------------------------------------------------------------------------------------|
| Flags | Flags carried in SRLG TLV. The Least Significant Bit (LSB) is set if the interface is numbered. |
| SRLGs | SRLG values.                                                                                    |

# show isis database-log

To display the entries in the Intermediate System-to-Intermediate System (IS-IS) database log, use the **show isis database-log** command in EXEC mode.

**show isis database-log** [**level** {**1** | **2**}] [**last number**| **first number**]

## Syntax Description

|                                      |                                                                                                               |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>level</b> { <b>1</b>   <b>2</b> } | (Optional) Displays the database log for Level 1 or Level 2 independently.                                    |
| <b>last number</b>                   | (Optional) Specifies that the output be restricted to the last <i>number</i> of entries. Range is 1 to 1000.  |
| <b>first number</b>                  | (Optional) Specifies that the output be restricted to the first <i>number</i> of entries. Range is 1 to 1000. |

## Command Default

Both Level 1 and Level 2 are configured if no level is specified.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis database-log** command:

```
RP/0/0/CPU0:router# show isis database-log
```

```

| LSPID   | <p>LSP identifier. The first six octets form the system ID of the router that originated the LSP.</p> <p>The next octet is the pseudonode ID. When this byte is zero, the LSP describes links from the system. When it is nonzero, the LSP is a so-called nonpseudonode LSP. This is similar to a router link-state advertisement (LSA) in the Open Shortest Path First (OSPF) protocol. The LSP describes the state of the originating router.</p> <p>For each LAN, the designated router for that LAN creates and floods a pseudonode LSP, describing all systems attached to that LAN.</p> <p>The last octet is the LSP number. If there is more data than can fit in a single LSP, the LSP is divided into multiple LSP fragments. Each fragment has a different LSP number. An asterisk (*) indicates that the LSP was originated by the system on which this command is issued.</p> |
| New LSP | New router or pseudonode appearing in the topology.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Old LSP | Old router or pseudonode leaving the topology.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Op      | Operation on the database: inserted (INS) or replaced (REP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Seq Num | Sequence number for the LSP that allows other systems to determine if they have received the latest information from the source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Field    | Description                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Holdtime | Time the LSP remains valid (in seconds). An LSP hold time of 0 indicates that this LSP was purged and is being removed from the link-state database (LSDB) of all routers. The value indicates how long the purged LSP stays in the LSDB before being completely removed. |
| OL       | Overload bit. Determines if the IS is congested. If the Overload bit is set, other routers do not use this system as a transit router when calculating routers. Only packets for destinations directly connected to the overloaded router are sent to this router.        |

# show isis fast-reroute

To display per-prefix LFA information, use the **show isis fast-reroute** command in EXEC mode.

**show isis fast-reroute** *A.B.C.D/length* | **detail** | **summary**

## Syntax Description

|                       |                                                                       |
|-----------------------|-----------------------------------------------------------------------|
| <i>A.B.C.D/length</i> | Network to show per-prefix LFA information.                           |
| <b>detail</b>         | Use to display tiebreaker information about the backup.               |
| <b>summary</b>        | Use to display the number of prefixes having protection per priority. |

## Command Default

None

## Command History

| Release       | Modification                 |
|---------------|------------------------------|
| Release 4.0.1 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from **show isis fast-reroute** command that displays per-prefix LFA information:

```
RP/0/0/CPU0:router# show isis fast-reroute 10.1.6.0/24
L1 10.1.6.0/24 [20/115]
    via 10.3.7.47, POS0/3/0/1, router2
    FRR backup via 10.1.7.145, GigabitEthernet0/1/0/3, router3
```

The following is sample output from **show isis fast-reroute detail** command that displays tie-breaker information about the backup:

```
RP/0/0/CPU0:router# show isis fast-reroute 10.1.6.0/24 detail
L1 10.1.6.0/24 [20/115] low priority
    via 10.3.7.47, POS0/3/0/1, router2
    FRR backup via 10.1.7.145, GigabitEthernet0/1/0/3, router3
    P: No, TM: 30, LC: Yes, NP: No, D: No
```

```
src router2.00-00, 192.168.0.47
L2 adv [20] native, propagated
```

The following is sample output from **show isis fast-reroute summary** command that displays the number of prefixes having protection per priority:

```
RP/0/0/CPU0:router#show isis fast-reroute summary
IS-IS frr IPv4 Unicast FRR summary
```

# show isis hostname

To display the entries in the Intermediate System-to-Intermediate System (IS-IS) router name-to-system ID mapping table, use the **show isis hostname** command in EXEC mode.

**show isis** [**instance** *instance-id*] **hostname**

## Syntax Description

**instance** *instance-id* (Optional) Displays the IS-IS router name-to-system ID mapping table for the specified IS-IS instance only.

The *instance-id* argument is the instance identifier (alphanumeric) defined by the **router isis** command.

## Command Default

No instance ID specified displays the IS-IS router name-to-system ID mapping table for all the IS-IS instances.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| Release 3.2 | This command was introduced. |

## Usage Guidelines

To use this command, you must be in a user group associated with a task group that includes appropriate task IDs. If the user group assignment is preventing you from using a command, contact your AAA administrator for assistance.

The **show isis hostname** command does not display entries if the dynamic hostnames are disabled.

## Task ID

| Task ID | Operations |
|---------|------------|
| isis    | read       |

## Examples

The following is sample output from the **show isis hostname** command with the **instance** and *instance-id* values specified:

```
RP/0/0/CPU0:router# show isis instance isp hostname

ISIS isp hostnames
  Level System ID      Dynamic Hostname
  1      0001.0000.0005 router
  2      * 0001.0000.0011 router-11
```

This table describes the significant fields shown in the display.

**Table 67: show isis instance isp hostname Field Descriptions**

| Field            | Description                                                                                                                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level            | IS-IS level of the router.                                                                                                                                                                                                     |
| System ID        | Dynamic hostname of the system. The hostname is specified using the <b>hostname</b> command. If the dynamic hostname is not known or <b>hostname dynamic disable</b> command has been executed, the 6-octet system ID is used. |
| Dynamic Hostname | Hostname of the router.                                                                                                                                                                                                        |
| *                | Local router.                                                                                                                                                                                                                  |
