Configuring OCSP Rules

The ASA examines OCSP rules in priority order, and applies the first one that matches. X.509 digital certificates are an alternative to using CRLs.

Note Make sure that you have configured a certificate map before you try to add OCSP rules. If a certificate map has not been configured, an error message appears. To configure a certificate map, choose **Configuration > Site-to-Site VPN > Advanced > Certificate to Connection Profile Maps > Rules > Add**.

To configure OCSP rules for obtaining revocation status of an X.509 digital certificate, perform the following steps:

Step 1 In the ASDM application window, choose **Configuration > Site-to-Site VPN > Certificate Management > CA Certificates > Add** to display the Install Certificates dialog box. Then click **More Options**.

Step 2 In the Configuration Options for CA Certificates pane, click the **OCSP Rules** tab.

Step 3 Choose the certificate map to match to this OCSP rule. Certificate maps match user permissions to specific fields in a certificate. The name of the CA that the ASA uses to validate responder certificates appears in the Certificate field. The priority number for the rule appears in the Index field. The URL of the OCSP server for this certificate appears in the URL field.

Step 4 To add a new OCSP rule, click **Add**.

The Add OCSP Rule dialog box appears.

Step 5 Choose the certificate map to use from the drop-down list.

Step 6 Choose the certificate to use from the drop-down list.

Step 7 Enter the priority number for the rule.

Step 8 Enter the URL of the OCSP server for this certificate.

Step 9 When you are done, click **OK** to close this dialog box.

The newly added OCSP rule appears in the list.

Step 10 To edit an existing OCSP rule, select it, and then click **Edit**.

Step 11 To delete an OCSP rule, select it, and then click **Delete**.

Step 12 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring Advanced CRL and OCSP Settings" section on page 49-17.

Configuring Advanced CRL and OCSP Settings

When a certificate is issued, it is valid for a fixed period of time. Sometimes a CA revokes a certificate before this time period expires; for example, because of security concerns or a change of name or association. CAs periodically issue a signed list of revoked certificates. Enabling revocation checking forces the ASA to check that the CA has not revoked the certificate being verified. The ASA supports two methods of checking revocation status: CRL and OCSP.

To configure additional CRL and OCSP settings, perform the following steps:

Step 1 In the ASDM application window, choose **Configuration > Site-to-Site VPN > Certificate Management > CA Certificates > Add** to display the Install Certificates dialog box. Then click **More Options**.

Step 2 In the Configuration Options for CA Certificates pane, click the **Advanced** tab.

Step 3 In the CRL Options area, enter the number of minutes between cache refreshes. The default is 60 minutes. The range is 1-1440 minutes. To avoid having to retrieve the same CRL from a CA repeatedly, the ASA can store retrieved CRLs locally, which is called CRL caching. The CRL cache capacity varies by platform and is cumulative across all contexts. If an attempt to cache a newly retrieved CRL would exceed its storage limits, the ASA removes the least recently used CRL until more space becomes available.

Step 4 Check the **Enforce next CRL update** check box to require valid CRLs to have a Next Update value that has not expired. Uncheck the **Enforce next CRL update** check box to let valid CRLs with no Next Update value or a Next Update value that has expired.

Step 5 In the OCSP Options area, enter the URL for the OCSP server. The ASA uses OCSP servers according to the following order:

1. OCSP URL in a match certificate override rule
2. OCSP URL configured in the selected OCSP Options attribute
3. AIA field of a user certificate

Step 6 By default, the **Disable nonce extension** check box is checked, which cryptographically binds requests with responses to avoid replay attacks. This process works by matching the extension in the request to that in the response, ensuring that they are the same. Uncheck the **Disable nonce extension** check box if the OCSP server you are using sends pregenerated responses that do not include this matching nonce extension.

Step 7 In the Other Options area, choose one of the following options:

- Check the **Accept certificates issued by this CA** check box to indicate that the ASA should accept certificates from the specified CA.
- Check the **Accept certificates issued by the subordinate CAs of this CA** check box to indicate that the ASA should accept certificates from the subordinate CA.

Step 8 Click **OK** to close this tab, and then click **Apply** to save your configuration changes.

What to Do Next

See the "Monitoring CRLs" section on page 49-18.

Monitoring CRLs

To monitor CRLs, perform the following steps:

Step 1 In the ASDM main application window, choose **Monitoring > Properties > CRL**.

Step 2 In the CRL area, choose the CA certificate name from the drop-down list.

Step 3 To display CRL details, click **View CRL**. For example:

```
CRL Issuer Name:
    cn=asa4.cisco.com
    LastUpdate: 09:58:34 UTC Nov 11 2009
    NextUpdate: 15:58:34 UTC Nov 11 2009
    Cached Until: 15:58:34 UTC Nov 11 2009
    Retrieved from CRL Distribution Point:
      ** CDP Not Published - Retrieved via SCEP
    Size (bytes): 224
    Associated Trustpoints: LOCAL-CA-SERVER
```

Step 4 When you are done, click **Clear CRL** to remove the CRL details and choose another CA certificate to view.

Configuring CA Certificates for Revocation

To configure CA certificates for revocation, perform the following steps:

Step 1 In the Configuration Options for CA Certificates pane, click the **Revocation Check** tab.

Step 2 To disable revocation checking of certificates, click the **Do not check certificates for revocation** radio button.

Step 3 To select one or more revocation checking methods (CRL or OCSP), click the **Check certificates for revocation** radio button.

Step 4 In the Revocation Methods area, available methods appear on the left. Click **Add** to move a method to the right and make it available. Click **Move Up** or **Move Down** to change the method order.

The methods that you choose are implemented in the order in which you add them. If a method returns an error, the next revocation checking method activates.

Step 5 Check the **Consider certificate valid if revocation checking returns errors** check box to ignore revocation checking errors during certificate validation.

Step 6 Click **OK** to close the Revocation Check tab. Alternatively, to continue, see the "Configuring CRL Retrieval Policy" section on page 49-19.

Configuring CRL Retrieval Policy

To configure the CRL retrieval policy, perform the following steps:

Step 1 In the Configuration Options for CA Certificates pane, click the **CRL Retrieval Policy** tab.

Step 2 Check the **Use CRL Distribution Point from the certificate** check box to direct revocation checking to the CRL distribution point from the certificate being checked.

Step 3 Check the **Use Static URLs configured below** check box to list specific URLs to be used for CRL retrieval. The URLs you select are implemented in the order in which you add them. If an error occurs with the specified URL, the next URL in order is taken.

Step 4 In the Static Configuration area, click **Add**.

The Add Static URL dialog box appears.

Step 5 In the URL field, enter the static URL to use for distributing the CRLs, and then click **OK**.

The URL that you entered appears in the Static URLs list.

Step 6 To change the static URL, select it, and then click **Edit**.

Step 7 To remove an existing static URL, select it, and then click **Delete**.

Step 8 To change the order in which the static URLs appear, click **Move Up** or **Move Down**.

Step 9 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring CRL Retrieval Methods" section on page 49-20.

Configuring CRL Retrieval Methods

To configure CRL retrieval methods, perform the following steps:

Step 1 In the Configuration Options for CA Certificates pane, click the **CRL Retrieval Methods** tab.

Step 2 Choose one of the following three retrieval methods:

- To enable LDAP for CRL retrieval, check the **Enable Lightweight Directory Access Protocol (LDAP)** check box. With LDAP, CRL retrieval starts an LDAP session by connecting to a named LDAP server, accessed by a password. The connection is on TCP port 389 by default. Enter the following required parameters:
  - Name
  - Password
  - Confirm Password
  - Default Server (server name)
  - Default Port (389)
- To enable HTTP for CRL retrieval, check the **Enable HTTP** check box.
- To enable SCEP for CRL retrieval, check the **Enable Simple Certificate Enrollment Protocol (SCEP)** check box.

Step 3 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring OCSP Rules" section on page 49-20.

Configuring OCSP Rules

The ASA examines OCSP rules in priority order, and applies the first one that matches. X.509 digital certificates are an alternative to using CRLs.

Note Make sure that you have configured a certificate map before you try to add OCSP rules. If a certificate map has not been configured, an error message appears. To configure a certificate map, choose **Configuration > Network (Client) Access, Advanced > IPsec > Certificate to Connection Profile Maps > Rules > Add**.

To configure OCSP rules for obtaining revocation status of an X.509 digital certificate, perform the following steps:

Step 1 In the Configuration Options for CA Certificates pane, click the **OCSP Rules** tab.

Step 2 Choose the certificate map to match to this OCSP rule. Certificate maps match user permissions to specific fields in a certificate. The name of the CA that the ASA uses to validate responder certificates appears in the Certificate field. The priority number for the rule appears in the Index field. The URL of the OCSP server for this certificate appears in the URL field.

Step 3 To add a new OCSP rule, click **Add**.

The Add OCSP Rule dialog box appears.

Step 4 Choose the certificate map to use from the drop-down list.

Step 5 Choose the certificate to use from the drop-down list.

Step 6 Enter the priority number for the rule.

Step 7 Enter the URL of the OCSP server for this certificate.

Step 8 When you are done, click **OK** to close this dialog box.

The newly added OCSP rule appears in the list.

Step 9 To edit an existing OCSP rule, select it, and then click **Edit**.

Step 10 To delete an OCSP rule, select it, and then click **Delete**.

Step 11 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring Advanced CRL and OCSP Settings" section on page 49-21.

Configuring Advanced CRL and OCSP Settings

When a certificate is issued, it is valid for a fixed period of time. Sometimes a CA revokes a certificate before this time period expires; for example, because of security concerns or a change of name or association. CAs periodically issue a signed list of revoked certificates. Enabling revocation checking forces the ASA to check that the CA has not revoked the certificate being verified. The ASA supports two methods of checking revocation status: CRL and OCSP.

To configure additional CRL and OCSP settings, perform the following steps:

Step 1 In the Configuration Options for CA Certificates pane, click the **Advanced** tab.

Step 2 In the CRL Options area, enter the number of minutes between cache refreshes. The default is 60 minutes. The range is 1-1440 minutes. To avoid having to retrieve the same CRL from a CA repeatedly, the ASA can store retrieved CRLs locally, which is called CRL caching. The CRL cache capacity varies by platform and is cumulative across all contexts. If an attempt to cache a newly retrieved CRL would exceed its storage limits, the ASA removes the least recently used CRL until more space becomes available.

Step 3 Check the **Enforce next CRL update** check box to require valid CRLs to have a Next Update value that has not expired. Uncheck the **Enforce next CRL update** check box to let valid CRLs with no Next Update value or a Next Update value that has expired.

Step 4 In the OCSP Options area, enter the URL for the OCSP server. The ASA uses OCSP servers according to the following order:

1. OCSP URL in a match certificate override rule
2. OCSP URL configured in the selected OCSP Options attribute
3. AIA field of a remote user certificate

Step 5 By default, the **Disable nonce extension** check box is checked, which cryptographically binds requests with responses to avoid replay attacks. This process works by matching the extension in the request to that in the response, ensuring that they are the same. Uncheck the **Disable nonce extension** check box if the OCSP server you are using sends pregenerated responses that do not include this matching nonce extension.

Step 6 In the Validation Policy area, choose one of the following options:

- Click the **SSL** radio button or the **IPsec** radio button to restrict the type of remote session that this CA can be used to validate.

- Click the **SSL and IPsec** radio buttons to let the CA validate both types of sessions.

Step 7 In the Other Options area, choose one of the following options:

- Check the **Accept certificates issued by this CA** check box to indicate that the ASA should accept certificates from the specified CA.
- Check the **Accept certificates issued by the subordinate CAs of this CA** check box to indicate that the ASA should accept certificates from the subordinate CA.

Step 8 Click **OK** to close this tab, and then click **Apply** to save your configuration changes.

What to Do Next

See the "Configuring Identity Certificates Authentication" section on page 49-22.

Configuring Identity Certificates Authentication

An identity certificate can be used to authenticate VPN access through the ASA. In the Identity Certificates Authentication pane, you can perform the following tasks:

- Add or import a new identity certificate.
- Display details of an identity certificate.
- Delete an existing identity certificate.
- Export an existing identity certificate.
- Install an existing identity certificate.
- Enroll for an identity certificate with Entrust.

This section includes the following topics:

- Adding or Importing an Identity Certificate, page 49-22
- Showing Identity Certificate Details, page 49-24
- Deleting an Identity Certificate, page 49-25
- Exporting an Identity Certificate, page 49-25
- Generating a Certificate Signing Request, page 49-25
- Installing Identity Certificates, page 49-26

Adding or Importing an Identity Certificate

To add or import a new identity certificate configuration, perform the following:

Step 1 In the main ASDM application window, choose **Configuration > Remote Access VPN > Certificate Management > Identity Certificates**.

Step 2 Click **Add**.

The Add Identity Certificate dialog box appears, with the selected trustpoint name displayed at the top.

Step 3 To import an identity certificate from an existing file, click the **Import the identity certificate from a file (PKCS12 format with Certificate(s) + Private Key)** radio button.

Step 4 Enter the passphrase used to decrypt the PKCS12 file.

Step 5 Enter the path name of the file, or click **Browse** to display the Import ID Certificate File dialog box. Find the certificate file, and then click **Import ID Certificate File**.

Step 6 To add a new identity certificate, click the **Add a new identity certificate** radio button.

Step 7 Click **New** to display the Add Key Pair dialog box.

Step 8 Choose the **RSA** or **ECDSA** key type.

Note The 4096-bit RSA keys are only supported on the 5580, 5585, or later platforms. If you are configuring a cryptography map to use an RSA or ECDSA trustpoint for authentication, you must first generate the key set. You can then create the trustpoint and reference it in the tunnel group configuration.

Step 9 To use the default key pair name, click the **Use default keypair name** radio button.

Step 10 To use a new key pair name, click the **Enter a new key pair name** radio button, and type the new name. The ASA supports multiple key pairs.

Step 11 Choose the modulus size from the drop-down list. If you are notsure of the modulus size, consult Entrust.

Step 12 Choose the key pair usage by clicking the **General purpose** radio button (default) or **Special** radio button. When you choose the **Special** radio button, the ASA generates two key pairs, one for signature use and one for encryption use. This selection indicates that two certificates are required for the corresponding identity.

Step 13 Click **Generate Now** to create new key pairs, and then click **Show** to display the Key Pair Details dialog box, which includes the following *display-only* information:

- The name of the key pair whose public key is to be certified.
- The time of day and the date when the key pair is generated.
- The usage of an RSA key pair.
- The modulus size (bits) of the key pairs: 512, 768, 1024, and 2048. The default is 1024.
- The key data, which includes the specific key data in text format.

Step 14 Click **OK** when you are done to close the Key Pair Details dialog box.

Step 15 Choose a certificate subject DN to form the DN in the identity certificate. and then click **Select** to display the Certificate Subject DN dialog box.

Step 16 Choose one or more DN attributes that you want to add from the drop-down list, enter a value, and then click **Add**. Available X.500 attributes for the Certificate Subject DN are the following:

- Common Name (CN)
- Department (OU)
- Company Name (O)
- Country (C)
- State/Province (ST)
- Location (L)
- E-mail Address (EA)

Step 17 Click **OK** when you are done to close the Certificate Subject DN dialog box.

Step 18 To create self-signed certificates, check the **Generate self-signed certificate** check box.

Step 19 To have the identity certificate act as the local CA, check the **Act as local certificate authority and issue dynamic certificates to TLS proxy** check box.

Step 20 To establish additional identity certificate settings, click **Advanced**.

The Advanced Options dialog box appears, with the following three tabs: Certificate Parameters, Enrollment Mode, and SCEP Challenge Password.

Note Enrollment mode settings and the SCEP challenge password are not available for self-signed certificates.

Step 21 Click the **Certificate Parameters** tab, and then enter the following information:

- The FQDN, an unambiguous domain name, to indicate the position of the node in the DNS tree hierarchy.
- The e-mail address associated with the identity certificate.
- The ASA IP address on the network in four-part, dotted-decimal notation.
- To add the ASA serial number to the certificate parameters, check the **Include serial number of the device** check box.

Step 22 Click the **Enrollment Mode** tab, and then enter the following information:

- Choose the enrollment method by clicking the **Request by manual enrollment** radio button or the **Request from a CA** radio button.
- The enrollment URL of the certificate to be automatically installed through SCEP.
- The maximum number of minutes allowed to retry installing an identity certificate. The default is one minute.
- The maximum number of retries allowed for installing an identity certificate. The default is zero, which indicates an unlimited number of retries within the retry period.

Step 23 Click the **SCEP Challenge Password** tab, and then enter the following information:

- The SCEP password
- The SCEP password confirmation

Step 24 Click **OK** when you are done to close the Advanced Options dialog box.

Step 25 Click **Add Certificate** in the Add Identity Certificate dialog box.

The new identity certificate appears in the Identity Certificates list.

Step 26 Click **Apply** to save the new identity certificate configuration.

Showing Identity Certificate Details

To show detailed information about the selected identity certificate, click **Show Details** to display the Certificate Details dialog box, which includes the following three *display-only* tabs:

- The General tab displays the values for type, serial number, status, usage, public key type, CRL distribution point, the times within which the certificate is valid, and associated trustpoints. The values apply to both available and pending status.
- The Issued to tab displays the X.500 fields of the subject DN or certificate owner and their values. The values apply only to available status.

- The Issued by tab displays the X.500 fields of the entity granting the certificate. The values apply only to available status.

Deleting an Identity Certificate

To remove an identity certificate configuration, select it, and then click **Delete**.

Note After you delete a certificate configuration, it cannot be restored. To recreate the deleted certificate, click **Add** to reenter all of the certificate configuration information.

Exporting an Identity Certificate

You can export a certificate configuration with all associated keys and certificates in PKCS12 format, which is the public key cryptography standard, and can be base64 encoded or in hexadecimal format. A complete configuration includes the entire chain (root CA certificate, identity certificate, key pair) but not enrollment settings (subject name, FQDN and so on). This feature is commonly used in a failover or load-balancing configuration to replicate certificates across a group of ASAs; for example, remote access clients calling in to a central organization that has several units to service the calls. These units must have equivalent certificate configurations. In this case, an administrator can export a certificate configuration and then import it across the group of ASAs.

To export an identity certificate, perform the following steps:

Step 1 Click **Export** to display the Export Certificate dialog box.

Step 2 Enter the name of the PKCS12 format file to use in exporting the certificate configuration. Alternatively, click **Browse** to display the Export ID Certificate File dialog box to find the file to which you want to export the certificate configuration.

Step 3 Choose the certificate format by clicking the **PKCS12 Format** radio button or the **PEM Format** radio button.

Step 4 Enter the passphrase used to encrypt the PKCS12 file for export.

Step 5 Confirm the encryption passphrase.

Step 6 Click **Export Certificate** to export the certificate configuration.

An information dialog box appears, informing you that the certificate configuration file has been successfully exported to the location that you specified.

Generating a Certificate Signing Request

To generate a certificate signing request to send to Entrust, perform the following steps:

Step 1 Click **Enroll ASA SSL VPN with Entrust** to display the Generate Certificate Signing Request dialog box.

Step 2 In the Key Pair area, perform the following steps:

a. Choose one of the configured key pairs from the drop-down list.

b. Click **Show** to display the Key Details dialog box, which provides information about the selected key pair, including date and time generated, usage (general or special purpose), modulus size, and key data.

c. Click **OK** when you are done to close Key Details dialog box.

d. Click **New** to display the Add Key Pair dialog box. To continue, go to Step 8 of the "Adding or Importing an Identity Certificate" section on page 49-22. When you generate the key pair, you can send it to the ASA or save it to a file.

Step 3 In the Certificate Subject DN area, enter the following information:

a. The FQDN or IP address of the ASA.

b. The name of the company.

c. The two-letter country code.

Step 4 In the Optional Parameters area, perform the following steps:

a. Click **Select** to display the Additional DN Attributes dialog box.

b. Choose the attribute to add from the drop-down list, and then enter a value.

c. Click **Add** to add each attribute to the attribute table.

d. Click **Delete** to remove an attribute from the attribute table.

e. Click **OK** when you are done to close the Additional DN Attributes dialog box.

The added attributes appear in the Additional DN Attributes field.

Step 5 Enter additional fully qualified domain name information if the CA requires it.

Step 6 Click **Generate Request** to generate the certificate signing request, which you can then send to Entrust, or save to a file and send later.

The Enroll with Entrust dialog box appears, with the CSR displayed.

Step 7 To complete the enrollment process, click the **request a certificate from Entrust** link by copying and pasting the CSR provided and submitting it through the Entrust web form, provided at http://www.entrust.net/cisco/. Alternatively, to enroll at a later time, save the generated CSR to a file, then click the **enroll with Entrust** link on the Identity Certificates pane to complete the enrollment process.

Step 8 Entrust issues a certificate after verifying the authenticity of your request. which may take several days. You then need to install the certificate by selecting the pending request in the Identity Certificate pane and clicking **Install**. Click **Close** to close the Enroll with Entrust dialog box.

Installing Identity Certificates

The Install button on the Identity Certificates pane is dimmed unless an enrollment is pending. Whenever the ASA receives a CSR, the Identity Certificates pane displays the pending ID certificate. When you select the pending Identity Certificate, the Install button activates.

When you transmit the pending request to a CA, the CA enrolls it and returns a certificate to the ASA. After you have received the certificate, click **Install** and highlight the appropriate identity certificate to complete the operation.

To installing a pending identity certificate, perform the following steps:

Step 1 In the Identity Certificates pane, click **Add** to display the Add Identity Certificate dialog box.

Step 2 In the Add Identity Certificate dialog box, click the **Add a new identity certificate** radio button.

Step 3 (Optional) Change the key pair or create a new key pair. A key pair is required.

Step 4 Enter the Certificate Subject DN information, and then click **Select** to display the Certificate Subject DN dialog box.

Step 5 Specify all of the subject DN attributes required by the CA involved, and then click **OK** to close the Certificate Subject DN dialog box.

Step 6 In the Add Identity Certificate dialog box, click **Advanced** to display the Advanced Options dialog box.

Step 7 To continue, see Steps 17 through 23 of the "Configuring Identity Certificates Authentication" section on page 49-22.

Step 8 In the Add Identity Certificate dialog box, click **Add Certificate**.

The Identity Certificate Request dialog box appears.

Step 9 Enter the CSR file name of type, text, such as c:\verisign-csr.txt, and then click **OK**.

Step 10 Send the CSR text file to the CA. Alternatively, you can paste the text file into the CSR enrollment page on the CA website.

Step 11 When the CA returns the Identity Certificate to you, go to the Identity Certificates pane, select the pending certificate entry, and click **Install**.

The Install Identity Certificate dialog box appears.

Step 12 Choose one of the following options by clicking the applicable radio button:

- **Install from a file**.

  Alternatively, click **Browse** to search for the file.

- **Paste the certificate data in base-64 format**.

  Paste the copied certificate data into the area provided.

Step 13 Click **Install Certificate**.

Step 14 Click **Apply** to save the newly installed certificate with the ASA configuration.

What to Do Next

See the "Configuring Code Signer Certificates" section on page 49-27.

Configuring Code Signer Certificates

Code signing appends a digital signature to the actual executable code. This digital signature provides enough information to authenticate the signer, and ensure that the code has not been modified after being signed.

Code signer certificates are special certificates whose associated private keys are used to create digital signatures. The certificates used to sign code are obtained from a CA, in which the signed code reveals the certificate origin. You can import code signer certificates on the Code Signer pane, or choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Java Code Signe**r.

In the Code Signer pane, you can perform the following tasks:

- Display details of a code signer certificate.
- Delete an existing code signer certificate.
- Import an existing code signer certificate.
- Export an existing code signer certificate.
- Enroll for a code signer certificate with Entrust.

This section includes the following topics:

- Showing Code Signer Certificate Details, page 49-28
- Deleting a Code Signer Certificate, page 49-28
- Importing a Code Signer Certificate, page 49-28
- Exporting a Code Signer Certificate, page 49-29

Showing Code Signer Certificate Details

To show detailed information about the selected identity certificate, click **Show Details** to display the Certificate Details dialog box, which includes the following three *display-only* tabs:

- The General tab displays the values for type, serial number, status, usage, public key type, CRL distribution point, the times within which the certificate is valid, and associated trustpoints. The values apply to both available and pending status.
- The Issued to tab displays the X.500 fields of the subject DN or certificate owner and their values. The values apply only to available status.
- The Issued by tab displays the X.500 fields of the entity granting the certificate. The values apply only to available status.

Deleting a Code Signer Certificate

To remove a code signer certificate configuration, select it, and then click **Delete**.

Note After you delete a certificate configuration, it cannot be restored. To recreate the deleted certificate, click **Import** to reenter all of the certificate configuration information.

Importing a Code Signer Certificate

To import a code signer certificate, perform the following steps:

Step 1 In the Code Signer pane, click **Import** to display the Import Certificate dialog box.

Step 2 Enter the passphrase used to decrypt the PKCS12-format file.

Step 3 Enter the name of the file to import, or click **Browse** to display the Import ID Certificate File dialog box and search for the file.

Step 4 Select the file to import and click **Import ID Certificate File**.

The selected certificate file appears in the Import Certificate dialog box.

Step 5 Click **Import Certificate**.

The imported certificate appears in the Code Signer pane.

Step 6 Click **Apply** to save the newly imported code signer certificate configuration.

Exporting a Code Signer Certificate

To export a code signer certificate, perform the following steps:

Step 1 In the Code Signer pane, click **Export** to display the Export Certificate dialog box.

Step 2 Enter the name of the PKCS12 format file to use in exporting the certificate configuration.

Step 3 In the Certificate Format area, to use the public key cryptography standard, which can be base64 encoded or in hexadecimal format, click the **PKCS12 format** radio button. Otherwise, click the **PEM format** radio button.

Step 4 Click **Browse** to display the **Export ID Certificate File** dialog box to find the file to which you want to export the certificate configuration.

Step 5 Select the file and click **Export ID Certificate File**.

The selected certificate file appears in the Export Certificate dialog box.

Step 6 Enter the passphrase used to decrypt the PKCS12 format file for export.

Step 7 Confirm the decryption passphrase.

Step 8 Click **Export Certificate** to export the certificate configuration.

What to Do Next

See the "Authenticating Using the Local CA" section on page 49-29.

Authenticating Using the Local CA

The local CA provides a secure, configurable in-house authority that resides on the ASA for certificate authentication to use with browser-based and client-based SSL VPN connections.

Users enroll by logging in to a specified website. The local CA integrates basic certificate authority operations on the ASA, deploys certificates, and provides secure revocation checking of issued certificates.

The local CA lets you perform the following tasks:

- Configure the local CA server.
- Revoke and unrevoke local CA certificates.
- Update CRLs.
- Add, edit, and delete local CA users.

This section includes the following topics:

- Configuring the Local CA Server, page 49-30

- Deleting the Local CA Server, page 49-32

Configuring the Local CA Server

To configure a local CA server on the ASA, perform the following steps:

Step 1 Choose **Configuration > Remote Access VPN > Certificate Management > Local Certificate Authority > CA Server**.

Step 2 To activate the local CA server, check the **Enable Certificate Authority Server** check box. The default setting is disabled (unchecked). After you enable the local CA server, the ASA generates the local CA server certificate, key pair, and necessary database files, then archives the local CA server certificate and key pair in a PKCS12 file.

Note Be sure to review all optional settings carefully before you enable the configured local CA. After you enable it, the certificate issuer name and key size server values cannot be changed.

The self-signed certificate key usage extension enables key encryption, key signature, CRL signature, and certificate signature.

Step 3 When you enable the local CA for the first time, you must enter and confirm an alphanumeric Enable passphrase, which must have a minimum of seven, alphanumeric characters. The passphrase protects the local CA certificate and the local CA certificate key pair archived in storage, and secures the local CA server from unauthorized or accidental shutdown. The passphrase is required to unlock the PKCS12 archive if the local CA certificate or key pair is lost and must be restored.

Note The Enable passphrase is required to enable the local CA server. Be sure to keep a record of the Enable passphrase in a safe location.

Step 4 Click **Apply** to save the local CA certificate and key pair, so the configuration is not lost if you reboot the ASA.

Step 5 To change or reconfigure the local CA after the local CA has been configured for the first time, you must shut down the local CA server on the ASA by unchecking the **Enable Certificate Authority Server** check box. In this state, the configuration and all associated files remain in storage and enrollment is disabled.

After the configured local CA has been enabled, the following two settings are *display-only*:

- The Issuer Name field, which lists the issuer subject name and domain name, and is formed using the username and the subject-name-default DN setting as cn=FQDN. The local CA server is the entity that grants the certificate. The default certificate name is provided in the format, cn=hostname.domainname.
- The CA Server Key Size setting, which is used for the server certificate generated for the local CA server. Key sizes can be 512, 768, 1024, or 2048 bits per key. The default is 1024 bits per key.

Step 6 From the drop-down list, choose the client key size of the key pair to be generated for each user certificate issued by the local CA server. Key sizes can be 512, 768, 1024, or 2048 bits per key. The default is 1024 bits per key.

Step 7 Enter the CA certificate lifetime value, which specifies the number of days that the CA server certificate is valid. The default is 3650 days (10 years). Make sure that you limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038.

The local CA server automatically generates a replacement CA certificate 30 days before expiration, which enables the replacement certificate to be exported and imported onto any other devices for local CA certificate validation of user certificates that have been issued by the local CA after they have expired.

To notify users of the upcoming expiration, the following syslog message appears in the Latest ASDM Syslog Messages pane:

```
%ASA-1-717049: Local CA Server certificate is due to expire in days and a replacement
certificate is available for export.
```

Note When notified of this automatic rollover, the administrator must take action to make sure that the new local CA certificate is imported to all necessary devices before it expires.

Step 8 Enter the client certificate lifetime value, which specifies the number of days that a user certificate issued by the CA server is valid. The default is 365 days (one year). Make sure that you limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038.

In the SMTP Server & Email Settings area, you set up e-mail access for the local CA server by specifying the following settings:

a. Enter the SMTP mail server name or IP address. Alternatively, click the ellipses (...) to display the Browse Server Name/IP Address dialog box, where you can choose the server name or IP address. Click **OK** when you are done to close the Browse Server Name/IP Address dialog box.

b. Enter the from address, from which to send e-mail messages to local CA users, in the format "adminname@hostname.com." Automatic e-mail messages carry one-time passwords to newly enrolled users and issue e-mail messages when certificates need to be renewed or updated.

c. Enter the subject, which specifies the subject line in all messages that are sent to users by the local CA server. If you do not specify a subject, the default is "Certificate Enrollment Invitation."

Step 9 To configure additional options, click the **More Options** drop-down arrow.

Step 10 Enter the CRL distribution point, which is the CRL location on the ASA. The default location is http://hostname.domain/+CSCOCA+/asa_ca.crl.

Step 11 To make the CRL available for HTTP download on a given interface and port, choose a publish-CRL interface from the drop-down list. Then enter the port number, which can be any port number from 1-65535. The default port number is TCP port 80.

Note You cannot rename the CRL; it always has the name, LOCAL-CA-SERVER.crl.

For example, enter the URL, http://10.10.10.100/user8/my_crl_file. In this case, only the interface with the specified IP address works and when the request comes in, the ASA matches the path, /user8/my_crl_file to the configured URL. When the path matches, the ASA returns the stored CRL file.

Step 12 Enter the CRL lifetime in hours that the CRL is valid. The default for the CA certificate is six hours.

The local CA updates and reissues the CRL each time that a user certificate is revoked or unrevoked, but if no revocation changes occur, the CRL is reissued once every CRL lifetime. You can force an immediate CRL update and regeneration by clicking **Request CRL** in the CA Certificates pane.

Step 13 Enter the database storage location to specify a storage area for the local CA configuration and data files. The ASA accesses and implements user information, issued certificates, and revocation lists using a local CA database. Alternatively, to specify an external file, enter the path name to the external file or click **Browse** to display the Database Storage Location dialog box.

Step 14 Choose the storage location from the list of folders that appears, and click **OK**.

Note Flash memory can store a database with 3500 users or less; a database of more than 3500 users requires external storage.

Step 15 Enter a default subject (DN string) to append to a username on issued certificates. The permitted DN attributes are provided in the following list:

- CN (Common Name)
- SN (Surname)
- O (Organization Name)
- L (Locality)
- C (Country)
- OU (Organization Unit)
- EA (E-mail Address)
- ST (State/Province)
- T (Title)

Step 16 Enter the number of hours for which an enrolled user can retrieve a PKCS12 enrollment file to enroll and retrieve a user certificate. The enrollment period is independent of the OTP expiration period. The default is 24 hours.

Note Certificate enrollment for the local CA is supported only for clientless SSL VPN connections. For this type of connection, communications between the client and the ASA is through a web browser that uses standard HTML.

Step 17 Enter the length of time that a one-time password e-mailed to an enrolling user is valid. The default is 72 hours.

Step 18 Enter the number of days before expiration reminders are e-mailed to users. The default is 14 days.

Step 19 Click **Apply** to save the new or modified CA certificate configuration. Alternatively, click **Rese**t to remove any changes and return to the original settings.

Deleting the Local CA Server

To remove the local CA server from the ASA, perform the following steps:

Step 1 In the CA Server pane, click **Delete Certificate Authority Serve**r.

The Delete Certificate Authority dialog box appears.

Step 2 To delete the CA server, click **OK**. To retain the CA server, click **Cancel**.

Note After you delete the local CA server, it cannot be restored or recovered. To recreate the deleted CA server configuration, you must reenter all of the CA server configuration information.

What to Do Next

See the "Managing the User Database" section on page 49-33.

Managing the User Database

The local CA user database includes user identification information and user status (enrolled, allowed, revoked, and so on). In the Manage User Database pane, you can perform the following tasks:

- Add a user to the local CA database.
- Change existing user identification information.
- Remove a user from the local CA database.
- Enroll a user.
- Update CRLs.
- E-mail OTPs to a user.
- View or regenerate (replace) an OTP.

This section includes the following topics:

- Adding a Local CA User, page 49-33
- Sending an Initial OTP or Replacing OTPs, page 49-34
- Editing a Local CA User, page 49-34
- Deleting a Local CA User, page 49-35
- Allowing User Enrollment, page 49-35
- Viewing or Regenerating an OTP, page 49-35

Adding a Local CA User

To add a local CA user, perform the following steps:

Step 1 To enter a new user into the local CA database, click **Add** to display the Add User dialog box.

Step 2 Enter a valid username.

Step 3 Enter an existing valid e-mail address.

Step 4 Enter the subject (DN string). Alternatively, click **Select** to display the Certificate Subject DN dialog box.

Step 5 Choose one or more DN attributes that you want to add from the drop-down list, enter a value, and then click **Add**. Available X.500 attributes for the Certificate Subject DN are the following:

- Common Name (CN)
- Department (OU)
- Company Name (O)
- Country (C)
- State/Province (ST)
- Location (L)

- E-mail Address (EA)

Step 6 Click **OK** when you are done to close the Certificate Subject DN dialog box.

Step 7 Check the **Allow enrollment** check box to enroll the user, and then click **Add User**.

The new user appears in the Manage User Database pane.

Sending an Initial OTP or Replacing OTPs

To automatically send an e-mail notice of enrollment permission with a unique OTP and the local CA enrollment URL to the newly added user, click **Email OTP**.

An Information dialog box appears indicating that the OTP was sent to the new user.

To automatically reissue a new OTP and send an e-mail notice with the new password to an existing or new user, click **Replace OTP**.

Editing a Local CA User

To modify information about an existing local CA user in the database, perform the following steps:

Step 1 Select the specific user and click **Edit** to display the Edit User dialog box.

Step 2 Enter a valid username.

Step 3 Enter an existing valid e-mail address.

Step 4 Enter the subject (DN string). Alternatively, click **Select** to display the Certificate Subject DN dialog box.

Step 5 Choose one or more DN attributes that you want to change from the drop-down list, enter a value, and then click **Add** or **Delete**. Available X.500 attributes for the Certificate Subject DN are the following:

- Common Name (CN)
- Department (OU)
- Company Name (O)
- Country (C)
- State/Province (ST)
- Location (L)
- E-mail Address (EA)

Step 6 Click **OK** when you are done to close the Certificate Subject DN dialog box.

Step 7 Check the **Allow enrollment** check box to reenroll the user, and then click **Edit User**.

The updated user details appear in the Manage User Database pane.

Deleting a Local CA User

To remove the user from the database and any certificates issued to that user from the local CA database, select the user, and then click **Delete**.

Note A deleted user cannot be restored. To recreate the deleted user record, click **Add** to reenter all of the user information.

Allowing User Enrollment

To enroll the selected user, click A**llow Enrollment**.

The status of the user changes to "enrolled" in the Manage User Database pane.

Note If the user is already enrolled, an error message appears.

Viewing or Regenerating an OTP

To view or regenerate the OTP of the selected user, perform the following steps:

Step 1 Click **View/Regenerate OTP** to display the View & Regenerate OTP dialog box.

The current OTP appears.

Step 2 After you are done, click **OK** to close the View & Regenerate OTP dialog box.

Step 3 To regenerate the OTP, click **Regenerate OTP**.

The newly generated OTP appears.

Step 4 Click **OK** to close the View & Regenerate OTP dialog box.

What to Do Next

See the "Managing User Certificates" section on page 49-35.

Managing User Certificates

To change the certificate status, perform the following steps:

Step 1 In the Manage User Certificates pane, select specific certificates by username or by certificate serial number.

Step 2 Choose one of the following options:

- If the user certificate lifetime period runs out, to remove user access, click **Revoke**. The local CA also marks the certificate as revoked in the certificate database, automatically updates the information, and reissues the CRL.

- To restore access, select a revoked certificate and click **Unrevoke**. The local CA also marks the certificate as unrevoked in the certificate database, automatically updates the certificate information, and reissues an updated CRL.

Step 3 Click **Apply** when you are done to save your changes.

What to Do Next

See the "Monitoring CRLs" section on page 49-36.

Monitoring CRLs

To monitor CRLs, perform the following steps:

Step 1 In the ASDM main application window, choose **Monitoring > Properties > CRL**.

Step 2 In the CRL area, choose the CA certificate name from the drop-down list.

Step 3 To display CRL details, click **View CRL**. For example:

```
CRL Issuer Name:
    cn=asa4.cisco.com
    LastUpdate: 09:58:34 UTC Nov 11 2010
    NextUpdate: 15:58:34 UTC Nov 11 2010
    Cached Until: 15:58:34 UTC Nov 11 2010
    Retrieved from CRL Distribution Point:
      ** CDP Not Published - Retrieved via SCEP
    Size (bytes): 224
    Associated Trustpoints: LOCAL-CA-SERVER
```

Step 4 When you are done, click **Clear CRL** to remove the CRL details and choose another CA certificate to view.

Feature History for Certificate Management

Table 49-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 49-1 Feature History for Certificate Management

Feature Name	Platform Releases	Feature Information
Certificate management	7.0(1)	Digital certificates (including CA certificates, identity certificates, and code signer certificates) provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that "sign" certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security. We introduced the following screens: Configuration > Remote Access VPN > Certificate Management Configuration > Site-to-Site VPN > Certificate Management. We introduced or modified the following screens: Configuration > Firewall > Advanced > Certificate Management > CA Certificates Configuration > Device Management > Certificate Management > CA Certificates.
SCEP proxy	8.4(1)	We introduced this feature, which provides secure deployment of device certificates from third-party CAs.

PART 9

Configuring Access Control

Configuring Access Rules

This chapter describes how to control network access through the ASA using access rules and includes the following sections:

- Information About Access Rules, page 51-1
- Licensing Requirements for Access Rules, page 51-6
- Guidelines and Limitations, page 51-6
- Default Settings, page 51-7
- Configuring Access Rules, page 51-7
- Feature History for Access Rules, page 51-13

Note You use access rules to control network access in both routed and transparent firewall modes. In transparent mode, you can use both access rules (for Layer 3 traffic) and EtherType rules (for Layer 2 traffic).

To access the ASA interface for management access, you do not also need an access rule allowing the host IP address. You only need to configure management access according to Chapter 52, "Configuring Management Access."

Information About Access Rules

Your access policy is made up of one or more access rules and/or EtherType rules per interface or globally for all interfaces.

You can use access rules in routed and transparent firewall mode to control IP traffic. An access rule permits or denies traffic based on the protocol, a source and destination IP address or network, and optionally the source and destination ports.

For transparent mode only, an EtherType rule controls network access for non-IP traffic. An EtherType rule permits or denies traffic based on the EtherType.

This section includes the following topics:

- General Information About Rules, page 51-2
- Information About Access Rules, page 51-4
- Information About EtherType Rules, page 51-5

General Information About Rules

This section describes information for both access rules and EtherType rules, and it includes the following topics:

- Implicit Permits, page 51-2
- Information About Interface Access Rules and Global Access Rules, page 51-2
- Using Access Rules and EtherType Rules on the Same Interface, page 51-2
- Rule Order, page 51-3
- Implicit Deny, page 51-3
- Using Remarks, page 51-3
- NAT and Access Rules, page 51-3
- Inbound and Outbound Rules, page 51-3
- Information About Access Rules, page 51-4

Implicit Permits

For routed mode, the following types of traffic are allowed through by default:

- IPv4 traffic from a higher security interface to a lower security interface.
- IPv6 traffic from a higher security interface to a lower security interface.

For transparent mode, the following types of traffic are allowed through by default:

- IPv4 traffic from a higher security interface to a lower security interface.
- IPv6 traffic from a higher security interface to a lower security interface.
- ARPs in both directions.

Note ARP traffic can be controlled by ARP inspection, but cannot be controlled by an access rule.

- BPDUs in both directions.

For other traffic, you need to use either an access rule (IPv4 and IPv6) or an EtherType rule (non-IPv4/IPv6).

Information About Interface Access Rules and Global Access Rules

You can apply an access rule to a specific interface, or you can apply an access rule globally to all interfaces. You can configure global access rules in conjunction with interface access rules, in which case, the specific interface access rules are always processed before the general global access rules.

Note Global access rules apply only to inbound traffic. See the "Inbound and Outbound Rules" section on page 51-3.

Using Access Rules and EtherType Rules on the Same Interface

You can apply both access rules and EtherType rules to each direction of an interface.

Rule Order

The order of rules is important. When the ASA decides whether to forward or drop a packet, the ASA tests the packet against each rule in the order in which the rules are listed. After a match is found, no more rules are checked. For example, if you create an access rule at the beginning that explicitly permits all traffic for an interface, no further rules are ever checked. For more information, see the "Implicit Deny" section on page 51-3.

You can disable a rule by making it inactive.

Implicit Deny

Access lists have an implicit deny at the end of the list, so unless you explicitly permit it, traffic cannot pass. For example, if you want to allow all users to access a network through the ASA except for particular addresses, then you need to deny the particular addresses and then permit all others.

For EtherType access lists, the implicit deny at the end of the access list does not affect IP traffic or ARPs; for example, if you allow EtherType 8037, the implicit deny at the end of the access list does not now block any IP traffic that you previously allowed with an extended access list (or implicitly allowed from a high security interface to a low security interface). However, if you explicitly deny all traffic with an EtherType ACE, then IP and ARP traffic is denied.

If you configure a global access rule, then the implicit deny comes *after* the global rule is processed. See the following order of operations:

1. Interface access rule.
2. Global access rule.
3. Implicit deny.

Using Remarks

In the ASDM access rule window, a remark that displays next to the rule is the one that was configured before the rule, so when you configure a remark from the CLI and then view it in an ASDM access rule window, the remark displays next to the rule that was configured after the remark in the CLI. However, the packet tracer in ASDM matches the remark that is configured after the matching rule in the CLI.

NAT and Access Rules

Access rules always use the real IP addresses when determining an access rule match, even if you configure NAT. For example, if you configure NAT for an inside server, 10.1.1.5, so that it has a publicly routable IP address on the outside, 209.165.201.5, then the access rule to allow the outside traffic to access the inside server needs to reference the server's real IP address (10.1.1.5), and not the mapped address (209.165.201.5).

Inbound and Outbound Rules

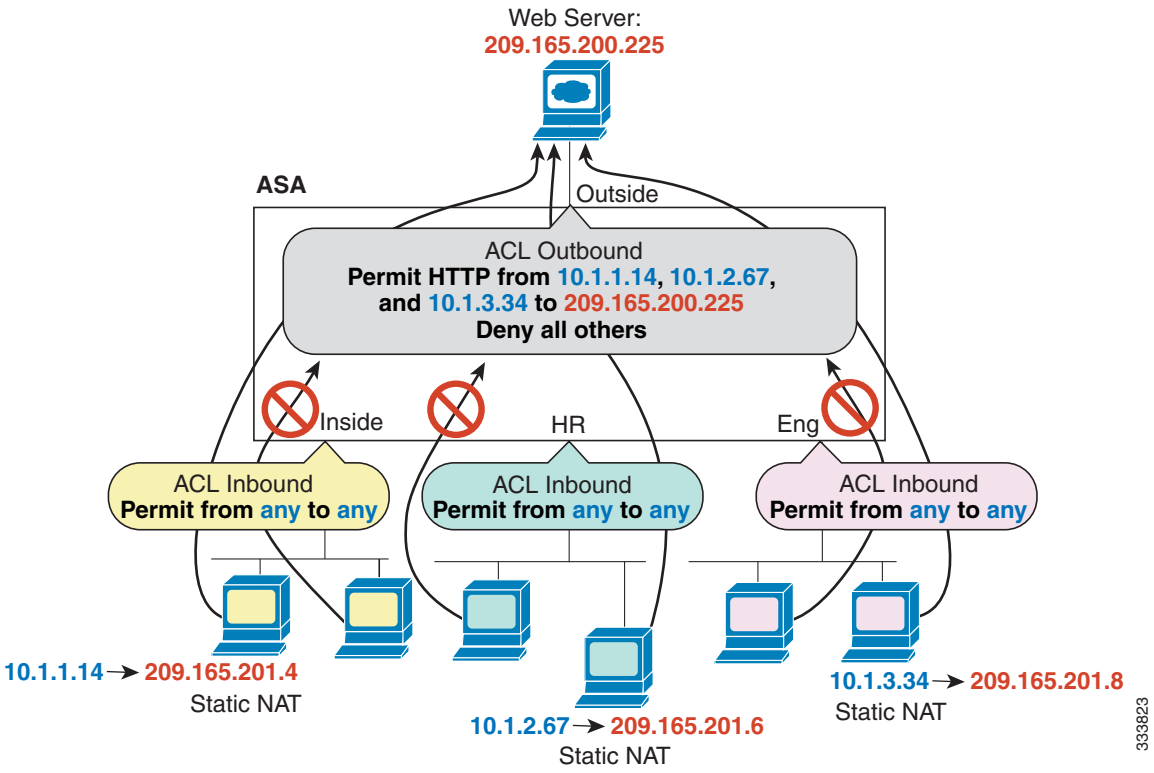
The ASA supports two types of access lists:

- Inbound—Inbound access rules apply to traffic as it enters an interface. Global access rules are always inbound.
- Outbound—Outbound access lists apply to traffic as it exits an interface.

Note "Inbound" and "outbound" refer to the application of an access list on an interface, either to traffic entering the ASA on an interface or traffic exiting the ASA on an interface. These terms do not refer to the movement of traffic from a lower security interface to a higher security interface, commonly known as inbound, or from a higher to lower interface, commonly known as outbound.

An outbound access list is useful, for example, if you want to allow only certain hosts on the inside networks to access a web server on the outside network. Rather than creating multiple inbound access lists to restrict access, you can create a single outbound access list that allows only the specified hosts. (See Figure 51-1.) The outbound access list prevents any other hosts from reaching the outside network.

Figure 51-1 Outbound Access List



Information About Access Rules

This section describes information about access rules and includes the following topics:

- Access Rules for Returning Traffic, page 51-5
- Allowing Broadcast and Multicast Traffic through the Transparent Firewall Using Access Rules, page 51-5
- Management Access Rules, page 51-5

Access Rules for Returning Traffic

For TCP and UDP connections for both routed and transparent mode, you do not need an access rule to allow returning traffic because the ASA allows all returning traffic for established, bidirectional connections.

For connectionless protocols such as ICMP, however, the ASA establishes unidirectional sessions, so you either need access rules to allow ICMP in both directions (by applying access lists to the source and destination interfaces), or you need to enable the ICMP inspection engine. The ICMP inspection engine treats ICMP sessions as bidirectional connections.

Allowing Broadcast and Multicast Traffic through the Transparent Firewall Using Access Rules

In routed firewall mode, broadcast and multicast traffic is blocked even if you allow it in an access rule, including unsupported dynamic routing protocols and DHCP (unless you configure DHCP relay). Transparent firewall mode can allow any IP traffic through. This feature is especially useful in multiple context mode, which does not allow dynamic routing, for example.

Note Because these special types of traffic are connectionless, you need to apply an access rule to both interfaces, so returning traffic is allowed through.

Table 51-1 lists common traffic types that you can allow through the transparent firewall.

Table 51-1 Transparent Firewall Special Traffic

Traffic Type	Protocol or Port	Notes
DHCP	UDP ports 67 and 68	If you enable the DHCP server, then the ASA does not pass DHCP packets.
EIGRP	Protocol 88	—
OSPF	Protocol 89	—
Multicast streams	The UDP ports vary depending on the application.	Multicast streams are always destined to a Class D address (224.0.0.0 to 239.x.x.x).
RIP (v1 or v2)	UDP port 520	—

Management Access Rules

You can configure access rules that control management traffic destined to the ASA. Access control rules for to-the-box management traffic (such as HTTP, Telnet, and SSH) have higher precedence than an management access rule. Therefore, such permitted management traffic will be allowed to come in even if explicitly denied by the to-the-box access list.

Information About EtherType Rules

This section describes EtherType rules and includes the following topics:

- Supported EtherTypes and Other Traffic, page 51-6
- Access Rules for Returning Traffic, page 51-6
- Allowing MPLS, page 51-6

Supported EtherTypes and Other Traffic

An EtherType rule controls the following:

- EtherType identified by a 16-bit hexadecimal number, including common types IPX and MPLS unicast or multicast.
- Ethernet V2 frames.
- BPDUs, which are permitted by default. BPDUs are SNAP-encapsulated, and the ASA is designed to specifically handle BPDUs.
- Trunk port (Cisco proprietary) BPDUs. Trunk BPDUs have VLAN information inside the payload, so the ASA modifies the payload with the outgoing VLAN if you allow BPDUs.
- IS-IS (supported in Version 8.4(5) only).

The following types of traffic are not supported:

- 802.3-formatted frames—These frames are not handled by the rule because they use a length field as opposed to a type field.

Access Rules for Returning Traffic

Because EtherTypes are connectionless, you need to apply the rule to both interfaces if you want traffic to pass in both directions.

Allowing MPLS

If you allow MPLS, ensure that Label Distribution Protocol and Tag Distribution Protocol TCP connections are established through the ASA by configuring both MPLS routers connected to the ASA to use the IP address on the ASA interface as the router-id for LDP or TDP sessions. (LDP and TDP allow MPLS routers to negotiate the labels (addresses) used to forward packets.)

On Cisco IOS routers, enter the appropriate command for your protocol, LDP or TDP. The *interface* is the interface connected to the ASA.

```
hostname(config)# mpls ldp router-id interface force
```

Or

```
hostname(config)# tag-switching tdp router-id interface force
```

Licensing Requirements for Access Rules

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

IPv6 Guidelines

Supports IPv6. (9.0 and later) The source and destination addresses can include any mix of IPv4 and IPv6 addresses. For pre-9.0 versions, you must create a separate IPv6 access rule.

Default Settings

See the "Implicit Permits" section on page 51-2.

Configuring Access Rules

This section includes the following topics:

- Adding an Access Rule, page 51-7
- Adding an EtherType Rule (Transparent Mode Only), page 51-8
- Configuring Management Access Rules, page 51-9
- Advanced Access Rule Configuration, page 51-10
- Configuring HTTP Redirect, page 51-12

Adding an Access Rule

To apply an access rule, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Access Rules**.

Step 2 Click **Add**, and choose one of the following options:

The Add Access Rule dialog box appears.

Step 3 From the Interface drop-down list, choose the interface on which to apply the rule. Choose **Any** to apply a global rule.

Step 4 In the Action field, click one of the following radio buttons next to the desired action:

- **Permit**—Permits access if the conditions are matched.
- **Deny**—Denies access if the conditions are matched.

Step 5 In the Source field, enter an IP address that specifies the network, interface IP, or any address from which traffic is permitted or denied to the specified destination. You may use either an IPv4 or IPv6 address.

For more information about enabling IPv6 on an interface, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 6 In the User field, enter a user name or group to the access list. Enter the user name in the format *domain_NetBIOS_name\user_name*. Enter the group name in the format *domain_NetBIOS_name\group_name*.

You can configure access rules based on user names and user group names rather than through source IP addresses. The ASA applies the security policies based on an association of IP addresses to Windows Active Directory login information and reports events based on the mapped user names instead of network IP addresses.

See the "Configuring Identity-Based Security Policy" section on page 47-15 for more information.

Step 7 To browse for a user name or user group, click the ellipsis (...) button. The Browse User dialog box appears.

Step 8 In the Destination field, enter an IP address that specifies the network, interface IP, any address to which traffic is permitted or denied from the source specified in the Source field. You may use either an IPv4 or IPv6 address.

Step 9 Select the service type.

Step 10 (Optional) To add a time range to your access rule that specifies when traffic can be allowed or denied, click **More Options** to expand the list.

a. To the right of the Time Range drop down list, click the browse button.

   The Browse Time Range dialog box appears.

b. Click **Add**.

   The Add Time Range dialog box appears.

c. In the Time Range Name field, enter a time range name, with no spaces.

d. Choose the Start Time and the End Time.

e. To specify additional time constraints for the time range, such as specifying the days of the week or the recurring weekly interval in which the time range will be active, click **Add**, and choose the specifications.

f. Click **OK** to apply the optional time range specifications.

Step 11 (Optional) In the Description field, add a text description about the access rule.

The description can contain multiple lines; however, each line can be no more than 100 characters in length.

Step 12 (Optional) Logging is enabled by default. You can disable logging by unchecking the check box, or you can change the logging level from the drop-down list. The default logging level is Informational.

Step 13 Click **OK**. The access rule appears with the newly configured access rules.

Step 14 Click **Apply** to save the access rule to your configuration.

You can edit or delete a particular access rule by selecting the rule and then clicking Edit or Delete.

Adding an EtherType Rule (Transparent Mode Only)

The EtherType Rules window shows access rules based on packet EtherTypes. EtherType rules are used to configure non-IP related traffic policies through the ASA when operating in transparent mode. In transparent mode, you can apply both extended and EtherType access rules to an interface. EtherType rules take precedence over the extended access rules.

For more information about EtherType rules, see the "Information About Access Rules" section on page 51-1.

To add an EtherType rule, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > EtherType Rules**.

Step 2 Click **Add**.

The Add EtherType rules window appears.

Step 3 (Optional) To specify the placement of the new EtherType rule, select an existing rule, and click **Insert...** to add the EtherType rule before the selected rule, or click **Insert After...** to add the EtherType rule after the selected rule.

Step 4 From the Interface drop-down list, choose the interface on which to apply the rule. Choose **Any** to apply a global rule.

Step 5 In the Action field, click one of the following radio buttons next to the desired action:

- **Permit**—Permits access if the conditions are matched.
- **Deny**—Denies access if the conditions are matched.

Step 6 In the EtherType field, choose an EtherType value from the drop-down list.

Step 7 (Optional) In the Description field, add a test description about the rule.

The description can contain multiple lines; however, each line can be no more than 100 characters in length.

Step 8 (Optional) To specify the direction for this rule, click **More Options** to expand the list, and then specify the direction by clicking one of the following radio buttons:

- **In**—Incoming traffic
- **Out**—Outgoing traffic

Step 9 Click **OK**.

Configuring Management Access Rules

You can configure an interface ACL that supports access control for to-the-box management traffic from a specific peer (or set of peers) to the security appliance. One scenario in which this type of ACL would be useful is when you want to block IKE Denial of Service attacks.

To configure an extended ACL that permits or denies packets for to-the-box traffic, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > Management Access Rules**.

Step 2 Click **Add**, and choose one of the following actions:

The Add Management Access Rule dialog box appears.

Step 3 From the Interface drop-down list, choose an interface on which to apply the rule. Choose **Any** to apply a global rule.

Step 4 In the Action field, click one of the following radio buttons to choose the action:

- **Permit**—Permits access if the conditions are matched.

- **Deny**—Denies access if the conditions are matched.

Step 5 In the Source field, enter an IP address that specifies the network object group, interface IP, or any address from which traffic is permitted or denied. You may use either an IPv4 or IPv6 address.

Note IPv6 must be enabled on at least one interface before you can configure an extended ACL with an IPv6 address. For more information about enabling IPv6 on an interface, see the "Configuring IPv6 Addressing" section on page 17-15

Step 6 In the Service field, add a service name for rule traffic, or click the ellipsis (...) to browse for a service.

Step 7 (Optional) In the Description field, add a description for this management access rule.

The description can contain multiple lines; however, each line can be no more than 100 characters in length.

Step 8 (Optional) Logging is enabled by default. You can disable logging by unchecking the check box, or you can change the logging level from the drop-down list. The default logging level is Informational.

Step 9 (Optional) To add a source service (TCP, UDP, and TCP-UDP only) and a time range to your access rule that specifies when traffic can be allowed or denied, click **More Options** to expand the list.If you want to turn off this Management Access Rule, uncheck **Enable Rule**.

- Add a source service in the Source Service field, or click the ellipsis (...) to browse for a service.

  The destination service and source service must be the same. Copy and paste the destination Service field to the Source Service field.
- To configure the logging interval (if you enable logging and choose a non-default setting), enter a value in seconds in the Logging Interval field.
- To select a predefined time range for this rule, from the Time Range drop-down list, choose a time range; or click the ellipsis (...) to browse for a time range. You can also specify additional time constraints for the time range, such as specifying the days of the week or the recurring weekly interval in which the time range will be active.

Step 10 Click **OK**. The dialog box closes, and the Management Access rule is added.

Step 11 Click **Apply**. The rule is saved in the running configuration.

Advanced Access Rule Configuration

The Advanced Access Rule Configuration dialog box lets you to set global access rule logging options.

When you enable logging, if a packet matches the access rule, the ASA creates a flow entry to track the number of packets received within a specific interval. The ASA generates a system log message at the first hit and at the end of each interval, identifying the total number of hits during the interval and reporting the time of the last hit.

Note The ASApane displays the hit count information in the "last rule hit" row. To view the rule hit count and timestamp, choose **Configuration > Firewall > Advanced > ACL Manager**, and hover the mouse pointer over a cell in the ACL Manager table.

At the end of each interval, the ASA resets the hit count to 0. If no packets match the access rule during an interval, the ASA deletes the flow entry.

A large number of flows can exist concurrently at any point of time. To prevent unlimited consumption of memory and CPU resources, the ASA places a limit on the number of concurrent deny flows; the limit is placed only on deny flows (and not permit flows) because they can indicate an attack. When the limit is reached, the ASA does not create a new deny flow until the existing flows expire. If someone initiates a denial of service attack, the ASA can create a very large number of deny flows in a very short period of time. Restricting the number of deny-flows prevents unlimited consumption of memory and CPU resources.

Prerequisites

These settings only apply if you enable the newer logging mechanism for the access rule.

Fields

- Maximum Deny-flows—The maximum number of deny flows permitted before the ASA stops logging, between 1 and the default value. The default is 4096.
- Alert Interval—The amount of time (1-3600 seconds) between system log messages (number 106101) that identify that the maximum number of deny flows was reached. The default is 300 seconds.
- Per User Override table—Specifies the state of the per user override feature. If the per user override feature is enabled on the inbound access rule, the access rule provided by a RADIUS server replaces the access rule configured on that interface. If the per user override feature is disabled, the access rule provided by the RADIUS server is combined with the access rule configured on that interface. If the inbound access rule is not configured for the interface, per user override cannot be configured.
-

  For VPN remote access traffic, the behavior depends on whether there is a VPN filter applied in the group policy (see the Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > General > More Options > Filter field) and whether you set the Per User Override option:

  – No Per User Override, no VPN filter —Traffic is matched against the interface ACL (per the default **Enable inbound VPN sessions to bypass interface access lists** setting (disabled) on the Configurartion > Remote Access VPN > Network (Client) Access > AnyConnect Connection Profiles pane).

  – No Per User Override, VPN filter —Traffic is matched first against the interface ACL, then against the VPN filter.

  – Per User Override, VPN filter —Traffic is matched against the VPN filter only.
- Object Group Search Setting—Reduces the amount of memory used to store service rules, but lengthens the amount of time to search for a matching access rule.

Access Rule Explosion

The security appliance allows you to turn off the expansion of access rules that contain certain object groups. When expansion is turned off, an object group search is used for lookup, which lowers the memory requirements for storing expanded rules but decreases the lookup performance. Because of the trade-off of performance for memory utilization, you can turn on and turn off the search.

To configure the option of turning off the expansion of access rules that contain s, perform the following steps:

Step 1 Choose **Configuration > Firewall > Access Rules**.

Step 2 Click the **Advanced** button.

Step 3 Check the **Enable Object Group Search Algorithm** check box.

Configuring HTTP Redirect

The HTTP Redirect table displays each interface on the ASA, shows whether it is configured to redirect HTTP connections to HTTPS, and the port number from which it redirects those connections.

Note To redirect HTTP, the interface requires an access list that permits HTTP. Otherwise, the interface cannot listen to the HTTP port.

The Configuration > Device Management > Advanced > HTTP Redirect > Edit pane lets you change the HTTP redirect setting of an interface or the port from which it redirects HTTP connections. Select the interface in the table and click **Edit**. You can also double-click an interface. The Edit HTTP/HTTPS Settings dialog box opens.

Edit HTTP/HTTPS Settings

The Edit HTTP/HTTPS Settings dialog box lets you change the HTTP redirect setting of an interface or the port number.

Fields

The Edit HTTP/HTTPS Settings dialog box includes the following fields:

- Interface—Identifies the interface on which the ASA redirects or does not redirect HTTP requests to HTTPS.
- Redirect HTTP to HTTPS—Check to redirect HTTP requests to HTTPS, or uncheck to not redirect HTTP requests to HTTPS.
- HTTP Port—Identifies the port from which the interface redirects HTTP connections. By default it listens to port 80.

For more information about access rules, see the "Information About Access Rules" section on page 51-1.

Feature History for Access Rules

Table 51-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 51-2 Feature History for Access Rules

Feature Name	Platform Releases	Feature Information
Interface access rules	7.0(1)	Controlling network access through the ASA using access lists. We introduced the following screen: Configuration > Firewall > Access Rules.
Global access rules	8.3(1)	Global access rules were introduced. We modified the following screen: Configuration > Firewall > Access Rules.
Support for Identity Firewall	8.4(2)	You can now use identity firewall users and groups for the source and destination. You can use an identity firewall ACL with access rules, AAA rules, and for VPN authentication.
EtherType ACL support for IS-IS traffic (transparent firewall mode)	8.4(5)	In transparent firewall mode, the ASA can now pass IS-IS traffic using an EtherType ACL. We modified the following screen: Configuration > Device Management > Management Access > EtherType Rules. *Not available in Version 8.5(1), 8.6(1), or 9.0(1).*
Support for TrustSec	9.0(1)	You can now use TrustSec security groups for the source and destination. You can use an identity firewall ACL with access rules.

Table 51-2 Feature History for Access Rules (continued)

Feature Name	Platform Releases	Feature Information
Unified ACL for IPv4 and IPv6	9.0(1)	ACLs now support IPv4 and IPv6 addresses. You can even specify a mix of IPv4 and IPv6 addresses for the source and destination. The **any** keyword was changed to represent IPv4 and IPv6 traffic. The **any4** and **any6** keywords were added to represent IPv4-only and IPv6-only traffic, respectively. The IPv6-specific ACLs are deprecated. Existing IPv6 ACLs are migrated to extended ACLs. See the release notes for more information about migration. We modified the following screens: Configuration > Firewall > Access Rules Configuration > Remote Access VPN > Network (Client) Access > Group Policies > General > More Options
Extended ACLand object enhancement to filter ICMP traffic by ICMP code	9.0(1)	ICMP traffic can now be permitted/denied based on ICMP code. We introduced or modified the following screens: Configuration > Firewall > Objects > Service Objects/Groups Configuration > Firewall > Access Rule

Configuring Management Access

This chapter describes how to access the ASA for system management through Telnet, SSH, and HTTPS (using ASDM), how to authenticate and authorize users, and how to create login banners.

This chapter includes the following sections:

- Configuring ASA Access for ASDM, Telnet, or SSH, page 52-1
- Configuring CLI Parameters, page 52-5
- Configuring File Access, page 52-8
- Configuring ICMP Access, page 52-12
- Configuring Management Access Over a VPN Tunnel, page 52-14
- Configuring AAA for System Administrators, page 52-15
- Monitoring Device Access, page 52-31
- Feature History for Management Access, page 52-32

Note To access the ASA interface for management access, you do not also need an access rule allowing the host IP address. You only need to configure management access according to the sections in this chapter.

Configuring ASA Access for ASDM, Telnet, or SSH

This section describes how to allow clients to access the ASA using ASDM, Telnet, or SSH and includes the following topics:

- Licensing Requirements for ASA Access for ASDM, Telnet, or SSH, page 52-1
- Guidelines and Limitations, page 52-2
- Configuring Management Access, page 52-3
- Using a Telnet Client, page 52-4
- Using an SSH Client, page 52-4

Licensing Requirements for ASA Access for ASDM, Telnet, or SSH

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Model Guidelines

For the ASASM, a session from the switch to the ASASM is a Telnet session, but Telnet access configuration according to this section is not required.

Additional Guidelines

- You cannot use Telnet to the lowest security interface unless you use Telnet inside a VPN tunnel.
- Management access to an interface other than the one from which you entered the ASA is not supported. For example, if your management host is located on the outside interface, you can only initiate a management connection directly to the outside interface. The only exception to this rule is through a VPN connection. See the "Configuring Management Access Over a VPN Tunnel" section on page 52-14.
- The ASA allows:
  - A maximum of 5 concurrent Telnet connections per context, if available, with a maximum of 100 connections divided among all contexts.
  - A maximum of 5 concurrent SSH connections per context, if available, with a maximum of 100 connections divided among all contexts.
  - A maximum of 5 concurrent ASDM instances per context, if available, with a maximum of 32 ASDM instances among all contexts.
- The ASA supports the SSH remote shell functionality provided in SSH Versions 1 and 2 and supports DES and 3DES ciphers.
- XML management over SSL and SSH is not supported.
- (8.4 and later) The SSH default username is no longer supported. You can no longer connect to the ASA using SSH with the **pix** or **asa** username and the login password. To use SSH, you must configure AAA authentication using Configuration > Device Management > Users/AAA > AAA Access > Authentication; then define a local user by choosing Configuration > Device Management > Users/AAA > User Accounts. If you want to use a AAA server for authentication instead of the local database, we recommend also configuring local authentication as a backup method.

- If you cannot make a Telnet or SSH connection to the ASA interface, make sure that you have enabled Telnet or SSH to the ASA according to the instructions in the "Configuring ASA Access for ASDM, Telnet, or SSH" section on page 52-1.

Configuring Management Access

To identify the client IP addresses allowed to connect to the ASA using Telnet, SSH, or ASDM, perform the following steps:

Detailed Steps

Step 1 Choose **Configuration > Device Management > Management Access > ASDM/HTTPS/Telnet/SSH**, and click **Add**.

The Add Device Access Configuration dialog box appears.

Step 2 Choose the type of session from the three options listed: **ASDM/HTTPS**, **Telnet**, or **SSH**.

Step 3 From the Interface Name drop-down list, choose the interface to use for administrative access.

Step 4 In the IP Address field, enter the IP address of the network or host that is allowed access. The field allows IPv6 addresses.

Note When you enter a colon (:) in the IP Address field for an IPv6 address, the Netmask field changes to Prefix Length.

Step 5 From the Mask drop-down list, choose the mask associated with the network or host that is allowed access.

Step 6 Click **OK**.

Step 7 Configure HTTP Settings.

a. Enable HTTP Server—Enable the HTTP server for ASDM access. This is enabled by default.

b. (Optional) Port Number—The default port is 443.

c. (Optional) Idle Timeout—The default idle timeout is 20 minutes.

d. (Optional) Session Timeout—By default, the session timeout is disabled. ASDM connections have no session time limit.

e. (Optional) Require client certificate to access ASDM on the following interfaces—Spercify the interface from the drop-down list.

Step 8 (Optional) Configure Telnet Settings.

a. Telnet Timeout—The default timeout value is 5 minutes.

Step 9 (Optional) Configure SSH Settings.

a. Allowed SSH Version(s)—The default value is 1 & 2.

b. SSH Timeout—The default timeout value is 5 minutes.

Step 10 Click **Apply**.

The changes are saved to the running configuration.

Step 11 (Required for SSH) You must also configure SSH authentication.

a. Choose **Configuration > Device Management > Users/AAA > AAA Access > Authentication**.

b. Check the **SSH** check box.

c. From the Server Group drop-down list, choose an already configured AAA server group name or the **LOCAL** database. To add AAA server groups, see the "Configuring AAA Server Groups" section on page 46-11.

d. (Optional) If you chose a AAA server group, you can configure the ASA to use the local database as a fallback method if the AAA server is unavailable. Check the **Use LOCAL when server group fails** check box. We recommend that you use the same username and password in the local database as the AAA server because the ASA prompt does not give any indication of which method is being used.

e. Click **Apply**.

f. If you chose the LOCAL database, add a local user. Choose **Configuration > Device Management > Users/AAA > User Accounts**, and then click **Add**.

The Add User Account-Identity dialog box appears.

g. In the Username field, enter a username from 4 to 64 characters long.

h. In the Password field, enter a password between 3 and 32 characters. Passwords are case-sensitive.

i. In the Confirm Password field, reenter the password.

For information about other fields, see the "Adding a User Account to the Local Database" section on page 46-20.

j. Click **OK,** then click **Apply**.

Using a Telnet Client

To gain access to the ASA CLI using Telnet, enter the login password. If you configure Telnet authentication (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20), then enter the username and password defined by the AAA server or local database.

Using an SSH Client

In the SSH client on your management host, enter the username and password. When starting an SSH session, a dot (.) displays on the ASA console before the following SSH user authentication prompt appears:

```
hostname(config)#.
```

The display of the dot does not affect the functionality of SSH. The dot appears at the console when generating a server key or decrypting a message using private keys during SSH key exchange before user authentication occurs. These tasks can take up to two minutes or longer. The dot is a progress indicator that verifies that the ASA is busy and has not hung.

Configuring CLI Parameters

This section includes the following topics:

- Licensing Requirements for CLI Parameters, page 52-5
- Guidelines and Limitations, page 52-5
- Configuring a Login Banner, page 52-5
- Customizing a CLI Prompt, page 52-6
- Changing the Console Timeout, page 52-8

Licensing Requirements for CLI Parameters

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Configuring a Login Banner

You can configure a message to display when a user connects to the ASA, before a user logs in, or before a user enters privileged EXEC mode.

Restrictions

After a banner is added, Telnet or SSH sessions to ASA may close if:

- There is not enough system memory available to process the banner message(s).
- A TCP write error occurs when trying to display banner message(s).

Guidelines

- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words “welcome” or “please,” as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

```
You have logged in to a secure device. If you are not authorized to access this
device, log out immediately or risk possible criminal consequences.
```

- See RFC 2196 for guidelines about banner messages.

To configure a login banner, perform the following steps:

Detailed Steps

Step 1 Choose **Configuration > Device Management > Management Access > Command Line (CLI) > Banner**, then add your banner text to the field for the type of banner that you are creating for the CLI:

- The session (exec) banner appears when a user accesses privileged EXEC mode at the CLI.
- The login banner appears when a user logs in to the CLI.
- The message-of-the-day (motd) banner appears when a user first connects to the CLI.
- The ASDM banner appears when a user connects to ASDM, after user authentication. The user is given two options for dismissing the banner:
  - Continue—Dismiss the banner and complete login.
  - Disconnect—Dismiss the banner and terminate the connection.
- Only ASCII characters are allowed, including a new line (Enter), which counts as two characters.
- Do not use tabs in the banner, because they are not preserved in the CLI version.
- There is no length limit for banners other than those for RAM and flash memory.
- You can dynamically add the hostname or domain name of the ASA by including the strings **$(hostname)** and **$(domain)**.
- If you configure a banner in the system configuration, you can use that banner text within a context by using the **$(system)** string in the context configuration.

Step 2 Click **Apply**.

The new banner is saved to the running configuration.

Customizing a CLI Prompt

The CLI Prompt pane lets you customize the prompt used during CLI sessions. By default, the prompt shows the hostname of the ASA. In multiple context mode, the prompt also displays the context name. You can display the following items in the CLI prompt:

cluster-unit	(Single and multiple mode) Displays the cluster unit name. Each unit in a cluster can have a unique name.
context	(Multiple mode only) Displays the name of the current context.
domain	Displays the domain name.
hostname	Displays the hostname.

priority	Displays the failover priority as pri (primary) or sec (secondary).
state	Displays the traffic-passing state of the unit. The following values appear for the state: • act—Failover is enabled, and the unit is actively passing traffic. • stby— Failover is enabled, and the unit is not passing traffic and is in a standby, failed, or another inactive state. • actNoFailover—Failover is not enabled, and the unit is actively passing traffic. • stbyNoFailover—Failover is not enabled, and the unit is not passing traffic. This condition might occur when there is an interface failure above the threshold on the standby unit. Shows the role (master or slave) of a unit in a cluster. For example, in the prompt ciscoasa/cl2/slave, the hostname is ciscoasa, the unit name is cl2, and the state name is slave.

Detailed Steps

To customize the CLI prompt, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > Command Line (CLI) > CLI Prompt**, then do any of the following to customize the prompt:

- To add an attribute to the prompt, click the attribute in the Available Prompts list and then click **Add**. You can add multiple attributes to the prompt. The attribute is moved from the Available Prompts list to the Selected Prompts list.
- To remove an attribute from the prompt, click the attribute in the Selected Prompts list and then click **Delete**. The attribute is moved from the Selected Prompts list to the Available Prompts list.
- To change the order in which the attributes appear in the command prompt, click the attribute in the Selected Prompts list and click **Move Up** or **Move Down** to change the order.

The prompt is changed and displays in the CLI Prompt Preview field.

Step 2 Click **Apply**.

The new prompt is saved to the running configuration.

Changing the Console Timeout

The console timeout sets how long a connection can remain in privileged EXEC mode or configuration mode; when the timeout is reached, the session drops into user EXEC mode. By default, the session does not time out. This setting does not affect how long you can remain connected to the console port, which never times out.

To change the console timeout, perform the following steps:

Detailed Steps

Step 1 To define a new timeout value in minutes, choose **Configuration > Device Management > Management Access > Command Line (CLI) > Console Timeout**.

Step 2 To specify an unlimited amount of time, enter **0**. The default value is 0.

Step 3 Click **Apply**.

The timeout value is changed and the change is saved to the running configuration.

Configuring File Access

This section includes the following topics:

- Licensing Requirements for File Access, page 52-8
- Guidelines and Limitations, page 52-8
- Configuring the FTP Client Mode, page 52-9
- Configuring the ASA as a Secure Copy Server, page 52-9
- Configuring the ASA as a TFTP Client, page 52-10
- Adding Mount Points, page 52-10

Licensing Requirements for File Access

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Configuring the FTP Client Mode

The ASA can use FTP to upload or download image files or configuration files to or from an FTP server. In passive FTP, the client initiates both the control connection and the data connection. The server, which is the recipient of the data connection in passive mode, responds with the port number to which it is listening for the specific connection.

To configure the FTP client to be in passive mode, perform the following steps:

Step 1 From the Configuration > Device Management > Management Access > File Access > FTP Client pane, check the **Specify FTP mode as passive** check box.

Step 2 Click **Apply**.

The FTP client configuration is changed and the change is saved to the running configuration.

Configuring the ASA as a Secure Copy Server

You can enable the secure copy server on the ASA. Only clients that are allowed to access the ASA using SSH can establish a secure copy connection.

Restrictions

This implementation of the secure copy server has the following limitations:

- The server can accept and terminate connections for secure copy, but cannot initiate them.
- The server does not have directory support. The lack of directory support limits remote client access to the ASA internal files.
- The server does not support banners.
- The server does not support wildcards.
- The ASA license must have the VPN-3DES-AES feature to support SSH Version 2 connections.

To configure the ASA as a secure copy server, perform the following steps:

Detailed Steps

Step 1 From the Configuration > Device Management > Management Access > File Access > Secure Copy (SCP) Server pane, check the **Enable secure copy server** check box.

Step 2 Click **Apply**.

The changes are saved to the running configuration. The ASA can function as an SCP server for transferring files to and from the device.

Configuring the ASA as a TFTP Client

TFTP is a simple client/server file transfer protocol, which is described in RFC 783 and RFC 1350 Rev. 2. You can configure the ASA as a TFTP *client* so that it can transfer a copy of its running configuration file to a TFTP *server* by choosing either **File > Save Running Configuration to TFTP Client** or **Tools > Command Line Interface**. In this way, you can back up and propagate configuration files to multiple ASAs.

The ASA supports only one TFTP client. The full path to the TFTP client is specified in Configuration > Device Management > Management Access > File Access > TFTP Client. After the TCP client has been configured in this pane, you can use a colon (:) to specify the IP address in the CLI **configure net** and **copy** commands. However, any other authentication or configuration of intermediate devices necessary for communication from the ASA to the TFTP client is done apart from this function.

To configure the ASA as a TFTP client for saving configuration files to a TFTP server, perform the following steps:

Step 1 From the Configuration > Device Management > Management Access > File Access > TFTP Client pane, check the **Enable** check box.

Step 2 From the Interface Name drop-down list, choose the interface to use as a TFTP client.

Step 3 In the IP Address field, enter the IP address of the TFTP server on which configuration files will be saved.

Step 4 In the Path field, enter the path to the TFTP server on which configuration files will be saved.

For example: /tftpboot/asa/config3

Step 5 Click **Apply**.

The changes are saved to the running configuration. This TFTP server will be used to save the ASA configuration files. For more information, see the "Saving the Running Configuration to a TFTP Server" section on page 101-27.

Adding Mount Points

This section includes the following topics:

- Adding a CIFS Mount Point, page 52-10
- Adding an FTP Mount Point, page 52-11

Adding a CIFS Mount Point

To define a Common Internet File System (CIFS) mount point, perform the following steps:

Step 1 From the Configuration > Device Management > Management Access > File Access > Mount-Points pane, click **Add > CIFS Mount Point**.

The Add CIFS Mount Point dialog box appears.

Step 2 Check the **Enable mount point** check box.

This option attaches the CIFS file system on the ASA to the UNIX file tree.

Step 3 In the Mount Point Name field, enter the name of an existing CIFS location.

Step 4 In the Server Name or IP Address field, enter the name or IP address of the server in which the mount point is located.

Step 5 In the Share Name field, enter the name of the folder on the CIFS server.

Step 6 In the NT Domain Name field, enter the name of the NT Domain in which the server resides.

Step 7 In the User Name field, enter the name of the user authorized for file system mounting on the server.

Step 8 In the Password field, enter the password for the user authorized for file system mounting on the server.

Step 9 In the Confirm Password field, reenter the password.

Step 10 Click **OK**.

The Add CIFS Mount Point dialog box closes.

Step 11 Click **Apply**.

The mount point is added to the ASA, and the change is saved to the running configuration.

Adding an FTP Mount Point

Note For an FTP mount point, the FTP server must have a UNIX directory listing style. Microsoft FTP servers have a default of the MS-DOS directory listing style.

To define an FTP mount point, perform the following steps:

Step 1 From the Configuration > Device Management > Management Access > File Access > Mount-Points pane, click **Add > FTP Mount Point**.

The Add FTP Mount Point dialog box appears.

Step 2 Check the **Enable** check box.

This option attaches the FTP file system on the ASA to the UNIX file tree.

Step 3 In the Mount Point Name field, enter the name of an existing FTP location.

Step 4 In the Server Name or IP Address field, enter the name or IP address of the server where the mount point is located.

Step 5 In the Mode field, click the radio button for the FTP mode (**Active** or **Passive**). When you choose Passive mode, the client initiates both the FTP control connection and the data connection. The server responds with the number of its listening port for this connection.

Step 6 In the Path to Mount field, enter the directory path name to the FTP file server.

Step 7 In the User Name field, enter the name of the user authorized for file system mounting on the server.

Step 8 In the Password field, enter the password for the user authorized for file system mounting on the server.

Step 9 In the Confirm Password field, reenter the password.

Step 10 Click **OK**.

The Add FTP Mount Point dialog box closes.

Step 11 Click **Apply**.

The mount point is added to the ASA, and the change is saved to the running configuration.

Configuring ICMP Access

By default, you can send ICMP packets to any ASA interface using either IPv4 or IPv6. This section tells how to limit ICMP management access to the ASA. You can protect the ASA from attacks by limiting the addresses of hosts and networks that are allowed to have ICMP access to the ASA.

Note For allowing ICMP traffic through the ASA, see Chapter 51, "Configuring Access Rules."

This section includes the following topics:

- Information About ICMP Access, page 52-12
- Licensing Requirements for ICMP Access, page 52-12
- Guidelines and Limitations, page 52-13
- Default Settings, page 52-13
- Configuring ICMP Access, page 52-13

Information About ICMP Access

ICMP in IPv6 functions the same as ICMP in IPv4. ICMPv6 generates error messages, such as ICMP destination unreachable messages and informational messages like ICMP echo request and reply messages. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process and path MTU discovery.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. See RFC 1195 and RFC 1435 for details about path MTU discovery.

If you configure ICMP rules, then the ASA uses a first match to the ICMP traffic followed by an implicit deny all entry. That is, if the first matched entry is a permit entry, the ICMP packet continues to be processed. If the first matched entry is a deny entry or an entry is not matched, the ASA discards the ICMP packet and generates a syslog message. An exception is when an ICMP rule is not configured; in that case, a permit statement is assumed.

Licensing Requirements for ICMP Access

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines

- The ASA does not respond to ICMP echo requests directed to a broadcast address.
- The ASA only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.
- If you cannot ping the ASA interface, make sure that you enable ICMP to the ASA for your IP address using the **icmp** command.

Default Settings

By default, you can send ICMP packets to any ASA interface using either IPv4 or IPv6.

Configuring ICMP Access

To configure ICMP access rules, perform the following steps:

Detailed Steps

Step 1 Choose **Configuration > Device Management > Management Access > ICMP**, and click **Add**.

Step 2 Choose which version of IP traffic to filter by clicking the applicable radio button:

- **Both** (filters IPv4 and IPv6 traffic)
- **IPv4** only
- **IPv6** only

Step 3 If you want to insert a rule into the ICMP table, select the rule that the new rule will precede, and click **Insert**.

The Create ICMP Rule dialog box appears in the right-hand pane.

Step 4 From the ICMP Type drop-down list, choose the type of ICMP message for this rule.

Step 5 From the Interface list, choose the destination ASA interface to which the rule is to be applied.

Step 6 In the IP Address field, do one of the following:

- Add a specific IP address for the host or network.
- Click **Any Address,** then go to Step 9.

Step 7 From the Mask drop-down list, choose the network mask.

Step 8 Click **OK**.

The Create ICMP Rule dialog box closes.

Step 9 (Optional) To set ICMP unreachable message limits, set the following options. Increasing the rate limit, along with enabling the **Decrement time to live for a connection** option on the Configuration > Firewall > Service Policy Rules > Rule Actions > Connection Settings dialog box, is required to allow a traceroute through the ASA that shows the ASA as one of the hops.

- Rate Limit—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
- Burst Size—Sets the burst rate, between 1 and 10. This keyword is not currently used by the system, so you can choose any value.

Step 10 Click **Apply**.

The ICMP rule is added to the ASA, and the change is saved to the running configuration.

Configuring Management Access Over a VPN Tunnel

If your VPN tunnel terminates on one interface, but you want to manage the ASA by accessing a different interface, you can identify that interface as a management-access interface. For example, if you enter the ASA from the outside interface, this feature lets you connect to the inside interface using ASDM, SSH, Telnet, or SNMP; or you can ping the inside interface when entering from the outside interface. Management access is available via the following VPN tunnel types: IPsec clients, IPsec site-to-site, and the AnyConnect SSL VPN client.

This section includes the following topics:

- Licensing Requirements for a Management Interface, page 52-14
- Guidelines and Limitations, page 52-2
- Configuring a Management Interface, page 52-15

Licensing Requirements for a Management Interface

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single mode.

Firewall Mode Guidelines

Supported in routed mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines

You can define only one management access interface.

Configuring a Management Interface

To configure the management interface, perform the following steps.

Detailed Steps

Step 1 From the Configuration > Device Management > Management Access > Management Interface pane, choose the interface with the highest security (the inside interface) from the Management Access Interface drop-down list.

Step 2 Click **Apply**.

The management interface is assigned, and the change is saved to the running configuration.

Configuring AAA for System Administrators

This section describes how to enable authentication and command authorization for system administrators. Before you configure AAA for system administrators, first configure the local database or AAA server according to procedures listed in Chapter 46, "Configuring AAA Servers and the Local Database."

This section includes the following topics:

- Information About AAA for System Administrators, page 52-16
- Licensing Requirements for AAA for System Administrators, page 52-19
- Prerequisites, page 52-19
- Guidelines and Limitations, page 52-20
- Default Settings, page 52-20
- Configuring Authentication for CLI, ASDM, and enable command Access, page 52-20
- Limiting User CLI and ASDM Access with Management Authorization, page 52-21
- Configuring Command Authorization, page 52-23
- Configuring Management Access Accounting, page 52-29
- Viewing the Currently Logged-In User, page 52-29
- Recovering from a Lockout, page 52-30

Information About AAA for System Administrators

This section describes AAA for system administrators and includes the following topics:

- Information About Management Authentication, page 52-16
- Information About Command Authorization, page 52-17

Information About Management Authentication

This section describes authentication for management access and includes the following topics:

- Comparing CLI Access with and without Authentication, page 52-16
- Comparing ASDM Access with and without Authentication, page 52-16
- Authenticating Sessions from the Switch to the ASA Services Module, page 52-16

Comparing CLI Access with and without Authentication

How you log into the ASA depends on whether or not you enable authentication:

- If you do not enable any authentication for Telnet, you do not enter a username; you enter the login password. For SSH, you enter the username and the login password. You access user EXEC mode.
- If you enable Telnet or SSH authentication according to this section, you enter the username and password as defined on the AAA server or local user database. You access user EXEC mode.

To enter privileged EXEC mode after logging in, enter the **enable** command. How **enable** works depends on whether you enable authentication:

- If you do not configure enable authentication, enter the system enable password when you enter the **enable** command. However, if you do not use enable authentication, after you enter the **enable** command, you are no longer logged in as a particular user. To maintain your username, use enable authentication.
- If you configure enable authentication, the ASA prompts you for your username and password again. This feature is particularly useful when you perform command authorization, in which usernames are important in determining the commands that a user can enter.

For enable authentication using the local database, you can use the **login** command instead of the **enable** command. **login** maintains the username but requires no configuration to turn on authentication.

Comparing ASDM Access with and without Authentication

By default, you can log into ASDM with a blank username and the enable password. Note that if you enter a username and password at the login screen (instead of leaving the username blank), ASDM checks the local database for a match.

If you configure HTTP authentication, you can no longer use ASDM with a blank username and the enable password.

Authenticating Sessions from the Switch to the ASA Services Module

For sessions from the switch to the ASASM (using the **session** command), you can configure Telnet authentication. For virtual console connections from the switch to the ASASM (using the **service-module session** command), you can configure serial port authentication.

In multiple context mode, you cannot configure any AAA commands in the system configuration. However, if you configure Telnet or serial authentication in the admin context, then authentication also applies to sessions from the switch to the ASASM. The admin context AAA server or local user database is used in this instance.

Information About Command Authorization

This section describes command authorization and includes the following topics:

- Supported Command Authorization Methods, page 52-17
- About Preserving User Credentials, page 52-17
- Security Contexts and Command Authorization, page 52-18

Supported Command Authorization Methods

You can use one of two command authorization methods:

- Local privilege levels—Configure the command privilege levels on the ASA. When a local, RADIUS, or LDAP (if you map LDAP attributes to RADIUS attributes) user authenticates for CLI access, the ASA places that user in the privilege level that is defined by the local database, RADIUS, or LDAP server. The user can access commands at the assigned privilege level and below. Note that all users access user EXEC mode when they first log in (commands at level 0 or 1). The user needs to authenticate again with the **enable** command to access privileged EXEC mode (commands at level 2 or higher), or they can log in with the **login** command (local database only).

Note You can use local command authorization without any users in the local database and without CLI or **enable** authentication. Instead, when you enter the **enable** command, you enter the system enable password, and the ASA places you in level 15. You can then create enable passwords for every level, so that when you enter **enable** *n* (2 to 15), the ASA places you in level *n*. These levels are not used unless you enable local command authorization (see the "Configuring Local Command Authorization" section on page 52-23). (See the command reference for more information about the **enable** command.)

- TACACS+ server privilege levels—On the TACACS+ server, configure the commands that a user or group can use after authenticating for CLI access. Every command that a user enters at the CLI is validated with the TACACS+ server.

About Preserving User Credentials

When a user logs into the ASA, that user is required to provide a username and password for authentication. The ASA retains these session credentials in case further authentication is needed later in the session.

When the following configurations are in place, a user needs only to authenticate with the local server for login. Subsequent serial authorization uses the saved credentials. The user is also prompted for the privilege level 15 password. When exiting privileged mode, the user is authenticated again. User credentials are not retained in privileged mode.

- The local server is configured to authenticate user access.
- Privilege level 15 command access is configured to require a password.
- The user account is configured for serial-only authorization (no access to console or ASDM).
- The user account is configured for privilege level 15 command access.

The following table shows how credentials are used in this case by the ASA.

Credentials required	Username and Password Authentication	Serial Authorization	Privileged Mode Command Authorization	Privileged Mode Exit Authorization
Username	Yes	No	No	Yes
Password	Yes	No	No	Yes
Privileged Mode Password	No	No	Yes	No

Security Contexts and Command Authorization

The following are important points to consider when implementing command authorization with multiple security contexts:

- AAA settings are discrete per context, not shared among contexts.

  When configuring command authorization, you must configure each security context separately. This configuration provides you the opportunity to enforce different command authorizations for different security contexts.

  When switching between security contexts, administrators should be aware that the commands permitted for the username specified when they login may be different in the new context session or that command authorization may not be configured at all in the new context. Failure to understand that command authorizations may differ between security contexts could confuse an administrator. This behavior is further complicated by the next point.

- New context sessions started with the **changeto** command always use the default enable_15 username as the administrator identity, regardless of which username was used in the previous context session. This behavior can lead to confusion if command authorization is not configured for the enable_15 user or if authorizations are different for the enable_15 user than for the user in the previous context session.

  This behavior also affects command accounting, which is useful only if you can accurately associate each command that is issued with a particular administrator. Because all administrators with permission to use the **changeto** command can use the enable_15 username in other contexts, command accounting records may not readily identify who was logged in as the enable_15 username. If you use different accounting servers for each context, tracking who was using the enable_15 username requires correlating the data from several servers.

  When configuring command authorization, consider the following:

  - An administrator with permission to use the **changeto** command effectively has permission to use all commands permitted to the enable_15 user in each of the other contexts.
  - If you intend to authorize commands differently per context, ensure that in each context the enable_15 username is denied use of commands that are also denied to administrators who are permitted use of the **changeto** command.

  When switching between security contexts, administrators can exit privileged EXEC mode and enter the **enable** command again to use the username that they need.

Note The system execution space does not support AAA commands; therefore, command authorization is not available in the system execution space.

Licensing Requirements for AAA for System Administrators

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Prerequisites

Depending on the feature, you can use the following:

- AAA server—See the "Configuring AAA Server Groups" section on page 46-11.
- Local Database—See the "Adding a User Account to the Local Database" section on page 46-20.

Prerequisites for Management Authentication

Before the ASA can authenticate a Telnet, SSH, or HTTP user, you must identify the IP addresses that are allowed to communicate with the ASA. For the ASASM, the exception is for access to the system in multiple context mode; a session from the switch to the ASASM is a Telnet session, but Telnet access configuration is not required. For more information, see the "Configuring ASA Access for ASDM, Telnet, or SSH" section on page 52-1.

Prerequisites for Local Command Authorization

- Configure **enable** authentication. (See the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20.)

  enable authentication is essential for maintaining the username after the user accesses the **enable** command.

  Alternatively, you can use the **login** command (which is the same as the **enable** command with authentication; for the local database only), which requires no configuration. We do not recommend this option because it is not as secure as **enable** authentication.

  You can also use CLI authentication, but it is not required.

- See the following prerequisites for each user type:
  - Local database users—Configure each user in the local database at a privilege level from 0 to 15.
  - RADIUS users—Configure the user with Cisco VSA CVPN3000-Privilege-Level with a value between 0 and 15.
  - LDAP users—Configure the user with a privilege level between 0 and 15, and then map the LDAP attribute to Cisco VSA CVPN3000-Privilege-Level according to the "Using User Login Credentials" section on page 46-8.

Prerequisites for TACACS+ Command Authorization

- Configure CLI and **enable** authentication (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20).

Prerequisites for Management Accounting

- Configure CLI and **enable** authentication (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20).

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Default Settings

Default Command Privilege Levels

By default, the following commands are assigned to privilege level 0. All other commands are assigned to privilege level 15.

- **show checksum**
- **show curpriv**
- **enable**
- **help**
- **show history**
- **login**
- **logout**
- **pager**
- **show pager**
- **clear pager**
- **quit**
- **show version**

If you move any configure mode commands to a lower level than 15, be sure to move the **configure** command to that level as well, otherwise, the user will not be able to enter configuration mode.

To view all privilege levels, see the "Viewing Local Command Privilege Levels" section on page 52-24.

Configuring Authentication for CLI, ASDM, and enable command Access

To configure management authentication, perform the following steps:

Detailed Steps

Step 1 To authenticate users who use the **enable** command, choose **Configuration > Device Management > Users/AAA > AAA Access > Authentication**, and configure the following settings:

a. Check the **Enable** check box.

b. From the Server Group drop-down list, choose a server group name or the LOCAL database.

c. (Optional) If you chose a AAA server, you can configure the ASA to use the local database as a fallback method if the AAA server is unavailable. Click the **Use LOCAL when server group fails** check box. We recommend that you use the same username and password in the local database as the AAA server, because the ASA prompt does not give any indication of which method is being used.

Step 2 To authenticate users who access the CLI or ASDM, choose **Configuration > Device Management > Users/AAA > AAA Access > Authentication**, and configure the following settings:

a. Check one or more of the following check boxes:

- **HTTP/ASDM**—Authenticates the ASDM client that accesses the ASA using HTTPS. HTTP management authentication does not support the SDI protocol for a AAA server group.
- **Serial**—Authenticates users who access the ASA using the console port. For the ASASM, this parameter affects the virtual console accessed from the switch using the **service-module session** command. For multiple mode access, see the "Authenticating Sessions from the Switch to the ASA Services Module" section on page 52-16.
- **SSH**—Authenticates users who access the ASA using SSH.
- **Telnet**—Authenticates users who access the ASA using Telnet. For the ASASM, this parameter also affects the session from the switch using the **session** command. For multiple mode access, see the "Authenticating Sessions from the Switch to the ASA Services Module" section on page 52-16.

b. For each service that you checked, from the Server Group drop-down list, choose a server group name or the LOCAL database.

c. (Optional) If you chose a AAA server, you can configure the ASA to use the local database as a fallback method if the AAA server is unavailable. Click the **Use LOCAL when server group fails** check box. We recommend that you use the same username and password in the local database as the AAA server because the ASA prompt does not give any indication of which method is being used.

Step 3 Click **Apply**.

Limiting User CLI and ASDM Access with Management Authorization

If you configure CLI or **enable** authentication, you can limit a local user, RADIUS, TACACS+, or LDAP user (if you map LDAP attributes to RADIUS attributes) from accessing the CLI, ASDM, or the **enable** command.

Note Serial access is not included in management authorization, so if you enable the Authentication > Serial option, then any user who authenticates can access the console port.

Detailed Steps

Step 1 To enable management authorization, choose **Configuration > Device Management > Users/AAA > AAA Access > Authorization**, and check the **Perform authorization for exec shell access > Enable** check box.

This option also enables support of administrative user privilege levels from RADIUS, which can be used in conjunction with local command privilege levels for command authorization. See the "Configuring Local Command Authorization" section on page 52-23 for more information.

Step 2 To configure the user for management authorization, see the following requirements for each AAA server type or local user:

- RADIUS or LDAP (mapped) users—Use the IETF RADIUS numeric Service-Type attribute, which maps to one of the following values:
  - Service-Type 6 (Administrative)—Allows full access to any services specified by the Authentication tab options
  - Service-Type 7 (NAS prompt)—Allows access to the CLI when you configure the Telnet or SSH authentication options, but denies ASDM configuration access if you configure the HTTP option. ASDM monitoring access is allowed. If you configure **enable** authentication with the Enable option, the user cannot access privileged EXEC mode using the **enable** command.
  - Service-Type 5 (Outbound)—Denies management access. The user cannot use any services specified by the Authentication tab options (excluding the **Serial** option; serial access is allowed). Remote access (IPsec and SSL) users can still authenticate and terminate their remote access sessions.
- TACACS+ users—Request authorization with the "service=shell" entry, and the server responds with PASS or FAIL.
  - PASS, privilege level 1—Allows full access to any services specified by the Authentication tab options.
  - PASS, privilege level 2 and higher—Allows access to the CLI when you configure the Telnet or SSH authentication options, but denies ASDM configuration access if you configure the HTTP option. ASDM monitoring access is allowed. If you configure **enable** authentication with the Enable option, the user cannot access privileged EXEC mode using the **enable** command.
  - FAIL—Denies management access. The user cannot use any services specified by the Authentication tab options (excluding the **Serial** option; serial access is allowed).
- Local users—Configure the Access Restriction option. By default, the access restriction is Full Access, which allows full access to any services specified by the Authentication tab options. For more information, see the "Adding a User Account to the Local Database" section on page 46-20.

Configuring Command Authorization

If you want to control access to commands, the ASA lets you configure command authorization, where you can determine which commands that are available to a user. By default when you log in, you can access user EXEC mode, which offers only minimal commands. When you enter the **enable** command (or the **login** command when you use the local database), you can access privileged EXEC mode and advanced commands, including configuration commands.

You can use one of two command authorization methods:

- Local privilege levels
- TACACS+ server privilege levels

For more information about command authorization, see the "Information About Command Authorization" section on page 52-17.

This section includes the following topics:

- Configuring Local Command Authorization, page 52-23
- Viewing Local Command Privilege Levels, page 52-24
- Configuring Commands on the TACACS+ Server, page 52-25
- Configuring TACACS+ Command Authorization, page 52-28

Configuring Local Command Authorization

Local command authorization lets you assign commands to one of 16 privilege levels (0 to 15). By default, each command is assigned either to privilege level 0 or 15. You can define each user to be at a specific privilege level, and each user can enter any command at the assigned privilege level or below. The ASA supports user privilege levels defined in the local database, a RADIUS server, or an LDAP server (if you map LDAP attributes to RADIUS attributes. See the "Using Certificates and User Login Credentials" section on page 46-8.)

To configure local command authorization, perform the following steps:

Detailed Steps

Step 1 To enable command authorization, choose **Configuration > Device Management > Users/AAA > AAA Access > Authorization**, and check the **Enable authorization for command access > Enable** check box.

Step 2 From the Server Group drop-down list, choose LOCAL.

Step 3 When you enable local command authorization, you have the option of manually assigning privilege levels to individual commands or groups of commands or enabling the predefined user account privileges.

- To use predefined user account privileges, click **Set ASDM Defined User Roles**.

  The ASDM Defined User Roles Setup dialog box shows the commands and their levels. Click **Yes** to use the predefined user account privileges: Admin (privilege level 15, with full access to all CLI commands; Read Only (privilege level 5, with read-only access); and Monitor Only (privilege level 3, with access to the Monitoring section only).

- To manually configure command levels, click **Configure Command Privileges**.

The Command Privileges Setup dialog box appears. You can view all commands by choosing --All Modes-- from the Command Mode drop-down list, or you can choose a configuration mode to view the commands available in that mode. For example, if you choose context, you can view all commands available in context configuration mode. If a command can be entered in user EXEC or privileged EXEC mode as well as configuration mode, and the command performs different actions in each mode, you can set the privilege level for these modes separately.

The Variant column displays show, clear, or cmd. You can set the privilege only for the show, clear, or configure form of the command. The configure form of the command is typically the form that causes a configuration change, either as the unmodified command (without the **show** or **clear** prefix) or as the **no** form.

To change the level of a command, double-click it or click **Edit**. You can set the level between 0 and 15. You can only configure the privilege level of the *main* command. For example, you can configure the level of all **aaa** commands, but not the level of the **aaa authentication** command and the **aaa authorization** command separately.

To change the level of all commands that appear, click **Select All** and then **Edit**.

Click **OK** to accept your changes.

Step 4 To support administrative user privilege levels from RADIUS, check the **Perform authorization for exec shell access > Enable** check box.

Without this option, the ASA only supports privilege levels for local database users and defaults all other types of users to level 15.

This option also enables management authorization for local, RADIUS, LDAP (mapped), and TACACS+ users. See the "Limiting User CLI and ASDM Access with Management Authorization" section on page 52-21 for more information.

Step 5 Click **Apply**.

The authorization settings are assigned, and the changes are saved to the running configuration.

Viewing Local Command Privilege Levels

The following commands when entered in the Tools > Command Line Interface tool, let you view privilege levels for commands.

Examples

For the **show running-config all privilege all** command, the ASA displays the current assignment of each CLI command to a privilege level. The following is sample output from this command:

Enter the following command in the Tools > Command Line Interface tool:

```
show running-config all privilege all
privilege show level 15 command aaa
privilege clear level 15 command aaa
privilege configure level 15 command aaa
privilege show level 15 command aaa-server
privilege clear level 15 command aaa-server
privilege configure level 15 command aaa-server
privilege show level 15 command access-group
privilege clear level 15 command access-group
privilege configure level 15 command access-group
privilege show level 15 command access-list
privilege clear level 15 command access-list
```

```
privilege configure level 15 command access-list
privilege show level 15 command activation-key
privilege configure level 15 command activation-key
....
```

The following example displays the command assignments for privilege level 10:

```
show running-config privilege level 10
privilege show level 10 command aaa
```

The following example displays the command assignments for the **access-list** command:

```
show running-config privilege command access-list
privilege show level 15 command access-list
privilege clear level 15 command access-list
privilege configure level 15 command access-list
```

Configuring Commands on the TACACS+ Server

You can configure commands on a Cisco Secure Access Control Server (ACS) TACACS+ server as a shared profile component, for a group, or for individual users. For third-party TACACS+ servers, see your server documentation for more information about command authorization support.

See the following guidelines for configuring commands in Cisco Secure ACS Version 3.1; many of these guidelines also apply to third-party servers:

- The ASA sends the commands to be authorized as shell commands, so configure the commands on the TACACS+ server as shell commands.

Note Cisco Secure ACS might include a command type called “pix-shell.” Do not use this type for ASA command authorization.

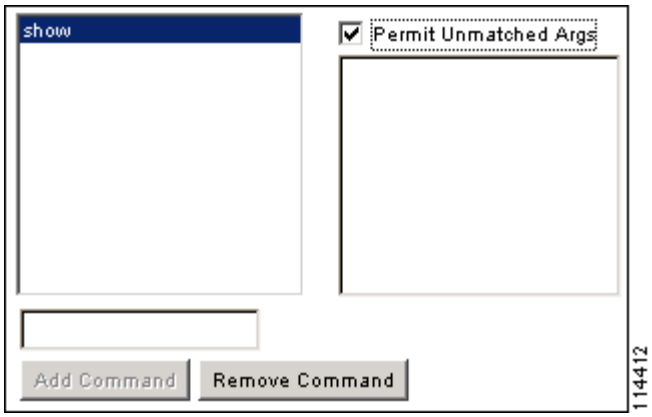
- The first word of the command is considered to be the main command. All additional words are considered to be arguments, which need to be preceded by **permit** or **deny**.

  For example, to allow the **show running-configuration aaa-server** command, add **show running-configuration** to the command field, and type **permit aaa-server** in the arguments field.

- You can permit all arguments of a command that you do not explicitly deny by checking the **Permit Unmatched Args** check box.

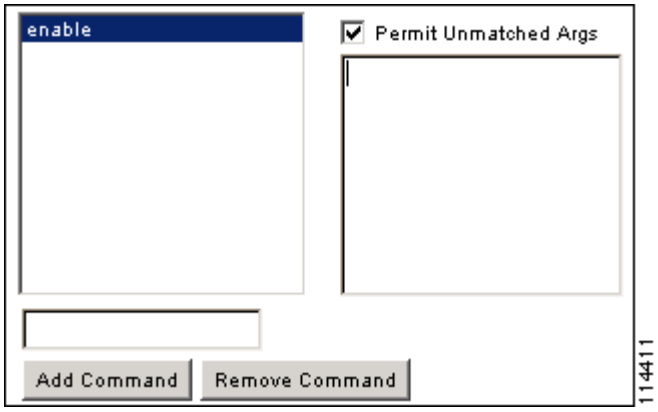
  For example, you can configure just the **show** command, and then all the **show** commands are allowed. We recommend using this method so that you do not have to anticipate every variant of a command, including abbreviations and a question mark, which shows CLI usage (see Figure 52-1).

Figure 52-1 Permitting All Related Commands



- For commands that are a single word, you *must* permit unmatched arguments, even if there are no arguments for the command, for example **enable** or **help** (see Figure 52-2).

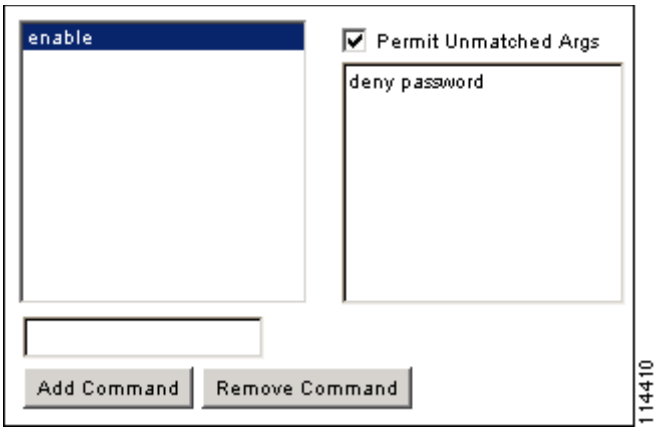
Figure 52-2 Permitting Single Word Commands



- To disallow some arguments, enter the arguments preceded by **deny**.

  For example, to allow **enable**, but not **enable password**, enter **enable** in the commands field, and **deny password** in the arguments field. Be sure to check the **Permit Unmatched Args** check box so that **enable** alone is still allowed (see Figure 52-3).

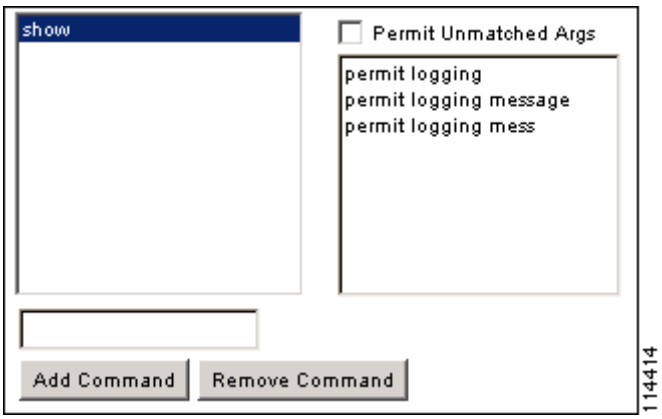
Figure 52-3 Disallowing Arguments



- When you abbreviate a command at the command line, the ASA expands the prefix and main command to the full text, but it sends additional arguments to the TACACS+ server as you enter them.

  For example, if you enter **sh log**, then the ASA sends the entire command to the TACACS+ server, **show logging**. However, if you enter **sh log mess**, then the ASA sends **show logging mess** to the TACACS+ server, and not the expanded command **show logging message**. You can configure multiple spellings of the same argument to anticipate abbreviations (see Figure 52-4).

Figure 52-4 Specifying Abbreviations



- We recommend that you allow the following basic commands for all users:
  - **show checksum**
  - **show curpriv**
  - **enable**
  - **help**
  - **show history**
  - **login**
  - **logout**
  - **pager**

- **show pager**
- **clear pager**
- **quit**
- **show version**

Configuring TACACS+ Command Authorization

If you enable TACACS+ command authorization, and a user enters a command at the CLI, the ASA sends the command and username to the TACACS+ server to determine if the command is authorized.

Before you enable TACACS+ command authorization, be sure that you are logged into the ASA as a user that is defined on the TACACS+ server, and that you have the necessary command authorization to continue configuring the ASA. For example, you should log in as an admin user with all commands authorized. Otherwise, you could become unintentionally locked out.

Do not save your configuration until you are sure that it works the way you want. If you get locked out because of a mistake, you can usually recover access by restarting the ASA. If you still get locked out, see the "Recovering from a Lockout" section on page 52-30.

Be sure that your TACACS+ system is completely stable and reliable. The necessary level of reliability typically requires that you have a fully redundant TACACS+ server system and fully redundant connectivity to the ASA. For example, in your TACACS+ server pool, include one server connected to interface 1, and another to interface 2. You can also configure local command authorization as a fallback method if the TACACS+ server is unavailable. In this case, you need to configure local users and command privilege levels according to procedures listed in the "Configuring Command Authorization" section on page 52-23.

To configure TACACS+ command authorization, perform the following steps:

Detailed Steps

Step 1 To perform command authorization using a TACACS+ server, choose **Configuration > Device Management > Users/AAA > AAA Access > Authorization**, and check the **Enable authorization for command access > Enable** check box.

Step 2 From the Server Group drop-down list, choose a AAA server group name.

Step 3 (Optional) you can configure the ASA to use the local database as a fallback method if the AAA server is unavailable. To do so, check the **Use LOCAL when server group fails** check box. We recommend that you use the same username and password in the local database as the AAA server, because the ASA prompt does not give any indication which method is being used. Be sure to configure users in the local database (see the "Adding a User Account to the Local Database" section on page 46-20) and command privilege levels (see the "Configuring Local Command Authorization" section on page 52-23).

Step 4 Click **Apply**.

The command authorization settings are assigned, and the changes are saved to the running configuration.

Configuring Management Access Accounting

You can send accounting messages to the TACACS+ accounting server when you enter any command other than **show** commands at the CLI. You can configure accounting when users log in, when they enter the **enable** command, or when they issue commands.

For command accounting, you can only use TACACS+ servers.

To configure management access and enable command accounting, perform the following steps:

Detailed Steps

Step 1 To enable accounting of users when they enter the **enable** command, perform the following steps:

a. Choose **Configuration > Device Management > Users/AAA > AAA Access > Accounting**, and check the **Require accounting to allow accounting of user activity > Enable** check box.

b. From the Server Group drop-down list, choose a RADIUS or TACACS+ server group name.

Step 2 To enable accounting of users when they access the ASA using Telnet, SSH, or the serial console, perform the following steps:

a. Under the Require accounting for the following types of connections area, check the check boxes for Serial, SSH, and/or Telnet.

b. For each connection type, from the Server Group drop-down list, choose a RADIUS or TACACS+ server group name.

Step 3 To configure command accounting, perform the following steps:

a. Under the Require command accounting area, check the **Enable** check box.

b. From the Server Group drop-down list, choose a TACACS+ server group name. RADIUS is not supported.

You can send accounting messages to the TACACS+ accounting server when you enter any command other than **show** commands at the CLI.

c. If you customize the command privilege level using the Command Privilege Setup dialog box, you can limit which commands the ASA accounts for by specifying a minimum privilege level in the Privilege level drop-down list. The ASA does not account for commands that are below the minimum privilege level.

Step 4 Click **Apply**.

The accounting settings are assigned, and the changes are saved to the running configuration.

Viewing the Currently Logged-In User

To view the current logged-in user, enter the following command in the Tools > Command Line Interface tool:

```
show curpriv
```

The following is sample output from the **show curpriv** command:

```
show curpriv
Username: admin
Current privilege level: 15
```

```
Current Mode/s: P_PRIV
```

Table 52-1 describes the **show curpriv** command output.

Table 52-1 show curpriv Command Output Description

Field	Description
Username	Username. If you are logged in as the default user, the name is enable_1 (user EXEC) or enable_15 (privileged EXEC).
Current privilege level	Levels range from 0 to 15. Unless you configure local command authorization and assign commands to intermediate privilege levels, levels 0 and 15 are the only levels that are used.
Current Mode/s	The available access modes are the following: • P_UNPR—User EXEC mode (levels 0 and 1) • P_PRIV—Privileged EXEC mode (levels 2 to 15) • P_CONF—Configuration mode

Recovering from a Lockout

In some circumstances, when you turn on command authorization or CLI authentication, you can be locked out of the ASA CLI. You can usually recover access by restarting the ASA. However, if you already saved your configuration, you might be locked out. Table 52-2 lists the common lockout conditions and how you might recover from them.

Table 52-2 CLI Authentication and Command Authorization Lockout Scenarios

Feature	Lockout Condition	Description	Workaround: Single Mode	Workaround: Multiple Mode
Local CLI authentication	No users in the local database	If you have no users in the local database, you cannot log in, and you cannot add any users.	Log in and reset the passwords and **aaa** commands.	Session into the ASA from the switch. From the system execution space, you can change to the context and add a user.
TACACS+ command authorization TACACS+ CLI authentication RADIUS CLI authentication	Server down or unreachable and you do not have the fallback method configured	If the server is unreachable, then you cannot log in or enter any commands.	1. Log in and reset the passwords and AAA commands. 2. Configure the local database as a fallback method so you do not get locked out when the server is down.	1. If the server is unreachable because the network configuration is incorrect on the ASA, session into the ASA from the switch. From the system execution space, you can change to the context and reconfigure your network settings. 2. Configure the local database as a fallback method so you do not get locked out when the server is down.

Table 52-2 CLI Authentication and Command Authorization Lockout Scenarios (continued)

Feature	Lockout Condition	Description	Workaround: Single Mode	Workaround: Multiple Mode
TACACS+ command authorization	You are logged in as a user without enough privileges or as a user that does not exist	You enable command authorization, but then find that the user cannot enter any more commands.	Fix the TACACS+ server user account. If you do not have access to the TACACS+ server and you need to configure the ASA immediately, then log into the maintenance partition and reset the passwords and **aaa** commands.	Session into the ASA from the switch. From the system execution space, you can change to the context and complete the configuration changes. You can also disable command authorization until you fix the TACACS+ configuration.
Local command authorization	You are logged in as a user without enough privileges	You enable command authorization, but then find that the user cannot enter any more commands.	Log in and reset the passwords and **aaa** commands.	Session into the ASA from the switch. From the system execution space, you can change to the context and change the user level.

Monitoring Device Access

To monitor device access, see the following panes:

Path	Purpose
Monitoring > Properties > Device Access > ASDM/HTTPS/Telnet/SSH Sessions	The top pane lists the connection types, session IDs, and IP addresses for users connected through ASDM, HTTPS, and Telnet sessions. To disconnect a specific session, click **Disconnect**. The bottom pane lists the clients, usernames, connection states, software versions, incoming encryption types, outgoing encryption types, incoming HMACs, and outgoing HMACs for users connected through SSH sessions. To disconnect a specific session, click **Disconnect**.
`Monitoring > Properties > Device Access > Authenticated Users`	Lists the usernames, IP addresses, dynamic ACLs, inactivity timeouts (if any), and absolute timeouts for users who were authenticated by AAA servers.
`Monitoring > Properties > Device Access > AAA Local Locked Out Users`	Lists the usernames of locked-out AAA local users, the number of failed attempts to authenticate, and the times that users were locked out. To clear a specific user who has been locked out, click **Clear Selected Lockout**. To clear all users who have been locked out, click **Clear All Lockouts**.

Feature History for Management Access

Table 52-3 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 52-3 Feature History for Management Access

Feature Name	Platform Releases	Feature Information
Management Access	7.0(1)	We introduced this feature. We introduced the following screens: Configuration > Device Management > Management Access > ASDM/HTTPS/Telnet/SSH Configuration > Device Management > Management Access > Command Line (CLI) > Banner Configuration > Device Management > Management Access > CLI Prompt Configuration > Device Management > Management Access > ICMP Configuration > Device Management > Management Access > File Access > FTP Client Configuration > Device Management > Management Access > File Access > Secure Copy (SCP) Server Configuration > Device Management > Management Access > File Access > Mount-Points Configuration > Device Management > Users/AAA > AAA Access > Authentication Configuration > Device Management > Users/AAA > AAA Access > Authorization Configuration > Device Management > Users/AAA > AAA Access > > Accounting.
Increased SSH security; the SSH default username is no longer supported.	8.4(2)	Starting in 8.4(2), you can no longer connect to the ASA using SSH with the pix or asa username and the login password. To use SSH, you must configure AAA authentication using the **aaa authentication ssh console LOCAL** command (CLI) or Configuration > Device Management > Users/AAA > AAA Access > Authentication (ASDM); then define a local user by entering the **username** command (CLI) or choosing Configuration > Device Management > Users/AAA > User Accounts (ASDM). If you want to use a AAA server for authentication instead of the local database, we recommend also configuring local authentication as a backup method.
For the ASASM in multiple context mode, support for Telnet and virtual console authentication from the switch.	8.5(1)	Although connecting to the ASASM from the switch in multiple context mode connects to the system execution space, you can configure authentication in the admin context to govern those connections.

Configuring AAA Rules for Network Access

This chapter describes how to enable AAA (pronounced “triple A”) for network access.

For information about AAA for management access, see the “Configuring AAA for System Administrators” section on page 52-15.

This chapter includes the following sections:

- AAA Performance, page 53-1
- Licensing Requirements for AAA Rules, page 53-1
- Guidelines and Limitations, page 53-2
- Configuring Authentication for Network Access, page 53-2
- Configuring Authorization for Network Access, page 53-11
- Configuring Accounting for Network Access, page 53-17
- Using MAC Addresses to Exempt Traffic from Authentication and Authorization, page 53-18
- Feature History for AAA Rules, page 53-19

AAA Performance

The ASA uses “cut-through proxy” to significantly improve performance compared to a traditional proxy server. The performance of a traditional proxy server suffers because it analyzes every packet at the application layer of the OSI model. The ASA cut-through proxy challenges a user initially at the application layer and then authenticates with standard AAA servers or the local database. After the ASA authenticates the user, it shifts the session flow, and all traffic flows directly and quickly between the source and destination while maintaining session state information.

Licensing Requirements for AAA Rules

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines

In clustering, this feature is only supported on the master unit.

Configuring Authentication for Network Access

This section includes the following topics:

- Information About Authentication, page 53-2
- Configuring Network Access Authentication, page 53-6
- Enabling the Redirection Method of Authentication for HTTP and HTTPS, page 53-7
- Enabling Secure Authentication of Web Clients, page 53-8
- Authenticating Directly with the ASA, page 53-9
- Configuring the Authentication Proxy Limit, page 53-11

Information About Authentication

The ASA lets you configure network access authentication using AAA servers. This section includes the following topics:

- One-Time Authentication, page 53-3
- Applications Required to Receive an Authentication Challenge, page 53-3
- ASA Authentication Prompts, page 53-3
- AAA Prompts and Identity Firewall, page 53-4
- AAA Rules as a Backup Authentication Method, page 53-5
- Static PAT and HTTP, page 53-5

One-Time Authentication

A user at a given IP address only needs to authenticate one time for all rules and types, until the authentication session expires. (See the Configuration > Firewall > Advanced > Global Timeouts pane for timeout values.) For example, if you configure the ASA to authenticate Telnet and FTP, and a user first successfully authenticates for Telnet, then as long as the authentication session exists, the user does not also have to authenticate for FTP.

Applications Required to Receive an Authentication Challenge

Although you can configure the ASA to require authentication for network access to any protocol or service, users can authenticate directly with HTTP, HTTPS, Telnet, or FTP only. A user must first authenticate with one of these services before the ASA allows other traffic requiring authentication.

The authentication ports that the ASA supports for AAA are fixed as follows:

- Port 21 for FTP
- Port 23 for Telnet
- Port 80 for HTTP
- Port 443 for HTTPS

ASA Authentication Prompts

For Telnet and FTP, the ASA generates an authentication prompt.

For HTTP, the ASA uses basic HTTP authentication by default, and provides an authentication prompt. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured in the Configuration > Firewall > AAA Rules > Advanced > AAA Rules Advanced Options dialog box; see the "Enabling the Redirection Method of Authentication for HTTP and HTTPS" section on page 53-7).

For HTTPS, the ASA generates a custom login screen. You can optionally configure the ASA to redirect users to an internal web page where they can enter their username and password (configured in the Configuration > Firewall > AAA Rules > Advanced > AAA Rules Advanced Options dialog box; see the "Enabling the Redirection Method of Authentication for HTTP and HTTPS" section on page 53-7).

Redirection is an improvement over the basic method because it provides an improved user experience when authenticating, and an identical user experience for HTTP and HTTPS in both Easy VPN and firewall modes. It also supports authenticating directly with the ASA.

You might want to continue to use basic HTTP authentication for the following reasons:

- You do not want the ASA to open listening ports.
- You use NAT on a router and you do not want to create a translation rule for the web page served by the ASA.
- Basic HTTP authentication might work better with your network.

For example non-browser applications, as when a URL is embedded in e-mail, might be more compatible with basic authentication.

After you authenticate correctly, the ASA redirects you to your original destination. If the destination server also has its own authentication, the user enters another username and password. If you use basic HTTP authentication and need to enter another username and password for the destination server, then you need to configure virtual HTTP (see the Configuration >Firewall > Advanced Options > Virtual Access pane).

Note If you use HTTP authentication, by default the username and password are sent from the client to the ASA in clear text; in addition, the username and password are sent on to the destination web server as well. See the "Enabling Secure Authentication of Web Clients" section on page 53-8 for information to secure your credentials.

For FTP, a user has the option of entering the ASA username followed by an at sign (@) and then the FTP username (name1@name2). For the password, the user enters the ASA password followed by an at sign (@) and then the FTP password (password1@password2). For example, enter the following text:

```
name> name1@name2
password> password1@password2
```

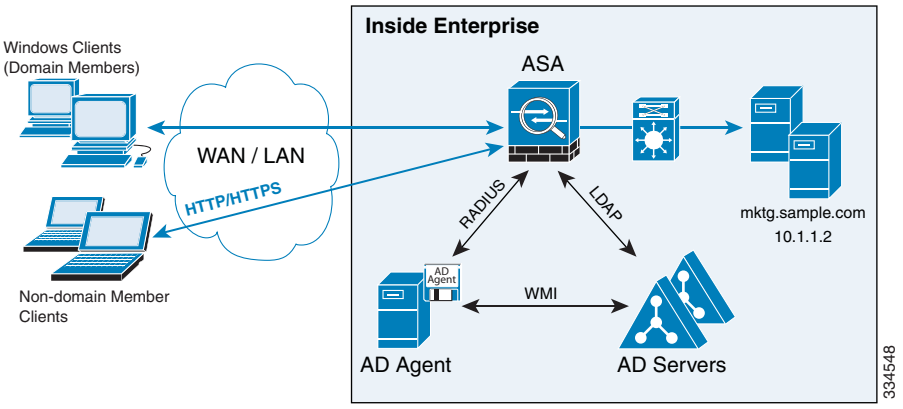
This feature is useful when you have cascaded firewalls that require multiple logins. You can separate several names and passwords by multiple at signs (@).

AAA Prompts and Identity Firewall

In an enterprise, some users log into the network by using other authentication mechanisms, such as authenticating with a web portal (cut-through proxy). For example, users with a Mac and Linux client might log into a web portal (cut-through proxy). Therefore, you must configure the identity firewall to allow these types of authentication in connection with identity-based access policies.

Figure 53-1 shows a deployment to support a cut-through proxy authentication captive portal. Active Directory servers and the AD Agent are installed on the main site LAN. However, the identity firewall is configured to support authentication of clients that are not part of the Active Directory domain.

Figure 53-1 Deployment Supporting Cut-through Proxy Authentication



The ASA designates users logging in through a web portal (cut-through proxy) as belonging to the Active Directory domain with which they authenticated.

The ASA reports users logging in through a web portal (cut-through proxy) to the AD Agent, which distributes the user information to all registered ASA devices. In this case, the identity firewall can associate the users with their Active Directory domain. Specifically, the user identity-IP address mappings of authenticated users are forwarded to all ASA contexts that contain the input interface where packets are received and authenticated.

Users can log in by using HTTP/HTTPS, FTP, Telnet, or SSH. When users log in with these authentication methods, the following guidelines apply:

- For HTTP/HTTPS traffic, an authentication window appears for unauthenticated users.

- For Telnet and FTP traffic, users must log in through the cut-through proxy server and again to the Telnet and FTP servers.
- A user can specify an Active Directory domain while providing login credentials (in the format, domain\username). The ASA automatically selects the associated AAA server group for the specified domain.
- If a user specifies an Active Directory domain while providing login credentials (in the format, domain\username), the ASA parses the domain and uses it to select an authentication server from the AAA servers that have been configured for the identity firewall. Only the username is passed to the AAA server.
- If the backslash (\) delimiter is not found in the login credentials, the ASA does not parse the domain and authentication is conducted with the AAA server that corresponds to the default domain configured for the identity firewall.
- If a default domain or a server group is not configured for that default domain, the ASA rejects the authentication.
- If the domain is not specified, the ASA selects the AAA server group for the default domain that is configured for the identity firewall.

AAA Rules as a Backup Authentication Method

An authentication rule (also known as "cut-through proxy") controls network access based on the user. Because this function is very similar to an access rule plus an identity firewall, AAA rules can now be used as a backup method of authentication if a user's AD login expires or a valid user has not yet logged into AD. For example, for any user without a valid login, you can trigger a AAA rule. To ensure that the AAA rule is only triggered for users that do not have valid logins, you can specify special usernames in the extended ACL that are used for the access rule and for the AAA rule: None (users without a valid login) and Any (users with a valid login). In the access rule, configure your policy as usual for users and groups, but then include a rule that permits all None users before deny any any; you must permit these users so they can later trigger a AAA rule. Then, configure a AAA rule that does not match Any users (these users are not subject to the AAA rule, and were handled already by the access rule), but matches all None users only to trigger AAA authentication for these users. After the user has successfully logged in via cut-through proxy, the traffic will flow normally again.

Static PAT and HTTP

For HTTP authentication, the ASA checks real ports when static PAT is configured. If it detects traffic destined for real port 80, regardless of the mapped port, the ASA intercepts the HTTP connection and enforces authentication.

For example, assume that outside TCP port 889 is translated to port 80 and that any relevant access lists permit the traffic:

```
object network obj-192.168.123.10-01
    host 192.168.123.10
    nat (inside,outside) static 10.48.66.155 service tcp 80 889
```

Then when users try to access 10.48.66.155 on port 889, the ASA intercepts the traffic and enforces HTTP authentication. Users see the HTTP authentication page in their web browsers before the ASA allows HTTP connection to complete.

If the local port is different than port 80, as in the following example:

```
object network obj-192.168.123.10-02
    host 192.168.123.10
```

```
nat (inside,outside) static 10.48.66.155 service tcp 111 889
```

Then users do not see the authentication page. Instead, the ASA sends an error message to the web browser indicating that the user must be authenticated before using the requested service.

Configuring Network Access Authentication

To configure network access authentication, perform the following steps:

Step 1 In the Configuration > Firewall > AAA Rules pane, choose **Add > Add Authentication Rule**.

The Add Authentication Rule dialog box appears.

Step 2 In the Interface drop-down list, choose the interface for applying the rule.

Tip In the Action field, click one of the following, depending on the implementation:

- **Authenticate**
- **Do not Authenticate**

Step 3 In the AAA Server Group drop-down list, choose a server group. To add a AAA server to the server group, click **Add Server**. See the "Testing Server Authentication and Authorization" section on page 46-27 for more information.

If you chose LOCAL for the AAA server group, you can optionally add a new user by clicking **Add User**. See the "Adding a User Account to the Local Database" section on page 46-20 for more information.

Step 4 In the Source field, add the source IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 5 In the Destination field, enter the destination IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 6 In the Service field, enter an IP service name or number for the destination service, or click the ellipsis (...) to choose a service.

Step 7 (Optional) In the Description field, enter a description.

Step 8 (Optional) Click **More Options** to do any of the following:

- To specify a source service for TCP or UDP, enter a TCP or UDP service in the Source Service field.
- The destination service and source service must be the same. Copy and paste the destination Service field to the Source Service field.
- To make the rule inactive, clear the **Enable Rule** check box.

  You may not want to remove a rule, but instead turn it off.
- To set a time range for the rule, In the Time Range drop-down list, choose an existing time range. To add a new time range, click the ellipsis (...). For more information, see the "Configuring Time Ranges" section on page 25-15.

Step 9 Click **OK**.

The Add Authentication Rule dialog box closes and the rule appears in the AAA Rules table.

Step 10 Click **Apply**.

The changes are saved to the running configuration.

For more information about authentication, see the "Information About Authentication" section on page 53-2.

Enabling the Redirection Method of Authentication for HTTP and HTTPS

This method of authentication enables HTTP(S) listening ports to authenticate network users. When you enable a listening port, the ASA serves an authentication page for direct connections and, by enabling redirection, for through traffic. This method also prevents the authentication credentials from continuing to the destination server. See the "ASA Authentication Prompts" section on page 53-3 for more information about the redirection method compared to the basic method.

To enable a AAA listener, perform the following steps:

Step 1 In the Configuration > Firewall > AAA Rules pane, click **Advanced**.

The AAA Rules Advanced Options dialog box appears.

Step 2 Under Interactive Authentication, click **Add**.

The Add Interactive Authentication Entry dialog box appears.

Step 3 For the Protocol, choose either **HTTP** or **HTTPS**. You can enable both by repeating this procedure and creating two separate rules.

Step 4 In the Interface drop-down list, choose the interface on which you want to enable the listener.

Step 5 In the Port drop-down list, choose the port or enter a number.

This is the port that the ASA listens on for direct or redirected traffic; the defaults are 80 (HTTP) and 443 (HTTPS). You can use any port number and retain the same functionality, but be sure your direct authentication users know the port number; redirected traffic is sent to the correct port number automatically, but direct authenticators must specify the port number manually.

Step 6 (Optional) Check **Redirect network users for authentication request**.

This option redirects through traffic to an authentication web page served by the ASA. Without this option, only traffic directed to the ASA interface can access the authentication web pages.

Note If you enable the redirect option, you cannot also configure static PAT for the same interface where you translate the interface IP address and the same port that is used for the listener; NAT succeeds, but authentication fails.

Step 7 Click **OK**, and then click **OK** again to close the AAA Rules Advanced Options dialog box.

Step 8 Click **Apply**.

The changes are saved to the running configuration.

Enabling Secure Authentication of Web Clients

If you use HTTP authentication, by default the username and password are sent from the client to the ASA in clear text; in addition, the username and password are sent to the destination web server as well.

The ASA provides the following methods for securing HTTP authentication:

- Enable the redirection method of authentication for HTTP—See the "Enabling the Redirection Method of Authentication for HTTP and HTTPS" section on page 53-7. This method prevents the authentication credentials from continuing to the destination server. See the "ASA Authentication Prompts" section on page 53-3 for more information about the redirection method compared to the basic method.
- Enable virtual HTTP— Virtual HTTP lets you authenticate separately with the ASA and with the HTTP server. Even if the HTTP server does not need a second authentication, this command achieves the effect of stripping the basic authentication credentials from the HTTP GET request. See the "Authenticating HTTP(S) Connections with a Virtual Server" section on page 53-9 for more information.
- Enable the exchange of usernames and passwords between a web client and the ASA with HTTPS—To enable the exchange of usernames and passwords between a web client and the ASA with HTTPS, perform the following steps:

  a. In the Configuration > Firewall > AAA Rules pane, click **Advanced**. The AAA Rules Advanced Options dialog box appears.

  b. Under Secure HTTP, click **Enable Secure HTTP**.

  c. Click **OK**, and then click **OK** again to close the AAA Rules Advanced Options dialog box.

  d. Click **Apply**.

  This is the only method that protects credentials between the client and the ASA, as well as between the ASA and the destination server. You can use this method alone, or in conjunction with either of the other methods so you can maximize your security.

  After enabling this feature, when a user requires authentication when using HTTP, the ASA redirects the HTTP user to an HTTPS prompt. After you authenticate correctly, the ASA redirects you to the original HTTP URL.

  Secured, web-client authentication has the following limitations:

  – A maximum of 16 concurrent HTTPS authentication sessions are allowed. If all 16 HTTPS authentication processes are running, a new connection requiring authentication will not succeed.

  – When the uauth timeout is set to unlimited, HTTPS authentication might not work. If a browser initiates multiple TCP connections to load a web page after HTTPS authentication, the first connection is let through, but the subsequent connections trigger authentication. As a result, users are continuously presented with an authentication page, even if the correct username and password are entered each time. To work around this, set the uauth timeout to one second (see the Configuration > Firewall > Advanced > Global Timeouts pane). However, this workaround opens a 1-second window of opportunity that might allow unauthenticated users to go through the firewall if they are coming from the same source IP address.

Because HTTPS authentication occurs on the SSL port 443, users must not configure an access ruleto block traffic from the HTTP client to the HTTP server on port 443. Furthermore, if static PAT is configured for web traffic on port 80, it must also be configured for the SSL port.

Authenticating Directly with the ASA

If you do not want to allow HTTP, HTTPS, Telnet, or FTP through the ASA but want to authenticate other types of traffic, you can authenticate with the ASA directly using HTTP, HTTPS, or Telnet.

This section includes the following topics:

- Authenticating HTTP(S) Connections with a Virtual Server, page 53-9
- Authenticating Telnet Connections with a Virtual Server, page 53-10

Authenticating HTTP(S) Connections with a Virtual Server

If you enabled the redirection method of HTTP and HTTPS authentication in the "Configuring Network Access Authentication" section on page 53-6, then you have also automatically enabled direct authentication.

When you use HTTP authentication on the ASA (see the"Configuring Network Access Authentication" section on page 53-6), the ASA uses basic HTTP authentication by default.

You can change the authentication method so that the ASA redirects HTTP connections to web pages generated by the ASA itself using the "Enabling the Redirection Method of Authentication for HTTP and HTTPS" section on page 53-7.

However, if you continue to use basic HTTP authentication, then you might need the virtual HTTP server when you have cascading HTTP authentications.

If the destination HTTP server requires authentication in addition to the ASA, then virtual HTTP lets you authenticate separately with the ASA (via a AAA server) and with the HTTP server. Without virtual HTTP, the same username and password that you used to authenticate with the ASA is sent to the HTTP server; you are not prompted separately for the HTTP server username and password. Assuming the username and password are not the same for the AAA and HTTP servers, then the HTTP authentication fails.

This feature redirects all HTTP connections that require AAA authentication to the virtual HTTP server on the ASA. The ASA prompts for the AAA server username and password. After the AAA server authenticates the user, the ASA redirects the HTTP connection back to the original server, but it does not include the AAA server username and password. Because the username and password are not included in the HTTP packet, the HTTP server prompts the user separately for the HTTP server username and password.

For inbound users (from lower security to higher security), you must also include the virtual HTTP address as a destination interface in the access rule applied to the source interface. Moreover, you must add a static NAT rule for the virtual HTTP IP address, even if NAT is not required. An identity NAT rule is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access rule to an inside interface, be sure to allow access to the virtual HTTP address. A static NAT rule is not required.

Note Do not set the uauth timeout duration to 0 seconds when using virtual HTTP, because this setting prevents HTTP connections to the real web server. See the "Configuring Global Timeouts" section on page 71-9.

You can authenticate directly with the ASA at the following URLs when you enable AAA for the interface:

http://*interface_ip*[**:***port*]**/netaccess/connstatus.html**
https://*interface_ip*[**:***port*]**/netaccess/connstatus.html**

To allow users to authenticate with the ASA virtual server separately from the HTTP server, perform the following steps:

Step 1 In the Configuration > Firewall > Advanced > Virtual Access > Virtual HTTP Server area, check the **Enable** check box.

Step 2 In the Virtual HTTP Server field, add the IP address of the virtual HTTP server.

Make sure this address is an unused address that is routed to the ASA. For example, if you perform NAT for inside addresses accessing an outside server, and you want to provide outside access to the virtual HTTP server, you can use one of the global NAT addresses for the virtual HTTP server address.

Step 3 (Optional) If you are using text-based browsers, where redirection does not happen automatically, check the **Display redirection warning** check box. This enables an alert to notify users when the HTTP connection is being redirected.

Step 4 Click **Apply**.

The virtual server is added and the changes are saved to the running configuration.

Authenticating Telnet Connections with a Virtual Server

Although you can configure network access authentication for any protocol or service(see the "Configuring Network Access Authentication" section on page 53-6), you can authenticate directly with HTTP, Telnet, or FTP only. A user must first authenticate with one of these services before other traffic that requires authentication is allowed through. If you do not want to allow HTTP, Telnet, or FTP traffic through the ASA, but want to authenticate other types of traffic, you can configure virtual Telnet; the user Telnets to a given IP address configured on the ASA, and the ASA issues a Telnet prompt.

When an unauthenticated user connects to the virtual Telnet IP address, the user is challenged for a username and password, and then authenticated by the AAA server. After the user is authenticated, the message "Authentication Successful" appears. Then the user can successfully access other services that require authentication.

For inbound users (from lower security to higher security), you must also include the virtual Telnet address as a destination interface in the access rule applied to the source interface. In addition, you must add a static NAT rule for the virtual Telnet IP address, even if NAT is not required. An identity NAT rule is typically used (where you translate the address to itself).

For outbound users, there is an explicit permit for traffic, but if you apply an access rule to an inside interface, be sure to allow access to the virtual Telnet address. A static NAT rule is not required.

To log out from the ASA, reconnect to the virtual Telnet IP address; you are prompted to log out.

To enable direct authentication using Telnet, perform the following steps:

Step 1 In the Configuration > Firewall > Advanced > Virtual Access > Virtual Telnet Server area, check the **Enable** check box.

Step 2 In the Virtual Telnet Server field, enter the IP address of the virtual Telnet server.

Make sure that this address is an unused address that is routed to the ASA. For example, if you perform NAT for inside addresses accessing an outside server, and you want to provide outside access to the virtual HTTP server, you can use one of the global NAT addresses for the virtual HTTP server address.

Step 3 Click **Apply**.

The virtual server is added and the changes are saved to the running configuration.

Configuring the Authentication Proxy Limit

You can manually configure the uauth session limit by setting the maximum number of concurrent proxy connections allowed per user.

To set the proxy limit, perform the following steps:

Step 1 Choose **Configuration > Firewall > AAA Rules**, then click **Advanced**.

The AAA Rules Advanced Options dialog box appears.

Step 2 In the Proxy Limit area, check the **Enable Proxy Limit** check box.

Step 3 In the Proxy Limit field, enter the number of concurrent proxy connections allowed per user, from 1 to 128.

Step 4 Click **OK**, then click **Apply**.

The changes are saved to the running configuration.

Configuring Authorization for Network Access

After a user authenticates for a given connection, the ASA can use authorization to further control traffic from the user.

This section includes the following topics:

- Configuring TACACS+ Authorization, page 53-11
- Configuring RADIUS Authorization, page 53-13

Configuring TACACS+ Authorization

You can configure the ASA to perform network access authorization with TACACS+. Authentication and authorization statements are independent; however, any unauthenticated traffic matched by an authorization rule will be denied.For authorization to succeed:

1. A user must first authenticate with the ASA.

   Because a user at a given IP address only needs to authenticate one time for all rules and types, if the authentication session has not expired, authorization can occur even if the traffic is not matched by an authentication rule.
2. After a user authenticates, the ASA checks the authorization rules for matching traffic.
3. If the traffic matches the authorization rule, the ASA sends the username to the TACACS+ server.
4. The TACACS+ server responds to the ASA with a permit or a deny for that traffic, based on the user profile.
5. The ASA enforces the authorization rule in the response.

See the documentation for your TACACS+ server for information about configuring network access authorizations for a user.

To configure TACACS+ authorization, perform the following steps:

Step 1 Enable authentication. For more information, see the "Configuring Network Access Authentication" section on page 53-6. If you have already enabled authentication, continue to the next step.

Step 2 In the Configuration > Firewall > AAA Rules pane, choose **Add > Add Authorization Rule**.

The Add Authorization Rule dialog box appears.

Step 3 In the Interface drop-down list, choose the interface for applying the rule.

Step 4 In the Action field, click one of the following, depending on the implementation:

- **Authorize**
- **Do not Authorize**

Step 5 In the AAA Server Group drop-down list, choose a server group. To add a AAA server to the server group, click **Add Server**. See the "Testing Server Authentication and Authorization" section on page 46-27 for more information.

Only TACACS+ servers are supported.

Step 6 In the Source field, add the source IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 7 In the Destination field, enter the destination IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 8 In the Service field, enter an IP service name or number for the destination service, or click the ellipsis (...) to choose a service.

Step 9 (Optional) In the Description field, enter a description.

Step 10 (Optional) Click **More Options** to do any of the following:

- To specify a source service for TCP or UDP, enter a TCP or UDP service in the Source Service field.
- The destination service and source service must be the same. Copy and paste the Destination Service field content into the Source Service field.
- To make the rule inactive, clear the **Enable Rule** check box.

  You may not want to remove a rule, but instead turn it off.
- To set a time range for the rule, in the Time Range drop-down list, choose an existing time range. To add a new time range, click the ellipsis (...). For more information, see the "Configuring Time Ranges" section on page 25-15.

Step 11 Click **OK**.

The Add Authorization Rule dialog box closes, and the rule appears in the AAA Rules table.

Step 12 Click **Apply**.

The changes are saved to the running configuration.

Configuring RADIUS Authorization

When authentication succeeds, the RADIUS protocol returns user authorizations in the access-accept message sent by a RADIUS server. For more information about configuring authentication, see the "Configuring Network Access Authentication" section on page 53-6.

When you configure the ASA to authenticate users for network access, you are also implicitly enabling RADIUS authorizations; therefore, this section contains no information about configuring RADIUS authorization on the ASA. It does provide information about how the ASA handles access list information received from RADIUS servers.

You can configure a RADIUS server to download an access list to the ASA or an access list name at the time of authentication. The user is authorized to do only what is permitted in the user-specific access list.

Note If you have enabled the Per User Override Setting (see the Configuration > Firewall > Access Rules > Advanced > Access Rules Advanced Options dialog box), be aware of the following effects of the per-user-override featureon authorization by user-specific access lists:

- Without the per-user-override feature, traffic for a user session must be permitted by both the interface access list and the user-specific access list.
- With the per-user-override feature, the user-specific access list determines what is permitted.

This section includes the following topics:

- Configuring a RADIUS Server to Send Downloadable Access Control Lists, page 53-13
- Configuring a RADIUS Server to Download Per-User Access Control List Names, page 53-17

Configuring a RADIUS Server to Send Downloadable Access Control Lists

This section describes how to configure Cisco Secure ACS or a third-party RADIUS server and includes the following topics:

- About the Downloadable Access List Feature and Cisco Secure ACS, page 53-13
- Configuring Cisco Secure ACS for Downloadable Access Lists, page 53-15
- Configuring Any RADIUS Server for Downloadable Access Lists, page 53-16
- Converting Wildcard Netmask Expressions in Downloadable Access Lists, page 53-17

About the Downloadable Access List Feature and Cisco Secure ACS

Downloadable access lists is the most scalable means of using Cisco Secure ACS to provide the appropriate access lists for each user. It provides the following capabilities:

- Unlimited access list size—Downloadable access lists are sent using as many RADIUS packets as required to transport the full access list from Cisco Secure ACS to the ASA.
- Simplified and centralized management of access lists—Downloadable access lists enable you to write a set of access lists once and apply it to many user or group profiles and distribute it to many ASAs.

This approach is most useful when you have very large access list sets that you want to apply to more than one Cisco Secure ACS user or group; however, its ability to simplify Cisco Secure ACS user and group management makes it useful for access lists of any size.

The ASA receives downloadable access lists from Cisco Secure ACS using the following process:

1. The ASA sends a RADIUS authentication request packet for the user session.
2. If Cisco Secure ACS successfully authenticates the user, Cisco Secure ACS returns a RADIUS access-accept message that includes the internal name of the applicable downloadable access list. The Cisco IOS cisco-av-pair RADIUS VSA (vendor 9, attribute 1) includes the following attribute-value pair to identify the downloadable access list set:

   ```
   ACS:CiscoSecure-Defined-ACL=acl-set-name
   ```

   where *acl-set-name* is the internal name of the downloadable access list, which is a combination of the name assigned to the access list by the Cisco Secure ACS administrator and the date and time that the access list was last modified.
3. The ASA examines the name of the downloadable access list and determines if it has previously received the named downloadable access list.
   - If the ASA has previously received the named downloadable access list, communication with Cisco Secure ACS is complete and the ASA applies the access list to the user session. Because the name of the downloadable access list includes the date and time that it was last modified, matching the name sent by Cisco Secure ACS to the name of an access list previously downloaded means that the ASA has the most recent version of the downloadable access list.
   - If the ASA has not previously received the named downloadable access list, it may have an out-of-date version of the access list or it may not have downloaded any version of the access list. In either case, the ASA issues a RADIUS authentication request using the downloadable access list name as the username in the RADIUS request and a null password attribute. In a cisco-av-pair RADIUS VSA, the request also includes the following attribute-value pairs:

     ```
     AAA:service=ip-admission
     AAA:event=acl-download
     ```

     In addition, the ASA signs the request with the Message-Authenticator attribute (IETF RADIUS attribute 80).
4. After receipt of a RADIUS authentication request that has a username attribute that includes the name of a downloadable access list, Cisco Secure ACS authenticates the request by checking the Message-Authenticator attribute. If the Message-Authenticator attribute is missing or incorrect, Cisco Secure ACS ignores the request. The presence of the Message-Authenticator attribute prevents malicious use of a downloadable access list name to gain unauthorized network access. The Message-Authenticator attribute and its use are defined in RFC 2869, RADIUS Extensions, available at http://www.ietf.org.
5. If the access list required is less than approximately 4 KB in length, Cisco Secure ACS responds with an access-accept message that includes the access list. The largest access list that can fit in a single access-accept message is slightly less than 4 KB, because part of the message must be other required attributes.

   Cisco Secure ACS sends the downloadable access list in a cisco-av-pair RADIUS VSA. The access list is formatted as a series of attribute-value pairs that each include an ACE and are numbered serially:

   ```
   ip:inacl#1=ACE-1
   ip:inacl#2=ACE-2
   .
   .
   .
   ip:inacl#n=ACE-n

   ip:inacl#1=permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
   ```

6. If the access list required is more than approximately 4 KB in length, Cisco Secure ACS responds with an access-challenge message that includes a portion of the access list, formatted as described previously, and a State attribute (IETF RADIUS attribute 24), which includes control data used by Cisco Secure ACS to track the progress of the download. Cisco Secure ACS fits as many complete attribute-value pairs into the cisco-av-pair RADIUS VSA as it can without exceeding the maximum RADIUS message size.

   The ASA stores the portion of the access list received and responds with another access-request message that includes the same attributes as the first request for the downloadable access list, plus a copy of the State attribute received in the access-challenge message.

   This process repeats until Cisco Secure ACS sends the last of the access list in an access-accept message.

Configuring Cisco Secure ACS for Downloadable Access Lists

You can configure downloadable access lists on Cisco Secure ACS as a shared profile component and then assign the access list to a group or to an individual user.

The access list definition consists of one or more ASA commands that are similar to the extended **access-list** command (see command reference), except without the following prefix:

access-list *acl_name* **extended**

The following example is a downloadable access list definition on Cisco Secure ACS version 3.3:

```
+---------------------------------------------+
| Shared profile Components                   |
|                                             |
|      Downloadable IP ACLs Content           |
|                                             |
| Name:    acs_ten_acl                        |
|                                             |
|      ACL Definitions                        |
|                                             |
| permit tcp any host 10.0.0.254              |
| permit udp any host 10.0.0.254              |
| permit icmp any host 10.0.0.254             |
| permit tcp any host 10.0.0.253              |
| permit udp any host 10.0.0.253              |
| permit icmp any host 10.0.0.253             |
| permit tcp any host 10.0.0.252              |
| permit udp any host 10.0.0.252              |
| permit icmp any host 10.0.0.252             |
| permit ip any any                           |
+---------------------------------------------+
```

For more information about creating downloadable access lists and associating them with users, see the user guide for your version of Cisco Secure ACS.

On the ASA, the downloaded access list has the following name:

#ACSACL#-ip-*acl_name-number*

The *acl_name* argument is the name that is defined on Cisco Secure ACS (*acs_ten_acl* in the preceding example), and *number* is a unique version ID generated by Cisco Secure ACS.

The downloaded access list on the ASA consists of the following lines:

```
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit tcp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit udp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit icmp any host 10.0.0.254
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit tcp any host 10.0.0.253
```

```
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit udp any host 10.0.0.253
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit icmp any host 10.0.0.253
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit tcp any host 10.0.0.252
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit udp any host 10.0.0.252
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit icmp any host 10.0.0.252
access-list #ACSACL#-ip-asa-acs_ten_acl-3b5385f7 permit ip any any
```

Configuring Any RADIUS Server for Downloadable Access Lists

You can configure any RADIUS server that supports Cisco IOS RADIUS VSAs to send user-specific access lists to the ASA in a Cisco IOS RADIUS cisco-av-pair VSA (vendor 9, attribute 1).

In the cisco-av-pair VSA, configure one or more ACEs that are similar to the **access-list extended** command (see command reference), except that you replace the following command prefix:

access-list *acl_name* **extended**

with the following text:

ip:inacl#*nnn***=**

The *nnn* argument is a number in the range from 0 to 999999999 that identifies the order of the command statement to be configured on the ASA. If this parameter is omitted, the sequence value is 0, and the order of the ACEs inside the cisco-av-pair RADIUS VSA is used.

The following example is an access list definition as it should be configured for a cisco-av-pair VSA on a RADIUS server:

```
ip:inacl#1=permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
ip:inacl#99=deny tcp any any
ip:inacl#2=permit udp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
ip:inacl#100=deny udp any any
ip:inacl#3=permit icmp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
```

For information about making unique per user the access lists that are sent in the cisco-av-pair attribute, see the documentation for your RADIUS server.

On the ASA, the downloaded access list name has the following format:

AAA-user-*username*

The *username* argument is the name of the user that is being authenticated.

The downloaded access list on the ASA consists of the following lines. Notice the order based on the numbers identified on the RADIUS server.

```
access-list  AAA-user-bcham34-79AD4A08 permit tcp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list  AAA-user-bcham34-79AD4A08 permit udp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list  AAA-user-bcham34-79AD4A08 permit icmp 10.1.0.0 255.0.0.0 10.0.0.0 255.0.0.0
access-list  AAA-user-bcham34-79AD4A08 deny tcp any any
access-list  AAA-user-bcham34-79AD4A08 deny udp any any
```

Downloaded access lists have two spaces between the word “access-list” and the name. These spaces serve to differentiate a downloaded access list from a local access list. In this example, “79AD4A08” is a hash value generated by the ASA to help determine when access list definitions have changed on the RADIUS server.

Converting Wildcard Netmask Expressions in Downloadable Access Lists

If a RADIUS server provides downloadable access lists to Cisco VPN 3000 series concentrators as well as to the ASA, you may need the ASA to convert wildcard netmask expressions to standard netmask expressions. This is because Cisco VPN 3000 series concentrators support wildcard netmask expressions, but the ASA only supports standard netmask expressions. Configuring the ASA to convert wildcard netmask expressions helps minimize the effects of these differences on how you configure downloadable access lists on your RADIUS servers. Translation of wildcard netmask expressions means that downloadable access lists written for Cisco VPN 3000 series concentrators can be used by the ASA without altering the configuration of the downloadable access lists on the RADIUS server.

You configure access list netmask conversion on a per-server basis when you add a server to a server group in the Configuration > Device Management > Users/AAA > AAA Server Groups > AAA Server Groups area. For more information, see the "Configuring AAA Server Groups" section on page 46-11.

Configuring a RADIUS Server to Download Per-User Access Control List Names

To download a name for an access list that you already created on the ASA from the RADIUS server when a user authenticates, configure the IETF RADIUS filter-id attribute (attribute number 11) as follows:

filter-id=*acl_name*

Note In Cisco Secure ACS, the values for filter-id attributes are specified in boxes in the HTML interface, omitting **filter-id=** and entering only *acl_name*.

For information about making the filter-id attribute value unique per user, see the documentation for your RADIUS server.

To create an access list on the ASA, see Chapter 26, "Using the ACL Manager."

Configuring Accounting for Network Access

The ASA can send accounting information to a RADIUS or TACACS+ server about any TCP or UDP traffic that passes through the ASA. If that traffic is also authenticated, then the AAA server can maintain accounting information by username. If the traffic is not authenticated, the AAA server can maintain accounting information by IP address. Accounting information includes session start and stop times, username, the number of bytes that pass through the ASA for the session, the service used, and the duration of each session.

To configure accounting, perform the following steps:

Step 1 If you want the ASA to provide accounting data per user, you must enable authentication. For more information, see the "Configuring Network Access Authentication" section on page 53-6. If you want the ASA to provide accounting data per IP address, enabling authentication is not necessary and you can continue to the next step.

Step 2 In the Configuration > Firewall > AAA Rules pane, choose **Add > Add Accounting Rule**.

The Add Accounting Rule dialog box appears.

Step 3 In the Interface drop-down list, choose the interface for applying the rule.

Step 4 In the Action field, click one of the following, depending on the implementation:

- **Account**
- **Do not Account**

Step 5 In the AAA Server Group drop-down list, choose a server group. To add a AAA server to the server group, click **Add Server**. See the "Testing Server Authentication and Authorization" section on page 46-27 for more information.

Step 6 In the Source field, enter the source IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 7 In the Destination field, enter the destination IP address, or click the ellipsis (...) to choose an IP address already defined in ASDM.

Step 8 In the Service field, enter an IP service name or number for the destination service, or click the ellipsis (...) to choose a service.

Step 9 (Optional) In the Description field, enter a description.

Step 10 (Optional) Click **More Options** to do any of the following:

- To specify a source service for TCP or UDP, enter a TCP or UDP service in the Source Service field.
- The destination service and source service must be the same. Copy and paste the Destination Service field content to the Source Service field.
- To make the rule inactive, clear the **Enable Rule** check box.

  You may not want to remove a rule, but instead turn it off.
- To set a time range for the rule, In the Time Range drop-down list, choose an existing time range. To add a new time range, click the ellipsis (...). For more information, see the "Configuring Time Ranges" section on page 25-15.

Step 11 Click **OK**.

The Add Accounting Rule dialog box closes and the rule appears in the AAA Rules table.

Step 12 Click **Apply**.

The changes are saved to the running configuration.

Using MAC Addresses to Exempt Traffic from Authentication and Authorization

The ASA can exempt from authentication and authorization any traffic from specific MAC addresses.

For example, if the ASA authenticates TCP traffic originating on a particular network but you want to allow unauthenticated TCP connections from a specific server, you would use a MAC exempt rule to exempt from authentication and authorization any traffic from the server specified by the rule. This feature is particularly useful to exempt devices such as IP phones that cannot respond to authentication prompts.

The order of entries matters, because the packet uses the first entry it matches, instead of a best match scenario. If you have a **permit** entry, and you want to deny an address that is allowed by the **permit** entry, be sure to enter the **deny** entry before the **permit** entry.

To use MAC addresses to exempt traffic from authentication and authorization, perform the following steps:

Step 1 In the Configuration > Firewall > AAA Rules pane, choose **Add > Add MAC Exempt Rule**.

The Add MAC Exempt Rule dialog box appears.

Step 2 In the Action drop-down list, click one of the following options, depending on the implementation:

- **MAC Exempt**
- **No MAC Exempt**

The MAC Exempt option allows traffic from the MAC address without having to authenticate or authorize. The No MAC Exempt option specifies a MAC address that is not exempt from authentication or authorization. You might need to add a **deny** entry if you permit a range of MAC addresses using a MAC address mask such as ffff.ffff.0000, and you want to force a MAC address in that range to be authenticated and authorized.

Step 3 In the MAC Address field, specify the source MAC address in 12-digit hexadecimal form; that is, nnnn.nnnn.nnnn.

Step 4 In the MAC Mask field, specify the portion of the MAC address that should be used for matching. For example, ffff.ffff.ffff matches the MAC address exactly. ffff.ffff.0000 matches only the first 8 digits.

Step 5 Click **OK**.

The Add MAC Exempt Rule dialog box closes and the rule appears in the AAA Rules table.

Step 6 Click **Apply**.

The changes are saved to the running configuration.

Feature History for AAA Rules

Table 53-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 53-1 Feature History for AAA Rules

Feature Name	Platform Releases	Feature Information
AAA Rules	7.0(1)	AAA Rules describe how to enable AAA for network access. We introduced the following screens: Configuration > Firewall > AAA Rules Configuration > Firewall > Advanced > Virtual Access.
Authentication using Cut-Through Proxy	9.0(1)	You can authenticate using AAA rules in conjunction with the Identity Firewall feature.

Configuring Web Cache Services Using WCCP

This chapter describes how to configure web caching services using WCCP, and includes the following sections:

- Information About WCCP, page 54-1
- Guidelines and Limitations, page 54-1
- Licensing Requirements for WCCP, page 54-3
- Adding or Editing WCCP Service Groups, page 54-3
- Configuring Packet Redirection, page 54-4
- WCCP Monitoring, page 54-4
- Feature History for WCCP, page 54-5

Information About WCCP

The purpose of web caching is to reduce latency and network traffic. Previously-accessed web pages are stored in a cache buffer, so if users need the page again, they can retrieve it from the cache instead of the web server.

WCCP specifies interactions between the ASA and external web caches. The feature transparently redirects selected types of traffic to a group of web cache engines to optimize resource usage and lower response times. The ASA only supports WCCP Version 2.

Using an ASA as an intermediary eliminates the need for a separate router to do the WCCP redirection, because the ASA redirects requests to cache engines. When the ASA determines that a packet needs redirection, it skips TCP state tracking, TCP sequence number randomization, and NAT on these traffic flows.

Guidelines and Limitations

The following WCCPv2 features are supported for the ASA:

- Redirection of multiple TCP and UDP port-destined traffic.
- Authentication for cache engines in a service group.
- Multiple cache engines in a service group.
- GRE encapsulation.

The following WCCPv2 features are not supported for the ASA:

- Multiple routers in a service group.
- Multicast WCCP.
- The Layer 2 redirect method.
- WCCP source address spoofing.
- WAAS devices.

WCCP Interaction With Other Features

In the ASA implementation of WCCP, the protocol interacts with other configurable features according to the following:

- Cut-through proxy will not work in combination with WCCP.
- An ingress access list entry always takes higher priority over WCCP. For example, if an access list does not permit a client to communicate with a server, then traffic is not redirected to a cache engine. Both ingress interface access lists and egress interface access lists are applied.
- TCP intercept, authorization, URL filtering, inspect engines, and IPS features are not applied to a redirected flow of traffic.
- When a cache engine cannot service a request and a packet is returned, or when a cache miss happens on a cache engine and it requests data from a web server, then the contents of the traffic flow is subject to all the other configured features of the ASA.
- If you have two WCCP services and they use two different redirection ACLs that overlap and match the same packets (with a deny or a permit action), the packets behave according to the first service-group found and installed rules. The packets are not passed thorugh all service-groups.

Failover Guidelines

Supports Active/Active and Active/Standby failover. WCCP redirect tables are not replicated to standby units. After a failover, packets are not redirected until the tables are rebuilt. Sessions redirected before failover are probably reset by the web server.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

Context Mode Guidelines

Supported in single mode and multiple context mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines

The ASA selects the highest IP address configured on any interface as the WCCP router ID. This address is used to establish a GRE tunnel with the cache engine.

WCCP does not support access lists that include a user, user group, or a fully qualified domain name object.

Licensing Requirements for WCCP

Table 54-1 shows the licensing requirements for WCCP.

Table 54-1 Licensing Requirements

Model	License Requirement
All models	Base License.

Configuring WCCP Service Groups

To allocate space and enable support of the specified WCCP service group, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Device Management > Advanced > WCCP > Service Groups**.

Step 2 To add a new service group, click **Add** to display the Add Service Group dialog box.

Step 3 To modify an existing service group, click **Edit** to display the Edit Service Group dialog box.

Step 4 To remove a selected service group, click **Delete**.

Step 5 To continue, see "Adding or Editing WCCP Service Groups" section on page 54-3.

Step 6 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Adding or Editing WCCP Service Groups

To add a new service group or change the service group parameters for a configured service group, perform the following steps:

Step 1 Click either the Web Cache Service or the Dynamic Service Number radio button. The maximum number of services, including those specified with a dynamic service identifier is 256.

Step 2 Enter the dynamic service identifier, which means the service definition is dictated by the cache. Valid dynamic service numbers are 0 to 254, and are used as the name of the service group.

Step 3 In the Options area, perform the following steps:

- **a.** Choose the predefined access list that controls traffic redirected to this service group.
- **b.** Choose the predefined access list that determines which web caches are allowed to participate in the service group. Only extended ACLs are allowed.
- **c.** Enter a password up to seven characters long, which is used for MD5 authentication for messages received from the service group.
- **d.** Confirm the password.
- **e.** Click **Manage** to display the ACL Manager window, where you can create or change an ACL.

Step 4 Click **OK** to close the Add or Edit Service Group dialog box.

Step 5 To continue, see the "Configuring Packet Redirection" section on page 54-4.

Configuring Packet Redirection

To configure packet redirection on the ingress of an interface using WCCP, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Device Management > Advanced > WCCP > Redirection**.

Step 2 To add a new WCCP packet redirection, click **Add** to display the Add WCCP Redirection dialog box.

Step 3 To modify an existing WCCP packet redirection, click **Edit** to display the Edit WCCP Redirection dialog box.

Step 4 To remove a selected WCCP packet redirection, click **Delete**.

Step 5 To continue, see the "Adding or Editing Packet Redirection" section on page 54-4.

Adding or Editing Packet Redirection

To add or change packet redirection on the ingress of an interface using WCCP, perform the following steps:

Step 1 Choose the interface on which to enable WCCP redirection from the drop-down list.

Step 2 Choose the service group from the drop-down list.

Step 3 Click **OK** to close the Edit WCCP Redirection dialog box.

Step 4 (Optional) If you need to create a new service group, click **New** to display the Add Service Group dialog box.

Step 5 (Optional) To continue, see the "Adding or Editing WCCP Service Groups" section on page 54-3.

WCCP Monitoring

To monitor WCCP, perform the following steps:

Path	Purpose
Tools > Command Line Interface Type **show running-config wccp**, then click **Send**.	Shows the current WCCP configuration.
Tools > Command Line Interface Type **show running-config wccp interface**, then click **Send**.	Shows the current WCCP interfaces status.

Path	Purpose
Monitoring > Properties > WCCP > WCCP Service Groups	Shows configured WCCP service groups.
Monitoring > Properties > WCCP > WCCP Redirection	Shows configured WCCP interface statistics.

Feature History for WCCP

Table 54-2 lists the release history for this feature. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 54-2 Feature History for WCCP

Feature Name	Releases	Feature Information
WCCP	7.2(1)	WCCP specifies interactions between the ASA and external web caches. We introduced the following screens: **Configuration > Device Management > Advanced > WCCP > Service Groups** **Configuration > Device Management > Advanced > WCCP > Redirection**

Configuring Public Servers

This section describes how to configure public servers, and includes the following topics:

- Information About Public Servers, page 55-1
- Licensing Requirements for Public Servers, page 55-1
- Guidelines and Limitations, page 55-1
- Adding a Public Server that Enables Static NAT, page 55-2
- Adding a Public Server that Enables Static NAT with PAT, page 55-2
- Editing Settings for a Public Server, page 55-3
- Feature History for Public Servers, page 55-4

Information About Public Servers

The Public Servers pane enables an administrator to provide internal and external users access to various application servers. This pane displays a list of public servers. internal and external addresses, the interfaces to which the internal or external addresses apply, the ability to translate the addresses, and the service that is exposed. You can add, edit, delete, or modify settings for existing public servers.

Licensing Requirements for Public Servers

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Adding a Public Server that Enables Static NAT

To add a public server that enables static NAT and creates a fixed translation of a real address to a mapped address, perform the following steps:

Step 1 In the Configuration > Firewall > Public Servers pane, click **Add** to add a new server.

The Add Public Server dialog box appears.

Step 2 From the Private Interface drop-down menu, select the name of the private interface to which the real server is connected.

Step 3 In the Private IP address field, enter the real IP address of the server (IPv4 only).

Step 4 In the Private Service field, click **Browse** to display the Browse Service dialog box, choose the actual service that is exposed to the outside, and click **OK**.

Optionally, from the Browse Service dialog box you can click **Add** to create a new service or service group. Multiple services from various ports can be opened to the outside. For more information about service objects and service groups, see the "Configuring Service Objects and Service Groups" section on page 25-4.

Step 5 From the Public Interface drop-down menu, enter the interface through which users from the outside can access the real server.

Step 6 In the Public Address field, enter the mapped IP address of the server, which is the address that is seen by the outside user.

Step 7 (Optional) To enable static PAT, check the **Specify if Public Service is different from private service** check box .

Step 8 Click **OK**. The configuration appears in the main pane.

Step 9 Click **Apply** to generate static NAT and a corresponding access rule for the traffic flow and to save the configuration.

For information about static NAT, see the "Information About Static NAT" section on page 39-3.

Adding a Public Server that Enables Static NAT with PAT

To add a public server that lets you specify a real and mapped protocol (TCP or UDP) to a port, perform the following steps:

Step 1 Choose **Configuration > Firewall > Public Servers**, then click **Add**.

The Add Public Server dialog box appears.

Step 2 From the Private Interface drop-down menu, choose the name of the private interface to which the real server is connected.

Step 3 In the Private IP address field, enter the real IP address of the server (only IPv4 is supported).

Step 4 In the Private Service field, click **Browse** to display the Browse Service dialog box

Step 5 Choose the actual service that is exposed to the outside, and click **OK**.

Optionally, from the Browse Service dialog box, click **Add** to create a new service or service group. Multiple services from various ports can be opened to the outside. For more information about service objects and service groups, see the "Configuring Service Objects and Service Groups" section on page 25-4.

Step 6 From the Public Interface drop-down menu, enter the interface through which users from the outside can access the real server.

Step 7 In the Public Address field, enter the mapped IP address of the server, which is the address that the outside user sees.

Step 8 Check the **Specify Public Service if different from Private Service** check box to enable static PAT.

Step 9 In the Public Service field, enter the mapped protocol (TCP or UDP only), or click **Browse** to choose a protocol from the list.

Step 10 Click **OK**.

Step 11 Click **Apply** to generate static NAT with PAT and a corresponding access rule for the traffic flow, and to save the configuration.

For information about static NAT with port address translation, see the "Information About Static NAT with Port Translation" section on page 39-4.

Editing Settings for a Public Server

To edit the settings for a public server, perform the following steps:

Step 1 Choose **Configuration > Firewall > Public Servers**, choose an existing public server, then click **Edit**.

The Edit Public Server dialog box appears.

Step 2 Make any necessary changes to the following settings:

- Private Interface—The interface to which the real server is connected.
- Private IP Address—The real IP address of the server.
- Private Service—The actual service that is running on the real server.
- Public Interface—The interface through which outside users can access the real server.
- Public Address—The IP address that is seen by outside users.
- Public Service—The service that is running on the translated address.

Step 3 Click **OK**, then click **Apply** to save your changes.

Feature History for Public Servers

Table 55-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 55-1 Feature History for Public Servers

Feature Name	Platform Releases	Feature Information
Public Servers	8.3(1)	Public servers provide internal and external users access to various application servers. We introduced the following screen: Configuration > Firewall > Public Servers

PART 10

Configuring Application Inspection

Getting Started with Application Layer Protocol Inspection

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection instead of passing the packet through the fast path (see the "Stateful Inspection Overview" section on page 1-24 for more information about the fast path). As a result, inspection engines can affect overall throughput. Several common inspection engines are enabled on the ASA by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- Information about Application Layer Protocol Inspection, page 57-1
- Guidelines and Limitations, page 57-3
- Default Settings, page 57-4
- Configuring Application Layer Protocol Inspection, page 57-6

Information about Application Layer Protocol Inspection

This section includes the following topics:

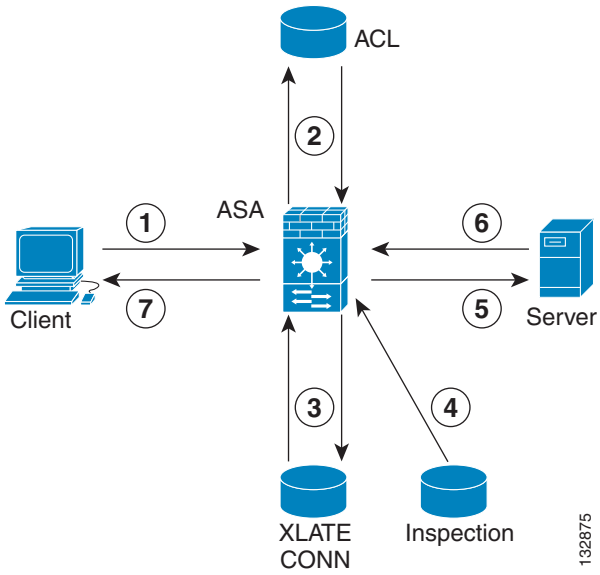
- How Inspection Engines Work, page 57-1
- When to Use Application Protocol Inspection, page 57-2

How Inspection Engines Work

As illustrated in Figure 57-1, the ASA uses three databases for its basic operation:

- Access lists—Used for authentication and authorization of connections based on specific networks, hosts, and services (TCP/UDP port numbers).
- Inspections—Contains a static, predefined set of application-level inspection functions.
- Connections (XLATE and CONN tables)—Maintains state and other information about each established connection. This information is used by the Adaptive Security Algorithm and cut-through proxy to efficiently forward traffic within established sessions.

Figure 57-1 How Inspection Engines Work



In Figure 57-1, operations are numbered in the order they occur, and are described as follows:

1. A TCP SYN packet arrives at the ASA to establish a new connection.
2. The ASA checks the access list database to determine if the connection is permitted.
3. The ASA creates a new entry in the connection database (XLATE and CONN tables).
4. The ASA checks the Inspections database to determine if the connection requires application-level inspection.
5. After the application inspection engine completes any required operations for the packet, the ASA forwards the packet to the destination system.
6. The destination system responds to the initial request.
7. The ASA receives the reply packet, looks up the connection in the connection database, and forwards the packet because it belongs to an established session.

The default configuration of the ASA includes a set of application inspection entries that associate supported protocols with specific TCP or UDP port numbers and that identify any special handling required.

When to Use Application Protocol Inspection

When a user establishes a connection, the ASA checks the packet against access lists, creates an address translation, and creates an entry for the session in the fast path, so that further packets can bypass time-consuming checks. However, the fast path relies on predictable port numbers and does not perform address translations inside a packet.

Many protocols open secondary TCP or UDP ports. The initial session on a well-known port is used to negotiate dynamically assigned port numbers.

Other applications embed an IP address in the packet that needs to match the source address that is normally translated when it goes through the ASA.

If you use applications like these, then you need to enable application inspection.

When you enable application inspection for a service that embeds IP addresses, the ASA translates embedded addresses and updates any checksum or other fields that are affected by the translation.

When you enable application inspection for a service that uses dynamically assigned ports, the ASA monitors sessions to identify the dynamic port assignments, and permits data exchange on these ports for the duration of the specific session.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Failover Guidelines

State information for multimedia sessions that require inspection are not passed over the state link for stateful failover. The exception is GTP, which is replicated over the state link.

IPv6 Guidelines

Supports IPv6 for the following inspections:

- DNS
- FTP
- HTTP
- ICMP
- SIP
- SMTP
- IPsec pass-through
- IPv6

Supports NAT64 for the following inspections:

- DNS
- FTP
- HTTP
- ICMP

Additional Guidelines and Limitations

Some inspection engines do not support PAT, NAT, outside NAT, or NAT between same security interfaces. See "Default Settings" for more information about NAT support.

For all the application inspections, the adaptive security appliance limits the number of simultaneous, active data connections to 200 connections. For example, if an FTP client opens multiple secondary connections, the FTP inspection engine allows only 200 active connections and the 201 connection is dropped and the adaptive security appliance generates a system error message.

Inspected protocols are subject to advanced TCP-state tracking, and the TCP state of these connections is not automatically replicated. While these connections are replicated to the standby unit, there is a best-effort attempt to re-establish a TCP state.

Default Settings

By default, the configuration includes a policy that matches all default application inspection traffic and applies inspection to the traffic on all interfaces (a global policy). Default application inspection traffic includes traffic to the default ports for each protocol. You can only apply one global policy, so if you want to alter the global policy, for example, to apply inspection to non-standard ports, or to add inspections that are not enabled by default, you need to either edit the default policy or disable it and apply a new one.

Table 57-1 lists all inspections supported, the default ports used in the default class map, and the inspection engines that are on by default, shown in bold. This table also notes any NAT limitations.

Table 57-1 Supported Application Inspection Engines

Application[1]	Default Port	NAT Limitations	Standards[2]	Comments
CTIQBE	TCP/2748	No extended PAT. No NAT64.	—	—
DCERPC	TCP/135	No NAT64.	—	—
DNS over UDP	UDP/53	No NAT support is available for name resolution through WINS.	RFC 1123	No PTR records are changed.
FTP	TCP/21	—	RFC 959	—
GTP	UDP/3386 UDP/2123	No extended PAT. No NAT64.	—	Requires a special license.
H.323 H.225 and **RAS**	TCP/1720 UDP/1718 UDP (RAS) 1718-1719	No NAT on same security interfaces. No static PAT. No extended PAT. No NAT64.	ITU-T H.323, H.245, H225.0, Q.931, Q.932	—
HTTP	TCP/80	—	RFC 2616	Beware of MTU limitations stripping ActiveX and Java. If the MTU is too small to allow the Java or ActiveX tag to be included in one packet, stripping may not occur.
ICMP	—	—	—	All ICMP traffic is matched in the default class map.
ICMP ERROR	—	—	—	All ICMP traffic is matched in the default class map.
ILS (LDAP)	TCP/389	No extended PAT. No NAT64.	—	—

Table 57-1 Supported Application Inspection Engines (continued)

Application[1]	Default Port	NAT Limitations	Standards[2]	Comments
Instant Messaging (IM)	Varies by client	No extended PAT. No NAT64.	RFC 3860	—
IP Options	—	No NAT64.	RFC 791, RFC 2113	All IP Options traffic is matched in the default class map.
MGCP	UDP/2427, 2727	No extended PAT. No NAT64.	RFC 2705bis-05	—
MMP	TCP 5443	No extended PAT. No NAT64.	—	—
NetBIOS Name Server over IP	UDP/137, 138 (Source ports)	No extended PAT. No NAT64.	—	NetBIOS is supported by performing NAT of the packets for NBNS UDP port 137 and NBDS UDP port 138.
PPTP	TCP/1723	No NAT64.	RFC 2637	—
RADIUS Accounting	1646	No NAT64.	RFC 2865	—
RSH	TCP/514	No PAT. No NAT64.	Berkeley UNIX	—
RTSP	TCP/554	No extended PAT. No outside NAT. No NAT64.	RFC 2326, 2327, 1889	No handling for HTTP cloaking.
ScanSafe	TCP/80 TCP/413	—	—	These ports are not included in the default-inspection-traffic class for the ScanSafe inspection.
SIP	TCP/5060 UDP/5060	No outside NAT. No NAT on same security interfaces. No extended PAT. No NAT64.	RFC 2543	—
SKINNY (SCCP)	TCP/2000	No outside NAT. No NAT on same security interfaces. No extended PAT. No NAT64.	—	Does not handle TFTP uploaded Cisco IP Phone configurations under certain circumstances.
SMTP and **ESMTP**	TCP/25	No NAT64.	RFC 821, 1123	—
SNMP	UDP/161, 162	No NAT or PAT.	RFC 1155, 1157, 1212, 1213, 1215	v.2 RFC 1902-1908; v.3 RFC 2570-2580.
SQL*Net	TCP/1521	No extended PAT. No NAT64.	—	v.1 and v.2.

Table 57-1 Supported Application Inspection Engines (continued)

Application[1]	Default Port	NAT Limitations	Standards[2]	Comments
Sun RPC over UDP and TCP	UDP/111	No extended PAT. No NAT64.	—	The default rule includes UDP port 111; if you want to enable Sun RPC inspection for TCP port 111, you need to create a new rule that matches TCP port 111 and performs Sun RPC inspection.
TFTP	UDP/69	No NAT64.	RFC 1350	Payload IP addresses are not translated.
WAAS	—	No extended PAT. No NAT64.	—	—
XDCMP	UDP/177	No extended PAT. No NAT64.	—	—

1. Inspection engines that are enabled by default for the default port are in bold.
2. The ASA is in compliance with these standards, but it does not enforce compliance on packets being inspected. For example, FTP commands are supposed to be in a particular order, but the ASA does not enforce the order.

Configuring Application Layer Protocol Inspection

This feature uses Security Policy Rules to create a service policy. Service policies provide a consistent and flexible way to configure ASA features. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. See Chapter 44, "Configuring a Service Policy," for more information.

Inspection is enabled by default for some applications. See the "Default Settings" section for more information. Use this section to modify your inspection policy.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Service Policy Rules**.

Step 2 Add or edit a service policy rule according to the "Adding a Service Policy Rule for Through Traffic" section on page 44-8.

If you want to match non-standard ports, then create a new rule for the non-standard ports. See the "Default Settings" section on page 57-4 for the standard ports for each inspection engine. You can combine multiple rules in the same service policy if desired, so you can create one rule to match certain traffic, and another to match different traffic. However, if traffic matches a rule that contains an inspection action, and then matches another rule that also has an inspection action, only the first matching rule is used.

Step 3 In the Edit Service Policy Rule > Rule Actions dialog box, click the **Protocol Inspection** tab.

For a new rule, the dialog box is called Add Service Policy Rule Wizard - Rule Actions.

Step 4 Select each inspection type that you want to apply.

Step 5 (Optional) Some inspection engines let you control additional parameters when you apply the inspection to the traffic. Click **Configure** for each inspection type to configure an inspect map.

You can either choose an existing map, or create a new one. You can predefine inspect maps in the Configuration > Firewall > Objects > Inspect Maps pane.

Step 6 You can configure other features for this rule if desired using the other Rule Actions tabs.

Step 7 Click **OK** (or **Finish** from the wizard).

Configuring Inspection of Basic Internet Protocols

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the ASA by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- DNS Inspection, page 58-1
- FTP Inspection, page 58-12
- HTTP Inspection, page 58-21
- ICMP Inspection, page 58-34
- ICMP Error Inspection, page 58-34
- Instant Messaging Inspection, page 58-35
- IP Options Inspection, page 58-36
- IPsec Pass Through Inspection, page 58-40
- IPv6 Inspection, page 58-43
- NetBIOS Inspection, page 58-45
- PPTP Inspection, page 58-46
- SMTP and Extended SMTP Inspection, page 58-47
- TFTP Inspection, page 58-55

DNS Inspection

This section describes DNS application inspection. This section includes the following topics:

- How DNS Application Inspection Works, page 58-2
- How DNS Rewrite Works, page 58-3
- Configuring DNS Rewrite, page 58-3

- Select DNS Inspect Map, page 58-5
- DNS Class Map, page 58-6
- Add/Edit DNS Traffic Class Map, page 58-6
- Add/Edit DNS Match Criterion, page 58-7
- DNS Inspect Map, page 58-8
- Add/Edit DNS Policy Map (Security Level), page 58-9
- Add/Edit DNS Policy Map (Details), page 58-11

How DNS Application Inspection Works

The ASA tears down the DNS session associated with a DNS query as soon as the DNS reply is forwarded by the ASA. The ASA also monitors the message exchange to ensure that the ID of the DNS reply matches the ID of the DNS query.

When DNS inspection is enabled, which is the default, the ASA performs the following additional tasks:

- Translates the DNS record based on the configuration completed using the **alias**, **static** and **nat** commands (DNS Rewrite). Translation only applies to the A-record in the DNS reply; therefore, DNS Rewrite does not affect reverse lookups, which request the PTR record.

Note DNS Rewrite is not applicable for PAT because multiple PAT rules are applicable for each A-record and the PAT rule to use is ambiguous.

- Enforces the maximum DNS message length (the default is 512 bytes and the maximum length is 65535 bytes). The ASA performs reassembly as needed to verify that the packet length is less than the maximum length configured. The ASA drops the packet if it exceeds the maximum length.

Note If you enter the **inspect dns** command without the **maximum-length** option, DNS packet size is not checked

- Enforces a domain-name length of 255 bytes and a label length of 63 bytes.
- Verifies the integrity of the domain-name referred to by the pointer if compression pointers are encountered in the DNS message.
- Checks to see if a compression pointer loop exists.

A single connection is created for multiple DNS sessions, as long as they are between the same two hosts, and the sessions have the same 5-tuple (source/destination IP address, source/destination port, and protocol). DNS identification is tracked by *app_id*, and the idle timer for each app_id runs independently.

Because the app_id expires independently, a legitimate DNS response can only pass through the ASA within a limited period of time and there is no resource build-up. However, if you enter the **show conn** command, you will see the idle timer of a DNS connection being reset by a new DNS session. This is due to the nature of the shared DNS connection and is by design.

How DNS Rewrite Works

When DNS inspection is enabled, DNS rewrite provides full support for NAT of DNS messages originating from any interface.

If a client on an inside network requests DNS resolution of an inside address from a DNS server on an outside interface, the DNS A-record is translated correctly. If the DNS inspection engine is disabled, the A-record is not translated.

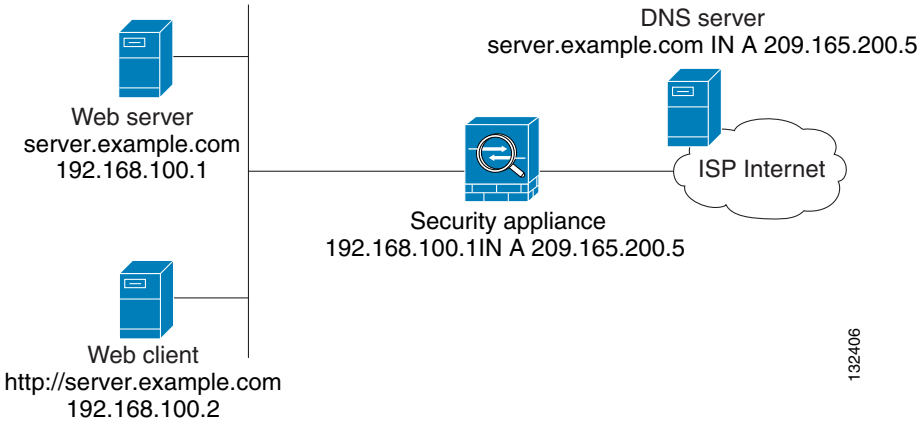
As long as DNS inspection remains enabled, you can configure DNS rewrite using a NAT rule.

DNS Rewrite performs two functions:

- Translating a public address (the routable or "mapped" address) in a DNS reply to a private address (the "real" address) when the DNS client is on a private interface.
- Translating a private address to a public address when the DNS client is on the public interface.

In Figure 58-1, the DNS server resides on the external (ISP) network The real address of the server (192.168.100.1) has been mapped using the **static** command to the ISP-assigned address (209.165.200.5). When a web client on the inside interface attempts to access the web server with the URL http://server.example.com, the host running the web client sends a DNS request to the DNS server to resolve the IP address of the web server. The ASA translates the non-routable source address in the IP header and forwards the request to the ISP network on its outside interface. When the DNS reply is returned, the ASA applies address translation not only to the destination address, but also to the embedded IP address of the web server, which is contained in the A-record in the DNS reply. As a result, the web client on the inside network gets the correct address for connecting to the web server on the inside network.

Figure 58-1 Translating the Address in a DNS Reply (DNS Rewrite)



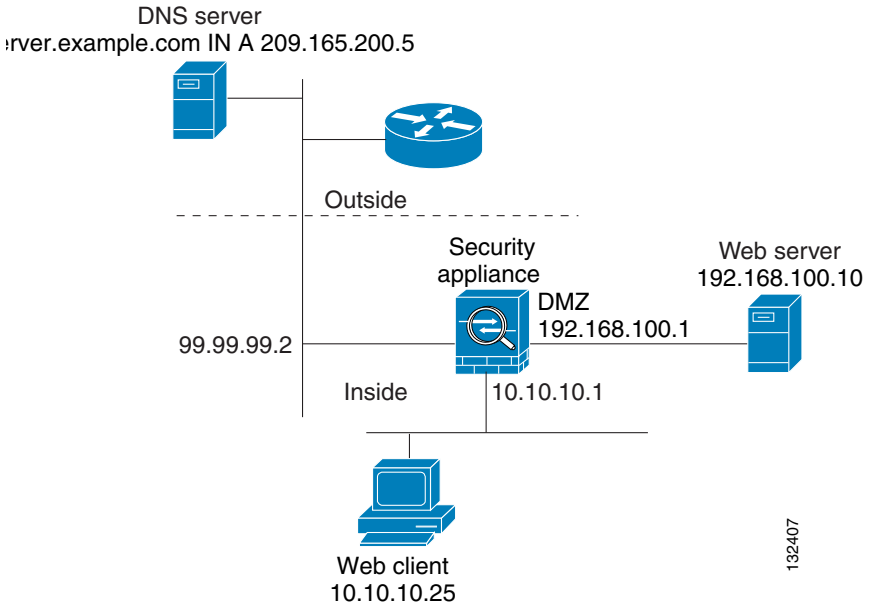
DNS rewrite also works if the client making the DNS request is on a DMZ network and the DNS server is on an inside interface.

Configuring DNS Rewrite

You configure DNS rewrite using the NAT configuration.

Figure 58-2 provides a more complex scenario to illustrate how DNS inspection allows NAT to operate transparently with a DNS server with minimal configuration.

Figure 58-2 DNS Rewrite with Three NAT Zones



In Figure 58-2, a web server, server.example.com, has the real address 192.168.100.10 on the DMZ interface of the ASA. A web client with the IP address 10.10.10.25 is on the inside interface and a public DNS server is on the outside interface. The site NAT policies are as follows:

- The outside DNS server holds the authoritative address record for server.example.com.
- Hosts on the outside network can contact the web server with the domain name server.example.com through the outside DNS server or with the IP address 209.165.200.5.
- Clients on the inside network can access the web server with the domain name server.example.com through the outside DNS server or with the IP address 192.168.100.10.

When a host or client on any interface accesses the DMZ web server, it queries the public DNS server for the A-record of server.example.com. The DNS server returns the A-record showing that server.example.com binds to address 209.165.200.5.

When a web client on the *outside* network attempts to access http://server.example.com, the sequence of events is as follows:

1. The host running the web client sends the DNS server a request for the IP address of server.example.com.
2. The DNS server responds with the IP address 209.165.200.225 in the reply.
3. The web client sends its HTTP request to 209.165.200.225.
4. The packet from the outside host reaches the ASA at the outside interface.
5. The static rule translates the address 209.165.200.225 to 192.168.100.10 and the ASA directs the packet to the web server on the DMZ.

When a web client on the *inside* network attempts to access http://server.example.com, the sequence of events is as follows:

1. The host running the web client sends the DNS server a request for the IP address of server.example.com.
2. The DNS server responds with the IP address 209.165.200.225 in the reply.

3. The ASA receives the DNS reply and submits it to the DNS application inspection engine.
4. The DNS application inspection engine does the following:
   a. Searches for any NAT rule to undo the translation of the embedded A-record address "[outside]:209.165.200.5". In this example, it finds the following static configuration:

```
object network obj-192.168.100.10-01
  host 192.168.100.10
  nat (dmz,outside) static 209.165.200.5 dns
```

   b. Uses the static rule to rewrite the A-record as follows because the **dns** option is included:

```
[outside]:209.165.200.225 --> [dmz]:192.168.100.10
```

   Note If the **dns** option were not included with the **nat** command, DNS Rewrite would not be performed and other processing for the packet continues.

   c. Searches for any NAT to translate the web server address, [dmz]:192.168.100.10, when communicating with the inside web client.

      No NAT rule is applicable, so application inspection completes.

      If a NAT rule (nat or static) were applicable, the **dns** option must also be specified. If the **dns** option were not specified, the A-record rewrite in step b would be reverted and other processing for the packet continues.
5. The ASA sends the HTTP request to server.example.com on the DMZ interface.

Select DNS Inspect Map

The Select DNS Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab >Select DNS Inspect Map

The Select DNS Map dialog box lets you select or create a new DNS map. A DNS map lets you change the configuration values used for DNS application inspection. The Select DNS Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default DNS inspection map—Specifies to use the default DNS map.
- Select a DNS map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Enable Botnet traffic filter DNS snooping— Enables Botnet Traffic Filter snooping, which compares the domain name with those on the dynamic database or static database, and adds the name and IP address to the Botnet Traffic Filter DNS reverse lookup cache. This cache is then used by the Botnet Traffic Filter when connections are made to the suspicious address. We suggest that you enable DNS snooping only on interfaces where external DNS requests are going. Enabling DNS snooping on all UDP DNS traffic, including that going to an internal DNS server, creates unnecessary load on the ASA. For example, if the DNS server is on the outside interface, you should enable DNS inspection with snooping for all UDP DNS traffic on the outside interface.
- Add—Opens the Add Policy Map dialog box for the inspection.

DNS Class Map

The DNS Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > DNS

The DNS Class Map pane lets you configure DNS class maps for DNS inspection.

An inspection class map matches application traffic with criteria specific to the application. You then identify the class map in the inspect map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspect map is that you can create more complex match criteria and you can reuse class maps. The applications that support inspection class maps are DNS, FTP, H.323, HTTP, IM, and SIP.

Fields

- Name—Shows the DNS class map name.
- Match Conditions—Shows the type, match criterion, and value in the class map.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the DNS class map.
  - Value—Shows the value to match in the DNS class map.
- Description—Shows the description of the class map.
- Add—Adds match conditions for the DNS class map.
- Edit—Edits match conditions for the DNS class map.
- Delete—Deletes match conditions for the DNS class map.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	•	•	•	—

Add/Edit DNS Traffic Class Map

The Add/Edit DNS Traffic Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > DNS > Add/Edit DNS Traffic Class Map

The Add/Edit DNS Traffic Class Map dialog box lets you define a DNS class map.

Fields

- Name—Enter the name of the DNS class map, up to 40 characters in length.
- Description—Enter the description of the DNS class map.
- Add—Adds a DNS class map.
- Edit—Edits a DNS class map.

- Delete—Deletes a DNS class map.

Add/Edit DNS Match Criterion

The Add/Edit DNS Match Criterion dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > DNS > Add/Edit DNS Traffic Class Map > Add/Edit DNS Match Criterion

The Add/Edit DNS Match Criterion dialog box lets you define the match criterion and value for the DNS class map.

Fields

- Match Type—Specifies whether the class map includes traffic that matches the criterion, or traffic that does not match the criterion.

  For example, if No Match is selected on the string "example.com," then any traffic that contains "example.com" is excluded from the class map.

- Criterion—Specifies which criterion of DNS traffic to match.
  - Header Flag—Match a DNS flag in the header.
  - Type—Match a DNS query or resource record type.
  - Class—Match a DNS query or resource record class.
  - Question—Match a DNS question.
  - Resource Record—Match a DNS resource record.
  - Domain Name—Match a domain name from a DNS query or resource record.
- Header Flag Criterion Values—Specifies the value details for the DNS header flag match.
  - Match Option—Specifies either an exact match or match all bits (bit mask match).
  - Match Value—Specifies to match either the header flag name or the header flag value.

    Header Flag Name—Lets you select one or more header flag names to match, including AA (authoritative answer), QR (query), RA (recursion available), RD (recursion denied), TC (truncation) flag bits.

    Header Flag Value—Lets you enter an arbitrary 16-bit value in hex to match.
- Type Criterion Values—Specifies the value details for the DNS type match.
  - DNS Type Field Name—Lists the DNS types to select.

    A—IPv4 address

    NS—Authoritative name server

    CNAME—Canonical name

    SOA—Start of a zone of authority

    TSIG—Transaction signature

    IXFR—Incremental (zone) transfer

    AXFR—Full (zone) transfer
  - DNS Type Field Value—Specifies to match either a DNS type field value or a DNS type field range.

    Value—Lets you enter an arbitrary value between 0 and 65535 to match.

Range—Lets you enter a range match. Both values between 0 and 65535.

- Class Criterion Values—Specifies the value details for the DNS class match.
  - DNS Class Field Name—Specifies to match on internet, the DNS class field name.
  - DNS Class Field Value—Specifies to match either a DNS class field value or a DNS class field range.

    Value—Lets you enter an arbitrary value between 0 and 65535 to match.

    Range—Lets you enter a range match. Both values between 0 and 65535.
- Question Criterion Values—Specifies to match on the DNS question section.
- Resource Record Criterion Values—Specifies to match on the DNS resource record section.
  - Resource Record— Lists the sections to match.

    Additional—DNS additional resource record

    Answer—DNS answer resource record

    Authority—DNS authority resource record
- Domain Name Criterion Values—Specifies to match on the DNS domain name.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

DNS Inspect Map

The DNS Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > DNS

The DNS pane lets you view previously configured DNS application inspection maps. A DNS map lets you change the default configuration values used for DNS application inspection.

DNS application inspection supports DNS message controls that provide protection against DNS spoofing and cache poisoning. User configurable rules allow certain DNS types to be allowed, dropped, and/or logged, while others are blocked. Zone transfer can be restricted between servers with this function, for example.

The Recursion Desired and Recursion Available flags in the DNS header can be masked to protect a public server from attack if that server only supports a particular internal zone. In addition, DNS randomization can be enabled avoid spoofing and cache poisoning of servers that either do not support randomization, or utilize a weak pseudo random number generator. Limiting the domain names that can be queried also restricts the domain names which can be queried, which protects the public server further.

A configurable DNS mismatch alert can be used as notification if an excessive number of mismatching DNS responses are received, which could indicate a cache poisoning attack. In addition, a configurable check to enforce a Transaction Signature be attached to all DNS messages is also supported.

Fields

- DNS Inspect Maps—Table that lists the defined DNS inspect maps.

- Add—Configures a new DNS inspect map. To edit a DNS inspect map, choose the DNS entry in the DNS Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the DNS Inspect Maps table.
- Security Level—Select the security level (high, medium, or low).
  - Low—Default.

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: disabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: disabled

    TSIG resource record: not enforced
  - Medium

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: enabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: enabled

    TSIG resource record: not enforced
  - High

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: enabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: enabled

    TSIG resource record: enforced
- Customize—Opens the Add/Edit DNS Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Low.

Add/Edit DNS Policy Map (Security Level)

The Add/Edit DNS Policy Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > DNS > DNS Inspect Map > Basic View

The Add/Edit DNS Policy Map pane lets you configure the security level and additional settings for DNS application inspection maps.

Fields

- Name—When adding a DNS map, enter the name of the DNS map. When editing a DNS map, the name of the previously configured DNS map is shown.
- Description—Enter the description of the DNS map, up to 200 characters in length.
- Security Level—Select the security level (high, medium, or low).
  - Low—Default.

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: disabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: disabled

    TSIG resource record: not enforced
  - Medium

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: enabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: enabled

    TSIG resource record: not enforced
  - High

    DNS Guard: enabled

    NAT rewrite: enabled

    Protocol enforcement: enabled

    ID randomization: enabled

    Message length check: enabled

    Message length maximum: 512

    Mismatch rate logging: enabled

    TSIG resource record: enforced
  - Default Level—Sets the security level back to the default level of Low.
- Details—Shows the Protocol Conformance, Filtering, Mismatch Rate, and Inspection tabs to configure additional settings.

Add/Edit DNS Policy Map (Details)

The Add/Edit DNS Policy Map pane lets you configure the security level and additional settings for DNS application inspection maps

Fields

- Name—When adding a DNS map, enter the name of the DNS map. When editing a DNS map, the name of the previously configured DNS map is shown.
- Description—Enter the description of the DNS map, up to 200 characters in length.
- Security Level—Shows the security level to configure.
- Protocol Conformance—Tab that lets you configure the protocol conformance settings for DNS.
  - Enable DNS guard function—Performs a DNS query and response mismatch check using the identification field in the DNS header. One response per query is allowed to go through the security appliance.
  - Enable NAT re-write function—Enables IP address translation in the A record of the DNS response.
  - Enable protocol enforcement—Enables DNS message format check, including domain name, label length, compression, and looped pointer check.
  - Randomize the DNS identifier for DNS query— Randomizes the DNS identifier in the DNS query message.
  - Enforce TSIG resource record to be present in DNS message—Requires that a TSIG resource record be present in DNS transactions. Actions taken when TSIG is enforced:

    Drop packet—Drops the packet (logging can be either enabled or disabled).

    Log—Enables logging.
- Filtering—Tab that lets you configure the filtering settings for DNS.
  - Global Settings—Applies settings globally.

    Drop packets that exceed specified maximum length (global)—Drops packets that exceed maximum length in bytes.

    Maximum Packet Length—Enter maximum packet length in bytes.
  - Server Settings—Applies settings on the server only.

    Drop packets that exceed specified maximum length———Drops packets that exceed maximum length in bytes.

    Maximum Packet Length—Enter maximum packet length in bytes.

    Drop packets sent to server that exceed length indicated by the RR—Drops packets sent to the server that exceed the length indicated by the Resource Record.
  - Client Settings—Applies settings on the client only.

    Drop packets that exceed specified maximum length———Drops packets that exceed maximum length in bytes.

    Maximum Packet Length—Enter maximum packet length in bytes.

    Drop packets sent to client that exceed length indicated by the RR—Drops packets sent to the client that exceed the length indicated by the Resource Record.
- Mismatch Rate—Tab that lets you configure the ID mismatch rate for DNS.

  - Enable Logging when DNS ID mismatch rate exceeds specified rate—Reports excessive instances of DNS identifier mismatches.

    Mismatch Instance Threshold—Enter the maximum number of mismatch instances before a system message log is sent.

    Time Interval—Enter the time period to monitor (in seconds).
- Inspections—Tab that shows you the DNS inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the DNS inspection.
  - Value—Shows the value to match in the DNS inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add DNS Inspect dialog box to add a DNS inspection.
  - Edit—Opens the Edit DNS Inspect dialog box to edit a DNS inspection.
  - Delete—Deletes a DNS inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

FTP Inspection

This section describes the FTP inspection engine. This section includes the following topics:

- FTP Inspection Overview, page 58-12
- Using Strict FTP, page 58-13
- Select FTP Map, page 58-14
- FTP Class Map, page 58-14
- Add/Edit FTP Traffic Class Map, page 58-15
- Add/Edit FTP Match Criterion, page 58-15
- FTP Inspect Map, page 58-16

FTP Inspection Overview

The FTP application inspection inspects the FTP sessions and performs four tasks:

- Prepares dynamic secondary data connection
- Tracks the FTP command-response sequence
- Generates an audit trail
- Translates the embedded IP address

FTP application inspection prepares secondary channels for FTP data transfer. Ports for these channels are negotiated through PORT or PASV commands. The channels are allocated in response to a file upload, a file download, or a directory listing event.

Note If you disable FTP inspection engines with the **no inspect ftp** command, outbound users can start connections only in passive mode, and all inbound FTP is disabled.

Using Strict FTP

Using strict FTP increases the security of protected networks by preventing web browsers from sending embedded commands in FTP requests. To enable strict FTP, click the **Configure** button next to FTP on the Configuration > Firewall > Service Policy Rules > Edit Service Policy Rule > Rule Actions > Protocol Inspection tab.

After you enable the **strict** option on an interface, FTP inspection enforces the following behavior:

- An FTP command must be acknowledged before the ASA allows a new command.
- The ASA drops connections that send embedded commands.
- The 227 and PORT commands are checked to ensure they do not appear in an error string.

Caution Using the **strict** option may cause the failure of FTP clients that are not strictly compliant with FTP RFCs.

If the **strict** option is enabled, each FTP command and response sequence is tracked for the following anomalous activity:

- Truncated command—Number of commas in the PORT and PASV reply command is checked to see if it is five. If it is not five, then the PORT command is assumed to be truncated and the TCP connection is closed.
- Incorrect command—Checks the FTP command to see if it ends with <CR><LF> characters, as required by the RFC. If it does not, the connection is closed.
- Size of RETR and STOR commands—These are checked against a fixed constant. If the size is greater, then an error message is logged and the connection is closed.
- Command spoofing—The PORT command should always be sent from the client. The TCP connection is denied if a PORT command is sent from the server.
- Reply spoofing—PASV reply command (227) should always be sent from the server. The TCP connection is denied if a PASV reply command is sent from the client. This prevents the security hole when the user executes “227 xxxxx a1, a2, a3, a4, p1, p2.”
- TCP stream editing—The ASA closes the connection if it detects TCP stream editing.
- Invalid port negotiation—The negotiated dynamic port value is checked to see if it is less than 1024. As port numbers in the range from 1 to 1024 are reserved for well-known connections, if the negotiated port falls in this range, then the TCP connection is freed.
- Command pipelining—The number of characters present after the port numbers in the PORT and PASV reply command is cross checked with a constant value of 8. If it is more than 8, then the TCP connection is closed.
- The ASA replaces the FTP server response to the SYST command with a series of Xs. to prevent the server from revealing its system type to FTP clients. To override this default behavior, use the **no mask-syst-reply** command in the FTP map.

Select FTP Map

The Select FTP Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select FTP Map

The Select FTP Map dialog box lets you enable strict FTP application inspection, select an FTP map, or create a new FTP map. An FTP map lets you change the configuration values used for FTP application inspection.The Select FTP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- FTP Strict (prevent web browsers from sending embedded commands in FTP requests)—Enables strict FTP application inspection, which causes the ASA to drop the connection when an embedded command is included in an FTP request.
- Use the default FTP inspection map—Specifies to use the default FTP map.
- Select an FTP map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

FTP Class Map

The FTP Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > FTP

The FTP Class Map pane lets you configure FTP class maps for FTP inspection.

An inspection class map matches application traffic with criteria specific to the application. You then identify the class map in the inspect map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspect map is that you can create more complex match criteria and you can reuse class maps. The applications that support inspection class maps are DNS, FTP, H.323, HTTP, IM, and SIP.

Fields

- Name—Shows the FTP class map name.
- Match Conditions—Shows the type, match criterion, and value in the class map.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the FTP class map.
  - Value—Shows the value to match in the FTP class map.
- Description—Shows the description of the class map.
- Add—Adds an FTP class map.
- Edit—Edits an FTP class map.
- Delete—Deletes an FTP class map.

Add/Edit FTP Traffic Class Map

The Add/Edit FTP Traffic Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > FTP > Add/Edit FTP Traffic Class Map

The Add/Edit FTP Traffic Class Map dialog box lets you define a FTP class map.

Fields

- Name—Enter the name of the FTP class map, up to 40 characters in length.
- Description—Enter the description of the FTP class map.
- Add—Adds an FTP class map.
- Edit—Edits an FTP class map.
- Delete—Deletes an FTP class map.

Add/Edit FTP Match Criterion

The Add/Edit FTP Match Criterion dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > FTP > Add/Edit FTP Traffic Class Map > Add/Edit FTP Match Criterion

The Add/Edit FTP Match Criterion dialog box lets you define the match criterion and value for the FTP class map.

Fields

- Match Type—Specifies whether the class map includes traffic that matches the criterion, or traffic that does not match the criterion.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of FTP traffic to match.
  - Request-Command—Match an FTP request command.
  - File Name—Match a filename for FTP transfer.
  - File Type—Match a file type for FTP transfer.
  - Server—Match an FTP server.
  - User Name—Match an FTP user.
- Request-Command Criterion Values—Specifies the value details for the FTP request command match.
  - Request Command—Lets you select one or more request commands to match.

    APPE—Append to a file.

    CDUP—Change to the parent of the current directory.

    DELE—Delete a file at the server site.

    GET—FTP client command for the retr (retrieve a file) command.

    HELP—Help information from the server.

    MKD—Create a directory.

PUT—FTP client command for the stor (store a file) command.

RMD—Remove a directory.

RNFR—Rename from.

RNTO—Rename to.

SITE—Specify a server specific command.

STOU—Store a file with a unique name.

- File Name Criterion Values—Specifies to match on the FTP transfer filename.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- File Type Criterion Values—Specifies to match on the FTP transfer file type.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Server Criterion Values—Specifies to match on the FTP server.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- User Name Criterion Values—Specifies to match on the FTP user.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

FTP Inspect Map

The FTP Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > FTP

The FTP pane lets you view previously configured FTP application inspection maps. An FTP map lets you change the default configuration values used for FTP application inspection.

FTP command filtering and security checks are provided using strict FTP inspection for improved security and control. Protocol conformance includes packet length checks, delimiters and packet format checks, command terminator checks, and command validation.

Blocking FTP based on user values is also supported so that it is possible for FTP sites to post files for download, but restrict access to certain users. You can block FTP connections based on file type, server name, and other attributes. System message logs are generated if an FTP connection is denied after inspection.

Fields

- FTP Inspect Maps—Table that lists the defined FTP inspect maps.
- Add—Configures a new FTP inspect map. To edit an FTP inspect map, choose the FTP entry in the FTP Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the FTP Inspect Maps table.
- Security Level—Select the security level (medium or low).
  - Low

    Mask Banner Disabled

    Mask Reply Disabled
  - Medium—Default.

    Mask Banner Enabled

    Mask Reply Enabled
  - File Type Filtering—Opens the Type Filtering dialog box to configure file type filters.
  - Customize—Opens the Add/Edit FTP Policy Map dialog box for additional settings.
  - Default Level—Sets the security level back to the default level of Medium.

File Type Filtering

The File Type Filtering dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > FTP > MIME File Type Filtering

The File Type Filtering dialog box lets you configure the settings for a file type filter.

Fields

- Match Type—Shows the match type, which can be a positive or negative match.
- Criterion—Shows the criterion of the inspection.
- Value—Shows the value to match in the inspection.
- Action—Shows the action if the match condition is met.
- Log—Shows the log state.
- Add—Opens the Add File Type Filter dialog box to add a file type filter.
- Edit—Opens the Edit File Type Filter dialog box to edit a file type filter.
- Delete—Deletes a file type filter.

- Move Up—Moves an entry up in the list.
- Move Down—Moves an entry down in the list.

Add/Edit FTP Policy Map (Security Level)

The Add/Edit FTP Policy Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > FTP > FTP Inspect Map > Basic View

The Add/Edit FTP Policy Map pane lets you configure the security level and additional settings for FTP application inspection maps.

Fields

- Name—When adding an FTP map, enter the name of the FTP map. When editing an FTP map, the name of the previously configured FTP map is shown.
- Description—Enter the description of the FTP map, up to 200 characters in length.
- Security Level—Select the security level (medium or low).
  - Low

    Mask Banner Disabled

    Mask Reply Disabled
  - Medium—Default.

    Mask Banner Enabled

    Mask Reply Enabled
  - File Type Filtering—Opens the Type Filtering dialog box to configure file type filters.
  - Default Level—Sets the security level back to the default level of Medium.
- Details—Shows the Parameters and Inspections tabs to configure additional settings.

Add/Edit FTP Policy Map (Details)

The Add/Edit FTP Policy Map (Details) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > FTP > FTP Inspect Map > Advanced View

The Add/Edit FTP Policy Map pane lets you configure the security level and additional settings for FTP application inspection maps.

Fields

- Name—When adding an FTP map, enter the name of the FTP map. When editing an FTP map, the name of the previously configured FTP map is shown.
- Description—Enter the description of the FTP map, up to 200 characters in length.
- Security Level—Shows the security level and file type filtering settings to configure.
- Parameters—Tab that lets you configure the parameters for the FTP inspect map.
  - Mask greeting banner from the server—Masks the greeting banner from the FTP server to prevent the client from discovering server information.

  - Mask reply to SYST command—Masks the reply to the syst command to prevent the client from discovering server information.
- Inspections—Tab that shows you the FTP inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the FTP inspection.
  - Value—Shows the value to match in the FTP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add FTP Inspect dialog box to add an FTP inspection.
  - Edit—Opens the Edit FTP Inspect dialog box to edit an FTP inspection.
  - Delete—Deletes an FTP inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit FTP Map

The Add/Edit FTP Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > FTP > FTP Inspect Map > Advanced View > Add/Edit FTP Inspect

The Add/Edit FTP Inspect dialog box lets you define the match criterion and value for the FTP inspect map.

Fields

- Single Match—Specifies that the FTP inspect has only one match statement.
- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of FTP traffic to match.
  - Request Command—Match an FTP request command.
  - File Name—Match a filename for FTP transfer.
  - File Type—Match a file type for FTP transfer.
  - Server—Match an FTP server.
  - User Name—Match an FTP user.
- Request Command Criterion Values—Specifies the value details for FTP request command match.
  - Request Command:

    APPE—Command that appends to a file.

    CDUP—Command that changes to the parent directory of the current working directory.

    DELE—Command that deletes a file.

    GET—Command that gets a file.

    HELP—Command that provides help information.

MKD—Command that creates a directory.

PUT—Command that sends a file.

RMD—Command that deletes a directory.

RNFR—Command that specifies rename-from filename.

RNTO—Command that specifies rename-to filename.

SITE—Commands that are specific to the server system. Usually used for remote administration.

STOU—Command that stores a file using a unique filename.

- File Name Criterion Values—Specifies the value details for FTP filename match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- File Type Criterion Values—Specifies the value details for FTP file type match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Server Criterion Values—Specifies the value details for FTP server match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- User Name Criterion Values—Specifies the value details for FTP user name match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Multiple Matches—Specifies multiple matches for the FTP inspection.
  - FTP Traffic Class—Specifies the FTP traffic class match.
  - Manage—Opens the Manage FTP Class Maps dialog box to add, edit, or delete FTP Class Maps.

- Action—Reset.
- Log—Enable or disable.

Verifying and Monitoring FTP Inspection

FTP application inspection generates the following log messages:

- An Audit record 303002 is generated for each file that is retrieved or uploaded.
- The FTP command is checked to see if it is RETR or STOR and the retrieve and store commands are logged.
- The username is obtained by looking up a table providing the IP address.
- The username, source IP address, destination IP address, NAT address, and the file operation are logged.
- Audit record 201005 is generated if the secondary dynamic channel preparation failed due to memory shortage.

In conjunction with NAT, the FTP application inspection translates the IP address within the application payload. This is described in detail in RFC 959.

HTTP Inspection

This section describes the HTTP inspection engine. This section includes the following topics:

- HTTP Inspection Overview, page 58-21
- Select HTTP Map, page 58-22
- HTTP Class Map, page 58-22
- Add/Edit HTTP Traffic Class Map, page 58-23
- Add/Edit HTTP Match Criterion, page 58-23
- HTTP Inspect Map, page 58-27
- “URI Filtering” section on page 58-28
- “Add/Edit HTTP Policy Map (Security Level)” section on page 58-28
- “Add/Edit HTTP Policy Map (Details)” section on page 58-29
- “Add/Edit HTTP Map” section on page 58-30

HTTP Inspection Overview

Use the HTTP inspection engine to protect against specific attacks and other threats that are associated with HTTP traffic. HTTP inspection performs several functions:

- Enhanced HTTP inspection
- URL screening through N2H2 or Websense

  See Information About URL Filtering, page 79-2 for information.
- Java and ActiveX filtering

The latter two features are configured in conjunction with Filter rules.

The enhanced HTTP inspection feature, which is also known as an application firewall and is available when you configure an HTTP map, can help prevent attackers from using HTTP messages for circumventing network security policy. It verifies the following for all HTTP messages:

- Conformance to RFC 2616
- Use of RFC-defined methods only.
- Compliance with the additional criteria.

Select HTTP Map

The Select HTTP Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select HTTP Map

The Select HTTP Map dialog box lets you select or create a new HTTP map. An HTTP map lets you change the configuration values used for HTTP application inspection. The Select HTTP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default HTTP inspection map—Specifies to use the default HTTP map.
- Select an HTTP map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

HTTP Class Map

The HTTP Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > HTTP

The HTTP Class Map pane lets you configure HTTP class maps for HTTP inspection.

An inspection class map matches application traffic with criteria specific to the application. You then identify the class map in the inspect map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspect map is that you can create more complex match criteria and you can reuse class maps. The applications that support inspection class maps are DNS, FTP, H.323, HTTP, IM, and SIP.

Fields

- Name—Shows the HTTP class map name.
- Match Conditions—Shows the type, match criterion, and value in the class map.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the HTTP class map.
  - Value—Shows the value to match in the HTTP class map.
- Description—Shows the description of the class map.
- Add—Adds an HTTP class map.
- Edit—Edits an HTTP class map.

- Delete—Deletes an HTTP class map.

Add/Edit HTTP Traffic Class Map

The Add/Edit HTTP Traffic Class Map dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > HTTP > Add/Edit HTTP Traffic Class Map

The Add/Edit HTTP Traffic Class Map dialog box lets you define a HTTP class map.

Fields

- Name—Enter the name of the HTTP class map, up to 40 characters in length.
- Description—Enter the description of the HTTP class map.
- Add—Adds an HTTP class map.
- Edit—Edits an HTTP class map.
- Delete—Deletes an HTTP class map.

Add/Edit HTTP Match Criterion

The Add/Edit HTTP Match Criterion dialog box is accessible as follows:

Configuration > Global Objects > Class Maps > HTTP > Add/Edit HTTP Traffic Class Map > Add/Edit HTTP Match Criterion

The Add/Edit HTTP Match Criterion dialog box lets you define the match criterion and value for the HTTP class map.

Fields

- Match Type—Specifies whether the class map includes traffic that matches the criterion, or traffic that does not match the criterion.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.

- Criterion—Specifies which criterion of HTTP traffic to match.
  - Request/Response Content Type Mismatch—Specifies that the content type in the response must match one of the MIME types in the accept field of the request.
  - Request Arguments—Applies the regular expression match to the arguments of the request.

    Regular Expression—Lists the defined regular expressions to match.

    Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

    Regular Expression Class—Lists the defined regular expression classes to match.

    Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
  - Request Body Length—Applies the regular expression match to the body of the request with field length greater than the bytes specified.

    Greater Than Length—Enter a field length value in bytes that request field lengths will be matched against.

- Request Body—Applies the regular expression match to the body of the request.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request Header Field Count—Applies the regular expression match to the header of the request with a maximum number of header fields.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Count—Enter the maximum number of header fields.

- Request Header Field Length—Applies the regular expression match to the header of the request with field length greater than the bytes specified.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Length—Enter a field length value in bytes that request field lengths will be matched against.

- Request Header Field—Applies the regular expression match to the header of the request.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request Header Count—Applies the regular expression match to the header of the request with a maximum number of headers.

  Greater Than Count—Enter the maximum number of headers.

- Request Header Length—Applies the regular expression match to the header of the request with length greater than the bytes specified.

  Greater Than Length—Enter a header length value in bytes.

- Request Header non-ASCII—Matches non-ASCII characters in the header of the request.

- Request Method—Applies the regular expression match to the method of the request.

  Method—Specifies to match on a request method: bcopy, bdelete, bmove, bpropfind, bproppatch, connect, copy, delete, edit, get, getattribute, getattributenames, getproperties, head, index, lock, mkcol, mkdir, move, notify, options, poll, post, propfind, proppatch, put, revadd, revlabel, revlog, revnum, save, search, setattribute, startrev, stoprev, subscribe, trace, unedit, unlock, unsubscribe.

  Regular Expression—Specifies to match on a regular expression.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request URI Length—Applies the regular expression match to the URI of the request with length greater than the bytes specified.

  Greater Than Length—Enter a URI length value in bytes.

- Request URI—Applies the regular expression match to the URI of the request.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Response Body—Applies the regex match to the body of the response.

  ActiveX—Specifies to match on ActiveX.

  Java Applet—Specifies to match on a Java Applet.

  Regular Expression—Specifies to match on a regular expression.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Response Body Length—Applies the regular expression match to the body of the response with field length greater than the bytes specified.

Greater Than Length—Enter a field length value in bytes that response field lengths will be matched against.

- Response Header Field Count—Applies the regular expression match to the header of the response with a maximum number of header fields.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Count—Enter the maximum number of header fields.

- Response Header Field Length—Applies the regular expression match to the header of the response with field length greater than the bytes specified.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Length—Enter a field length value in bytes that response field lengths will be matched against.

- Response Header Field—Applies the regular expression match to the header of the response.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Response Header Count—Applies the regular expression match to the header of the response with a maximum number of headers.

  Greater Than Count—Enter the maximum number of headers.

- Response Header Length—Applies the regular expression match to the header of the response with length greater than the bytes specified.

  Greater Than Length—Enter a header length value in bytes.

- Response Header non-ASCII—Matches non-ASCII characters in the header of the response.

- Response Status Line—Applies the regular expression match to the status line.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

HTTP Inspect Map

The HTTP Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > HTTP

The HTTP pane lets you view previously configured HTTP application inspection maps. An HTTP map lets you change the default configuration values used for HTTP application inspection.

HTTP application inspection scans HTTP headers and body, and performs various checks on the data. These checks prevent various HTTP constructs, content types, and tunneling and messaging protocols from traversing the security appliance.

HTTP application inspection can block tunneled applications and non-ASCII characters in HTTP requests and responses, preventing malicious content from reaching the web server. Size limiting of various elements in HTTP request and response headers, URL blocking, and HTTP server header type spoofing are also supported.

Fields

- HTTP Inspect Maps—Table that lists the defined HTTP inspect maps.
- Add—Configures a new HTTP inspect map. To edit an HTTP inspect map, choose the HTTP entry in the HTTP Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the HTTP Inspect Maps table.
- Security Level—Select the security level (low, medium, or high).
  - Low—Default.

    Protocol violation action: Drop connection

    Drop connections for unsafe methods: Disabled

    Drop connections for requests with non-ASCII headers: Disabled

    URI filtering: Not configured

    Advanced inspections: Not configured
  - Medium

    Protocol violation action: Drop connection

    Drop connections for unsafe methods: Allow only GET, HEAD, and POST

    Drop connections for requests with non-ASCII headers: Disabled

    URI filtering: Not configured

    Advanced inspections: Not configured
  - High

Protocol violation action: Drop connection and log

Drop connections for unsafe methods: Allow only GET and HEAD.

Drop connections for requests with non-ASCII headers: Enabled

URI filtering: Not configured

Advanced inspections: Not configured

- URI Filtering—Opens the URI Filtering dialog box to configure URI filters.
- Customize—Opens the Edit HTTP Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Medium.

URI Filtering

The URI Filtering dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > HTTP > URI Filtering

The URI Filtering dialog box lets you configure the settings for an URI filter.

Fields

- Match Type—Shows the match type, which can be a positive or negative match.
- Criterion—Shows the criterion of the inspection.
- Value—Shows the value to match in the inspection.
- Action—Shows the action if the match condition is met.
- Log—Shows the log state.
- Add—Opens the Add URI Filtering dialog box to add a URI filter.
- Edit—Opens the Edit URI Filtering dialog box to edit a URI filter.
- Delete—Deletes an URI filter.
- Move Up—Moves an entry up in the list.
- Move Down—Moves an entry down in the list.

Add/Edit HTTP Policy Map (Security Level)

The Add/Edit HTTP Policy Map (Security Level) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > HTTP > HTTP Inspect Map > Basic View

The Add/Edit HTTP Policy Map pane lets you configure the security level and additional settings for HTTP application inspection maps.

Fields

- Name—When adding an HTTP map, enter the name of the HTTP map. When editing an HTTP map, the name of the previously configured HTTP map is shown.
- Description—Enter the description of the HTTP map, up to 200 characters in length.
- Security Level—Select the security level (low, medium, or high).
  - Low—Default.

Protocol violation action: Drop connection

Drop connections for unsafe methods: Disabled

Drop connections for requests with non-ASCII headers: Disabled

URI filtering: Not configured

Advanced inspections: Not configured

- Medium

  Protocol violation action: Drop connection

  Drop connections for unsafe methods: Allow only GET, HEAD, and POST

  Drop connections for requests with non-ASCII headers: Disabled

  URI filtering: Not configured

  Advanced inspections: Not configured

- High

  Protocol violation action: Drop connection and log

  Drop connections for unsafe methods: Allow only GET and HEAD.

  Drop connections for requests with non-ASCII headers: Enabled

  URI filtering: Not configured

  Advanced inspections: Not configured

- URI Filtering—Opens the URI Filtering dialog box which lets you configure the settings for an URI filter.
- Default Level—Sets the security level back to the default.

- Details—Shows the Parameters and Inspections tabs to configure additional settings.

Add/Edit HTTP Policy Map (Details)

The Add/Edit HTTP Policy Map (Details) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > HTTP > HTTP Inspect Map > Advanced View

The Add/Edit HTTP Policy Map pane lets you configure the security level and additional settings for HTTP application inspection maps.

Fields

- Name—When adding an HTTP map, enter the name of the HTTP map. When editing an HTTP map, the name of the previously configured HTTP map is shown.
- Description—Enter the description of the HTTP map, up to 200 characters in length.
- Security Level—Shows the security level and URI filtering settings to configure.
- Parameters—Tab that lets you configure the parameters for the HTTP inspect map.
  - Check for protocol violations—Checks for HTTP protocol violations.

    Action—Drop Connection, Reset, Log.

    Log—Enable or disable.
  - Spoof server string—Replaces the server HTTP header value with the specified string.

Spoof String—Enter a string to substitute for the server header field. Maximum is 82 characters.

- Body Match Maximum—The maximum number of characters in the body of an HTTP message that should be searched in a body match. Default is 200 bytes. A large number will have a significant impact on performance.

- Inspections—Tab that shows you the HTTP inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the HTTP inspection.
  - Value—Shows the value to match in the HTTP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add HTTP Inspect dialog box to add an HTTP inspection.
  - Edit—Opens the Edit HTTP Inspect dialog box to edit an HTTP inspection.
  - Delete—Deletes an HTTP inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit HTTP Map

The Add/Edit HTTP Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > HTTP > HTTP Inspect Map > Advanced View > Add/Edit HTTP Inspect

The Add/Edit HTTP Inspect dialog box lets you define the match criterion and value for the HTTP inspect map.

Fields

- Single Match—Specifies that the HTTP inspect has only one match statement.
- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of HTTP traffic to match.
  - Request/Response Content Type Mismatch—Specifies that the content type in the response must match one of the MIME types in the accept field of the request.
  - Request Arguments—Applies the regular expression match to the arguments of the request.

    Regular Expression—Lists the defined regular expressions to match.

    Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

    Regular Expression Class—Lists the defined regular expression classes to match.

    Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
  - Request Body Length—Applies the regular expression match to the body of the request with field length greater than the bytes specified.

Greater Than Length—Enter a field length value in bytes that request field lengths will be matched against.

- Request Body—Applies the regular expression match to the body of the request.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request Header Field Count—Applies the regular expression match to the header of the request with a maximum number of header fields.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Count—Enter the maximum number of header fields.

- Request Header Field Length—Applies the regular expression match to the header of the request with field length greater than the bytes specified.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Length—Enter a field length value in bytes that request field lengths will be matched against.

- Request Header Field—Applies the regular expression match to the header of the request.

  Predefined—Specifies the request header fields: accept, accept-charset, accept-encoding, accept-language, allow, authorization, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, cookie, date, expect, expires, from, host, if-match, if-modified-since, if-none-match, if-range, if-unmodified-since, last-modified, max-forwards, pragma, proxy-authorization, range, referer, te, trailer, transfer-encoding, upgrade, user-agent, via, warning.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request Header Count—Applies the regular expression match to the header of the request with a maximum number of headers.

  Greater Than Count—Enter the maximum number of headers.

- Request Header Length—Applies the regular expression match to the header of the request with length greater than the bytes specified.

  Greater Than Length—Enter a header length value in bytes.

- Request Header non-ASCII—Matches non-ASCII characters in the header of the request.

- Request Method—Applies the regular expression match to the method of the request.

  Method—Specifies to match on a request method: bcopy, bdelete, bmove, bpropfind, bproppatch, connect, copy, delete, edit, get, getattribute, getattributenames, getproperties, head, index, lock, mkcol, mkdir, move, notify, options, poll, post, propfind, proppatch, put, revadd, revlabel, revlog, revnum, save, search, setattribute, startrev, stoprev, subscribe, trace, unedit, unlock, unsubscribe.

  Regular Expression—Specifies to match on a regular expression.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Request URI Length—Applies the regular expression match to the URI of the request with length greater than the bytes specified.

  Greater Than Length—Enter a URI length value in bytes.

- Request URI—Applies the regular expression match to the URI of the request.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Response Body—Applies the regex match to the body of the response.

  ActiveX—Specifies to match on ActiveX.

  Java Applet—Specifies to match on a Java Applet.

  Regular Expression—Specifies to match on a regular expression.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

– Response Body Length—Applies the regular expression match to the body of the response with field length greater than the bytes specified.

  Greater Than Length—Enter a field length value in bytes that response field lengths will be matched against.

– Response Header Field Count—Applies the regular expression match to the header of the response with a maximum number of header fields.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Count—Enter the maximum number of header fields.

– Response Header Field Length—Applies the regular expression match to the header of the response with field length greater than the bytes specified.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Greater Than Length—Enter a field length value in bytes that response field lengths will be matched against.

– Response Header Field—Applies the regular expression match to the header of the response.

  Predefined—Specifies the response header fields: accept-ranges, age, allow, cache-control, connection, content-encoding, content-language, content-length, content-location, content-md5, content-range, content-type, date, etag, expires, last-modified, location, pragma, proxy-authenticate, retry-after, server, set-cookie, trailer, transfer-encoding, upgrade, vary, via, warning, www-authenticate.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

– Response Header Count—Applies the regular expression match to the header of the response with a maximum number of headers.

  Greater Than Count—Enter the maximum number of headers.

– Response Header Length—Applies the regular expression match to the header of the response with length greater than the bytes specified.

Greater Than Length—Enter a header length value in bytes.

- Response Header non-ASCII—Matches non-ASCII characters in the header of the response.
- Response Status Line—Applies the regular expression match to the status line.

  Regular Expression—Lists the defined regular expressions to match.

  Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  Regular Expression Class—Lists the defined regular expression classes to match.

  Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Multiple Matches—Specifies multiple matches for the HTTP inspection.
  - H323 Traffic Class—Specifies the HTTP traffic class match.
  - Manage—Opens the Manage HTTP Class Maps dialog box to add, edit, or delete HTTP Class Maps.
- Action—Drop connection, reset, or log.
- Log—Enable or disable.

ICMP Inspection

The ICMP inspection engine allows ICMP traffic to have a "session" so it can be inspected like TCP and UDP traffic. Without the ICMP inspection engine, we recommend that you do not allow ICMP through the ASA in an access list. Without stateful inspection, ICMP can be used to attack your network. The ICMP inspection engine ensures that there is only one response for each request, and that the sequence number is correct.

ICMP Error Inspection

When this feature is enabled, the ASA creates translation sessions for intermediate hops that send ICMP error messages, based on the NAT configuration. The ASA overwrites the packet with the translated IP addresses.

When disabled, the ASA does not create translation sessions for intermediate nodes that generate ICMP error messages. ICMP error messages generated by the intermediate nodes between the inside host and the ASA reach the outside host without consuming any additional NAT resource. This is undesirable when an outside host uses the traceroute command to trace the hops to the destination on the inside of the ASA. When the ASA does not translate the intermediate hops, all the intermediate hops appear with the mapped destination IP address.

The ICMP payload is scanned to retrieve the five-tuple from the original packet. Using the retrieved five-tuple, a lookup is performed to determine the original address of the client. The ICMP error inspection engine makes the following changes to the ICMP packet:

- In the IP Header, the mapped IP is changed to the real IP (Destination Address) and the IP checksum is modified.
- In the ICMP Header, the ICMP checksum is modified due to the changes in the ICMP packet.
- In the Payload, the following changes are made:
  - Original packet mapped IP is changed to the real IP

- Original packet mapped port is changed to the real Port
- Original packet IP checksum is recalculated

Instant Messaging Inspection

This section describes the IM inspection engine. This section includes the following topics:

- IM Inspection Overview, page 58-35
- Select IM Map, page 58-36

IM Inspection Overview

The IM inspect engine lets you apply fine grained controls on the IM application to control the network usage and stop leakage of confidential data, propagation of worms, and other threats to the corporate network.

Adding a Class Map for IM Inspection

Use the Add Service Policy Rule Wizard - Rule Actions dialog box to configure IP Options inspection.

This wizard is available from the Configuration > Firewall > Service Policy Rules > Add > Add Service Policy Rule Wizard - Rule Actions dialog box.

Step 1 Choose **Configuration > Firewall > Objects > Class Maps > Instant Messaging (IM)**. The table displaying the configured class maps for Instant Messaging Inspection appears.

Step 2 To add a new class map, click **Add**. The Add Instant Messaging (IM) Traffic Class Map dialog box appears.

Step 3 Enter a name for the class map.

Step 4 (Optional) Enter a description for the class map. The description can contain up to 200 characters.

Step 5 In the Match Option field, click an option for the class map:

- Match All—Specifies that traffic must match all criteria to match the class map. By default, the Match All option is selected.
- Match Any—Specifies that the traffic matches the class map if it matches at least one of the criteria.

Step 6 Click **Add** to add a match criteria for the class map. The Add Instant Messaging (IM) Match Criterion dialog box appears.

Step 7 In the Match Type field, click the Match or No Match radio button.

Step 8 In the Criterion drop-down list, select one of the following options and specify the criteria value. Depending on which option you select, the Value fields dynamically refresh to display the appropriate values for that criteria.

- Protocol—Select to match traffic of a specific IM protocol, such as Yahoo Messenger or MSN Messenger.
- Service—Select to match a specific IM service, such as chat, file-transfer, webcam, voice-chat, conference, or games.

- Version—Select to match the version of the IM message. In the Value fields, click the **Regular Expression** or **Regular Expression Class** option and select an expression from the drop-down list.

  See Configuring Regular Expressions, page 25-10.

- Client Login Name—Select to match the source login name of the IM message. In the Value fields, click the **Regular Expression** or **Regular Expression Class** option and select an expression from the drop-down list.

  See Configuring Regular Expressions, page 25-10.

- Client Peer Login Name—Select to match the destination login name of the IM message. In the Value fields, click the **Regular Expression** or **Regular Expression Class** option and select an expression from the drop-down list.

  See Configuring Regular Expressions, page 25-10.

- Source IP Address—Select to match the source IP address of the IM message. In the Value fields, enter the IP address and netmask of the message source.

- Destination IP Address—Select to match the destination IP address of the IM message. In the Value fields, enter the IP address and netmask of the message destination.

- Filename—Select to match the filename of the IM message. In the Value fields, click the **Regular Expression** or **Regular Expression Class** option and select an expression from the drop-down list.

  See Configuring Regular Expressions, page 25-10.

Step 9 Click **OK** to save the criteria. The Add Instant Messaging (IM) Match Criterion dialog box closes and the criteria appears in the Match Criterion table.

Step 10 Click **OK** to save the class map.

Select IM Map

The Select IM Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select IM Map

The Select IM Map dialog box lets you select or create a new IM map. An IM map lets you change the configuration values used for IM application inspection. The Select IM Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Add—Opens the Add Policy Map dialog box for the inspection.

IP Options Inspection

This section describes the IP Options inspection engine. This section includes the following topics:

- IP Options Inspection Overview, page 58-37
- Configuring IP Options Inspection, page 58-37
- Select IP Options Inspect Map, page 58-39
- IP Options Inspect Map, page 58-39
- Add/Edit IP Options Inspect Map, page 58-39

IP Options Inspection Overview

Each IP packet contains an IP header with the Options field. The Options field, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for most common communications. In particular, IP Options include provisions for time stamps, security, and special routing. Use of IP Options is optional, and the field can contain zero, one, or more options.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the ASA. Configuring this inspection instructs the ASA to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

IP Options inspection can check for the following three IP options in a packet:

- End of Options List (EOOL) or IP Option 0—This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.
- No Operation (NOP) or IP Option 1—The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as "internal padding" to align the options on a 32-bit boundary.
- Router Alert (RTRALT) or IP Option 20—This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

Note IP Options inspection is included by default in the global inspection policy. Therefore, the ASA allows RSVP traffic that contains packets with the Router Alert option (option 20) when the ASA is in routed mode.

Dropping RSVP packets containing the Router Alert option can cause problems in VoIP implementations.

When you configure the ASA to clear the Router Alert option from IP headers, the IP header changes in the following ways:

- The Options field is padded so that the field ends on a 32 bit boundary.
- Internet header length (IHL) changes.
- The total length of the packet changes.
- The checksum is recomputed.

If an IP header contains additional options other than EOOL, NOP, or RTRALT, regardless of whether the ASA is configured to allow these options, the ASA will drop the packet.

Configuring IP Options Inspection

Use the Add Service Policy Rule Wizard - Rule Actions dialog box to configure IP Options inspection.

This wizard is available from the Configuration > Firewall > Service Policy Rules > Add > Add Service Policy Rule Wizard - Rule Actions dialog box.

Step 1 Open the Add Service Policy Rule Wizard by selecting **Configuration > Firewall > Service Policy Rules > Add**.

Perform the steps to complete the Service Policy, Traffic Classification Criteria, and Traffic Match - Destination Port pages of the wizard. See the "Adding a Service Policy Rule for Through Traffic" section on page 44-8.

The Add Service Policy Rule Wizard - Rule Actions dialog box opens.

Step 2 Check the **IP-Options** check box.

Step 3 Click **Configure**.

The Select IP Options Inspect Map dialog box opens.

Step 4 Perform one of the following:

- Click the **Use the default IP-Options inspection map** radio button to use the default IP Options map. The default map drops packets containing all the inspected IP options, namely End of Options List (EOOL), No Operation (NOP), and Router Alert (RTRALT).
- Click the **Select an IP-Options inspect map for fine control over inspection** radio button to select a defined application inspection map.
- Click Add to open the Add IP-Options Inspect Map dialog box and create a new inspection map.

Step 5 (Optional) If you clicked **Add** to create a new inspection map, define the following values for IP Options Inspection:

a. Enter a name for the inspection map.

b. Enter a description for the inspection map, up to 200 characters long.

c. From the Parameters area, select which IP options you want to pass through the ASA or clear and then pass through the ASA:

– Allow packets with the End of Options List (EOOL) option

This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.

– Allow packets with the No Operation (NOP) option

The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as "internal padding" to align the options on a 32-bit boundary.

– Allow packets with the Router Alert (RTRALT) option

This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

– Clear the option value from the packets

When an option is checked, the **Clear the option value from the packets** check box becomes available for that option. Select the **Clear the option value from the packets** check box to clear the option from the packet before allowing the packet through the ASA.

d. Click **OK**.

Step 6 Click **OK**.

Step 7 Click **Finish**.

Select IP Options Inspect Map

The Select IP Options Inspect Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select IM Map

The Select IP-Options Inspect Map dialog box lets you select or create a new IP Options inspection map. Use this inspection map to control whether the ASA drops, passes, or clears IP packets containing the following IP options—End of Options List, No Operations, and Router Alert.

Fields

- Use the default IP-Options inspection map—Specifies to use the default IP Options map. The default map drops packets containing all the inspected IP options, namely End of Options List (EOOL), No Operation (NOP), and Router Alert (RTRALT).
- Select an IP-Options map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add IP Options Inspect Map dialog box for the inspection.

IP Options Inspect Map

The IP Options Inspect Maps pane lets you view previously configured IP Options inspection maps. An IP Options inspection map lets you change the default configuration values used for IP Option inspection.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the security appliance. Configuring this inspection instructs the security appliance to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

In particular, you can control whether the security appliance drops, clears, or passes packets containing the Router Alert (RTRALT) option. Dropping RSVP packets containing the Router Alert option can cause problems in VoIP implementations. Therefore, you can create IP Options inspection maps to pass packets containing the RTRALT option.

Fields

IP Options Inspect Maps—Table that lists the defined IP Options inspect maps.

Add—Configures a new IP Options inspect map.

Edit—Edits an existing IP Options inspect map. To edit an IP Options inspect map, choose the entry in the table and click Edit.

Delete—Deletes the inspect map selected in the IP Options Inspect Maps table.

Add/Edit IP Options Inspect Map

The Add/Edit IP Options Inspect Map lets you configure the settings for IP Options inspection maps.

Fields

- Name—When adding an IP Options inspection map, enter the name of the map. When editing a map, the name of the previously configured map is shown.
- Description—Enter the description of the IP Options inspection map, up to 200 characters in length.

- Parameters—Select which IP options you want to pass through the ASA or clear and then pass through the ASA:
  - Allow packets with the End of Options List (EOOL) option

  This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.
  - Allow packets with the No Operation (NOP) option

  The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as "internal padding" to align the options on a 32-bit boundary.
  - Allow packets with the Router Alert (RTRALT) option

  This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.
  - Clear the option value from the packets

  When an option is checked, the **Clear the option value from the packets** check box becomes available for that option. Select the **Clear the option value from the packets** check box to clear the option from the packet before allowing the packet through the ASA.

IPsec Pass Through Inspection

This section describes the IPsec Pass Through inspection engine. This section includes the following topics:

- IPsec Pass Through Inspection Overview, page 58-40
- Select IPsec-Pass-Thru Map, page 58-41
- IPsec Pass Through Inspect Map, page 58-41
- Add/Edit IPsec Pass Thru Policy Map (Security Level), page 58-42
- Add/Edit IPsec Pass Thru Policy Map (Details), page 58-42

IPsec Pass Through Inspection Overview

Internet Protocol Security (IPsec) is a protocol suite for securing IP communications by authenticating and encrypting each IP packet of a data stream. IPsec also includes protocols for establishing mutual authentication between agents at the beginning of the session and negotiation of cryptographic keys to be used during the session. IPsec can be used to protect data flows between a pair of hosts (for example, computer users or servers), between a pair of security gateways (such as routers or firewalls), or between a security gateway and a host.

IPsec Pass Through application inspection provides convenient traversal of ESP (IP protocol 50) and AH (IP protocol 51) traffic associated with an IKE UDP port 500 connection. It avoids lengthy access list configuration to permit ESP and AH traffic and also provides security using timeout and max connections.

Specify IPsec Pass Through inspection parameters to identify a specific map to use for defining the parameters for the inspection. Configure a policy map for Specify IPsec Pass Through inspection to access the parameters configuration, which lets you specify the restrictions for ESP or AH traffic. You can set the per client max connections and the idle timeout in parameters configuration.

NAT and non-NAT traffic is permitted. However, PAT is not supported.

Select IPsec-Pass-Thru Map

The Select IPsec-Pass-Thru Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select IPsec-Pass-Thru Map

The Select IPsec-Pass-Thru dialog box lets you select or create a new IPsec map. An IPsec map lets you change the configuration values used for IPsec application inspection. The Select IPsec Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default IPsec inspection map—Specifies to use the default IPsec map.
- Select an IPsec map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

IPsec Pass Through Inspect Map

The IPsec Pass Through Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > IPsec Pass Through

The IPsec Pass Through pane lets you view previously configured IPsec Pass Through application inspection maps. An IPsec Pass Through map lets you change the default configuration values used for IPsec Pass Through application inspection. You can use an IPsec Pass Through map to permit certain flows without using an access list.

Fields

- IPsec Pass Through Inspect Maps—Table that lists the defined IPsec Pass Through inspect maps.
- Add—Configures a new IPsec Pass Through inspect map. To edit an IPsec Pass Through inspect map, select the IPsec Pass Through entry in the IPsec Pass Through Inspect Maps table and click Customize.
- Delete—Deletes the inspect map selected in the IPsec Pass Through Inspect Maps table.
- Security Level—Select the security level (high or low).
  - Low—Default.

    Maximum ESP flows per client: Unlimited.

    ESP idle timeout: 00:10:00.

    Maximum AH flows per client: Unlimited.

    AH idle timeout: 00:10:00.
  - High

Maximum ESP flows per client:10.

ESP idle timeout: 00:00:30.

Maximum AH flows per client: 10.

AH idle timeout: 00:00:30.

- Customize—Opens the Add/Edit IPsec Pass Thru Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Low.

Add/Edit IPsec Pass Thru Policy Map (Security Level)

The Add/Edit IPsec Pass Thru Policy Map (Security Level) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > IPsec Pass Through>
IPsec Pass Through Inspect Map > Basic View

The Add/Edit IPsec Pass Thru Policy Map pane lets you configure the security level and additional settings for IPsec Pass Thru application inspection maps.

Fields

- Name—When adding an IPsec Pass Thru map, enter the name of the IPsec Pass Thru map. When editing an IPsec Pass Thru map, the name of the previously configured IPsec Pass Thru map is shown.
- Security Level—Select the security level (high or low).
  - Low—Default.

    Maximum ESP flows per client: Unlimited.

    ESP idle timeout: 00:10:00.

    Maximum AH flows per client: Unlimited.

    AH idle timeout: 00:10:00.
  - High

    Maximum ESP flows per client:10.

    ESP idle timeout: 00:00:30.

    Maximum AH flows per client: 10.

    AH idle timeout: 00:00:30.
  - Default Level—Sets the security level back to the default level of Low.
- Details—Shows additional parameter settings to configure.

Add/Edit IPsec Pass Thru Policy Map (Details)

The Add/Edit IPsec Pass Thru Policy Map (Details) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps >IPsec Pass Through >
IPsec Pass Through Inspect Map > Advanced View

The Add/Edit IPsec Pass Thru Policy Map pane lets you configure the security level and additional settings for IPsec Pass Thru application inspection maps.

Fields

- Name—When adding an IPsec Pass Thru map, enter the name of the IPsec Pass Thru map. When editing an IPsec Pass Thru map, the name of the previously configured IPsec Pass Thru map is shown.
- Description—Enter the description of the IPsec Pass Through map, up to 200 characters in length.
- Security Level—Shows the security level settings to configure.
- Parameters—Configures ESP and AH parameter settings.
  - Limit ESP flows per client—Limits ESP flows per client.

    Maximum—Specify maximum limit.
  - Apply ESP idle timeout—Applies ESP idle timeout.

    Timeout—Specify timeout.
  - Limit AH flows per client—Limits AH flows per client.

    Maximum—Specify maximum limit.
  - Apply AH idle timeout—Applies AH idle timeout.

    Timeout—Specify timeout.

IPv6 Inspection

You can configure IPv6 Inspection by using MPF rules to selectively block IPv6 traffic based on the extension header. IPv6 packets are subjected to an early security check. The ASA always passes hop-by-hop and destination option types of extension headers while blocking router header and no next header.

You can enable default IPv6 inspection or define IPv6 inspection. By defining an MPF policy map for IPv6 inspection you can configure the ASA to selectively drop IPv6 packets based on following types of extension headers found anywhere in the IPv6 packet:

- Hop-by-Hop Options
- Routing (Type 0)
- Fragment
- Destination Options
- Authentication
- Encapsulating Security Payload

In addition, default IPv6 inspection checks conformance to RFC 2460 for type and order of extension headers in IPv6 packets:

- IPv6 header
- Hop-by-Hop Options header (0)
- Destination Options header (60)
- Routing header (43)
- Fragment header (44)
- Authentication (51)
- Encapsulating Security Payload header(50)

- Destination Options header (60)
- No Next Header (59)

When a policy map is not configured for IPv6inspection or a configured policy map is not associated with an interface, the ASA drops packets with any mobility type and a routing-type IPv6 extension header that arrive at the interface.

When an IPv6 inspection policy map is created, the ASA automatically generates a configuration to drop packets that match header routing-type in the range 0-255.

Configuring an IPv6 Inspection Policy Map

You can configure a policy map for IPv6 inspection to handle IPv6 extension headers. The IPv6 policy map is applied to each classified IPv6 packet on the specified direction. Currently, only incoming IPv6 traffic is inspected.

Step 1 Choose **Configuration > Firewall > Objects > Inspect Maps > IPv6**. The Configure IPv6 Maps pane appears.

Step 2 Click **Add**. The Add IPv6 Inspection Map dialog box appears.

Step 3 Enter a name and description for the inspection map.

By default, the Enforcement tab is selected and the following options are selected:

- Permit only known extension headers
- Enforce extension header order

When **Permit only known extension headers** is selected, the ASA verifies the IPv6 extension header.

When **Enforce extension header order** is selected, the order of IPv6 extension headers as defined in the RFC 2460 Specification is enforced.

When these options are specified and an error is detected, the ASA drops the packet and logs the action.

Step 4 To configuring matching in the extension header, click the **Header Matches** tab.

Step 5 Click **Add** to add a match. The Add IPv6 Inspect dialog box appears.

Step 6 Select a criterion for the match.

When you select any of the following criteria, you can configure to the ASA to drop or log when an IPv6 packet arrives mathcing the criterion:

- Authentication (AH) header
- Destination Options header
- Encapsulating Security Payload (ESP) header
- Fragment header
- Hop-by-Hop Options header

When Routing header is selected and an IPv6 routing extension header is detected, the ASA takes the specified action when the routing type is matched or a number when the specified routing type range is matched.

When Header count is selected and an IPv6 routing extension header is detected, the ASA takes the specified action when number of IPv6 extension headers in the packet is more than the specified value.

When Routing header address count is selected, and an IPv6 routing extension header is detected, the ASA takes the specified action when the number of addresses in the type 0 routing header is more than the value you configure.

Step 7 Click **OK** to save the match criterion.

Step 8 Click **OK** to save the IPv6 inspect map.

NetBIOS Inspection

This section describes the IM inspection engine. This section includes the following topics:

- NetBIOS Inspection Overview, page 58-45
- Select NETBIOS Map, page 58-45
- "NetBIOS Inspect Map" section on page 58-45
- "Add/Edit NetBIOS Policy Map" section on page 58-46

NetBIOS Inspection Overview

NetBIOS inspection is enabled by default. The NetBios inspection engine translates IP addresses in the NetBios name service (NBNS) packets according to the ASA NAT configuration.

Select NETBIOS Map

The Select NETBIOS Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select NetBIOS Map

The Select NETBIOS Map dialog box lets you select or create a new NetBIOS map. A NetBIOS map lets you change the configuration values used for NetBIOS application inspection. The Select NetBIOS Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default IM inspection map—Specifies to use the default NetBIOS map.
- Select a NetBIOS map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

NetBIOS Inspect Map

The NetBIOS Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > NetBIOS

The NetBIOS pane lets you view previously configured NetBIOS application inspection maps. A NetBIOS map lets you change the default configuration values used for NetBIOS application inspection.

NetBIOS application inspection performs NAT for the embedded IP address in the NetBIOS name service packets and NetBIOS datagram services packets. It also enforces protocol conformance, checking the various count and length fields for consistency.

Fields

- NetBIOS Inspect Maps—Table that lists the defined NetBIOS inspect maps.
- Add—Configures a new NetBIOS inspect map.
- Edit—Edits the selected NetBIOS entry in the NetBIOS Inspect Maps table.
- Delete—Deletes the inspect map selected in the NetBIOS Inspect Maps table.

Add/Edit NetBIOS Policy Map

The Add/Edit NetBIOS Policy Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > NetBIOS > NetBIOS Inspect Map > View

The Add/Edit NetBIOS Policy Map pane lets you configure the protocol violation settings for NetBIOS application inspection maps.

Fields

- Name—When adding a NetBIOS map, enter the name of the NetBIOS map. When editing an NetBIOS map, the name of the previously configured NetBIOS map is shown.
- Description—Enter the description of the NetBIOS map, up to 200 characters in length.
- Check for protocol violations—Checks for protocol violations and executes specified action.
  - Action—Drop packet or log.
  - Log—Enable or disable.

PPTP Inspection

PPTP is a protocol for tunneling PPP traffic. A PPTP session is composed of one TCP channel and usually two PPTP GRE tunnels. The TCP channel is the control channel used for negotiating and managing the PPTP GRE tunnels. The GRE tunnels carries PPP sessions between the two hosts.

When enabled, PPTP application inspection inspects PPTP protocol packets and dynamically creates the GRE connections and xlates necessary to permit PPTP traffic. Only Version 1, as defined in RFC 2637, is supported.

PAT is only performed for the modified version of GRE [RFC 2637] when negotiated over the PPTP TCP control channel. Port Address Translation is *not* performed for the unmodified version of GRE [RFC 1701, RFC 1702].

Specifically, the ASA inspects the PPTP version announcements and the outgoing call request/response sequence. Only PPTP Version 1, as defined in RFC 2637, is inspected. Further inspection on the TCP control channel is disabled if the version announced by either side is not Version 1. In addition, the outgoing-call request and reply sequence are tracked. Connections and xlates are dynamic allocated as necessary to permit subsequent secondary GRE data traffic.

The PPTP inspection engine must be enabled for PPTP traffic to be translated by PAT. Additionally, PAT is only performed for a modified version of GRE (RFC2637) and only if it is negotiated over the PPTP TCP control channel. PAT is not performed for the unmodified version of GRE (RFC 1701 and RFC 1702).

As described in RFC 2637, the PPTP protocol is mainly used for the tunneling of PPP sessions initiated from a modem bank PAC (PPTP Access Concentrator) to the headend PNS (PPTP Network Server). When used this way, the PAC is the remote client and the PNS is the server.

However, when used for VPN by Windows, the interaction is inverted. The PNS is a remote single-user PC that initiates connection to the head-end PAC to gain access to a central network.

SMTP and Extended SMTP Inspection

This section describes the IM inspection engine. This section includes the following topics:

- SMTP and ESMTP Inspection Overview, page 58-47
- Select ESMTP Map, page 58-48
- ESMTP Inspect Map, page 58-48
- MIME File Type Filtering, page 58-49
- Add/Edit ESMTP Policy Map (Security Level), page 58-50
- Add/Edit ESMTP Policy Map (Details), page 58-51
- Add/Edit ESMTP Inspect, page 58-52

SMTP and ESMTP Inspection Overview

ESMTP application inspection provides improved protection against SMTP-based attacks by restricting the types of SMTP commands that can pass through the ASA and by adding monitoring capabilities.

ESMTP is an enhancement to the SMTP protocol and is similar is most respects to SMTP. For convenience, the term SMTP is used in this document to refer to both SMTP and ESMTP. The application inspection process for extended SMTP is similar to SMTP application inspection and includes support for SMTP sessions. Most commands used in an extended SMTP session are the same as those used in an SMTP session but an ESMTP session is considerably faster and offers more options related to reliability and security, such as delivery status notification.

Extended SMTP application inspection adds support for these extended SMTP commands, including AUTH, EHLO, ETRN, HELP, SAML, SEND, SOML, STARTTLS, and VRFY. Along with the support for seven RFC 821 commands (DATA, HELO, MAIL, NOOP, QUIT, RCPT, RSET), the ASA supports a total of fifteen SMTP commands.

Other extended SMTP commands, such as ATRN, ONEX, VERB, CHUNKING, and private extensions and are not supported. Unsupported commands are translated into Xs, which are rejected by the internal server. This results in a message such as “500 Command unknown: 'XXX'.” Incomplete commands are discarded.

The ESMTP inspection engine changes the characters in the server SMTP banner to asterisks except for the “2”, “0”, “0” characters. Carriage return (CR) and linefeed (LF) characters are ignored.

With SMTP inspection enabled, a Telnet session used for interactive SMTP may hang if the following rules are not observed: SMTP commands must be at least four characters in length; must be terminated with carriage return and line feed; and must wait for a response before issuing the next reply.

An SMTP server responds to client requests with numeric reply codes and optional human-readable strings. SMTP application inspection controls and reduces the commands that the user can use as well as the messages that the server returns. SMTP inspection performs three primary tasks:

- Restricts SMTP requests to seven basic SMTP commands and eight extended commands.
- Monitors the SMTP command-response sequence.
- Generates an audit trail—Audit record 108002 is generated when invalid character embedded in the mail address is replaced. For more information, see RFC 821.

SMTP inspection monitors the command and response sequence for the following anomalous signatures:

- Truncated commands.
- Incorrect command termination (not terminated with <CR><LR>).
- The MAIL and RCPT commands specify who are the sender and the receiver of the mail. Mail addresses are scanned for strange characters. The pipeline character (|) is deleted (changed to a blank space) and "<" ,">" are only allowed if they are used to define a mail address (">" must be preceded by "<").
- Unexpected transition by the SMTP server.
- For unknown commands, the ASA changes all the characters in the packet to X. In this case, the server generates an error code to the client. Because of the change in the packed, the TCP checksum has to be recalculated or adjusted.
- TCP stream editing.
- Command pipelining.

Select ESMTP Map

The Select ESMTP Map dialog box is accessible as follows:

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab >Select ESMTP Map

The Select ESMTP Map dialog box lets you select or create a new ESMTP map. An ESMTP map lets you change the configuration values used for ESMTP application inspection. The Select ESMTP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default ESMTP inspection map—Specifies to use the default ESMTP map.
- Select an ESMTP map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

ESMTP Inspect Map

The ESMTP Inspect Map dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > ESMTP

The ESMTP pane lets you view previously configured ESMTP application inspection maps. An ESMTP map lets you change the default configuration values used for ESMTP application inspection.

Since ESMTP traffic can be a main source of attack from spam, phising, malformed messages, buffer overflows, and buffer underflows, detailed packet inspection and control of ESMTP traffic are supported. Application security and protocol conformance enforce the sanity of the ESMTP message as well as detect several attacks, block senders and receivers, and block mail relay.

Fields

- ESMTP Inspect Maps—Table that lists the defined ESMTP inspect maps.
- Add—Configures a new ESMTP inspect map. To edit an ESMTP inspect map, choose the ESMTP entry in the ESMTP Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the ESMTP Inspect Maps table.
- Security Level—Select the security level (high, medium, or low).
  - Low—Default.

    Log if command line length is greater than 512

    Log if command recipient count is greater than 100

    Log if body line length is greater than 1000

    Log if sender address length is greater than 320

    Log if MIME file name length is greater than 255
  - Medium

    Obfuscate Server Banner

    Drop Connections if command line length is greater than 512

    Drop Connections if command recipient count is greater than 100

    Drop Connections if body line length is greater than 1000

    Drop Connections if sender address length is greater than 320

    Drop Connections if MIME file name length is greater than 255
  - High

    Obfuscate Server Banner

    Drop Connections if command line length is greater than 512

    Drop Connections if command recipient count is greater than 100

    Drop Connections if body line length is greater than 1000

    Drop Connections and log if sender address length is greater than 320

    Drop Connections and log if MIME file name length is greater than 255
  - MIME File Type Filtering—Opens the MIME Type Filtering dialog box to configure MIME file type filters.
  - Customize—Opens the Add/Edit ESMTP Policy Map dialog box for additional settings.
  - Default Level—Sets the security level back to the default level of Low.

MIME File Type Filtering

The MIME File Type Filtering dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > ESMTP > MIME File Type Filtering

The MIME File Type Filtering dialog box lets you configure the settings for a MIME file type filter.

Fields

- Match Type—Shows the match type, which can be a positive or negative match.
- Criterion—Shows the criterion of the inspection.
- Value—Shows the value to match in the inspection.
- Action—Shows the action if the match condition is met.
- Log—Shows the log state.
- Add—Opens the Add MIME File Type Filter dialog box to add a MIME file type filter.
- Edit—Opens the Edit MIME File Type Filter dialog box to edit a MIME file type filter.
- Delete—Deletes a MIME file type filter.
- Move Up—Moves an entry up in the list.
- Move Down—Moves an entry down in the list.

Add/Edit ESMTP Policy Map (Security Level)

The Add/Edit ESMTP Policy Map (Security Level) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > ESMTP > ESMTP Inspect Map > Basic View

The Add/Edit ESMTP Policy Map pane lets you configure the security level and additional settings for ESMTP application inspection maps.

Fields

- Name—When adding an ESMTP map, enter the name of the ESMTP map. When editing an ESMTP map, the name of the previously configured ESMTPS map is shown.
- Description—Enter the description of the ESMTP map, up to 200 characters in length.
- Security Level—Select the security level (high, medium, or low).
  - Low—Default.

    Log if command line length is greater than 512

    Log if command recipient count is greater than 100

    Log if body line length is greater than 1000

    Log if sender address length is greater than 320

    Log if MIME file name length is greater than 255
  - Medium

    Obfuscate Server Banner

    Drop Connections if command line length is greater than 512

    Drop Connections if command recipient count is greater than 100

    Drop Connections if body line length is greater than 1000

    Drop Connections if sender address length is greater than 320

    Drop Connections if MIME file name length is greater than 255
  - High

Obfuscate Server Banner

Drop Connections if command line length is greater than 512

Drop Connections if command recipient count is greater than 100

Drop Connections if body line length is greater than 1000

Drop Connections and log if sender address length is greater than 320

Drop Connections and log if MIME file name length is greater than 255

  - MIME File Type Filtering—Opens the MIME Type Filtering dialog box to configure MIME file type filters.
  - Default Level—Sets the security level back to the default level of Low.
- Details—Shows the Parameters and Inspections tabs to configure additional settings.

Add/Edit ESMTP Policy Map (Details)

The Add/Edit ESMTP Policy Map (Details) dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > ESMTP > ESMTP Inspect Map > Advanced View

The Add/Edit ESMTP Policy Map pane lets you configure the security level and additional settings for ESMTP application inspection maps.

Fields

- Name—When adding an ESMTP map, enter the name of the ESMTP map. When editing an ESMTP map, the name of the previously configured ESMTP map is shown.
- Description—Enter the description of the ESMTP map, up to 200 characters in length.
- Security Level—Shows the security level and mime file type filtering settings to configure.
- Parameters—Tab that lets you configure the parameters for the ESMTP inspect map.
  - Mask server banner—Enforces banner obfuscation.
  - Configure Mail Relay—Enables ESMTP mail relay.

    Domain Name—Specifies a local domain.

    Action—Drop connection or log.

    Log—Enable or disable.
- Inspections—Tab that shows you the ESMTP inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the ESMTP inspection.
  - Value—Shows the value to match in the ESMTP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add ESMTP Inspect dialog box to add an ESMTP inspection.
  - Edit—Opens the Edit ESMTP Inspect dialog box to edit an ESMTP inspection.
  - Delete—Deletes an ESMTP inspection.
  - Move Up—Moves an inspection up in the list.

- Move Down—Moves an inspection down in the list.

Add/Edit ESMTP Inspect

The Add/Edit ESMTP Inspect dialog box is accessible as follows:

Configuration > Global Objects > Inspect Maps > ESMTP > ESMTP Inspect Map > Advanced View > Add/Edit ESMTP Inspect

The Add/Edit ESMTP Inspect dialog box lets you define the match criterion and value for the ESMTP inspect map.

Fields

- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string "example.com," then any traffic that contains "example.com" is excluded from the class map.
- Criterion—Specifies which criterion of ESMTP traffic to match.
  - Body Length—Match body length at specified length in bytes.
  - Body Line Length—Match body line length matching at specified length in bytes.
  - Commands—Match commands exchanged in the ESMTP protocol.
  - Command Recipient Count—Match command recipient count greater than number specified.
  - Command Line Length—Match command line length greater than length specified in bytes.
  - EHLO Reply Parameters—Match an ESMTP ehlo reply parameter.
  - Header Length—Match header length at length specified in bytes.
  - Header To Fields Count—Match header To fields count greater than number specified.
  - Invalid Recipients Count—Match invalid recipients count greater than number specified.
  - MIME File Type—Match MIME file type.
  - MIME Filename Length—Match MIME filename.
  - MIME Encoding—Match MIME encoding.
  - Sender Address—Match sender email address.
  - Sender Address Length—Match sender email address length.
- Body Length Criterion Values—Specifies the value details for body length match.
  - Greater Than Length—Body length in bytes.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- Body Line Length Criterion Values—Specifies the value details for body line length match.
  - Greater Than Length—Body line length in bytes.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- Commands Criterion Values—Specifies the value details for command match.
  - Available Commands Table:

AUTH

DATA

EHLO

ETRN

HELO

HELP

MAIL

NOOP

QUIT

RCPT

RSET

SAML

SOML

VRFY

  - Add—Adds the selected command from the Available Commands table to the Selected Commands table.
  - Remove—Removes the selected command from the Selected Commands table.
  - Primary Action—Mask, Reset, Drop Connection, None, Limit Rate (pps).
  - Log—Enable or disable.
  - Rate Limit—Do not limit rate, Limit Rate (pps).
- Command Recipient Count Criterion Values—Specifies the value details for command recipient count match.
  - Greater Than Count—Specify command recipient count.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- Command Line Length Criterion Values—Specifies the value details for command line length.
  - Greater Than Length—Command line length in bytes.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- EHLO Reply Parameters Criterion Values—Specifies the value details for EHLO reply parameters match.
  - Available Parameters Table:

    8bitmime

    auth

    binarymime

    checkpoint

    dsn

    ecode

etrn

others

pipelining

size

vrfy

  - Add—Adds the selected parameter from the Available Parameters table to the Selected Parameters table.
  - Remove—Removes the selected command from the Selected Commands table.
  - Action—Reset, Drop Connection, Mask, Log.
  - Log—Enable or disable.
- Header Length Criterion Values—Specifies the value details for header length match.
  - Greater Than Length—Header length in bytes.
  - Action—Reset, Drop Connection, Mask, Log.
  - Log—Enable or disable.
- Header To Fields Count Criterion Values—Specifies the value details for header To fields count match.
  - Greater Than Count—Specify command recipient count.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- Invalid Recipients Count Criterion Values—Specifies the value details for invalid recipients count match.
  - Greater Than Count—Specify command recipient count.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- MIME File Type Criterion Values—Specifies the value details for MIME file type match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
  - Action—Reset, drop connection, log.
  - Log—Enable or disable.
- MIME Filename Length Criterion Values—Specifies the value details for MIME filename length match.
  - Greater Than Length—MIME filename length in bytes.
  - Action—Reset, Drop Connection, Log.
  - Log—Enable or disable.
- MIME Encoding Criterion Values—Specifies the value details for MIME encoding match.

  - Available Encodings table

    7bit

    8bit

    base64

    binary

    others

    quoted-printable
  - Add—Adds the selected parameter from the Available Encodings table to the Selected Encodings table.
  - Remove—Removes the selected command from the Selected Commands table.
  - Action—Reset, Drop Connection, Log.
  - Log—Enable or disable.
- Sender Address Criterion Values—Specifies the value details for sender address match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
  - Action—Reset, Drop Connection, Log.
  - Log—Enable or disable.
- Sender Address Length Criterion Values—Specifies the value details for sender address length match.
  - Greater Than Length—Sender address length in bytes.
  - Action—Reset, Drop Connection, Log.
  - Log—Enable or disable.

TFTP Inspection

TFTP inspection is enabled by default.

TFTP, described in RFC 1350, is a simple protocol to read and write files between a TFTP server and client.

The ASA inspects TFTP traffic and dynamically creates connections and translations, if necessary, to permit file transfer between a TFTP client and server. Specifically, the inspection engine inspects TFTP read request (RRQ), write request (WRQ), and error notification (ERROR).

A dynamic secondary channel and a PAT translation, if necessary, are allocated on a reception of a valid read (RRQ) or write (WRQ) request. This secondary channel is subsequently used by TFTP for file transfer or error notification.

Only the TFTP server can initiate traffic over the secondary channel, and at most one incomplete secondary channel can exist between the TFTP client and server. An error notification from the server closes the secondary channel.

TFTP inspection must be enabled if static PAT is used to redirect TFTP traffic.

Configuring Inspection for Voice and Video Protocols

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the ASA by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- CTIQBE Inspection, page 59-1
- H.323 Inspection, page 59-2
- MGCP Inspection, page 59-12
- RTSP Inspection, page 59-16
- SIP Inspection, page 59-20
- Skinny (SCCP) Inspection, page 59-31

CTIQBE Inspection

This section describes CTIQBE application inspection. This section includes the following topics:

- CTIQBE Inspection Overview, page 59-1
- Limitations and Restrictions, page 59-2

CTIQBE Inspection Overview

CTIQBE protocol inspection supports NAT, PAT, and bidirectional NAT. This enables Cisco IP SoftPhone and other Cisco TAPI/JTAPI applications to work successfully with Cisco CallManager for call setup across the ASA.

TAPI and JTAPI are used by many Cisco VoIP applications. CTIQBE is used by Cisco TSP to communicate with Cisco CallManager.

Limitations and Restrictions

The following summarizes limitations that apply when using CTIQBE application inspection:

- CTIQBE application inspection does not support configurations with the **alias** command.
- Stateful failover of CTIQBE calls is not supported.
- Debugging CTIQBE inspection may delay message transmission, which may have a performance impact in a real-time environment. When you enable this debugging or logging and Cisco IP SoftPhone seems unable to complete call setup through the ASA, increase the timeout values in the Cisco TSP settings on the system running Cisco IP SoftPhone.

The following summarizes special considerations when using CTIQBE application inspection in specific scenarios:

- If two Cisco IP SoftPhones are registered with different Cisco CallManagers, which are connected to different interfaces of the ASA, calls between these two phones fails.
- When Cisco CallManager is located on the higher security interface compared to Cisco IP SoftPhones, if NAT or outside NAT is required for the Cisco CallManager IP address, the mapping must be static as Cisco IP SoftPhone requires the Cisco CallManager IP address to be specified explicitly in its Cisco TSP configuration on the PC.
- When using PAT or Outside PAT, if the Cisco CallManager IP address is to be translated, its TCP port 2748 must be statically mapped to the same port of the PAT (interface) address for Cisco IP SoftPhone registrations to succeed. The CTIQBE listening port (TCP 2748) is fixed and is not user-configurable on Cisco CallManager, Cisco IP SoftPhone, or Cisco TSP.

H.323 Inspection

This section describes the H.323 application inspection. This section includes the following topics:

- H.323 Inspection Overview, page 59-3
- How H.323 Works, page 59-3
- H.239 Support in H.245 Messages, page 59-4
- Limitations and Restrictions, page 59-4
- Select H.323 Map, page 59-5
- H.323 Class Map, page 59-5
- Add/Edit H.323 Traffic Class Map, page 59-6
- Add/Edit H.323 Match Criterion, page 59-6
- H.323 Inspect Map, page 59-7
- Phone Number Filtering, page 59-8
- Add/Edit H.323 Policy Map (Security Level), page 59-8
- Add/Edit H.323 Policy Map (Details), page 59-9
- Add/Edit HSI Group, page 59-11
- Add/Edit H.323 Map, page 59-11

H.323 Inspection Overview

H.323 inspection provides support for H.323 compliant applications such as Cisco CallManager and VocalTec Gatekeeper. H.323 is a suite of protocols defined by the International Telecommunication Union for multimedia conferences over LANs. The ASA supports H.323 through Version 6, including H.323 v3 feature Multiple Calls on One Call Signaling Channel.

With H.323 inspection enabled, the ASA supports multiple calls on the same call signaling channel, a feature introduced with H.323 Version 3. This feature reduces call setup time and reduces the use of ports on the ASA.

The two major functions of H.323 inspection are as follows:

- NAT the necessary embedded IPv4 addresses in the H.225 and H.245 messages. Because H.323 messages are encoded in PER encoding format, the ASA uses an ASN.1 decoder to decode the H.323 messages.
- Dynamically allocate the negotiated H.245 and RTP/RTCP connections.

How H.323 Works

The H.323 collection of protocols collectively may use up to two TCP connection and four to eight UDP connections. FastConnect uses only one TCP connection, and RAS uses a single UDP connection for registration, admissions, and status.

An H.323 client can initially establish a TCP connection to an H.323 server using TCP port 1720 to request Q.931 call setup. As part of the call setup process, the H.323 terminal supplies a port number to the client to use for an H.245 TCP connection. In environments where H.323 gatekeeper is in use, the initial packet is transmitted using UDP.

H.323 inspection monitors the Q.931 TCP connection to determine the H.245 port number. If the H.323 terminals are not using FastConnect, the ASA dynamically allocates the H.245 connection based on the inspection of the H.225 messages.

Note The H.225 connection can also be dynamically allocated when using RAS.

Within each H.245 message, the H.323 endpoints exchange port numbers that are used for subsequent UDP data streams. H.323 inspection inspects the H.245 messages to identify these ports and dynamically creates connections for the media exchange. RTP uses the negotiated port number, while RTCP uses the next higher port number.

The H.323 control channel handles H.225 and H.245 and H.323 RAS. H.323 inspection uses the following ports.

- 1718—Gate Keeper Discovery UDP port
- 1719—RAS UDP port
- 1720—TCP Control Port

You must permit traffic for the well-known H.323 port 1719 for RAS signaling. Additionally, you must permit traffic for the well-known H.323 port 1720 for the H.225 call signaling; however, the H.245 signaling ports are negotiated between the endpoints in the H.225 signaling. When an H.323 gatekeeper is used, the ASA opens an H.225 connection based on inspection of the ACF and RCF nmessages.

After inspecting the H.225 messages, the ASA opens the H.245 channel and then inspects traffic sent over the H.245 channel as well. All H.245 messages passing through the ASA undergo H.245 application inspection, which translates embedded IP addresses and opens the media channels negotiated in H.245 messages.

The H.323 ITU standard requires that a TPKT header, defining the length of the message, precede the H.225 and H.245, before being passed on to the reliable connection. Because the TPKT header does not necessarily need to be sent in the same TCP packet as H.225 and H.245 messages, the ASA must remember the TPKT length to process and decode the messages properly. For each connection, the ASA keeps a record that contains the TPKT length for the next expected message.

If the ASA needs to perform NAT on IP addresses in messages, it changes the checksum, the UUIE length, and the TPKT, if it is included in the TCP packet with the H.225 message. If the TPKT is sent in a separate TCP packet, the ASA proxy ACKs that TPKT and appends a new TPKT to the H.245 message with the new length.

Note The ASA does not support TCP options in the Proxy ACK for the TPKT.

Each UDP connection with a packet going through H.323 inspection is marked as an H.323 connection and times out with the H.323 timeout as configured in the Configuration > Firewall > Advanced > Global Timeouts pane.

Note You can enable call setup between H.323 endpoints when the Gatekeeper is inside the network. The ASA includes options to open pinholes for calls based on the RegistrationRequest/RegistrationConfirm (RRQ/RCF) messages. Because these RRQ/RCF messages are sent to and from the Gatekeeper, the calling endpoint's IP address is unknown and the ASA opens a pinhole through source IP address/port 0/0. By default, this option is disabled.

H.239 Support in H.245 Messages

The ASA sits between two H.323 endpoints. When the two H.323 endpoints set up a telepresentation session so that the endpoints can send and receive a data presentation, such as spreadsheet data, the ASA ensure successful H.239 negotiation between the endpoints.

H.239 is a standar that provides the ability for H.300 series endpoints to open an additional video channel in a single call. In a call, an endpoint (such as a video phone), sends a channel for video and a channel for data presentation. The H.239 negotiation occurs on the H.245 channel.

The ASA opens pinholes for the additional media channel and the media control channel. The endpoints use open logical channel message (OLC) to signal a new channel creation. The message extension is part of H.245 version 13.

The decoding and encoding of of the telepresentation session is enabled by default. H.239 encoding and decoding is preformed by ASN.1 coder.

Limitations and Restrictions

The following are some of the known issues and limitations when using H.323 application inspection:

- Static PAT may not properly translate IP addresses embedded in optional fields within H.323 messages. If you experience this kind of problem, do not use static PAT with H.323.

- H.323 application inspection is not supported with NAT between same-security-level interfaces.
- When a NetMeeting client registers with an H.323 gatekeeper and tries to call an H.323 gateway that is also registered with the H.323 gatekeeper, the connection is established but no voice is heard in either direction. This problem is unrelated to the ASA.
- If you configure a network static address where the network static address is the same as a third-party netmask and address, then any outbound H.323 connection fails.
- Configuring both H.323 inspection and communication in and out of the same interface on the ASA is not supported. When you configure both these features, the ASA cannot correctly establish NetMeeting calls because it modifies the H.225 setup message incorrectly by changing the destCallSignalAddress field to point to itself rather than the NetMeeting destination endpoint.

  To workaround this limitation, perform one of the following actions:

  - Configure the ASA so that either H.323 inspection or communication in and out of the same interface, but not both, is set up on the device.
  - Configure inside to inside traffic to use NAT 0.

Select H.323 Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select H.323 Map

The Select H.323 Map dialog box lets you select or create a new H.323 map. An H.323 map lets you change the configuration values used for H.323 application inspection. The Select H.323 Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default H.323 inspection map—Specifies to use the default H.323 map.
- Select an H.323 map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

H.323 Class Map

Configuration > Global Objects > Class Maps > H.323

The H.323 Class Map pane lets you configure H.323 class maps for H.323 inspection.

An inspection class map matches application traffic with criteria specific to the application. You then identify the class map in the inspect map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspect map is that you can create more complex match criteria and you can reuse class maps. The applications that support inspection class maps are DNS, FTP, H.323, HTTP, IM, and SIP.

Fields

- Name—Shows the H.323 class map name.
- Match Conditions—Shows the type, match criterion, and value in the class map.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the H.323 class map.

  - Value—Shows the value to match in the H.323 class map.
- Description—Shows the description of the class map.
- Add—Adds an H.323 class map.
- Edit—Edits an H.323 class map.
- Delete—Deletes an H.323 class map.

Add/Edit H.323 Traffic Class Map

Configuration > Global Objects > Class Maps > H.323 > Add/Edit H.323 Traffic Class Map

The Add/Edit H.323 Traffic Class Map dialog box lets you define a H.323 class map.

Fields

- Name—Enter the name of the H.323 class map, up to 40 characters in length.
- Description—Enter the description of the H.323 class map.
- Add—Adds an H.323 class map.
- Edit—Edits an H.323 class map.
- Delete—Deletes an H.323 class map.

Add/Edit H.323 Match Criterion

Configuration > Global Objects > Class Maps > H.323 > Add/Edit H.323 Traffic Class Map > Add/Edit H.323 Match Criterion

The Add/Edit H.323 Match Criterion dialog box lets you define the match criterion and value for the H.323 class map.

Fields

- Match Type—Specifies whether the class map includes traffic that matches the criterion, or traffic that does not match the criterion.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of H.323 traffic to match.
  - Called Party—Match the called party.
  - Calling Party—Match the calling party.
  - Media Type—Match the media type.
- Called Party Criterion Values—Specifies to match on the H.323 called party.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Calling Party Criterion Values—Specifies to match on the H.323 calling party.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Media Type Criterion Values—Specifies which media type to match.
  - Audio—Match audio type.
  - Video—Match video type.
  - Data—Match data type.

H.323 Inspect Map

Configuration > Global Objects > Inspect Maps > H.323

The H.323 pane lets you view previously configured H.323 application inspection maps. An H.323 map lets you change the default configuration values used for H.323 application inspection.

H.323 inspection supports RAS, H.225, and H.245, and its functionality translates all embedded IP addresses and ports. It performs state tracking and filtering and can do a cascade of inspect function activation. H.323 inspection supports phone number filtering, dynamic T.120 control, H.245 tunneling control, HSI groups, protocol state tracking, H.323 call duration enforcement, and audio/video control.

Fields

- H.323 Inspect Maps—Table that lists the defined H.323 inspect maps.
- Add—Configures a new H.323 inspect map. To edit an H.323 inspect map, choose the H.323 entry in the H.323 Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the H.323 Inspect Maps table.
- Security Level—Select the security level (low, medium, or high).
  - Low—Default.

    State Checking h225 Disabled

    State Checking ras Disabled

    Call Party Number Disabled

    Call duration Limit Disabled

    RTP conformance not enforced
  - Medium

    State Checking h225 Enabled

    State Checking ras Enabled

    Call Party Number Disabled

    Call duration Limit Disabled

    RTP conformance enforced

    Limit payload to audio or video, based on the signaling exchange: no

- High

  State Checking h225 Enabled

  State Checking ras Enabled

  Call Party Number Enabled

  Call duration Limit 1:00:00

  RTP conformance enforced

  Limit payload to audio or video, based on the signaling exchange: yes
- Phone Number Filtering—Opens the Phone Number Filtering dialog box to configure phone number filters.
- Customize—Opens the Add/Edit H.323 Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Medium.

Phone Number Filtering

Configuration > Global Objects > Inspect Maps > H323 > Phone Number Filtering

The Phone Number Filtering dialog box lets you configure the settings for a phone number filter.

Fields

- Match Type—Shows the match type, which can be a positive or negative match.
- Criterion—Shows the criterion of the inspection.
- Value—Shows the value to match in the inspection.
- Action—Shows the action if the match condition is met.
- Log—Shows the log state.
- Add—Opens the Add Phone Number Filter dialog box to add a phone number filter.
- Edit—Opens the Edit Phone Number Filter dialog box to edit a phone number filter.
- Delete—Deletes a phone number filter.
- Move Up—Moves an entry up in the list.
- Move Down—Moves an entry down in the list.

Add/Edit H.323 Policy Map (Security Level)

Configuration > Global Objects > Inspect Maps > H323 > H323 Inspect Map > Basic View

The Add/Edit H.323 Policy Map pane lets you configure the security level and additional settings for H.323 application inspection maps.

Fields

- Name—When adding an H.323 map, enter the name of the H.323 map. When editing an H.323 map, the name of the previously configured H.323 map is shown.
- Description—Enter the description of the H323 map, up to 200 characters in length.
- Security Level—Select the security level (low, medium, or high).

  - Low—Default.

    State Checking h225 Disabled

    State Checking ras Disabled

    Call Party Number Disabled

    Call duration Limit Disabled

    RTP conformance not enforced
  - Medium

    State Checking h225 Enabled

    State Checking ras Enabled

    Call Party Number Disabled

    Call duration Limit Disabled

    RTP conformance enforced

    Limit payload to audio or video, based on the signaling exchange: no
  - High

    State Checking h225 Enabled

    State Checking ras Enabled

    Call Party Number Enabled

    Call duration Limit 1:00:00

    RTP conformance enforced

    Limit payload to audio or video, based on the signaling exchange: yes
  - Phone Number Filtering—Opens the Phone Number Filtering dialog box which lets you configure the settings for a phone number filter.
  - Default Level—Sets the security level back to the default.
- Details—Shows the State Checking, Call Attributes, Tunneling and Protocol Conformance, HSI Group Parameters, and Inspections tabs to configure additional settings.

Add/Edit H.323 Policy Map (Details)

Configuration > Global Objects > Inspect Maps > H323 > H323 Inspect Map > Advanced View

The Add/Edit H.323 Policy Map pane lets you configure the security level and additional settings for H.323 application inspection maps.

Fields

- Name—When adding an H.323 map, enter the name of the H.323 map. When editing an H.323 map, the name of the previously configured H.323 map is shown.
- Description—Enter the description of the H.323 map, up to 200 characters in length.
- Security Level—Shows the security level and phone number filtering settings to configure.
- State Checking—Tab that lets you configure state checking parameters for the H.323 inspect map.
  - Check state transition of H.225 messages—Enforces H.323 state checking on H.225 messages.
  - Check state transition of RAS messages—Enforces H.323 state checking on RAS messages.

  - Check RFC messages and open pinholes for call signal addresses in RFQ messages

Note You can enable call setup between H.323 endpoints when the Gatekeeper is inside the network. The ASA includes options to open pinholes for calls based on the RegistrationRequest/RegistrationConfirm (RRQ/RCF) messages. Because these RRQ/RCF messages are sent to and from the Gatekeeper, the calling endpoint's IP address is unknown and the ASA opens a pinhole through source IP address/port 0/0. By default, this option is disabled. You can enable this option by setting the option in the H.323 Inspect Map.

- Call Attributes—Tab that lets you configure call attributes parameters for the H.323 inspect map.
  - Enforce call duration limit—Enforces the absolute limit on a call.

    Call Duration Limit—Time limit for the call (hh:mm:ss).
  - Enforce presence of calling and called party numbers—Enforces sending call party numbers during call setup.
- Tunneling and Protocol Conformance—Tab that lets you configure tunneling and protocol conformance parameters for the H.323 inspect map.
  - Check for H.245 tunneling—Allows H.245 tunneling.

    Action—Drop connection or log.
  - Check RTP packets for protocol conformance—Checks RTP/RTCP packets on the pinholes for protocol conformance.

    Limit payload to audio or video, based on the signaling exchange—Enforces the payload type to be audio or video based on the signaling exchange.
- HSI Group Parameters—Tab that lets you configure an HSI group.
  - HSI Group ID—Shows the HSI Group ID.
  - IP Address—Shows the HSI Group IP address.
  - Endpoints—Shows the HSI Group endpoints.
  - Add—Opens the Add HSI Group dialog box to add an HSI group.
  - Edit—Opens the Edit HSI Group dialog box to edit an HSI group.
  - Delete—Deletes an HSI group.
- Inspections—Tab that shows you the H.323 inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the H.323 inspection.
  - Value—Shows the value to match in the H.323 inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add H.323 Inspect dialog box to add an H.323 inspection.
  - Edit—Opens the Edit H.323 Inspect dialog box to edit an H.323 inspection.
  - Delete—Deletes an H.323 inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit HSI Group

Configuration > Global Objects > Inspect Maps > H323 > H323 Inspect Map > Advanced View > Add/Edit HSI Group

The Add/Edit HSI Group dialog box lets you configure HSI Groups.

Fields

- Group ID—Enter the HSI group ID.
- IP Address—Enter the HSI IP address.
- Endpoints—Lets you configure the IP address and interface of the endpoints.
  - IP Address—Enter an endpoint IP address.
  - Interface—Specifies an endpoint interface.
- Add—Adds the HSI group defined.
- Delete—Deletes the selected HSI group.

Add/Edit H.323 Map

Configuration > Global Objects > Inspect Maps > H232 > H323 Inspect Map > Advanced View > Add/Edit H323 Inspect

The Add/Edit H.323 Inspect dialog box lets you define the match criterion and value for the H.323 inspect map.

Fields

- Single Match—Specifies that the H.323 inspect has only one match statement.
- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of H.323 traffic to match.
  - Called Party—Match the called party.
  - Calling Party—Match the calling party.
  - Media Type—Match the media type.
- Called Party Criterion Values—Specifies to match on the H.323 called party.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Calling Party Criterion Values—Specifies to match on the H.323 calling party.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Media Type Criterion Values—Specifies which media type to match.
  - Audio—Match audio type.
  - Video—Match video type.
  - Data—Match data type.
- Multiple Matches—Specifies multiple matches for the H.323 inspection.
  - H323 Traffic Class—Specifies the H.323 traffic class match.
  - Manage—Opens the Manage H323 Class Maps dialog box to add, edit, or delete H.323 Class Maps.
- Action—Drop packet, drop connection, or reset.

MGCP Inspection

This section describes MGCP application inspection. This section includes the following topics:

- MGCP Inspection Overview, page 59-12
- Select MGCP Map, page 59-14
- MGCP Inspect Map, page 59-14
- Gateways and Call Agents, page 59-15
- Add/Edit MGCP Policy Map, page 59-15
- Add/Edit MGCP Group, page 59-16

MGCP Inspection Overview

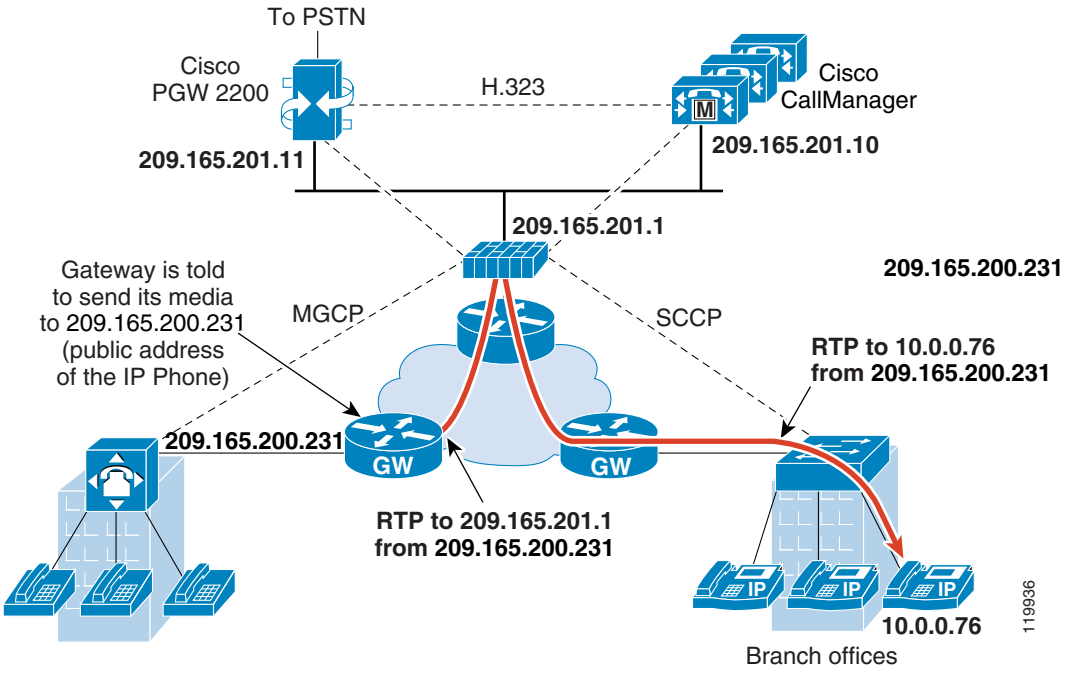
MGCP is a master/slave protocol used to control media gateways from external call control elements called media gateway controllers or call agents. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Using NAT and PAT with MGCP lets you support a large number of devices on an internal network with a limited set of external (global) addresses. Examples of media gateways are:

- Trunking gateways, that interface between the telephone network and a Voice over IP network. Such gateways typically manage a large number of digital circuits.
- Residential gateways, that provide a traditional analog (RJ11) interface to a Voice over IP network. Examples of residential gateways include cable modem/cable set-top boxes, xDSL devices, broad-band wireless devices.
- Business gateways, that provide a traditional digital PBX interface or an integrated soft PBX interface to a Voice over IP network.

Note To avoid policy failure when upgrading from ASA version 7.1, all layer 7 and layer 3 policies must have distinct names. For instance, a previously configured policy map with the same name as a previously configured MGCP map must be changed before the upgrade.

MGCP messages are transmitted over UDP. A response is sent back to the source address (IP address and UDP port number) of the command, but the response may not arrive from the same address as the command was sent to. This can happen when multiple call agents are being used in a failover configuration and the call agent that received the command has passed control to a backup call agent, which then sends the response. Figure 59-1 illustrates how NAT can be used with MGCP.

Figure 59-1 Using NAT with MGCP



MGCP endpoints are physical or virtual sources and destinations for data. Media gateways contain endpoints on which the call agent can create, modify and delete connections to establish and control media sessions with other multimedia endpoints. Also, the call agent can instruct the endpoints to detect certain events and generate signals. The endpoints automatically communicate changes in service state to the call agent.

MGCP transactions are composed of a command and a mandatory response. There are eight types of commands:

- CreateConnection
- ModifyConnection
- DeleteConnection
- NotificationRequest
- Notify
- AuditEndpoint
- AuditConnection

- RestartInProgress

The first four commands are sent by the call agent to the gateway. The Notify command is sent by the gateway to the call agent. The gateway may also send a DeleteConnection. The registration of the MGCP gateway with the call agent is achieved by the RestartInProgress command. The AuditEndpoint and the AuditConnection commands are sent by the call agent to the gateway.

All commands are composed of a Command header, optionally followed by a session description. All responses are composed of a Response header, optionally followed by a session description.

- The port on which the gateway receives commands from the call agent. Gateways usually listen to UDP port 2427.
- The port on which the call agent receives commands from the gateway. Call agents usually listen to UDP port 2727.

Note MGCP inspection does not support the use of different IP addresses for MGCP signaling and RTP data. A common and recommended practice is to send RTP data from a resilient IP address, such as a loopback or virtual IP address; however, the ASA requires the RTP data to come from the same address as MGCP signalling.

Select MGCP Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select MGCP Map

The Select MGCP Map dialog box lets you select or create a new MGCP map. An MGCP map lets you change the configuration values used for MGCP application inspection. The Select MGCP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default MGCP inspection map—Specifies to use the default MGCP map.
- Select an MGCP map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

MGCP Inspect Map

Configuration > Global Objects > Inspect Maps > MGCP

The MGCP pane lets you view previously configured MGCP application inspection maps. An MGCP map lets you change the default configuration values used for MGCP application inspection. You can use an MGCP map to manage connections between VoIP devices and MGCP call agents.

Fields

- MGCP Inspect Maps—Table that lists the defined MGCP inspect maps.
- Add—Configures a new MGCP inspect map.
- Edit—Edits the selected MGCP entry in the MGCP Inspect Maps table.
- Delete—Deletes the inspect map selected in the MGCP Inspect Maps table.

Gateways and Call Agents

Configuration > Global Objects > Inspect Maps > MGCP > Gateways and Call Agents

The Gateways and Call Agents dialog box lets you configure groups of gateways and call agents for the map.

Fields

- Group ID—Identifies the ID of the call agent group. A call agent group associates one or more call agents with one or more MGCP media gateways. The gateway IP address can only be associated with one group ID. You cannot use the same gateway with different group IDs. The valid range is from 0 to 2147483647Criterion—Shows the criterion of the inspection.
- Gateways—Identifies the IP address of the media gateway that is controlled by the associated call agent. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Normally, a gateway sends commands to the default MGCP port for call agents, 2727.
- Call Agents—Identifies the IP address of a call agent that controls the MGCP media gateways in the call agent group. Normally, a call agent sends commands to the default MGCP port for gateways, 2427.
- Add—Displays the Add MGCP dialog box, which you can use to define a new application inspection map.
- Edit—Displays the Edit MGCP dialog box, which you can use to modify the application inspection map selected in the application inspection map table.
- Delete—Deletes the application inspection map selected in the application inspection map table.

Add/Edit MGCP Policy Map

Configuration > Global Objects > Inspect Maps > MGCP > MGCP Inspect Map > View

The Add/Edit MGCP Policy Map pane lets you configure the command queue, gateway, and call agent settings for MGCP application inspection maps.

Fields

- Name—When adding an MGCP map, enter the name of the MGCP map. When editing an MGCP map, the name of the previously configured MGCP map is shown.
- Description—Enter the description of the MGCP map, up to 200 characters in length.
- Command Queue—Tab that lets you specify the permitted queue size for MGCP commands.
  - Command Queue Size—Specifies the maximum number of commands to queue. The valid range is from 1 to 2147483647.
- Gateways and Call Agents—Tab that lets you configure groups of gateways and call agents for this map.
  - Group ID—Identifies the ID of the call agent group. A call agent group associates one or more call agents with one or more MGCP media gateways. The gateway IP address can only be associated with one group ID. You cannot use the same gateway with different group IDs. The valid range is from 0 to 2147483647Criterion—Shows the criterion of the inspection.

- Gateways—Identifies the IP address of the media gateway that is controlled by the associated call agent. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Normally, a gateway sends commands to the default MGCP port for call agents, 2727.
- Call Agents—Identifies the IP address of a call agent that controls the MGCP media gateways in the call agent group. Normally, a call agent sends commands to the default MGCP port for gateways, 2427.
- Add—Displays the Add MGCP Group dialog box, which you can use to define a new MGCP group of gateways and call agents.
- Edit—Displays the Edit MGCP dialog box, which you can use to modify the MGCP group selected in the Gateways and Call Agents table.
- Delete—Deletes the MGCP group selected in the Gateways and Call Agents table.

Add/Edit MGCP Group

Configuration > Global Objects > Inspect Maps > MGCP > Add/Edit MGCP Group

The Add/Edit MGCP Group dialog box lets you define the configuration of an MGCP group that will be used when MGCP application inspection is enabled.

Fields

- Group ID—Specifies the ID of the call agent group. A call agent group associates one or more call agents with one or more MGCP media gateways. The valid range is from 0 to 2147483647.
  - Gateway to Be Added—Specifies the IP address of the media gateway that is controlled by the associated call agent. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Normally, a gateway sends commands to the default MGCP port for call agents, 2727.
  - Add—Adds the specified IP address to the IP address table.
  - Delete—Deletes the selected IP address from the IP address table.
  - IP Address—Lists the IP addresses of the gateways in the call agent group.
- Call Agents
  - Call Agent to Be Added—Specifies the IP address of a call agent that controls the MGCP media gateways in the call agent group. Normally, a call agent sends commands to the default MGCP port for gateways, 2427.
  - Add—Adds the specified IP address to the IP address table.
  - Delete—Deletes the selected IP address from the IP address table.
  - IP Address—Lists the IP addresses of the call agents in the call agent group.

RTSP Inspection

This section describes RTSP application inspection. This section includes the following topics:

- RTSP Inspection Overview, page 59-17

- Using RealPlayer, page 59-17
- Restrictions and Limitations, page 59-18
- Select RTSP Map, page 59-18
- RTSP Inspect Map, page 59-18
- Add/Edit RTSP Policy Map, page 59-18
- Add/Edit RTSP Inspect, page 59-19

RTSP Inspection Overview

The RTSP inspection engine lets the ASA pass RTSP packets. RTSP is used by RealAudio, RealNetworks, Apple QuickTime 4, RealPlayer, and Cisco IP/TV connections.

Note For Cisco IP/TV, use RTSP TCP port 554 and TCP 8554.

RTSP applications use the well-known port 554 with TCP (rarely UDP) as a control channel. The ASA only supports TCP, in conformity with RFC 2326. This TCP control channel is used to negotiate the data channels that is used to transmit audio/video traffic, depending on the transport mode that is configured on the client.

The supported RDT transports are: rtp/avp, rtp/avp/udp, x-real-rdt, x-real-rdt/udp, and x-pn-tng/udp.

The ASA parses Setup response messages with a status code of 200. If the response message is travelling inbound, the server is outside relative to the ASA and dynamic channels need to be opened for connections coming inbound from the server. If the response message is outbound, then the ASA does not need to open dynamic channels.

Because RFC 2326 does not require that the client and server ports must be in the SETUP response message, the ASA keeps state and remembers the client ports in the SETUP message. QuickTime places the client ports in the SETUP message and then the server responds with only the server ports.

RTSP inspection supports PAT or dual-NAT. The ASA provides TCP fragment reassembly support, a scalable parsing routine on RTSP, and security enhancements that protect RTSP traffic.

Using RealPlayer

When using RealPlayer, it is important to properly configure transport mode. For the ASA, add an **access-list** command from the server to the client or vice versa. For RealPlayer, change transport mode by clicking **Options>Preferences>Transport>RTSP Settings**.

If using TCP mode on the RealPlayer, select the **Use TCP to Connect to Server** and **Attempt to use TCP for all content** check boxes. On the ASA, there is no need to configure the inspection engine.

If using UDP mode on the RealPlayer, select the **Use TCP to Connect to Server** and **Attempt to use UDP for static content** check boxes, and for live content not available via Multicast. On the ASA, add an **inspect rtsp** *port* command.

Restrictions and Limitations

The following restrictions apply to the RSTP inspection.

- The ASA does not support multicast RTSP or RTSP messages over UDP.
- The ASA does not have the ability to recognize HTTP cloaking where RTSP messages are hidden in the HTTP messages.
- With Cisco IP/TV, the number of translates the ASA performs on the SDP part of the message is proportional to the number of program listings in the Content Manager (each program listing can have at least six embedded IP addresses).
- You can configure NAT for Apple QuickTime 4 or RealPlayer. Cisco IP/TV only works with NAT if the Viewer and Content Manager are on the outside network and the server is on the inside network.

Select RTSP Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select NetBIOS Map

The Select RTSP Map dialog box lets you select or create a new RTSP map. An RTSP map lets you change the configuration values used for RTSP application inspection. The Select RTSP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default RTSP inspection map—Specifies to use the default RTSP inspection map.
- Select a RTSP inspect map for fine control over inspection—Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

RTSP Inspect Map

Configuration > Global Objects > Inspect Maps > RADIUS

The RTSP pane lets you view previously configured RTSP application inspection maps. An RTSP map lets you change the default configuration values used for RTSP application inspection. You can use an RTSP map to protect RTSP traffic.

Fields

- RTSP Inspect Maps—Table that lists the defined RTSP inspect maps.
- Add—Configures a new RTSP inspect map.
- Edit—Edits the selected RTSP entry in the RTSP Inspect Maps table.
- Delete—Deletes the inspect map selected in the RTSP Inspect Maps table.

Add/Edit RTSP Policy Map

Configuration > Global Objects > Inspect Maps > MGCP > MGCP Inspect Map > View

The Add/Edit RTSP Policy Map pane lets you configure the parameters and inspections settings for RTSP application inspection maps.

Fields

- Name—When adding an RTSP map, enter the name of the RTSP map. When editing an RTSP map, the name of the previously configured RTSP map is shown.
- Description—Enter the description of the RTSP map, up to 200 characters in length.
- Parameters—Tab that lets you restrict usage on reserved ports during media port negotiation, and lets you set the URL length limit.
  - Enforce Reserve Port Protection—Lets you restrict the use of reserved ports during media port negotiation.
  - Maximum URL Length—Specifies the maximum length of the URL allowed in the message. Maximum value is 6000.
- Inspections—Tab that shows you the RTSP inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the RTSP inspection.
  - Value—Shows the value to match in the RTSP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add RTSP Inspect dialog box to add a RTSP inspection.
  - Edit—Opens the Edit RTSP Inspect dialog box to edit a RTSP inspection.
  - Delete—Deletes a RTSP inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit RTSP Inspect

Configuration > Global Objects > Inspect Maps > SIP > SIP Inspect Map > Advanced View > Add/Edit SIP Inspect

The Add/Edit RTSP Inspect dialog box lets you define the match criterion, values, and actions for the RTSP inspect map.

Fields

- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of RTSP traffic to match.
  - URL Filter—Match URL filtering.
  - Request Method—Match an RTSP request method.
- URL Filter Criterion Values—Specifies to match URL filtering. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.

  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- URL Filter Actions—Primary action and log settings.
  - Action—Drop connection or log.
  - Log—Enable or disable.
- Request Method Criterion Values—Specifies to match an RTSP request method.
  - Request Method—Specifies a request method: announce, describe, get_parameter, options, pause, play, record, redirect, setup, set_parameters, teardown.
- Request Method Actions—Primary action settings.
  - Action—Limit rate (pps).

SIP Inspection

This section describes SIP application inspection. This section includes the following topics:

- SIP Inspection Overview, page 59-20
- SIP Instant Messaging, page 59-21
- Select SIP Map, page 59-22
- SIP Class Map, page 59-23
- Add/Edit SIP Traffic Class Map, page 59-23
- Add/Edit SIP Match Criterion, page 59-24
- SIP Inspect Map, page 59-26
- Add/Edit SIP Policy Map (Security Level), page 59-27
- Add/Edit SIP Policy Map (Details), page 59-28
- Add/Edit SIP Inspect, page 59-29

SIP Inspection Overview

SIP, as defined by the IETF, enables call handling sessions, particularly two-party audio conferences, or “calls.” SIP works with SDP for call signalling. SDP specifies the ports for the media stream. Using SIP, the ASA can support any SIP VoIP gateways and VoIP proxy servers. SIP and SDP are defined in the following RFCs:

- SIP: Session Initiation Protocol, RFC 3261
- SDP: Session Description Protocol, RFC 2327

To support SIP calls through the ASA, signaling messages for the media connection addresses, media ports, and embryonic connections for the media must be inspected, because while the signaling is sent over a well-known destination port (UDP/TCP 5060), the media streams are dynamically allocated. Also, SIP embeds IP addresses in the user-data portion of the IP packet. SIP inspection applies NAT for these embedded IP addresses.

The following limitations and restrictions apply when using PAT with SIP:

- If a remote endpoint tries to register with a SIP proxy on a network protected by the ASA, the registration fails under very specific conditions, as follows:
  - PAT is configured for the remote endpoint.
  - The SIP registrar server is on the outside network.
  - The port is missing in the contact field in the REGISTER message sent by the endpoint to the proxy server.
- If a SIP device transmits a packet in which the SDP portion has an IP address in the owner/creator field (o=) that is different than the IP address in the connection field (c=), the IP address in the o= field may not be properly translated. This is due to a limitation in the SIP protocol, which does not provide a port value in the o= field.

SIP Instant Messaging

Instant Messaging refers to the transfer of messages between users in near real-time. SIP supports the Chat feature on Windows XP using Windows Messenger RTC Client version 4.7.0105 only. The MESSAGE/INFO methods and 202 Accept response are used to support IM as defined in the following RFCs:

- Session Initiation Protocol (SIP)-Specific Event Notification, RFC 3265
- Session Initiation Protocol (SIP) Extension for Instant Messaging, RFC 3428

MESSAGE/INFO requests can come in at any time after registration/subscription. For example, two users can be online at any time, but not chat for hours. Therefore, the SIP inspection engine opens pinholes that time out according to the configured SIP timeout value. This value must be configured at least five minutes longer than the subscription duration. The subscription duration is defined in the Contact Expires value and is typically 30 minutes.

Because MESSAGE/INFO requests are typically sent using a dynamically allocated port other than port 5060, they are required to go through the SIP inspection engine.

Note Only the Chat feature is currently supported. Whiteboard, File Transfer, and Application Sharing are not supported. RTC Client 5.0 is not supported.

SIP inspection translates the SIP text-based messages, recalculates the content length for the SDP portion of the message, and recalculates the packet length and checksum. It dynamically opens media connections for ports specified in the SDP portion of the SIP message as address/ports on which the endpoint should listen.

SIP inspection has a database with indices CALL_ID/FROM/TO from the SIP payload. These indices identify the call, the source, and the destination. This database contains the media addresses and media ports found in the SDP media information fields and the media type. There can be multiple media addresses and ports for a session. The ASA opens RTP/RTCP connections between the two endpoints using these media addresses/ports.

The well-known port 5060 must be used on the initial call setup (INVITE) message; however, subsequent messages may not have this port number. The SIP inspection engine opens signaling connection pinholes, and marks these connections as SIP connections. This is done for the messages to reach the SIP application and be translated.

As a call is set up, the SIP session is in the "transient" state until the media address and media port is received from the called endpoint in a Response message indicating the RTP port the called endpoint listens on. If there is a failure to receive the response messages within one minute, the signaling connection is torn down.

Once the final handshake is made, the call state is moved to active and the signaling connection remains until a BYE message is received.

If an inside endpoint initiates a call to an outside endpoint, a media hole is opened to the outside interface to allow RTP/RTCP UDP packets to flow to the inside endpoint media address and media port specified in the INVITE message from the inside endpoint. Unsolicited RTP/RTCP UDP packets to an inside interface does not traverse the ASA, unless the ASA configuration specifically allows it.

Select SIP Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select SIP Map

The Select SIP Map dialog box lets you select or create a new SIP map. A SIP map lets you change the configuration values used for SIP application inspection. The Select SIP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default SIP inspection map—Specifies to use the default SIP map.
- Select a SIP map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.
- Enable encrypted traffic inspection check box—Select to enable the radio buttons to select a proxy type.
- Proxy Type
  - TLS Proxy radio button—Use TLS Proxy to enable inspection of encrypted traffic.
  - Phone Proxy radio button—Specifies to associate the Phone Proxy with the TLS Proxy that you select from the TLS Proxy Name field.

    Configure button—Opens the Configure the Phone Proxy dialog box so that you can specify or edit Phone Proxy configuration settings.
  - UC-IME Proxy ratio button—Specifies to associate the UC-IME Proxy (Cisco Intercompany Media Engine proxy) with the TLS Proxy that you select from the TLS Proxy Name field.

    Configure button—Opens the Configure the UC-IME Proxy dialog box so that you can specify or edit UC-IME Proxy configuration settings.
- TLS Proxy Name:—Name of existing TLS Proxy.
- Manage—Opens the Add TLS Proxy dialog box to add a TLS Proxy.

Only one TLS proxy can be assigned to the Phone Proxy or UC-IME Proxy at a time. If you configure more than one service policy rule for Phone Proxy or UC-IME Proxy inspection and attempt to assign a different TLS proxy to them, ASDM displays a warning that all other service policy rules with Phone Proxy or UC-IME inspection will be changed to use the latest selected TLS proxy.

The UC-IME Proxy configuration requires two TLS proxies – one for outbound traffic and one for inbound. Rather than associating the TLS proxies directly with the UC-IME Proxy, as is the case with phone proxy, the TLS proxies are associated with it indirectly via SIP inspection rules.

You associate a TLS proxy with the Phone Proxy while defining a SIP inspection action . ASDM will convert the association to the existing phone proxy.

SIP Class Map

Configuration > Global Objects > Class Maps > SIP

The SIP Class Map pane lets you configure SIP class maps for SIP inspection.

An inspection class map matches application traffic with criteria specific to the application. You then identify the class map in the inspect map and enable actions. The difference between creating a class map and defining the traffic match directly in the inspect map is that you can create more complex match criteria and you can reuse class maps. The applications that support inspection class maps are DNS, FTP, H.323, HTTP, IM, and SIP.

Fields

- Name—Shows the SIP class map name.
- Match Conditions—Shows the type, match criterion, and value in the class map.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the SIP class map.
  - Value—Shows the value to match in the SIP class map.
- Description—Shows the description of the class map.
- Add—Adds a SIP class map.
- Edit—Edits a SIP class map.
- Delete—Deletes a SIP class map.

Add/Edit SIP Traffic Class Map

Configuration > Global Objects > Class Maps > SIP > Add/Edit SIP Traffic Class Map

The Add/Edit SIP Traffic Class Map dialog box lets you define a SIP class map.

Fields

- Name—Enter the name of the SIP class map, up to 40 characters in length.
- Description—Enter the description of the SIP class map.
- Add—Adds a SIP class map.
- Edit—Edits a SIP class map.
- Delete—Deletes a SIP class map.

Add/Edit SIP Match Criterion

Configuration > Global Objects > Class Maps > SIP > Add/Edit SIP Traffic Class Map > Add/Edit SIP Match Criterion

The Add/Edit SIP Match Criterion dialog box lets you define the match criterion and value for the SIP class map.

Fields

- Match Type—Specifies whether the class map includes traffic that matches the criterion, or traffic that does not match the criterion.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of SIP traffic to match.
  - Called Party—Match the called party as specified in the To header.
  - Calling Party—Match the calling party as specified in the From header.
  - Content Length—Match the Content Length header, between 0 and 65536.
  - Content Type—Match the Content Type header.
  - IM Subscriber—Match the SIP IM subscriber.
  - Message Path—Match the SIP Via header.
  - Request Method—Match the SIP request method.
  - Third-Party Registration—Match the requester of a third-party registration.
  - URI Length—Match a URI in the SIP headers, between 0 and 65536.
- Called Party Criterion Values—Specifies to match the called party. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Calling Party Criterion Values—Specifies to match the calling party. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Content Length Criterion Values—Specifies to match a SIP content header of a length greater than specified.
  - Greater Than Length—Enter a header length value in bytes.
- Content Type Criterion Values—Specifies to match a SIP content header type.

  - SDP—Match an SDP SIP content header type.
  - Regular Expression—Match a regular expression.

    Regular Expression—Lists the defined regular expressions to match.

    Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

    Regular Expression Class—Lists the defined regular expression classes to match.

    Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- IM Subscriber Criterion Values—Specifies to match the IM subscriber. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Message Path Criterion Values—Specifies to match a SIP Via header. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Request Method Criterion Values—Specifies to match a SIP request method.
  - Request Method—Specifies a request method: ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, unknown, update.
- Third-Party Registration Criterion Values—Specifies to match the requester of a third-party registration. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- URI Length Criterion Values—Specifies to match a URI of a selected type and greater than the specified length in the SIP headers.
  - URI type—Specifies to match either SIP URI or TEL URI.
  - Greater Than Length—Length in bytes.

SIP Inspect Map

Configuration > Global Objects > Inspect Maps > SIP

The SIP pane lets you view previously configured SIP application inspection maps. A SIP map lets you change the default configuration values used for SIP application inspection.

SIP is a widely used protocol for Internet conferencing, telephony, presence, events notification, and instant messaging. Partially because of its text-based nature and partially because of its flexibility, SIP networks are subject to a large number of security threats.

SIP application inspection provides address translation in message header and body, dynamic opening of ports and basic sanity checks. It also supports application security and protocol conformance, which enforce the sanity of the SIP messages, as well as detect SIP-based attacks.

Fields

- SIP Inspect Maps—Table that lists the defined SIP inspect maps.
- Add—Configures a new SIP inspect map. To edit a SIP inspect map, choose the SIP entry in the SIP Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the SIP Inspect Maps table.
- Security Level—Select the security level (high or low).
  - Low—Default.

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Permitted.

    Hide server's and endpoint's IP addresses: Disabled.

    Mask software version and non-SIP URIs: Disabled.

    Ensure that the number of hops to destination is greater than 0: Enabled.

    RTP conformance: Not enforced.

    SIP conformance: Do not perform state checking and header validation.
  - Medium

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Permitted.

    Hide server's and endpoint's IP addresses: Disabled.

    Mask software version and non-SIP URIs: Disabled.

    Ensure that the number of hops to destination is greater than 0: Enabled.

    RTP conformance: Enforced.

    Limit payload to audio or video, based on the signaling exchange: No

    SIP conformance: Drop packets that fail state checking.
  - High

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Denied.

    Hide server's and endpoint's IP addresses: Disabled.

    Mask software version and non-SIP URIs: Enabled.

Ensure that the number of hops to destination is greater than 0: Enabled.

RTP conformance: Enforced.

Limit payload to audio or video, based on the signaling exchange: Yes

SIP conformance: Drop packets that fail state checking and packets that fail header validation.

- Customize—Opens the Add/Edit SIP Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Low.

Add/Edit SIP Policy Map (Security Level)

Configuration > Global Objects > Inspect Maps > SIP > SIP Inspect Map > Basic View

The Add/Edit SIP Policy Map pane lets you configure the security level and additional settings for SIP application inspection maps.

Fields

- Name—When adding a SIP, enter the name of the SIP map. When editing a SIP map, the name of the previously configured SIP map is shown.
- Description—Enter the description of the SIP map, up to 200 characters in length.
- Security Level—Select the security level (high or low).
  - Low—Default.

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Permitted.

    Hide server's and endpoint's IP addresses: Disabled.

    Mask software version and non-SIP URIs: Disabled.

    Ensure that the number of hops to destination is greater than 0: Enabled.

    RTP conformance: Not enforced.

    SIP conformance: Do not perform state checking and header validation.
  - Medium

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Permitted.

    Hide server's and endpoint's IP addresses: Disabled.

    Mask software version and non-SIP URIs: Disabled.

    Ensure that the number of hops to destination is greater than 0: Enabled.

    RTP conformance: Enforced.

    Limit payload to audio or video, based on the signaling exchange: No

    SIP conformance: Drop packets that fail state checking.
  - High

    SIP instant messaging (IM) extensions: Enabled.

    Non-SIP traffic on SIP port: Denied.

    Hide server's and endpoint's IP addresses: Disabled.

Mask software version and non-SIP URIs: Enabled.

Ensure that the number of hops to destination is greater than 0: Enabled.

RTP conformance: Enforced.

Limit payload to audio or video, based on the signaling exchange: Yes

SIP conformance: Drop packets that fail state checking and packets that fail header validation.

  - Default Level—Sets the security level back to the default.
- Details—Shows additional filtering, IP address privacy, hop count, RTP conformance, SIP conformance, field masking, and inspections settings to configure.

Add/Edit SIP Policy Map (Details)

Configuration > Global Objects > Inspect Maps > SIP > SIP Inspect Map > Advanced View

The Add/Edit SIP Policy Map pane lets you configure the security level and additional settings for SIP application inspection maps.

Fields

- Name—When adding a SIP, enter the name of the SIP map. When editing a SIP map, the name of the previously configured SIP map is shown.
- Description—Enter the description of the SIP map, up to 200 characters in length.
- Security Level—Shows the security level settings to configure
- Filtering—Tab that lets you configure the filtering settings for SIP.
  - Enable SIP instant messaging (IM) extensions—Enables Instant Messaging extensions. Default is enabled.
  - Permit non-SIP traffic on SIP port—Permits non-SIP traffic on SIP port. Permitted by default.
- IP Address Privacy—Tab that lets you configure the IP address privacy settings for SIP.
  - Hide server's and endpoint's IP addresses—Enables IP address privacy. Disabled by default.
- Hop Count—Tab that lets you configure the hop count settings for SIP.
  - Ensure that number of hops to destination is greater than 0—Enables check for the value of Max-Forwards header is zero.

    Action—Drop packet, Drop Connection, Reset, Log.

    Log—Enable or Disable.
- RTP Conformance—Tab that lets you configure the RTP conformance settings for SIP.
  - Check RTP packets for protocol conformance—Checks RTP/RTCP packets flowing on the pinholes for protocol conformance.

    Limit payload to audio or video, based on the signaling exchange—Enforces payload type to be audio/video based on the signaling exchange.
- SIP Conformance—Tab that lets you configure the SIP conformance settings for SIP.
  - Enable state transition checking—Enables SIP state checking.

    Action—Drop packet, Drop Connection, Reset, Log.

    Log—Enable or Disable.
  - Enable strict validation of header fields—Enables validation of SIP header fields.

Action—Drop packet, Drop Connection, Reset, Log.

Log—Enable or Disable.

- Field Masking—Tab that lets you configure the field masking settings for SIP.
  - Inspect non-SIP URIs—Enables non-SIP URI inspection in Alert-Info and Call-Info headers.

    Action—Mask or Log.

    Log—Enable or Disable.
  - Inspect server's and endpoint's software version—Inspects SIP endpoint software version in User-Agent and Server headers.

    Action—Mask or Log.

    Log—Enable or Disable.
- Inspections—Tab that shows you the SIP inspection configuration and lets you add or edit.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the SIP inspection.
  - Value—Shows the value to match in the SIP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add SIP Inspect dialog box to add a SIP inspection.
  - Edit—Opens the Edit SIP Inspect dialog box to edit a SIP inspection.
  - Delete—Deletes a SIP inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit SIP Inspect

Configuration > Global Objects > Inspect Maps > SIP > SIP Inspect Map > Advanced View > Add/Edit SIP Inspect

The Add/Edit SIP Inspect dialog box lets you define the match criterion and value for the SIP inspect map.

Fields

- Single Match—Specifies that the SIP inspect has only one match statement.
- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string "example.com," then any traffic that contains "example.com" is excluded from the class map.
- Criterion—Specifies which criterion of SIP traffic to match.
  - Called Party—Match a called party as specified in the To header.
  - Calling Party—Match a calling party as specified in the From header.
  - Content Length—Match a content length header.
  - Content Type—Match a content type header.
  - IM Subscriber—Match a SIP IM subscriber.

  - Message Path—Match a SIP Via header.
  - Request Method—Match a SIP request method.
  - Third-Party Registration—Match the requester of a third-party registration.
  - URI Length—Match a URI in the SIP headers.
- Called Party Criterion Values—Specifies to match the called party. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Calling Party Criterion Values—Specifies to match the calling party. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Content Length Criterion Values—Specifies to match a SIP content header of a length greater than specified.
  - Greater Than Length—Enter a header length value in bytes.
- Content Type Criterion Values—Specifies to match a SIP content header type.
  - SDP—Match an SDP SIP content header type.
  - Regular Expression—Match a regular expression.

    Regular Expression—Lists the defined regular expressions to match.

    Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.

    Regular Expression Class—Lists the defined regular expression classes to match.

    Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- IM Subscriber Criterion Values—Specifies to match the IM subscriber. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.

- Message Path Criterion Values—Specifies to match a SIP Via header. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- Request Method Criterion Values—Specifies to match a SIP request method.
  - Request Method—Specifies a request method: ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, unknown, update.
- Third-Party Registration Criterion Values—Specifies to match the requester of a third-party registration. Applies the regular expression match.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
- URI Length Criterion Values—Specifies to match a URI in the SIP headers greater than specified length.
  - URI type—Specifies to match either SIP URI or TEL URI.
  - Greater Than Length—Length in bytes.
- Multiple Matches—Specifies multiple matches for the SIP inspection.
  - SIP Traffic Class—Specifies the SIP traffic class match.
  - Manage—Opens the Manage SIP Class Maps dialog box to add, edit, or delete SIP Class Maps.
- Actions—Primary action and log settings.
  - Action—Drop packet, drop connection, reset, log. Note: Limit rate (pps) action is available for request methods invite and register.
  - Log—Enable or disable.

Skinny (SCCP) Inspection

This section describes SCCP application inspection. This section includes the following topics:

- SCCP Inspection Overview, page 59-32
- Supporting Cisco IP Phones, page 59-32
- Restrictions and Limitations, page 59-33
- Select SCCP (Skinny) Map, page 59-33
- SCCP (Skinny) Inspect Map, page 59-34
- Message ID Filtering, page 59-35

- Add/Edit SCCP (Skinny) Policy Map (Security Level), page 59-35
- Add/Edit SCCP (Skinny) Policy Map (Details), page 59-36
- Add/Edit Message ID Filter, page 59-37

SCCP Inspection Overview

Note For specific information about setting up the Phone Proxy on the ASA, which is part of the Cisco Unified Communications architecture and supports IP phone deployment, see Chapter 65, "Configuring the Cisco Phone Proxy.".

Skinny (SCCP) is a simplified protocol used in VoIP networks. Cisco IP Phones using SCCP can coexist in an H.323 environment. When used with Cisco CallManager, the SCCP client can interoperate with H.323 compliant terminals.

The ASA supports PAT and NAT for SCCP. PAT is necessary if you have more IP phones than global IP addresses for the IP phones to use. By supporting NAT and PAT of SCCP Signaling packets, Skinny application inspection ensures that all SCCP signalling and media packets can traverse the ASA.

Normal traffic between Cisco CallManager and Cisco IP Phones uses SCCP and is handled by SCCP inspection without any special configuration. The ASA also supports DHCP options 150 and 66, which it accomplishes by sending the location of a TFTP server to Cisco IP Phones and other DHCP clients. Cisco IP Phones might also include DHCP option 3 in their requests, which sets the default route.

Note The ASA supports inspection of traffic from Cisco IP Phones running SCCP protocol version 19 and earlier.

Supporting Cisco IP Phones

Note For specific information about setting up the Phone Proxy on the ASA, which is part of the Cisco Unified Communications architecture and supports IP phone deployment, see Chapter 65, "Configuring the Cisco Phone Proxy."

In topologies where Cisco CallManager is located on the higher security interface with respect to the Cisco IP Phones, if NAT is required for the Cisco CallManager IP address, the mapping must be **static** as a Cisco IP Phone requires the Cisco CallManager IP address to be specified explicitly in its configuration. An static identity entry allows the Cisco CallManager on the higher security interface to accept registrations from the Cisco IP Phones.

Cisco IP Phones require access to a TFTP server to download the configuration information they need to connect to the Cisco CallManager server.

When the Cisco IP Phones are on a lower security interface compared to the TFTP server, you must use an access list to connect to the protected TFTP server on UDP port 69. While you do need a static entry for the TFTP server, this does not have to be an identity static entry. When using NAT, an identity static entry maps to the same IP address. When using PAT, it maps to the same IP address and port.

When the Cisco IP Phones are on a *higher* security interface compared to the TFTP server and Cisco CallManager, no access list or static entry is required to allow the Cisco IP Phones to initiate the connection.

Restrictions and Limitations

The following are some of the known issues and limitations when using SCCP application inspection:

- PAT does not work with configurations containing the **alias** command.
- Outside NAT or PAT is *not* supported.

  If the address of an internal Cisco CallManager is configured for NAT or PAT to a different IP address or port, registrations for external Cisco IP Phones fail because the ASA currently does not support NAT or PAT for the file content transferred over TFTP.

  Although the ASA supports NAT of TFTP messages and opens a pinhole for the TFTP file, the ASA cannot translate the Cisco CallManager IP address and port embedded in the Cisco IP Phone configuration files that are transferred by TFTP during phone registration.
- The ASA supports stateful failover of SCCP calls except for calls that are in the middle of call setup.
- When the ASA is running in transparent firewall mode, it blocks SCCP voice traffic because pinholes are not opened for the connection. Displaying debugging messages for SCCP inspection indicate that RTP and RTCP channels are not open. This limication affects communication between IP Phones and the Unified Communications Manager.

  To workaround this limitation, perform one of the following actions to open secondary connections:

  – (Preferred) Install static route entries for IP Phones or convert to routed mode.

  – Configure static ARP entries for IP Phones

    Example:

    ```
    UC Manager---IP Phone 1---Inside ASA (Transparent)---Outside ASA---IP Phone 2
    ```

    In this example, configure a static ARP entry for IP Phone 1 on the ASA to send RTP and RTCP traffic from IP Phone 2 to IP Phone 1.

Select SCCP (Skinny) Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select SCCP Map

The Select SCCP (Skinny) Map dialog box lets you select or create a new SCCP (Skinny) map. An SCCP (Skinny) map lets you change the configuration values used for SCCP (Skinny) application inspection. The Select SCCP (Skinny) Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default SCCP (Skinny) inspection map—Specifies to use the default SCCP (Skinny) map.
- Select an SCCP (Skinny) map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.
- Encrypted Traffic Inspection—Lets you specify TLS proxy settings for the inspect map.

- Do not inspect Encrypted Traffic—Disables the inspection of Skinny application inspection.
- Use Phone Proxy to enable inspection of encrypted traffic—Uses the Phone Proxy configured on the ASA to inspect Skinny application traffic. See Chapter 65, "Configuring the Cisco Phone Proxy."
- Use TLS Proxy to enable inspection of encrypted traffic—Specifies to use Transaction Layer Security Proxy to enable inspection of encryped traffic.

  TLS Proxy Name:—Name of existing TLS Proxy.

  New—Opens the Add TLS Proxy dialog box to add a TLS Proxy.

SCCP (Skinny) Inspect Map

Configuration > Global Objects > Inspect Maps > SCCP (Skinny)

The SCCP (Skinny) pane lets you view previously configured SCCP (Skinny) application inspection maps. An SCCP (Skinny) map lets you change the default configuration values used for SCCP (Skinny) application inspection.

Skinny application inspection performs translation of embedded IP address and port numbers within the packet data, and dynamic opening of pinholes. It also performs additional protocol conformance checks and basic state tracking.

Fields

- SCCP (Skinny) Inspect Maps—Table that lists the defined SCCP (Skinny) inspect maps.
- Add—Configures a new SCCP (Skinny) inspect map. To edit an SCCP (Skinny) inspect map, choose the SCCP (Skinny) entry in the SCCP (Skinny) Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the SCCP (Skinny) Inspect Maps table.
- Security Level—Select the security level (high or low).
  - Low—Default.

    Registration: Not enforced.

    Maximum message ID: 0x181.

    Minimum prefix length: 4

    Media timeout: 00:05:00

    Signaling timeout: 01:00:00.

    RTP conformance: Not enforced.
  - Medium

    Registration: Not enforced.

    Maximum message ID: 0x141.

    Minimum prefix length: 4.

    Media timeout: 00:01:00.

    Signaling timeout: 00:05:00.

    RTP conformance: Enforced.

    Limit payload to audio or video, based on the signaling exchange: No.
  - High

Registration: Enforced.

Maximum message ID: 0x141.

Minimum prefix length: 4.

Maximum prefix length: 65536.

Media timeout: 00:01:00.

Signaling timeout: 00:05:00.

RTP conformance: Enforced.

Limit payload to audio or video, based on the signaling exchange: Yes.

- Message ID Filtering—Opens the Messaging ID Filtering dialog box for configuring message ID filters.
- Customize—Opens the Add/Edit SCCP (Skinny) Policy Map dialog box for additional settings.
- Default Level—Sets the security level back to the default level of Low.

Message ID Filtering

Configuration > Global Objects > Inspect Maps > SCCP (Skinny) > Message ID Filtering

The Message ID Filtering dialog box lets you configure the settings for a message ID filter.

Fields

- Match Type—Shows the match type, which can be a positive or negative match.
- Criterion—Shows the criterion of the inspection.
- Value—Shows the value to match in the inspection.
- Action—Shows the action if the match condition is met.
- Log—Shows the log state.
- Add—Opens the Add Message ID Filtering dialog box to add a message ID filter.
- Edit—Opens the Edit Message ID Filtering dialog box to edit a message ID filter.
- Delete—Deletes a message ID filter.
- Move Up—Moves an entry up in the list.
- Move Down—Moves an entry down in the list.

Add/Edit SCCP (Skinny) Policy Map (Security Level)

Configuration > Global Objects > Inspect Maps > SCCP (Skinny) > SCCP (Skinny) Inspect Map > Basic View

The Add/Edit SCCP (Skinny) Policy Map pane lets you configure the security level and additional settings for SCCP (Skinny) application inspection maps.

Fields

- Name—When adding an SCCP (Skinny) map, enter the name of the SCCP (Skinny) map. When editing an SCCP (Skinny) map, the name of the previously configured SCCP (Skinny) map is shown.
- Description—Enter the description of the SCCP (Skinny) map, up to 200 characters in length.

- Security Level—Select the security level (high or low).
  - Low—Default.

    Registration: Not enforced.

    Maximum message ID: 0x181.

    Minimum prefix length: 4

    Media timeout: 00:05:00

    Signaling timeout: 01:00:00.

    RTP conformance: Not enforced.
  - Medium

    Registration: Not enforced.

    Maximum message ID: 0x141.

    Minimum prefix length: 4.

    Media timeout: 00:01:00.

    Signaling timeout: 00:05:00.

    RTP conformance: Enforced.

    Limit payload to audio or video, based on the signaling exchange: No.
  - High

    Registration: Enforced.

    Maximum message ID: 0x141.

    Minimum prefix length: 4.

    Maximum prefix length: 65536.

    Media timeout: 00:01:00.

    Signaling timeout: 00:05:00.

    RTP conformance: Enforced.

    Limit payload to audio or video, based on the signaling exchange: Yes.
  - Message ID Filtering—Opens the Messaging ID Filtering dialog box for configuring message ID filters.
  - Default Level—Sets the security level back to the default.
- Details—Shows additional parameter, RTP conformance, and message ID filtering settings to configure.

Add/Edit SCCP (Skinny) Policy Map (Details)

Configuration > Global Objects > Inspect Maps > SCCP (Skinny) > SCCP (Skinny) Inspect Map > Advanced View

The Add/Edit SCCP (Skinny) Policy Map pane lets you configure the security level and additional settings for SCCP (Skinny) application inspection maps.

Fields

- Name—When adding an SCCP (Skinny) map, enter the name of the SCCP (Skinny) map. When editing an SCCP (Skinny) map, the name of the previously configured SCCP (Skinny) map is shown.
- Description—Enter the description of the DNS map, up to 200 characters in length.
- Security Level—Shows the security level and message ID filtering settings to configure.
- Parameters—Tab that lets you configure the parameter settings for SCCP (Skinny).
  - Enforce endpoint registration—Enforce that Skinny endpoints are registered before placing or receiving calls.

    Maximum Message ID—Specify value of maximum SCCP message ID allowed.
  - SCCP Prefix Length—Specifies prefix length value in Skinny messages.

    Minimum Prefix Length—Specify minimum value of SCCP prefix length allowed.

    Maximum Prefix Length—Specify maximum value of SCCP prefix length allowed.
  - Media Timeout—Specify timeout value for media connections.
  - Signaling Timeout—Specify timeout value for signaling connections.
- RTP Conformance—Tab that lets you configure the RTP conformance settings for SCCP (Skinny).
  - Check RTP packets for protocol conformance—Checks RTP/RTCP packets flowing on the pinholes for protocol conformance.

    Limit payload to audio or video, based on the signaling exchange—Enforces the payload type to be audio/video based on the signaling exchange.
- Message ID Filtering—Tab that lets you configure the message ID filtering settings for SCCP (Skinny).
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the inspection.
  - Value—Shows the value to match in the inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add Message ID Filtering dialog box to add a message ID filter.
  - Edit—Opens the Edit Message ID Filtering dialog box to edit a message ID filter.
  - Delete—Deletes a message ID filter.
  - Move Up—Moves an entry up in the list.
  - Move Down—Moves an entry down in the list.

Add/Edit Message ID Filter

Configuration > Global Objects > Inspect Maps > SCCP (Skinny) > SCCP (Skinny) Inspect Map > Advanced View > Add/Edit Message ID Filter

The Add Message ID Filter dialog box lets you configure message ID filters.

Fields

- Match Type—Specifies whether traffic should match or not match the values.

For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.

- Criterion—Specifies which criterion of SCCP (Skinny) traffic to match.
  - Message ID—Match specified message ID.

    Message ID—Specify value of maximum SCCP message ID allowed.
  - Message ID Range—Match specified message ID range.

    Lower Message ID—Specify lower value of SCCP message ID allowed.

    Upper Message ID—Specify upper value of SCCP message ID allowed.
- Action—Drop packet.
- Log—Enable or disable.

Configuring Inspection of Database and Directory Protocols

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the ASA by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- ILS Inspection, page 60-1
- SQL*Net Inspection, page 60-2
- Sun RPC Inspection, page 60-3

ILS Inspection

The ILS inspection engine provides NAT support for Microsoft NetMeeting, SiteServer, and Active Directory products that use LDAP to exchange directory information with an ILS server.

The ASA supports NAT for ILS, which is used to register and locate endpoints in the ILS or SiteServer Directory. PAT cannot be supported because only IP addresses are stored by an LDAP database.

For search responses, when the LDAP server is located outside, NAT should be considered to allow internal peers to communicate locally while registered to external LDAP servers. For such search responses, xlates are searched first, and then DNAT entries to obtain the correct address. If both of these searches fail, then the address is not changed. For sites using NAT 0 (no NAT) and not expecting DNAT interaction, we recommend that the inspection engine be turned off to provide better performance.

Additional configuration may be necessary when the ILS server is located inside the ASA border. This would require a hole for outside clients to access the LDAP server on the specified port, typically TCP 389.

Because ILS traffic only occurs on the secondary UDP channel, the TCP connection is disconnected after the TCP inactivity interval. By default, this interval is 60 minutes and can be adjusted using the **timeout** command.

ILS/LDAP follows a client/server model with sessions handled over a single TCP connection. Depending on the client's actions, several of these sessions may be created.

During connection negotiation time, a BIND PDU is sent from the client to the server. Once a successful BIND RESPONSE from the server is received, other operational messages may be exchanged (such as ADD, DEL, SEARCH, or MODIFY) to perform operations on the ILS Directory. The ADD REQUEST and SEARCH RESPONSE PDUs may contain IP addresses of NetMeeting peers, used by H.323 (SETUP and CONNECT messages) to establish the NetMeeting sessions. Microsoft NetMeeting v2.X and v3.X provides ILS support.

The ILS inspection performs the following operations:

- Decodes the LDAP REQUEST/RESPONSE PDUs using the BER decode functions
- Parses the LDAP packet
- Extracts IP addresses
- Translates IP addresses as necessary
- Encodes the PDU with translated addresses using BER encode functions
- Copies the newly encoded PDU back to the TCP packet
- Performs incremental TCP checksum and sequence number adjustment

ILS inspection has the following limitations:

- Referral requests and responses are not supported
- Users in multiple directories are not unified
- Single users having multiple identities in multiple directories cannot be recognized by NAT

Note Because H.225 call signalling traffic only occurs on the secondary UDP channel, the TCP connection is disconnected after the interval specified by the TCP option in the Configuration > Firewall > Advanced > Global Timeouts pane. By default, this interval is set at 60 minutes.

SQL*Net Inspection

SQL*Net inspection is enabled by default.

The SQL*Net protocol consists of different packet types that the ASA handles to make the data stream appear consistent to the Oracle applications on either side of the ASA.

The default port assignment for SQL*Net is 1521. This is the value used by Oracle for SQL*Net, but this value does not agree with IANA port assignments for Structured Query Language (SQL).

Note Disable SQL*Net inspection when SQL data transfer occurs on the same port as the SQL control TCP port 1521. The security appliance acts as a proxy when SQL*Net inspection is enabled and reduces the client window size from 65000 to about 16000 causing data transfer issues.

The ASA translates all addresses and looks in the packets for all embedded ports to open for SQL*Net Version 1.

For SQL*Net Version 2, all DATA or REDIRECT packets that immediately follow REDIRECT packets with a zero data length will be fixed up.

The packets that need fix-up contain embedded host/port addresses in the following format:

```
(ADDRESS=(PROTOCOL=tcp)(DEV=6)(HOST=a.b.c.d)(PORT=a))
```

SQL*Net Version 2 TNSFrame types (Connect, Accept, Refuse, Resend, and Marker) will not be scanned for addresses to NAT nor will inspection open dynamic connections for any embedded ports in the packet.

SQL*Net Version 2 TNSFrames, Redirect, and Data packets will be scanned for ports to open and addresses to NAT, if preceded by a REDIRECT TNSFrame type with a zero data length for the payload. When the Redirect message with data length zero passes through the ASA, a flag will be set in the connection data structure to expect the Data or Redirect message that follows to be translated and ports to be dynamically opened. If one of the TNS frames in the preceding paragraph arrive after the Redirect message, the flag will be reset.

The SQL*Net inspection engine will recalculate the checksum, change IP, TCP lengths, and readjust Sequence Numbers and Acknowledgment Numbers using the delta of the length of the new and old message.

SQL*Net Version 1 is assumed for all other cases. TNSFrame types (Connect, Accept, Refuse, Resend, Marker, Redirect, and Data) and all packets will be scanned for ports and addresses. Addresses will be translated and port connections will be opened.

Sun RPC Inspection

This section describes Sun RPC application inspection. This section includes the following topics:

- Sun RPC Inspection Overview, page 60-3
- "SUNRPC Server" section on page 60-4
- "Add/Edit SUNRPC Service" section on page 60-4

Sun RPC Inspection Overview

The Sun RPC inspection engine enables or disables application inspection for the Sun RPC protocol. Sun RPC is used by NFS and NIS. Sun RPC services can run on any port. When a client attempts to access an Sun RPC service on a server, it must learn the port that service is running on. It does this by querying the port mapper process, usually rpcbind, on the well-known port of 111.

The client sends the Sun RPC program number of the service and the port mapper process responds with the port number of the service. The client sends its Sun RPC queries to the server, specifying the port identified by the port mapper process. When the server replies, the ASA intercepts this packet and opens both embryonic TCP and UDP connections on that port.

The following limitations apply to Sun RPC inspection:

- NAT or PAT of Sun RPC payload information is not supported.
- Sun RPC inspection supports inbound access lists only. Sun RPC inspection does not support outbound access lists because the inspection engine uses dynamic access lists instead of secondary connections. Dynamic access lists are always added on the ingress direction and not on egress; therefore, this inspection engine does not support outbound access lists. To view the dynamic access lists configured for the ASA, use the **show asp table classify domain permit** command. For information about the **show asp table classify domain permit** command, see the CLI configuration guide.

SUNRPC Server

Configuration > Properties > SUNRPC Server

The Configuration > Firewall > Advanced > SUNRPC Server pane shows which SunRPC services can traverse the ASA and their specific timeout, on a per server basis.

Fields

- Interface—Displays the interface on which the SunRPC server resides.
- IP address—Displays the IP address of the SunRPC server.
- Mask—Displays the subnet mask of the IP Address of the SunRPC server.
- Service ID—Displays the SunRPC program number, or service ID, allowed to traverse the ASA.
- Protocol—Displays the SunRPC transport protocol (TCP or UDP).
- Port—Displays the SunRPC protocol port range.
- Timeout—Displays the idle time after which the access for the SunRPC service traffic is closed.

Add/Edit SUNRPC Service

Configuration > Properties > SUNRPC Server > Add/Edit SUNRPC Service

The Configuration > Firewall > Advanced > SUNRPC Server > Add/Edit SUNRPC Service dialog box lets you specify what SunRPC services are allowed to traverse the ASA and their specific timeout, on a per-server basis.

Fields

- Interface Name—Specifies the interface on which the SunRPC server resides.
- Protocol—Specifies the SunRPC transport protocol (TCP or UDP).
- IP address—Specifies the IP address of the SunRPC server.
- Port—Specifies the SunRPC protocol port range.
- Mask—Specifies the subnet mask of the IP Address of the SunRPC server.
- Timeout—Specifies the idle time after which the access for the SunRPC service traffic is closed. Format is HH:MM:SS.
- Service ID—Specifies the SunRPC program number, or service ID, allowed to traverse the ASA.

Configuring Inspection for Management Application Protocols

This chapter describes how to configure application layer protocol inspection. Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection instead of passing the packet through the fast path. As a result, inspection engines can affect overall throughput.

Several common inspection engines are enabled on the ASA by default, but you might need to enable others depending on your network.

This chapter includes the following sections:

- DCERPC Inspection, page 61-1
- GTP Inspection, page 61-4
- RADIUS Accounting Inspection, page 61-10
- RSH Inspection, page 61-13
- SNMP Inspection, page 61-13
- XDMCP Inspection, page 61-15

DCERPC Inspection

This section describes the DCERPC inspection engine. This section includes the following topics:

- DCERPC Overview, page 61-1
- “Select DCERPC Map” section on page 61-2
- “DCERPC Inspect Map” section on page 61-2
- “Add/Edit DCERPC Policy Map” section on page 61-3

DCERPC Overview

DCERPC is a protocol widely used by Microsoft distributed client and server applications that allows software clients to execute programs on a server remotely.

This typically involves a client querying a server called the Endpoint Mapper listening on a well known port number for the dynamically allocated network information of a required service. The client then sets up a secondary connection to the server instance providing the service. The security appliance allows the appropriate port number and network address and also applies NAT, if needed, for the secondary connection.

DCERPC inspect maps inspect for native TCP communication between the EPM and client on well known TCP port 135. Map and lookup operations of the EPM are supported for clients. Client and server can be located in any security zone. The embedded server IP address and Port number are received from the applicable EPM response messages. Since a client may attempt multiple connections to the server port returned by EPM, multiple use of pinholes are allowed, which have user configurable timeouts.

Note DCERPC inspection only supports communication between the EPM and clients to open pinholes through theASA. Clients using RPC communication that does not use the EPM is not supported with DCERPC inspection.

Select DCERPC Map

Add/Edit Service Policy Rule Wizard > Rule Actions >
Protocol Inspection Tab >Select DCERPC Map

The Select DCERPC Map dialog box lets you select or create a new DCERPC map. A DCERPC map lets you change the configuration values used for DCERPC application inspection. The Select DCERPC Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default DCERPC inspection map—Specifies to use the default DCERPC map.
- Select a DCERPC map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

DCERPC Inspect Map

Configuration > Global Objects > Inspect Maps > DCERPC

The DCERPC pane lets you view previously configured DCERPC application inspection maps. A DCERPC map lets you change the default configuration values used for DCERPC application inspection.

DCERPC is a protocol widely used by Microsoft distributed client and server applications that allows software clients to execute programs on a server remotely.

This typically involves a client querying a server called the Endpoint Mapper (EPM) listening on a well known port number for the dynamically allocated network information of a required service. The client then sets up a secondary connection to the server instance providing the service. The security appliance allows the appropriate port number and network address and also applies NAT, if needed, for the secondary connection.

DCERPC inspect maps inspect for native TCP communication between the EPM and client on well known TCP port 135. Map and lookup operations of the EPM are supported for clients. Client and server can be located in any security zone. The embedded server IP address and Port number are received from the applicable EPM response messages. Because a client may attempt multiple connections to the server port returned by EPM, multiple use of pinholes are allowed, which have user configurable timeouts.

Fields

- DCERPC Inspect Maps—Table that lists the defined DCERPC inspect maps.
- Add—Configures a new DCERPC inspect map. To edit a DCERPC inspect map, choose the DCERPC entry in the DCERPC Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the DCERPC Inspect Maps table.
- Security Level—Select the security level (high, medium, or low).
  - Low

    Pinhole timeout: 00:02:00

    Endpoint mapper service: not enforced

    Endpoint mapper service lookup: enabled

    Endpoint mapper service lookup timeout: 00:05:00
  - Medium—Default.

    Pinhole timeout: 00:01:00

    Endpoint mapper service: not enforced

    Endpoint mapper service lookup: disabled.
  - High

    Pinhole timeout: 00:01:00

    Endpoint mapper service: enforced

    Endpoint mapper service lookup: disabled
  - Customize—Opens the Add/Edit DCERPC Policy Map dialog box for additional settings.
  - Default Level—Sets the security level back to the default level of Medium.

Add/Edit DCERPC Policy Map

Configuration > Global Objects > Inspect Maps > DCERPC > DCERPC Inspect Map > Basic/Advanced View

The Add/Edit DCERPC Policy Map pane lets you configure the security level and parameters for DCERPC application inspection maps.

Fields

- Name—When adding a DCERPC map, enter the name of the DCERPC map. When editing a DCERPC map, the name of the previously configured DCERPC map is shown.
- Description—Enter the description of the DCERPC map, up to 200 characters in length.
- Security Level—Select the security level (high, medium, or low).
  - Low

    Pinhole timeout: 00:02:00

Endpoint mapper service: not enforced

Endpoint mapper service lookup: enabled

Endpoint mapper service lookup timeout: 00:05:00

- Medium—Default.

  Pinhole timeout: 00:01:00

  Endpoint mapper service: not enforced

  Endpoint mapper service lookup: disabled.

- High

  Pinhole timeout: 00:01:00

  Endpoint mapper service: enforced

  Endpoint mapper service lookup: disabled

- Default Level—Sets the security level back to the default level of Medium.

- Details—Shows the Parameters to configure additional settings.
  - Pinhole Timeout—Sets the pinhole timeout. Because a client may use the server information returned by the endpoint mapper for multiple connections, the timeout value is configurable based on the client application environment. Range is from 0:0:1 to 1193:0:0. Default is 2 minutes.
  - Enforce endpoint-mapper service—Enforces endpoint mapper service during binding.
  - Enable endpoint-mapper service lookup—Enables the lookup operation of the endpoint mapper service. If disabled, the pinhole timeout is used.

    Enforce Service Lookup Timeout—Enforces the service lookup timeout specified.

    Service Lookup Timeout—Sets the timeout for pinholes from lookup operation.

GTP Inspection

This section describes the GTP inspection engine. This section includes the following topics:

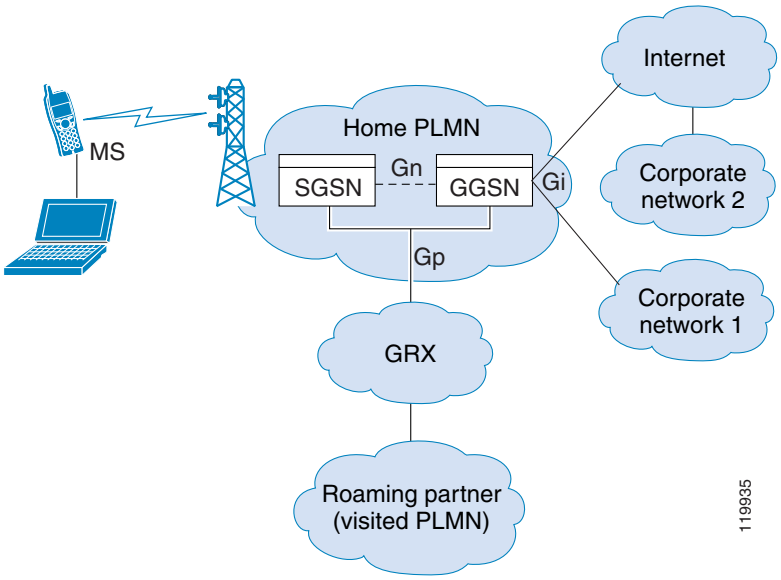
- GTP Inspection Overview, page 61-5
- "Select GTP Map" section on page 61-5
- "GTP Inspect Map" section on page 61-6
- "IMSI Prefix Filtering" section on page 61-7
- "Add/Edit GTP Policy Map (Security Level)" section on page 61-7
- "Add/Edit GTP Policy Map (Details)" section on page 61-8
- "Add/Edit GTP Map" section on page 61-9

Note GTP inspection requires a special license.

GTP Inspection Overview

GPRS provides uninterrupted connectivity for mobile subscribers between GSM networks and corporate networks or the Internet. The GGSN is the interface between the GPRS wireless data network and other networks. The SGSN performs mobility, data session management, and data compression (See Figure 61-1).

Figure 61-1 GPRS Tunneling Protocol



The UMTS is the commercial convergence of fixed-line telephony, mobile, Internet and computer technology. UTRAN is the networking protocol used for implementing wireless networks in this system. GTP allows multi-protocol packets to be tunneled through a UMTS/GPRS backbone between a GGSN, an SGSN and the UTRAN.

GTP does not include any inherent security or encryption of user data, but using GTP with the ASA helps protect your network against these risks.

The SGSN is logically connected to a GGSN using GTP. GTP allows multiprotocol packets to be tunneled through the GPRS backbone between GSNs. GTP provides a tunnel control and management protocol that allows the SGSN to provide GPRS network access for a mobile station by creating, modifying, and deleting tunnels. GTP uses a tunneling mechanism to provide a service for carrying user data packets.

Note When using GTP with failover, if a GTP connection is established and the active unit fails before data is transmitted over the tunnel, the GTP data connection (with a "j" flag set) is not replicated to the standby unit. This occurs because the active unit does not replicate embryonic connections to the standby unit.

Select GTP Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab >Select GTP Map

The Select GTP Map dialog box lets you select or create a new GTP map. A GTP map lets you change the configuration values used for GTP application inspection. The Select GTP Map table provides a list of previously configured maps that you can select for application inspection.

Note GTP inspection requires a special license. If you try to enable GTP application inspection on a ASA without the required license, the ASA displays an error message.

Fields

- Use the default GTP inspection map—Specifies to use the default GTP map.
- Select an GTP map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

GTP Inspect Map

Configuration > Global Objects > Inspect Maps > GTP

The GTP pane lets you view previously configured GTP application inspection maps. A GTP map lets you change the default configuration values used for GTP application inspection.

GTP is a relatively new protocol designed to provide security for wireless connections to TCP/IP networks, such as the Internet. You can use a GTP map to control timeout values, message sizes, tunnel counts, and GTP versions traversing the security appliance.

Note GTP inspection is not available without a special license.

Fields

- GTP Inspect Maps—Table that lists the defined GTP inspect maps.
- Add—Configures a new GTP inspect map. To edit a GTP inspect map, choose the GTP entry in the GTP Inspect Maps table and click **Customize**.
- Delete—Deletes the inspect map selected in the GTP Inspect Maps table.
- Security Level—Security level low only.
  - Do not Permit Errors
  - Maximum Number of Tunnels: 500
  - GSN timeout: 00:30:00
  - Pdp-Context timeout: 00:30:00
  - Request timeout: 00:01:00
  - Signaling timeout: 00:30:00.
  - Tunnel timeout: 01:00:00.
  - T3-response timeout: 00:00:20.
  - Drop and log unknown message IDs.
- IMSI Prefix Filtering—Opens the IMSI Prefix Filtering dialog box to configure IMSI prefix filters.
- Customize—Opens the Add/Edit GTP Policy Map dialog box for additional settings.

- Default Level—Sets the security level back to the default.

IMSI Prefix Filtering

Configuration > Global Objects > Inspect Maps > GTP > IMSI Prefix Filtering

The IMSI Prefix tab lets you define the IMSI prefix to allow within GTP requests.

Fields

- Mobile Country Code—Defines the non-zero, three-digit value identifying the mobile country code. One or two-digit entries will be prepended by 0 to create a three-digit value.
- Mobile Network Code—Defines the two or three-digit value identifying the network code.
- Add—Add the specified country code and network code to the IMSI Prefix table.
- Delete—Deletes the specified country code and network code from the IMSI Prefix table.

Add/Edit GTP Policy Map (Security Level)

Configuration > Global Objects > Inspect Maps > GTP > GTP Inspect Map > Basic View

The Add/Edit GTP Policy Map pane lets you configure the security level and additional settings for GTP application inspection maps.

Fields

- Name—When adding a GTP map, enter the name of the GTP map. When editing a GTP map, the name of the previously configured GTP map is shown.
- Description—Enter the description of the GTP map, up to 200 characters in length.
- Security Level—Security level low only.

  Do not Permit Errors

  Maximum Number of Tunnels: 500

  GSN timeout: 00:30:00

  Pdp-Context timeout: 00:30:00

  Request timeout: 00:01:00

  Signaling timeout: 00:30:00.

  Tunnel timeout: 01:00:00.

  T3-response timeout: 00:00:20.

  Drop and log unknown message IDs.

  – IMSI Prefix Filtering—Opens the IMSI Prefix Filtering dialog box to configure IMSI prefix filters.
  – Default Level—Sets the security level back to the default.
- Details—Shows the Parameters, IMSI Prefix Filtering, and Inspections tabs to configure additional settings.

Add/Edit GTP Policy Map (Details)

Configuration > Global Objects > Inspect Maps > GTP > GTP Inspect Map > Advanced View

The Add/Edit GTP Policy Map pane lets you configure the security level and additional settings for GTP application inspection maps.

Fields

- Name—When adding a GTP map, enter the name of the GTP map. When editing a GTP map, the name of the previously configured GTP map is shown.
- Description—Enter the description of the GTP map, up to 200 characters in length.
- Security Level—Shows the security level and IMSI prefix filtering settings to configure.
- Permit Parameters—Tab that lets you configure the permit parameters for the GTP inspect map.
  - Object Groups to Add

    From object group—Specify an object group or use the browse button to open the Add Network Object Group dialog box.

    To object group—Specify an object group or use the browse button to open the Add Network Object Group dialog box.
  - Add—Add the specified country code and network code to the IMSI Prefix table.
  - Delete—Deletes the specified country code and network code from the IMSI Prefix table.
  - Permit Errors—Lets any packets that are invalid or that encountered an error during inspection to be sent through the ASA instead of being dropped. By default, all invalid packets or packets that failed during parsing are dropped.
- General Parameters—Tab that lets you configure the general parameters for the GTP inspect map.
  - Maximum Number of Requests—Lets you change the default for the maximum request queue size allowed. The default for the maximum request queue size is 200. Specifies the maximum number of GTP requests that will be queued waiting for a response. The permitted range is from 1 to 9999999.
  - Maximum Number of Tunnels—Lets you change the default for the maximum number of tunnels allowed. The default tunnel limit is 500. Specifies the maximum number of tunnels allowed. The permitted range is from 1 to 9999999 for the global overall tunnel limit.
  - Timeouts

    GSN timeout—Lets you change the default for the maximum period of inactivity before a GSN is removed. The default is 30 minutes. Timeout is in the format *hh*:*mm*:*ss*, where *hh* specifies the hour, *mm* specifies the minutes, and *ss* specifies the seconds. A value 0 means never tear down.

    PDP-Context timeout—Lets you change the default for the maximum period of inactivity before receiving the PDP Context for a GTP session. The default is 30 minutes. Timeout is in the format *hh*:*mm*:*ss*, where *hh* specifies the hour, *mm* specifies the minutes, and *ss* specifies the seconds. A value 0 means never tear down.

    Request Queue—Lets you change the default for the maximum period of inactivity before receiving the GTP message during a GTP session. The default is 1 minute. Timeout is in the format *hh*:*mm*:*ss*, where *hh* specifies the hour, *mm* specifies the minutes, and *ss* specifies the seconds. A value 0 means never tear down.

Signaling—Lets you change the default for the maximum period of inactivity before a GTP signaling is removed. The default is 30 minutes. Timeout is in the format *hh*:*mm*:*ss*, where *hh* specifies the hour, *mm* specifies the minutes, and *ss* specifies the seconds. A value 0 means never tear down.

Tunnel—Lets you change the default for the maximum period of inactivity for the GTP tunnel. The default is 1 hour. Timeout is in the format *hh*:*mm*:*ss*, where *hh* specifies the hour, *mm* specifies the minutes, and *ss* specifies the seconds. A value 0 means never tear down Request timeout—Specifies the GTP Request idle timeout.

T3-Response timeout—Specifies the maximum wait time for a response before removing the connection.

- IMSI Prefix Filtering—Tab that lets you configure the IMSI prefix filtering for the GTP inspect map.
  - Mobile Country Code—Defines the non-zero, three-digit value identifying the mobile country code. One or two-digit entries will be prepended by 0 to create a three-digit value.
  - Mobile Network Code—Defines the two or three-digit value identifying the network code.
  - Add—Add the specified country code and network code to the IMSI Prefix table.
  - Delete—Deletes the specified country code and network code from the IMSI Prefix table.
- Inspections—Tab that lets you configure the GTP inspect maps.
  - Match Type—Shows the match type, which can be a positive or negative match.
  - Criterion—Shows the criterion of the GTP inspection.
  - Value—Shows the value to match in the GTP inspection.
  - Action—Shows the action if the match condition is met.
  - Log—Shows the log state.
  - Add—Opens the Add GTP Inspect dialog box to add an GTP inspection.
  - Edit—Opens the Edit GTP Inspect dialog box to edit an GTP inspection.
  - Delete—Deletes an GTP inspection.
  - Move Up—Moves an inspection up in the list.
  - Move Down—Moves an inspection down in the list.

Add/Edit GTP Map

Configuration > Global Objects > Inspect Maps > GTP > GTP Inspect Map > Add/Edit GTP Map

The Add/Edit GTP Inspect dialog box lets you define the match criterion and value for the GTP inspect map.

Fields

- Match Type—Specifies whether traffic should match or not match the values.

  For example, if No Match is selected on the string “example.com,” then any traffic that contains “example.com” is excluded from the class map.
- Criterion—Specifies which criterion of GTP traffic to match.
  - Access Point Name—Match on access point name.
  - Message ID—Match on the message ID.

  - Message Length—Match on the message length
  - Version—Match on the version.
- Access Point Name Criterion Values—Specifies an access point name to be matched. By default, all messages with valid APNs are inspected, and any APN is allowed.
  - Regular Expression—Lists the defined regular expressions to match.
  - Manage—Opens the Manage Regular Expressions dialog box, which lets you configure regular expressions.
  - Regular Expression Class—Lists the defined regular expression classes to match.
  - Manage—Opens the Manage Regular Expression Class dialog box, which lets you configure regular expression class maps.
  - Action—Drop.
  - Log—Enable or disable.
- Message ID Criterion Values—Specifies the numeric identifier for the message that you want to match. The valid range is 1 to 255. By default, all valid message IDs are allowed.
  - Value—Specifies whether value is an exact match or a range.

    Equals—Enter a value.

    Range—Enter a range of values.
  - Action—Drop packet or limit rate (pps).
  - Log—Enable or disable.
- Message Length Criterion Values—Lets you change the default for the maximum message length for the UDP payload that is allowed.
  - Minimum value—Specifies the minimum number of bytes in the UDP payload. The range is from 1 to 65536.
  - Maximum value—Specifies the maximum number of bytes in the UDP payload. The range is from 1 to 65536.
  - Action—Drop packet.
  - Log—Enable or disable.
- Version Criterion Values—Specifies the GTP version for messages that you want to match. The valid range is 0-255. Use 0 to identify Version 0 and 1 to identify Version 1. Version 0 of GTP uses port 3386, while Version 1 uses port 2123. By default all GTP versions are allowed.
  - Value—Specifies whether value is an exact match or a range.

    Equals—Enter a value.

    Range—Enter a range of values.
  - Action—Drop packet.
  - Log—Enable or disable.

RADIUS Accounting Inspection

This section describes the IM inspection engine. This section includes the following topics:

- RADIUS Accounting Inspection Overview, page 61-11

- Select RADIUS Accounting Map, page 61-11
- Add RADIUS Accounting Policy Map, page 61-11
- RADIUS Inspect Map, page 61-12
- RADIUS Inspect Map Host, page 61-12
- RADIUS Inspect Map Other, page 61-13

RADIUS Accounting Inspection Overview

One of the well known problems is the over-billing attack in GPRS networks. The over-billing attack can cause consumers anger and frustration by being billed for services that they have not used. In this case, a malicious attacker sets up a connection to a server and obtains an IP address from the SGSN. When the attacker ends the call, the malicious server will still send packets to it, which gets dropped by the GGSN, but the connection from the server remains active. The IP address assigned to the malicious attacker gets released and reassigned to a legitimate user who will then get billed for services that the attacker will use.

RADIUS accounting inspection prevents this type of attack by ensuring the traffic seen by the GGSN is legitimate. With the RADIUS accounting feature properly configured, the security appliance tears down a connection based on matching the Framed IP attribute in the Radius Accounting Request Start message with the Radius Accounting Request Stop message. When the Stop message is seen with the matching IP address in the Framed IP attribute, the security appliance looks for all connections with the source matching the IP address.

You have the option to configure a secret pre-shared key with the RADIUS server so the security appliance can validate the message. If the shared secret is not configured, the security appliance does not need to validate the source of the message and will only check that the source IP address is one of the configured addresses allowed to send the RADIUS messages.

Note When using RADIUS accounting inspection with GPRS enabled, theASA checks for the 3GPP-Session-Stop-Indicator in the Accounting Request STOP messages to properly handle secondary PDP contexts. Specifically, the ASA requires that the Accounting Request STOP messages include the 3GPP-SGSN-Address attribute before it will temrinate the user sessions and all associated connections. Some third-party GGSNs might not send this attribute by default.

Select RADIUS Accounting Map

The Select RADIUS Accounting Map dialog box lets you select a defined RADIUS accounting map or define a new one.

Fields

- Add—Lets you add a new RADIUS accounting map.

Add RADIUS Accounting Policy Map

The Add RADIUS Accounting Policy Map dialog box lets you add the basic settings for the RADIUS accounting map.

Fields

- Name—Enter the name of the previously configured RADIUS accounting map.
- Description—Enter the description of the RADIUS accounting map, up to 100 characters in length.
- Host Parameters tab:
  - Host IP Address—Specify the IP address of the host that is sending the RADIUS messages.
  - Key: (optional)—Specify the key.
  - Add—Adds the host entry to the Host table.
  - Delete—Deletes the host entry from the Host table.
- Other Parameters tab:
  - Attribute Number—Specify the attribute number to validate when an Accounting Start is received.
  - Add—Adds the entry to the Attribute table.
  - Delete—Deletes the entry from the Attribute table.
  - Send response to the originator of the RADIUS message—Sends a message back to the host from which the RADIUS message was sent.
  - Enforce timeout—Enables the timeout for users.
  - Users Timeout—Timeout for the users in the database (hh:mm:ss).

RADIUS Inspect Map

The RADIUS pane lets you view previously configured RADIUS application inspection maps. A RADIUS map lets you change the default configuration values used for RADIUS application inspection. You can use a RADIUS map to protect against an overbilling attack.

Fields

- Name—Enter the name of the inspect map, up to 40 characters in length.
- Description—Enter the description of the inspect map, up to 200 characters in length.
- RADIUS Inspect Maps—Table that lists the defined RADIUS inspect maps. The defined inspect maps are also listed in the RADIUS area of the Inspect Maps tree.
- Add—Adds the new RADIUS inspect map to the defined list in the RADIUS Inspect Maps table and to the RADIUS area of the Inspect Maps tree. To configure the new RADIUS map, select the RADIUS entry in Inspect Maps tree.
- Delete—Deletes the application inspection map selected in the RADIUS Inspect Maps table and from the RADIUS area of the Inspect Maps tree.

RADIUS Inspect Map Host

The RADIUS Inspect Map Host Parameters pane lets you configure the host parameter settings for the inspect map.

Fields

- Name—Shows the name of the previously configured RADIUS accounting map.
- Description—Enter the description of the RADIUS accounting map, up to 200 characters in length.
- Host Parameters—Lets you configure host parameters.
  - Host IP Address—Specify the IP address of the host that is sending the RADIUS messages.
  - Key: (optional)—Specify the key.
- Add—Adds the host entry to the Host table.
- Delete—Deletes the host entry from the Host table.

RADIUS Inspect Map Other

The RADIUS Inspect Map Other Parameters pane lets you configure additional parameter settings for the inspect map.

Fields

- Name—Shows the name of the previously configured RADIUS accounting map.
- Description—Enter the description of the RADIUS accounting map, up to 200 characters in length.
- Other Parameters—Lets you configure additional parameters.
  - Send response to the originator of the RADIUS message—Sends a message back to the host from which the RADIUS message was sent.
  - Enforce timeout—Enables the timeout for users.

    Users Timeout—Timeout for the users in the database (hh:mm:ss).
  - Enable detection of GPRS accounting—Enables detection of GPRS accounting. This option is only available when GTP/GPRS license is enabled.
  - Validate Attribute—Attribute information.

    Attribute Number—Specify the attribute number to validate when an Accounting Start is received.

    Add—Adds the entry to the Attribute table.

    Delete—Deletes the entry from the Attribute table.

RSH Inspection

RSH inspection is enabled by default. The RSH protocol uses a TCP connection from the RSH client to the RSH server on TCP port 514. The client and server negotiate the TCP port number where the client listens for the STDERR output stream. RSH inspection supports NAT of the negotiated port number if necessary.

SNMP Inspection

This section describes the IM inspection engine. This section includes the following topics:

- SNMP Inspection Overview, page 61-14

- "Select SNMP Map" section on page 61-14
- "SNMP Inspect Map" section on page 61-14

SNMP Inspection Overview

SNMP application inspection lets you restrict SNMP traffic to a specific version of SNMP. Earlier versions of SNMP are less secure; therefore, denying certain SNMP versions may be required by your security policy. The ASA can deny SNMP versions 1, 2, 2c, or 3. You control the versions permitted by creating an SNMP map.

You then apply the SNMP map when you enable SNMP inspection according to the "Configuring Application Layer Protocol Inspection" section on page 57-6.

Select SNMP Map

Add/Edit Service Policy Rule Wizard > Rule Actions > Protocol Inspection Tab > Select SNMP Map

The Select SNMP Map dialog box lets you select or create a new SNMP map. An SNMP map lets you change the configuration values used for SNMP application inspection. The Select SNMP Map table provides a list of previously configured maps that you can select for application inspection.

Fields

- Use the default SNMP inspection map—Specifies to use the default SNMP map.
- Select an SNMP map for fine control over inspection**—**Lets you select a defined application inspection map or add a new one.
- Add—Opens the Add Policy Map dialog box for the inspection.

SNMP Inspect Map

Configuration > Global Objects > Inspect Maps > SNMP

The SNMP pane lets you view previously configured SNMP application inspection maps. An SNMP map lets you change the default configuration values used for SNMP application inspection.

Fields

- Map Name—Lists previously configured application inspection maps. Select a map and click **Edit** to view or change an existing map.
- Add—Configures a new SNMP inspect map.
- Edit—Edits the selected SNMP entry in the SNMP Inspect Maps table.
- Delete—Deletes the inspect map selected in the SNMP Inspect Maps table.

Add/Edit SNMP Map

Configuration > Global Objects > Inspect Maps > SNMP > Add/Edit SNMP Map (You can get to this dialog box through various paths.)

The Add/Edit SNMP Map dialog box lets you create a new SNMP map for controlling SNMP application inspection.

Fields

- SNMP Map Name—Defines the name of the application inspection map.
- SNMP version 1—Enables application inspection for SNMP version 1.
- SNMP version 2 (party based)—Enables application inspection for SNMP version 2.
- SNMP version 2c (community based)—Enables application inspection for SNMP version 2c.
- SNMP version 3—Enables application inspection for SNMP version 3.

XDMCP Inspection

XDMCP inspection is enabled by default; however, the XDMCP inspection engine is dependent upon proper configuration of the **established** command.

XDMCP is a protocol that uses UDP port 177 to negotiate X sessions, which use TCP when established.

For successful negotiation and start of an XWindows session, the ASA must allow the TCP back connection from the Xhosted computer. To permit the back connection, use the **established** command on the ASA. Once XDMCP negotiates the port to send the display, The **established** command is consulted to verify if this back connection should be permitted.

During the XWindows session, the manager talks to the display Xserver on the well-known port 6000 | n. Each display has a separate connection to the Xserver, as a result of the following terminal setting.

```
setenv DISPLAY Xserver:n
```

where *n* is the display number.

When XDMCP is used, the display is negotiated using IP addresses, which the ASA can NAT if needed. XDCMP inspection does not support PAT.

PART 11

Configuring Unified Communications

Information About Cisco Unified Communications Proxy Features

This chapter describes how to configure the adaptive security appliance for Cisco Unified Communications Proxy features.

This chapter includes the following sections:

- Information About the Adaptive Security Appliance in Cisco Unified Communications, page 63-1
- TLS Proxy Applications in Cisco Unified Communications, page 63-3
- Licensing for Cisco Unified Communications Proxy Features, page 63-4

Information About the Adaptive Security Appliance in Cisco Unified Communications

This section describes the Cisco UC Proxy features on the Cisco ASA 5500 series appliances. The purpose of a proxy is to terminate and reoriginate connections between a client and server. The proxy delivers a range of security functions such as traffic inspection, protocol conformance, and policy control to ensure security for the internal network. An increasingly popular function of a proxy is to terminate encrypted connections in order to apply security policies while maintaining confidentiality of connections. The Cisco ASA 5500 Series appliances are a strategic platform to provide proxy functions for unified communications deployments.

The Cisco UC Proxy includes the following solutions:

Phone Proxy: Secure remote access for Cisco encrypted endpoints, and VLAN traversal for Cisco softphones

The phone proxy feature enables termination of Cisco SRTP/TLS-encrypted endpoints for secure remote access. The phone proxy allows large scale deployments of secure phones without a large scale VPN remote access hardware deployment. End-user infrastructure is limited to just the IP endpoint, without VPN tunnels or hardware.

The Cisco adaptive security appliance phone proxy is the replacement product for the Cisco Unified Phone Proxy. Additionally, the phone proxy can be deployed for voice/data VLAN traversal for softphone applications. Cisco IP Communicator (CIPC) traffic (both media and signaling) can be proxied through the ASA, thus traversing calls securely between voice and data VLANs.

For information about the differences between the TLS proxy and phone proxy, go to the following URL for Unified Communications content, including TLS Proxy vs. Phone Proxy white paper:

http://www.cisco.com/go/secureuc

TLS Proxy: Decryption and inspection of Cisco Unified Communications encrypted signaling

End-to-end encryption often leaves network security appliances "blind" to media and signaling traffic, which can compromise access control and threat prevention security functions. This lack of visibility can result in a lack of interoperability between the firewall functions and the encrypted voice, leaving businesses unable to satisfy both of their key security requirements.

The ASA is able to intercept and decrypt encrypted signaling from Cisco encrypted endpoints to the Cisco Unified Communications Manager (Cisco UCM), and apply the required threat protection and access control. It can also ensure confidentiality by re-encrypting the traffic onto the Cisco UCM servers.

Typically, the ASA TLS Proxy functionality is deployed in campus unified communications network. This solution is ideal for deployments that utilize end to end encryption and firewalls to protect Unified Communications Manager servers.

Mobility Proxy: Secure connectivity between Cisco Unified Mobility Advantage server and Cisco Unified Mobile Communicator clients

Cisco Unified Mobility solutions include the Cisco Unified Mobile Communicator (Cisco UMC), an easy-to-use software application for mobile handsets that extends enterprise communications applications and services to mobile phones and the Cisco Unified Mobility Advantage (Cisco UMA) server. The Cisco Unified Mobility solution streamlines the communication experience, enabling single number reach and integration of mobile endpoints into the Unified Communications infrastructure.

The security appliance acts as a proxy, terminating and reoriginating the TLS signaling between the Cisco UMC and Cisco UMA. As part of the proxy security functionality, inspection is enabled for the Cisco UMA Mobile Multiplexing Protocol (MMP), the protocol between Cisco UMC and Cisco UMA.

Presence Federation Proxy: Secure connectivity between Cisco Unified Presence servers and Cisco/Microsoft Presence servers

Cisco Unified Presence solution collects information about the availability and status of users, such as whether they are using communication devices, such as IP phones at particular times. It also collects information regarding their communications capabilities, such as whether web collaboration or video conferencing is enabled. Using user information captured by Cisco Unified Presence, applications such as Cisco Unified Personal Communicator and Cisco UCM can improve productivity by helping users connect with colleagues more efficiently through determining the most effective way for collaborative communication.

Using the ASA as a secure presence federation proxy, businesses can securely connect their Cisco Unified Presence (Cisco UP) servers to other Cisco or Microsoft Presence servers, enabling intra-enterprise communications. The security appliance terminates the TLS connectivity between the servers, and can inspect and apply policies for the SIP communications between the servers.

Cisco Intercompany Media Engine Proxy: Secure connectivity between Cisco UCM servers in different enterprises for IP Phone traffic

As more unified communications are deployed within enterprises, cases where business-to-business calls utilize unified communications on both sides with the Public Switched Network (PSTN) in the middle become increasingly common. All outside calls go over circuits to telephone providers and from there are delivered to all external destinations.

The Cisco Intercompany Media Engine gradually creates dynamic, encrypted VoIP connections between businesses, so that a collection of enterprises that work together end up looking like one giant business with secure VoIP interconnections between them.

There are three components to a Cisco Intercompany Media Engine deployment within an enterprise: a Cisco Intercompany Media Engine server, a call agent (the Cisco Unified Communications Manager) and an ASA running the Cisco Intercompany Media Engine Proxy.

The ASA provides perimeter security by encrypting signaling connections between enterprises and preventing unathorized calls. An ASA running the Cisco Intercompany Media Engine Proxy can either be deployed as an Internet firewall or be designated as a Cisco Intercompany Media Engine Proxy and placed in the DMZ, off the path of the regular Internet traffic.

TLS Proxy Applications in Cisco Unified Communications

Table 63-1 shows the Cisco Unified Communications applications that utilize the TLS proxy on the ASA.

Table 63-1 TLS Proxy Applications and the Security Appliance

Application	TLS Client	TLS Server	Client Authentication	Security Appliance Server Role	Security Appliance Client Role
Phone Proxy and TLS Proxy	IP phone	Cisco UCM	Yes	Proxy certificate, self-signed or by internal CA	Local dynamic certificate signed by the ASA CA (might not need certificate for phone proxy application)
Mobility Proxy	Cisco UMC	Cisco UMA	No	Using the Cisco UMA private key or certificate impersonation	Any static configured certificate
Presence Federation Proxy	Cisco UP or MS LCS/OCS	Cisco UP or MS LCS/OCS	Yes	Proxy certificate, self-signed or by internal CA	Using the Cisco UP private key or certificate impersonation

The ASA supports TLS proxy for various voice applications. For the phone proxy, the TLS proxy running on the ASA has the following key features:

- The ASA forces remote IP phones connecting to the phone proxy through the Internet to be in secured mode even when the Cisco UCM cluster is in non-secure mode.
- The TLS proxy is implemented on the ASA to intercept the TLS signaling from IP phones.
- The TLS proxy decrypts the packets, sends packets to the inspection engine for NAT rewrite and protocol conformance, optionally encrypts packets, and sends them to Cisco UCM or sends them in clear text if the IP phone is configured to be in nonsecure mode on the Cisco UCM.
- The ASA acts as a media terminator as needed and translates between SRTP and RTP media streams.
- The TLS proxy is a transparent proxy that works based on establishing trusted relationship between the TLS client, the proxy (the ASA), and the TLS server.

For the Cisco Unified Mobility solution, the TLS client is a Cisco UMA client and the TLS server is a Cisco UMA server. The ASA is between a Cisco UMA client and a Cisco UMA server. The mobility proxy (implemented as a TLS proxy) for Cisco Unified Mobility allows the use of an imported PKCS-12 certificate for server proxy during the handshake with the client. Cisco UMA clients are not required to present a certificate (no client authentication) during the handshake.

For the Cisco Unified Presence solution, the ASA acts as a TLS proxy between the Cisco UP server and the foreign server. This allows the ASA to proxy TLS messages on behalf of the server that initiates the TLS connection, and route the proxied TLS messages to the client. The ASA stores certificate trustpoints for the server and the client, and presents these certificates on establishment of the TLS session.

Licensing for Cisco Unified Communications Proxy Features

The Cisco Unified Communications proxy features supported by the ASA require a Unified Communications Proxy license:

- Phone proxy
- TLS proxy for encrypted voice inspection
- Presence federation proxy
- Intercompany media engine proxy

Note In Version 8.2(2) and later, the Mobility Advantage proxy no longer requires a Unified Communications Proxy license.

The following table shows the Unified Communications Proxy license details by platform for the phone proxy, TLS proxy for encrypted voice inspection, and presence federation proxy:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement[1]
ASA 5505	Base License and Security Plus License: 2 sessions. *Optional license: 24 sessions.*
ASA 5510	Base License and Security Plus License: 2 sessions. *Optional licenses: 24, 50, or 100 sessions.*
ASA 5520	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5540	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5550	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5580	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]

Model	License Requirement[1]
ASA 5512-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5515-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5525-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5545-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5555-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-10	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-20, -40, or -60	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASASM	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]

1. The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit:
   - Phone Proxy
   - Presence Federation Proxy
   - Encrypted Voice Inspection

   Other applications that use TLS proxy sessions do not count towards the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license).

   Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used.

   You independently set the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. When you apply a UC license that is higher than the default TLS proxy limit, the ASA automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license.

   Note: For license part numbers ending in “K8” (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in “K9” (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.

   Note: If you clear the configuration, then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the to raise the limit again (in ASDM, use the **TLS Proxy** pane). If you use failover and use **File > Save Running Configuration to Standby Unit** on the primary unit to force a configuration synchronization, the **clear configure all** command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning.

   You might also use SRTP encryption sessions for your connections:
   - For K8 licenses, SRTP sessions are limited to 250.
   - For K9 licenses, there is not limit.

   Note: Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.
2. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

Table 63-2 shows the default and maximum TLS session details by platform.

Table 63-2 Default and Maximum TLS Sessions on the Security Appliance

Security Appliance Platform	Default TLS Sessions	Maximum TLS Sessions
ASA 5505	10	80
ASA 5510	100	200
ASA 5520	300	1200
ASA 5540	1000	4500
ASA 5550	2000	4500
ASA 5580	4000	13,000

The following table shows the Unified Communications Proxy license details by platform for intercompany media engine proxy:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement
All models	Intercompany Media Engine license. When you enable the Intercompany Media Engine (IME) license, you can use TLS proxy sessions up to the configured TLS proxy limit. If you also have a Unified Communications (UC) license installed that is higher than the default TLS proxy limit, then the ASA sets the limit to be the UC license limit plus an additional number of sessions depending on your model. You can manually configure the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. If you also install the UC license, then the TLS proxy sessions available for UC are also available for IME sessions. For example, if the configured limit is 1000 TLS proxy sessions, and you purchase a 750-session UC license, then the first 250 IME sessions do not affect the sessions available for UC. If you need more than 250 sessions for IME, then the remaining 750 sessions of the platform limit are used on a first-come, first-served basis by UC and IME. • For a license part number ending in "K8", TLS proxy sessions are limited to 1000. • For a license part number ending in "K9", the TLS proxy limit depends on your configuration and the platform model. **Note** K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted. You might also use SRTP encryption sessions for your connections: • For a K8 license, SRTP sessions are limited to 250. • For a K9 license, there is no limit. **Note** Only calls that require encryption/decryption for media are counted toward the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count toward the limit.

For more information about licensing, see Chapter 5, "Managing Feature Licenses."

Using the Cisco Unified Communication Wizard

This chapter describes how to configure the adaptive security appliance for Cisco Unified Communications Proxy features.

This chapter includes the following sections:

- Information about the Cisco Unified Communication Wizard, page 64-1
- Licensing Requirements for the Unified Communication Wizard, page 64-3
- Guidelines and Limitations, page 64-4
- Configuring the Phone Proxy by using the Unified Communication Wizard, page 64-4
- Configuring the Mobility Advantage by using the Unified Communication Wizard, page 64-11
- Configuring the Presence Federation Proxy by using the Unified Communication Wizard, page 64-14
- Configuring the UC-IME by using the Unified Communication Wizard, page 64-16
- Working with Certificates in the Unified Communication Wizard, page 64-23

Information about the Cisco Unified Communication Wizard

Note The Unified Communication Wizard is supported for the ASA version 8.3(1) and later.

The Unified Communication Wizard assists you in configuring the following Unified Communications proxies on the ASA:

- Cisco Phone Proxy

  See Configuring the Phone Proxy by using the Unified Communication Wizard, page 64-4.
- Cisco Mobility Advantage Proxy

  See Configuring the Mobility Advantage by using the Unified Communication Wizard, page 64-11.
- Cisco Presence Federation Proxy

  See Configuring the Presence Federation Proxy by using the Unified Communication Wizard, page 64-14.
- Cisco Intercompany Media Engine Proxy

  See Configuring the UC-IME by using the Unified Communication Wizard, page 64-16.

The wizard simplifies the configuration of the Unified Communications proxies in the following ways:

- You enter all required data in the wizard steps. You are not required to navigate various ASDM screens to configure the Unified Communications proxies.
- The wizard generates configuration settings for the Unified Communications proxies where possible, automatically, without requiring you to enter data. For example, the wizard configures the required access lists, IP address translation (NAT and PAT) statements, self-signed certificates, TLS proxies, and application inspection.
- The wizard displays network diagrams to illustrate data collection.

To access the Unified Communication Wizard, choose one of the following paths in the main ASDM application window:

- **Wizards > Unified Communication Wizard**.
- **Configuration > Firewall > Unified Communications,** and then click **Unified Communication Wizard**.

Phone Proxy: Secure remote access for Cisco encrypted endpoints, and VLAN traversal for Cisco softphones

The phone proxy feature enables termination of Cisco SRTP/TLS-encrypted endpoints for secure remote access. The phone proxy allows large scale deployments of secure phones without a large scale VPN remote access hardware deployment. End-user infrastructure is limited to just the IP endpoint, without VPN tunnels or hardware.

The Cisco adaptive security appliance phone proxy is the replacement product for the Cisco Unified Phone Proxy. Additionally, the phone proxy can be deployed for voice/data VLAN traversal for softphone applications. Cisco IP Communicator (CIPC) traffic (both media and signaling) can be proxied through the ASA, thus traversing calls securely between voice and data VLANs.

For information about the differences between the TLS proxy and phone proxy, go to the following URL for Unified Communications content, including TLS Proxy vs. Phone Proxy white paper:

http://www.cisco.com/go/secureuc

Mobility Advantage Proxy: Secure connectivity between Cisco Mobility Advantage server and Cisco Unified Mobile Communicator clients

Cisco Mobility Advantage solutions include the Cisco Unified Mobile Communicator (Cisco UMC), an easy-to-use software application for mobile handsets that extends enterprise communications applications and services to mobile phones and the Cisco Unified Mobility Advantage (Cisco UMA) server. The Cisco Mobility Advantage solution streamlines the communication experience, enabling single number reach and integration of mobile endpoints into the Unified Communications infrastructure.

The security appliance acts as a proxy, terminating and reoriginating the TLS signaling between the Cisco UMC and Cisco UMA. As part of the proxy security functionality, inspection is enabled for the Cisco UMA Mobile Multiplexing Protocol (MMP), the protocol between Cisco UMC and Cisco UMA.

Presence Federation Proxy: Secure connectivity between Cisco Unified Presence servers and Cisco/Microsoft Presence servers

Cisco Unified Presence solution collects information about the availability and status of users, such as whether they are using communication devices, such as IP phones at particular times. It also collects information regarding their communications capabilities, such as whether web collaboration or video conferencing is enabled. Using user information captured by Cisco Unified Presence, applications such as Cisco Unified Personal Communicator and Cisco UCM can improve productivity by helping users connect with colleagues more efficiently through determining the most effective way for collaborative communication.

Using the ASA as a secure presence federation proxy, businesses can securely connect their Cisco Unified Presence (Cisco UP) servers to other Cisco or Microsoft Presence servers, enabling intra-enterprise communications. The security appliance terminates the TLS connectivity between the servers, and can inspect and apply policies for the SIP communications between the servers.

Cisco Intercompany Media Engine Proxy: Secure connectivity between Cisco UCM servers in different enterprises for IP Phone traffic

As more unified communications are deployed within enterprises, cases where business-to-business calls utilize unified communications on both sides with the Public Switched Network (PSTN) in the middle become increasingly common. All outside calls go over circuits to telephone providers and from there are delivered to all external destinations.

The Cisco Intercompany Media Engine (UC-IME) gradually creates dynamic, encrypted VoIP connections between businesses, so that a collection of enterprises that work together end up looking like one giant business with secure VoIP interconnections between them.

There are three components to a Cisco Intercompany Media Engine deployment within an enterprise: a Cisco Intercompany Media Engine server, a call agent (the Cisco Unified Communications Manager) and an ASA running the Cisco Intercompany Media Engine Proxy.

The ASA provides perimeter security by encrypting signaling connections between enterprises and preventing unauthorized calls. An ASA running the Cisco Intercompany Media Engine Proxy can either be deployed as an Internet firewall or be designated as a Cisco Intercompany Media Engine Proxy and placed in the DMZ, off the path of the regular Internet traffic.

Licensing Requirements for the Unified Communication Wizard

To run the Unified Communication Wizard in ASDM, you require the following license:

Model	License Requirement
All models	Base License

However, to run each of the Unified Communications proxy features created by the wizard, you must have the appropriate Unified Communications Proxy licenses.

The Cisco Unified Communications proxy features supported by the ASA require a Unified Communications Proxy license:

- Cisco Phone Proxy
- TLS proxy for encrypted voice inspection
- Presence Federation Proxy
- Cisco Intercompany Media Engine Proxy

See Licensing for Cisco Unified Communications Proxy Features, page 63-4 for more information.

Note The Cisco Intercompany Media Engine Proxy does not appear as an option in the Unified Communication Wizard unless the license required for this proxy is installed on the ASA.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6 addresses.

Additional Guidelines and Limitations

Using the Unified Communication Wizard to create the Unified Communications proxies has the following limitations and requirements:

- You must configure at least two interfaces on the ASA to use the UC Wizard to configure a Unified Communications proxy.
- For all Unified Communications proxies to function correctly, you must synchronize the clock on the ASA and all servers associated with each proxy, such as the Cisco Unified Communication Manager server, the Cisco Mobility Advantage server, the Cisco Unified Presence server, and the Cisco Intercompany Media Engine server.
- When you configure the Cisco Intercompany Media Engine Proxy for an off-path deployment, you must ensure that the public IP addresses and ports of the Cisco Unified Communications Manager servers and the public IP address for the media termination address are accessible from the Internet. The summary page of the Unified Communication Wizard reminds you of the requirements.
- If the ASA on which you configure the Cisco Mobility Advantage Proxy and the Cisco Presence Federation Proxy is located behind another firewall, you must ensure that the public IP addresses for the Cisco Mobility Advantage server and the Cisco Unified Presence server are accessible from the Internet.
- If you use the Unified Communication Wizard to create to the Presence Federation Proxy and the Cisco Intercompany Media Engine Proxy, you might be required to adjust the configuration of the access lists created automatically by the wizard for each proxy. See Chapter 68, “Configuring Cisco Unified Presence” and Chapter 69, “Configuring Cisco Intercompany Media Engine Proxy”, respectively, for information about the access list requirements required by each proxy.

Configuring the Phone Proxy by using the Unified Communication Wizard

To configure the Cisco Unified Presence proxy by using ASDM, choose Wizards > Unified Communications Wizard from the menu. The Unified Communications Wizard opens. From the first page, select the Phone Proxy option under the Remote Access section.

The wizard automatically creates the necessary TLS proxy, then guides you through creating the Phone Proxy instance, importing and installing the required certificates, and finally enables the SIP and SCCP inspection for the Phone Proxy traffic automatically.

Note Any configuration created by the wizard should be maintained through the wizard to ensure proper synchronization. For example, if you create a phone proxy configuration through the UC wizard and then modify the configuration outside of the wizard, the rest of the wizard configuration is not updated, and the wizard configuration is not synchronized.

Therefore, if you choose to change some part of the phone proxy configuration outside of the wizard, it is your responsibility to keep the rest of the configuration in synchronization.

The wizard guides you through four steps to configure the Phone Proxy:

Step 1 Select the Phone Proxy option.

Step 2 Specify settings to define the Cisco Unified Communications Manager (UCM) servers and TFTP servers, such the IP address and the address translation settings of each server, and the Cisco UCM cluster security mode. See Configuring the Private Network for the Phone Proxy, page 64-5 and Configuring Servers for the Phone Proxy, page 64-6.

Step 3 If required, enable Certificate Authority Proxy Function (CAPF). See Enabling Certificate Authority Proxy Function (CAPF) for IP Phones, page 64-8.

Step 4 Configure the public IP phone network, such as address translation settings for remote IP phones, whether to enable service setting for IP phones, and the HTTP proxy used by the IP phones. Configuring the Public IP Phone Network, page 64-9

Step 5 Specify the media termination address settings of the Cisco UCM. Configuring the Media Termination Address for Unified Communication Proxies, page 64-10.

The wizard completes by displaying a summary of the configuration created for Phone Proxy.

Configuring the Private Network for the Phone Proxy

The values that you specify in this page configure the connection from the ASA to the Cisco UCMs and TFTP servers by creating the necessary address translation settings and access control list entries.

Additionally, you specify the security mode for the Cisco UCM cluster. In a nonsecure cluster mode or a mixed mode where the phones are configured as nonsecure, the phone proxy behaves in the following ways:

- The TLS connections from the phones are terminated on the ASA and a TCP connection is initiated to the Cisco UCM.
- SRTP sent from external IP phones to the internal network IP phone via the ASA is converted to RTP.

In a mixed mode cluster where the internal IP phones are configured as authenticated, the TLS connection is not converted to TCP to the Cisco UCM but the SRTP is converted to RTP.

In a mixed mode cluster where the internal IP phone is configured as encrypted, the TLS connection remains a TLS connection to the Cisco UCM and the SRTP from the remote phone remains SRTP to the internal IP phone.

Step 1 From the Interface drop-down list, choose the interface on which the ASA listens for the Cisco UCM servers and TFTP servers. The Cisco UCM servers and TFTP servers must reside on the same interface.

Step 2 Specify each entity in the network (all Cisco UCM and TFTP servers) that the IP phones must trust. Click **Add** to add the servers. See Configuring Servers for the Phone Proxy, page 64-6.

To modify the configuration of a server already added to the configuration, select the server in the table and click **Edit**. The Edit Server dialog appears. See Configuring Servers for the Phone Proxy, page 64-6. At least one Cisco UCM and at least one TFTP server must be configured for the phone proxy.

Step 3 Specify the security mode of the Cisco UCM cluster by clicking one of the following options in the Unified CM Cluster Mode field:

- Non-secure—Specifies the cluster to be in nonsecure mode when configuring the Phone Proxy feature.
- Mixed—Specifies the cluster to be in mixed mode when configuring the Phone Proxy feature.

  If you selected the Mixed security mode, the Generate and Export LDC Certificate button becomes available.

Step 4 For a Mixed security mode only, configure local dynamic certificates (LDC) for the IP phones by performing the following steps:

a. Click the **Generate and Export LDC Certificate** button.

A dialog box appears stating “Enrollment succeeded,” which indicates that the LDC was generated.

b. Click **OK** to close the Enrollment Status dialog box. The Export certificate dialog box appears.

c. In the Export to File field, enter the file name and path for the LDC or click browse to locate and select an existing file.

d. Click the **Export Certificate** button. A dialog box appears indicating that the file was exported successfully.

e. Click **OK** to close the dialog box. A dialog box appears reminding you to install the LDC on the Cisco UCMs.

f. Click **OK** to close the dialog box.

Once configured, the ASA presents this unique, dynamically-created certificate to the Cisco UCM on behalf of the IP phones.

Step 5 Click **Next**.

Configuring Servers for the Phone Proxy

The values that you specify in this page generate address translation settings, access list entries, trustpoints, and the corresponding CTL file entries for each server.

You must add a server for each entity in the network that the IP phones must trust. These servers include all Cisco UCM servers in the cluster and all the TFTP servers.

You must add at least one TFTP server and at least one Cisco UCM server for the phone proxy. You can configure up to five TFTP servers for the phone proxy. The TFTP server is assumed to be behind the firewall on the trusted network; therefore, the phone proxy intercepts the requests between the IP phones and TFTP server.

The servers that the IP phones must trust can be deployed on the network in one of the following ways:

- All the services required by the Cisco UCM server, namely the Cisco UCM, TFTP, and CAPF services, are running on one server. In this deployment, only one instance of each service exists. For this deployment, you can select Unified CM+ TFTP as the server type. You can either use Address only or Address and ports for address translation. Cisco recommends that you specify Address and ports for increased security.
- Deployments for larger enterprises might have redundant Cisco UCMs and dedicated servers for TFTP and CAPF services. In that type of deployment, use Address only for voice address translation and Address only or Address and ports for TFTP.

Table 64-1 lists the ports that are configured for Address and port translation by default:

Table 64-1 Port Configuration

Address	Default Port	Description
TFTP Server	69	Allows incoming TFTP
Cisco UCM	2000	Allows incoming non-secure SCCP
Cisco UCM	2443	Allows incoming secure SCCP
Cisco UCM	5061	Allows incoming secure SIP

Step 1 In the Server Type field, select the server from the drop-down list: Unified CM, TFTP, or Unified CM + TFTP. Select Unified CM + TFTP when the Cisco UCM and TFTP server reside on the same device.

Note Depending on which type of server you select (Unified CM or TFTP), only the necessary fields in this dialog box become available. Specifically, if the server type is Unified CM, the TFTP section in the dialog is unavailable. If the server type is TFTP, the Voice section is unavailable.

Step 2 In the Private Address field, specify the actual internal IP address of the server.

Step 3 In the FQDN field, enter the fully-qualified domain name of the server, which includes the hostname and domain name; for example, `ucm.cisco.com` (where `ucm` is the hostname and `cisco.com` is the domain name).

If you are configuring a Unified CM server, enter the fully-qualified domain name configured on the Cisco UCM.

If you are configuring a TFTP server, only specify the TFTP server fully-qualified domain name when that server is configured with FQDN. If the TFTP server is not configured with FQDN, you can leave the field blank.

Note Entering the fully-qualified domain name allows the ASA to perform hostname resolution when DNS lookup is not configured on the ASA or the configured DNS servers are unavailable.See the command reference for information about the **dns domain-lookup** command.

Step 4 In the Address Translation section, select whether to use the interface IP address or to enter a different IP address.

Selecting the Use interface IP radio button configures the server to use the IP address of the public interface. You select the public interface in step 4 of the wizard when you configure the public network for the phone proxy.

If the Use interface IP radio button is selected, you must specify port translation settings in the Voice and TFTP sections. Address-only translation is available only when you specify an IP address other than the IP address of the public interface.

When you select the Address only radio button, the ASA performs address translation on all traffic between the server and the IP phones. Selecting the Address and ports radio button limits address translation to the specified ports.

Step 5 (Unified CM or Unified CM + TFTP servers only) In the Voice section, configure inspection of SIP or SCCP protocol traffic, or both SIP and SCCP protocol traffic by completing the following fields:

a. In the Translation Type field, specify whether to use the Address only or the Address and ports.

When the deployment has redundant Cisco UCM servers and dedicated servers for TFTP and CAPF services, select Address only for voice address translation.

Select the Address and ports option when you want to limit address translation to the specified ports.

b. In the Voice Protocols field, select the inspection protocols supported by the IP phones deployed in the enterprise. Depending on which inspection protocols you select—SCCP, SIP, or SCCP and SIP—only the ports fields for the selected voice protocols are available.

c. In the Port Translation section, enter the private and public ports for the voice protocols.

The default values for the voice ports appear in the text fields. If necessary, change the private ports to match the settings on the Cisco UCM. The values you set for the public ports are used by the IP phones to traverse the ASA and communicate with the Cisco UCM.

The secure SCCP private port and public port are automatically configured. These port numbers are automatically set to the value of the non-secure port number plus 443.

Step 6 (TFTP or Unified CM + TFTP servers only) In the TFTP section, you can select either Address only or Address and port for address translation. Cisco recommends that you specify Address and port for increased security. Specifying Address and port configures the TFTP server to listen on port 69 for TFTP requests.

When the server type is Unified CM + TFTP, the wizard configures the same type of address translation for Voice and TFTP; for example, when the server type is Unified CM + TFTP and the Address only option is selected, the wizard creates a global address translation rule for all traffic to and from the server. In this case, configuring port translation for the TFTP server would be redundant.

Step 7 Click **OK** to add the server to the phone proxy configuration and return to step 2 of the wizard.

Enabling Certificate Authority Proxy Function (CAPF) for IP Phones

As an alternative to authenticating remote IP phones through the TLS handshake, you can configure authentication via locally significant certificate (LSC) provisioning. With LSC provisioning, you create a password for each remote IP phone user and each user enters the password on the remote IP phones to retrieve the LSC.

Because using LSC provisioning to authenticate remote IP phones requires the IP phones first register in nonsecure mode, Cisco recommends LSC provisioning be done inside the corporate network before giving the IP phones to end-users. Otherwise, having the IP phones register in nonsecure mode requires the Administrator to open the nonsecure signaling port for SIP and SCCP on the ASA.

See also the Cisco Unified Communications Manager Security Guide for information on Using the Certificate Authority Proxy Function (CAPF) to install a locally significant certificate (LSC).

If your network includes Cisco IP Communicators (CIPC) or you have LSC enabled IP phones, you must import the CAPF certificate from the Cisco UCM. The certificate will be used to generate the LSC on the IP phones.

If the Cisco UCM has more than one CAPF certificate, you must import all of them to the ASA. However, the wizard supports configuring only one CAPF certificate, which is the default. To import more than one CAPF certificate, go to Configuration > Device Management > Certificate Management > Identity Certificates.

You can configure LSC provisioning for additional end-user authentication. See the Cisco Unified Communications Manager configuration guide for information.

Step 1 Check the **Enable Certificate Authority Proxy Function** check box. The remaining fields in the page become available.

Step 2 Enter the private IP address of the LSC provider.

Step 3 In the Public Address field, specify whether to use the IP address of the ASA public interface or enter an IP address.

Specifying the private and public IP addresses for the LSC provider, creates an access list entry that allows the IP phones to contact the Cisco UCM by opening the CAPF port for LSC provisioning.

Step 4 In the Translation Type field, select the Address only or Address and ports radio button.

The IP phones must contact the CAPF service on the Cisco UCM. The address translation type (Address only versus Address and ports) you select for CAPF must match the address translation type of the Cisco UCM on which the CAPF service is running. You set the address translation type for that Cisco UCM server in the previous step of this wizard (see Configuring Servers for the Phone Proxy, page 64-6),

By default, the CAPF Service uses port 3804. Modify this default value only when it is modified on the Cisco UCM.

Step 5 If you selected the Address and ports radio button, enter the private and public ports for the CAPF service.

Step 6 Click the **Install CAPF Certificate** button. The Install Certificate dialog box appears. See Installing a Certificate, page 64-23.

Step 7 Click **Next**.

Configuring the Public IP Phone Network

The values that you specify in this page generate the address translation rules used for the IP phones and configure how the ASA handles IP phone settings.

Step 1 From the Interface drop-down list, choose the interface on which the ASA listens for connections from IP phones.

Step 2 To preserve Call Manager configuration on the IP phones, check the Preserve the Unified CM's configuration on the phone's service check box. When this check box is uncheck, the following service settings are disabled on the IP phones:

- Web Access
- PC Port
- Voice VLAN access

- Gratuitous ARP
- Span to PC Port

Step 3 To configure address translation for IP phones, check the Enable address translation for IP phones check box. Select whether to use the IP address of the ASA private interface (which you selected in step 2 of the wizard) or enter an IP address.

Configuring address translation for IP phone configures the address used by the IP phones. All traffic from the outside network converges into one source IP address so that, if there is another corporate firewall in the network, a pinhole needs to be opened only for that IP address rather than for all traffic.

Step 4 To configure an HTTP proxy for the Phone Proxy feature that is written into the IP phone's configuration file under the <proxyServerURL> tag, do the following:

a. Check the Configure an HTTP proxy to redirect phone URLs... check box.

b. In the IP Address field, type the IP address of the HTTP proxy

c. In the Port field, enter the listening port of the HTTP proxy.

The IP address you enter should be the global IP address based on where the IP phone and HTTP proxy server is located. You can enter a hostname in the IP Address field when that hostname can be resolved to an IP address by the adaptive security appliance (for example, DNS lookup is configured) because the adaptive security appliance will resolve the hostname to an IP address. If a port is not specified, the default will be 8080.

d. In the Interface field, select the interface on which the HTTP proxy resides on the adaptive security appliance.

Setting the proxy server configuration option for the Phone Proxy allows for an HTTP proxy on the DMZ or external network in which all the IP phone URLs are directed to the proxy server for services on the phones. This setting accommodates nonsecure HTTP traffic, which is not allowed back into the corporate network.

Step 5 Click **Next**.

Configuring the Media Termination Address for Unified Communication Proxies

The data from this step generates the MTA instance to be added to the Phone Proxy and the UC-IME proxy.

The phone proxy and the UC-IME proxy use the media termination address for Secure RTP (SRTP) and RTP traffic. SRTP traffic sent from external IP phones to the internal network IP phone via the ASA is converted to RTP traffic. The traffic is terminated on the adaptive security appliance. SRTP provides message authentication and replay protection to Internet media traffic such as audio and video. RTP defines a standardized packet format for delivering audio and video over the Internet.

For the UC-IME proxy and the Phone Proxy to be fully functional, you must ensure that the public IP address for the media termination address (MTA) is accessible from the Internet. The summary page of the Unified Communication Wizard reminds you of this requirement.

The MTA IP addresses that you specify must meet specific requirements. See Media Termination Instance Prerequisites, page 65-6 for information.

Step 1 In the field for the private IP address, enter the IP address on which private media traffic terminates. The IP address must be within the same subnet as the private interface IP address. The correct subnet range is provided to the right of the field for the private IP address.

Step 2 In the field for the public IP address, enter the IP address on which public media traffic terminates. The IP address must be within the same subnet as the public interface IP address. The correct subnet range is provided to the right of the field for the public IP address.

Step 3 Specify the minimum and maximum values for the RTP port range for the media termination instance.

Port values must be within the range of 1024 to 65535.

Step 4 Click **Next**.

The wizard completes by displaying a summary of the configuration created for proxy.

Configuring the Mobility Advantage by using the Unified Communication Wizard

Note The Unified Communication Wizard is supported for the ASA version 8.3(1) and later.

The Unified Communication wizard guides you through the steps to configure the Mobility Advantage proxy. Choose **Wizards > Unified Communication Wizard** from the menu. The Unified Communication Wizard opens. Click the Cisco Mobility Advantage Proxy radio button under the Remote Access section.

When using the wizard to create the Mobility Advantage proxy, ASDM automatically creates the necessary TLS proxies, enables MMP inspection for the Mobility Advantage traffic, generates address translation (NAT) statements, and creates the access rules that are necessary to allow traffic between the Cisco Mobility Advantage server and the mobility clients.

The following steps provide the high-level overview for configuring the Mobility Advantage proxy:

Step 1 Specify settings to define the private and public network topology, such the public and private network interfaces, and the IP addresses of the Cisco Mobility Advantage server. See Configuring the Topology for the Cisco Mobility Advantage Proxy, page 64-12.

Step 2 Configure the certificates that are exchanged between the Cisco Mobility Advantage server and the ASA. See Configuring the Server-Side Certificates for the Cisco Mobility Advantage Proxy, page 64-12.

Step 3 Configure the client-side certificate management, namely the certificates that are exchanged between the Unified Mobile Communicator clients and the ASA. See Configuring the Client-Side Certificates for the Cisco Mobility Advantage Proxy, page 64-13.

The wizard completes by displaying a summary of the configuration created for Mobility Advantage Proxy.

Configuring the Topology for the Cisco Mobility Advantage Proxy

When configuring the Mobility Advantage Proxy, you specify settings to define the private and public network topology, such the private and public network interfaces, and the private and public IP addresses of the Cisco Mobility Advantage server.

The values that you specify in this page generate the following configuration settings for the Mobility Advantage Proxy:

- Static PAT for the Cisco Mobility Advantage server
- Static NAT for Cisco Unified Mobile Communicator clients if the Enable address translation for Mobility clients check box is checked.
- Access lists to allow Cisco Unified Mobile Communicator clients to access the Cisco Mobility Advantage server

Step 1 In the Private Network area, choose the interface from the drop-down list.

Step 2 In the Unified MA Server area, enter the private and public IP address for the Cisco Mobility Advantage server. Entering ports for these IP addresses is optional. By default port number 5443 is entered, which is the default TCP port for MMP inspection.

Step 3 In the FQDN field, enter the domain name for the Cisco Mobility Advantage server. This domain name is included in the certificate signing request that you generate later in this wizard.

Step 4 In the Public Network area, choose an interface from the drop-down list.

The proxy uses this interface for configuring static PAT for the Cisco Mobility Advantage server and the access lists to allow Cisco Unified Mobile Communicator clients to access the Cisco Mobility Advantage server.

Step 5 **To configure whether address translation (NAT) is used by** Cisco Unified Mobile Communicator clients, check the **Enable address translation for Mobility clients** check box and choose whether to use the IP address of the public interface or whether to enter an IP address.

Step 6 Click **Next**.

Configuring the Server-Side Certificates for the Cisco Mobility Advantage Proxy

A trusted relationship between the ASA and the Cisco UMA server can be established with self-signed certificates. The ASA's identity certificate is exported, and then uploaded on the Cisco UMA server truststore. The Cisco UMA server certificate is downloaded, and then uploaded on the ASA truststore.

The supports using self-signed certificates only at this step.

Step 1 In the ASA's Identity Certificate area, click **Generate and Export ASA's Identity Certificate**.

An information dialog boxes appear indicating that the enrollment seceded. In the Enrollment Status dialog box, click **OK**. The Export certificate dialog box appears.

Note

- If an identity certificate for the ASA has already been created, the button in this area appears as **Export ASA's Identity Certificate** and the Export certificate dialog box immediately appears.

- When using the wizard to configure the Cisco Mobility Advantage proxy, the wizard only supports installing self-signed certificates.

Step 2 Export the identity certificate generated by the wizard for the ASA. See Exporting an Identity Certificate, page 64-23.

Step 3 In the Unified MA Server's Certificate area, click **Install Unified MA Server's Certificate**. The Install Certificate dialog appears.

Step 4 Locate the file containing the Cisco Mobility Advantage server certificate or paste the certificate details in the dialog box. See Installing a Certificate, page 64-23.

Step 5 Click **Next**.

Note See the Cisco Mobility Advantage server documentation for information on how to export the certificate for this server.

Configuring the Client-Side Certificates for the Cisco Mobility Advantage Proxy

To establish a trust relationship between the Cisco Unified Mobile Communicator (UMC) clients and the ASA, the ASA uses a CA-signed certificate that is configured with the Cisco Mobility Advantage server's FQDN (also referred to as certificate impersonation).

In the Client-Side Certificate Management page, you enter both the intermediate CA certificate (if applicable, as in the cases of Verisign) and the signed ASA identity certificate.

Note If the ASA already has a signed identity certificate, you can skip Step 1 in this procedure and proceed directly to Step 2.

Step 1 In the ASA's Identity Certificate area, click **Generate CSR**. The CSR parameters dialog box appears.

For information about specifying additional parameters for the certificate signing request (CSR), see Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy, page 64-24.

Information dialog boxes appear indicating that the wizard is delivering the settings to the ASA and retrieving the certificate key pair information. The Identity Certificate Request dialog box appears.

For information about saving the CSR that was generated and submitting it to a CA, see Saving the Identity Certificate Request, page 64-25.

Step 2 Click **Install ASA's Identity Certificate**. Install the certificate. See Installing the ASA Identity Certificate on the Mobility Advantage Server, page 64-26.

Step 3 Click **Install Root CA's Certificate**. The Install Certificate dialog box appears. Install the certificate. See Installing a Certificate, page 64-23.

Step 4 Click **Next**.

The wizard completes by displaying a summary of the configuration created for Mobility Advantage Proxy.

Configuring the Presence Federation Proxy by using the Unified Communication Wizard

Note The Unified Communication Wizard is supported for the ASA version 8.3(1) and later.

To configure the Cisco Unified Presence proxy by using ASDM, choose **Wizards > Unified Communication Wizard** from the menu. The Unified Communication Wizard opens. From the first page, select the Cisco Unified Presence Proxy option under the Business-to-Business section.

When using the wizard to create the Cisco Presence Federation proxy, ASDM automatically creates the necessary TLS proxies, enables SIP inspection for the Presence Federation traffic, generates address translation (static PAT) statements for the local Cisco Unified Presence server, and creates access lists to allow traffic between the local Cisco Unified Presence server and remote servers.

The following steps provide the high-level overview for configuring the Presence Federation Proxy:

Step 1 Specify settings to define the private and public network topology, such the private and public IP address of the Presence Federation server. See Configuring the Topology for the Cisco Presence Federation Proxy, page 64-14.

Step 2 Configure the local-side certificate management, namely the certificates that are exchanged between the local Unified Presence Federation server and the ASA. See Configuring the Local-Side Certificates for the Cisco Presence Federation Proxy, page 64-15.

Step 3 Configure the remote-side certificate management, namely the certificates that are exchanged between the remote server and the ASA. See Configuring the Remote-Side Certificates for the Cisco Presence Federation Proxy, page 64-15.

The wizard completes by displaying a summary of the configuration created for the Presence Federation proxy.

Configuring the Topology for the Cisco Presence Federation Proxy

When configuring the Presence Federation Proxy, you specify settings to define the private and public network topology, such the private and public network interfaces, and the private and public IP addresses of the Cisco Unified Presence server.

The values that you specify in this page generate the following configuration settings for the Presence Federation Proxy:

- Static PAT for the local Cisco Unified Presence server
- Access lists for traffic between the local Cisco Unified Presence server and remote servers

Step 1 In the Private Network area, choose the interface from the drop-down list.

Step 2 In the Unified Presence Server area, enter the private and public IP address for the Unified Presence server. Entering ports for these IP addresses is optional. By default port number 5061 is entered, which is the default TCP port for SIP inspection.

Step 3 In the FQDN field, enter the domain name for the Unified Presence server. This domain name is included in the certificate signing request that you generate later in this wizard.

Step 4 In the Public Network area, choose the interface of the public network from the drop-down list. The proxy uses this interface for configuring static PAT for the local Cisco Unified Presence server and for configuring access lists to allow remote servers to access the Cisco Unified Presence server.

Step 5 Click **Next**.

Configuring the Local-Side Certificates for the Cisco Presence Federation Proxy

Within an enterprise, setting up a trust relationship is achievable by using self-signed certificates. The supports using self-signed certificates only at this step.

Step 1 In the ASA's Identity Certificate area, click **Generate and Export ASA's Identity Certificate**.

An information dialog box appears indicating that enrollment succeeded. In the Enrollment Status dialog box, click **OK**. The Export certificate dialog box appears.

Note

- If an identity certificate for the ASA has already been created, the button in this area appears as **Export ASA's Identity Certificate** and the Export certificate dialog box immediately appears.
- When using the wizard to configure the Cisco Presence Federation proxy, the wizard only supports installing self-signed certificates.

Step 2 Export the identity certificate generated by the wizard for the ASA. See Exporting an Identity Certificate, page 64-23.

Step 3 Local Unified Presence Server's Certificate area, click **Install Server's Certificate**. The Install Certificate dialog appears.

Step 4 Locate the file containing the Cisco Unified Presence server certificate or paste the certificate details in the dialog box. See Installing a Certificate, page 64-23.

Step 5 Click **Next**.

Note See the Cisco Unified Presence server documentation for information on how to export the certificate for this server.

Configuring the Remote-Side Certificates for the Cisco Presence Federation Proxy

Establishing a trust relationship across enterprises or across administrative domains is key for federation. Across enterprises you must use a trusted third-party CA (such as, VeriSign). The security appliance obtains a certificate with the FQDN of the Cisco Unified Presence server (certificate impersonation).

For the TLS handshake, the two entities, namely the local entity and a remote entity, could validate the peer certificate via a certificate chain to trusted third-party certificate authorities. The local entity and the remote entity enroll with the CAs. The ASA as the TLS proxy must be trusted by both the local and remote entities. The security appliance is always associated with one of the enterprises. Within that enterprise, the entity and the security appliance authenticate each other by using a self-signed certificate.

To establish a trusted relationship between the security appliance and the remote entity, the security appliance can enroll with the CA on behalf of the Cisco Unified Presence server for the local entity. In the enrollment request, the local entity identity (domain name) is used.

To establish the trust relationship, the security appliance enrolls with the third party CA by using the Cisco Unified Presence server FQDN as if the security appliance is the Cisco Unified Presence server.

Note If the ASA already has a signed identity certificate, you can skip Step 1 in this procedure and proceed directly to Step 2.

Step 1 In the ASA's Identity Certificate area, click **Generate CSR**. The CSR parameters dialog box appears.

For information about specifying additional parameters for the certificate signing request (CSR), see Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy, page 64-24.

Information dialog boxes appear indicating that the wizard is delivering the settings to the ASA and retrieving the certificate key pair information. The Identity Certificate Request dialog box appears.

For information about saving the CSR that was generated and submitting it to a CA, see Saving the Identity Certificate Request, page 64-25.

Step 2 Click **Install ASA's Identity Certificate**. See Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers, page 64-26.

Step 3 Click **Remote Server's CA's Certificate**. The Install Certificate dialog box appears. Install the certificate. See Installing a Certificate, page 64-23.

Note You must install a root CA certificate for each remote entity that communicates with the ASA because different organizations might be using different CAs.

Step 4 Click **Next**.

The wizard completes by displaying a summary of the configuration created for the Presence Federation proxy.

Configuring the UC-IME by using the Unified Communication Wizard

Note The Unified Communication Wizard is supported for the ASA version 8.3(1) and later.

To configure the Cisco Intercompany Media Engine Proxy by using ASDM, choose **Wizards > Unified Communication Wizard** from the menu. The Unified Communication Wizard opens. From the first page, select the Cisco Intercompany Media Engine Proxy option under the Business-to-Business section and click **Next**.

Note The Cisco Intercompany Media Engine Proxy does not appear as an option in the Unified Communication Wizard unless the license required for this proxy is installed on the ASA.

When using the wizard to create the Cisco Intercompany Media Engine Proxy, ASDM automatically creates the necessary TLS proxies, enables SIP inspection for Cisco Intercompany Media Engine traffic, generates address translation (static PAT) statements for local Cisco Unified Communications Manager servers, and creates access lists to allow traffic between the local Cisco Unified Communications Manager servers and the remote servers.

The following steps provide the high-level overview for configuring the Cisco Intercompany Media Engine Proxy:

Step 1 Select the topology of the Cisco Intercompany Media Engine Proxy, namely whether the security appliance is an edge firewall with all Internet traffic flowing through it or whether the security appliance is off the path of the main Internet traffic (referred to as an off-path deployment). See Configuring the Topology for the Cisco Intercompany Media Engine Proxy, page 64-17.

Step 2 Specify private network settings such as the Cisco UCM IP addresses and the ticket settings. See Configuring the Private Network Settings for the Cisco Intercompany Media Engine Proxy, page 64-18.

Step 3 Specify the public network settings. See Configuring the Public Network Settings for the Cisco Intercompany Media Engine Proxy, page 64-20.

Step 4 Specify the media termination address settings of the Cisco UMC. See Configuring the Media Termination Address for Unified Communication Proxies, page 64-10.

Step 5 Configure the local-side certificate management, namely the certificates that are exchanged between the local Cisco Unified Communications Manager servers and the security appliance. See Configuring the Local-Side Certificates for the Cisco Intercompany Media Engine Proxy, page 64-21.

Step 6 Configure the remote-side certificate management, namely the certificates that are exchanged between the remote server and the ASA. This certificate is presented to remote servers so that they can authenticate the ASA as a trusted server. See Configuring the Remote-Side Certificates for the Cisco Intercompany Media Engine Proxy, page 64-22.

The wizard completes by displaying a summary of the configuration created for the Cisco Intercompany Media Engine.

Configuring the Topology for the Cisco Intercompany Media Engine Proxy

Step 1 Select the topology of your ICME deployment by clicking one of the following options:

- All Internet traffic flows through the ASA radio button. This option is also referred to as a basic deployment.
- This ASA is off the path of the regular Internet traffic. This option is also referred to as an off-path deployment.

Step 2 Click **Next**.

Basic Deployment

In a basic deployment, the Cisco Intercompany Media Engine Proxy sits in-line with the Internet firewall such that all Internet traffic traverses the ASA. In this deployment, a single Cisco UCM or a Cisco UCM cluster is centrally deployed within the enterprise, along with a Cisco Intercompany Media Engine server (and perhaps a backup). A single Internet connection traverses the ASA, which is enabled with the Cisco Intercompany Media Engine Proxy.

The ASA sits on the edge of the enterprise and inspects SIP signaling by creating dynamic SIP trunks between enterprises.

Off-path Deployment

In an off path deployment, inbound and outbound Cisco Intercompany Media Engine calls pass through an ASA enabled with the Cisco Intercompany Media Engine Proxy. The ASA is located in the DMZ and configured to support primarily Cisco Intercompany Media Engine. Normal Internet facing traffic does not flow through this ASA.

For all inbound calls, the signaling is directed to the ASA because destined Cisco UCMs are configured with the global IP address on the ASA. For outbound calls, the called party could be any IP address on the Internet; therefore, the ASA is configured with a mapping service that dynamically provides an internal IP address on the ASA for each global IP address of the called party on the Internet.

Cisco UCM sends all outbound calls directly to the mapped internal IP address on the ASA instead of the global IP address of the called party on the Internet. The ASA then forwards the calls to the global IP address of the called party.

Note When you configure the Cisco Intercompany Media Engine for an off-path deployment, you must ensure that the public IP addresses and ports of the Cisco Unified Communications Manager servers and the public IP address for the media termination address are accessible from the Internet. The summary page of the Unified Communication Wizard reminds you of the requirements.

Configuring the Private Network Settings for the Cisco Intercompany Media Engine Proxy

When configuring the Cisco Intercompany Media Engine Proxy, you specify settings to define the private network topology, such the private network interface, the IP addresses of the Cisco Unified Communications servers, and ticket verification. Additionally, when the Cisco Unified Communications servers are operating in secure mode, you specify the X.509 subject name for the Cisco Intercompany Media Engine Proxy,

The values that you specify in this page generate the following configuration settings for the Cisco Intercompany Media Engine Proxy:

- The list of Cisco Unified Communications servers
- The ticket epoch and password used by the Cisco Intercompany Media Engine Proxy
- For an off-path deployment only, the mapping service on the same interface as the Cisco Unified Communications server

Step 1 To configure the Cisco Intercompany Media Engine Proxy as part of a basic deployment, select the interface that connects to the local Cisco Unified Communications servers.

Or

To configure the Cisco Intercompany Media Engine Proxy as part of an off-path deployment, complete the following steps:

a. From the Listening Interface drop-down list, choose the interface on which the ASA listens for the mapping requests.

b. In the Port field, enter a number between 1024 and 65535 as the TCP port on which the ASA listens for the mapping requests. The port number must be 1024 or higher to avoid conflicts with other services on the device, such as Telnet or SSH. By default, the port number is TCP 8060.

c. From the UC-IME Interface drop-down list, choose the interface that the ASA uses to connect to the remote ASA that is enabled with the Cisco Intercompany Media Engine Proxy.

Note In a basic and an off-path deployment, all Cisco Unified Communications servers must be on the same interface.

Step 2 In the Unified CM Servers area, the wizard displays the private IP address, public IP address, and security mode of any Cisco Unified Communications server configured on the ASA. If necessary, click **Add** to add a Cisco Unified Communications server. You must include an entry for each Cisco UCM in the cluster with Cisco Intercompany Media Engine that has a SIP trunk enabled.

Step 3 In the Ticket Epoch field, enter a integer from 1-255.

The epoch indicates the number of times that password has changed. When the proxy is configured the first time and a password entered for the first time, enter 1 for the epoch integer. Each time you change the password, increment the epoch to indicate the new password. You must increment the epoch value each time your change the password. Typically, you increment the epoch sequentially; however, the security appliance allows you to choose any value when you update the epoch.

If you change the epoch value, the current password is invalidated and you must enter a new password.

Step 4 In the Ticket Password field, enter a minimum of 10 and a maximum of 64 printable character from the US-ASCII character set. The allowed characters include 0x21 to 0x73 inclusive, and exclude the space character. The ticket password is stored onto flash.

Note We recommend a password of at least 20 characters. Only one password can be configured at a time.

The epoch and password that you configure on the ASA must match the epoch and password configured on the Cisco Intercompany Media Engine server. See the Cisco Intercompany Media Engine server documentation for information.

Step 5 In the Confirm Password field, reenter the password.

Step 6 In the X.509 Subject Name field, enter the distinguished name (DN) of the local enterprise. The name that you enter must match the name configured for the Cisco Unified Communications servers in the cluster. See the Cisco Unified Communications server documentation for information.

Step 7 Click **Next**.

Adding a Cisco Unified Communications Manager Server for the UC-IME Proxy

You must include an entry for each Cisco UCM in the cluster with Cisco Intercompany Media Engine Proxy that has a SIP trunk enabled.

Step 1 Enter the private IP address and port number (in the range 5000-6000) for the Cisco UCM server.

Step 2 In the Address Translation area, enter the public IP address for the Cisco UCM server.

Step 3 If necessary, enter the port number for the public IP address by clicking the Translate address and port radio button and entering a number (in the range 5000-6000) in the Port field.

Step 4 In the Security Mode area, click the Secure or Non-secure radio button. Specifying secure for Cisco UCM or Cisco UCM cluster indicates that Cisco UCM or Cisco UCM cluster is initiating TLS.

If you specify that some of the Cisco UCM servers are operating in secure mode, the Unified Communications Wizard includes a step in the proxy configuration to generate certificates for the local-side communication between the ASA and that Cisco UCM server. See Configuring the Local-Side Certificates for the Cisco Intercompany Media Engine Proxy, page 64-21.

Step 5 Click **OK**.

Configuring the Public Network Settings for the Cisco Intercompany Media Engine Proxy

The public network configuration depends on the deployment scenario you selected in the topology step of this wizard. Specifically, when you are configuring the UC-IME proxy as part of an off-path deployment, this step of the wizard displays fields for address translation, requiring that you specify the private IP address for the UC-IME proxy. Specifying this private IP address, translates IP addresses for inbound traffic.

In an off-path deployment, any existing ASA that you have deployed in your environment are not capable of transmitting Cisco Intercompany Media Engine traffic. Therefore, off-path signaling requires that outside addresses translate to an inside (private) IP address. The inside interface address can be used for this mapping service configuration. For the Cisco Intercompany Media Engine Proxy, the ASA creates dynamic mappings for external addresses to the internal IP address.

The values that you specify in this page generate the following configuration settings for the Cisco Intercompany Media Engine Proxy:

- Static PAT for the Cisco Unified Communications servers
- Access lists for traffic between the local and the remote servers

Step 1 In the Configure public network area, choose an interface from the Interface drop-down list.

Step 2 When configuring an off-path deployment, in the Address Translation area, specify whether to use the private IP address for the public network.

Or

Click the Specify IP address radio button and enter an IP address in the field.

Step 3 Click **Next**.

Configuring the Local-Side Certificates for the Cisco Intercompany Media Engine Proxy

Completing this step of the wizard generates a self-signed certificate for the ASA. The server proxy certificate is automatically generated using the subject name provided in an earlier step of this wizard.

The wizard supports using self-signed certificates only.

A trusted relationship between the ASA and the Cisco UMA server can be established with self-signed certificates. The certificates are used by the security appliance and the Cisco UCMs to authenticate each other, respectively, during TLS handshakes.

The ASA's identity certificate is exported, and then needs to be installed on each Cisco Unified Communications Manager (UCM) server in the cluster with the proxy and each identity certificate from the Cisco UCMs need to be installed on the security appliance.

This step in the Unified Communications Wizard only appears when the UC-IME proxy that you are creating has at least one secure Cisco Unified Communications Manager server defined. See Configuring the Topology for the Cisco Intercompany Media Engine Proxy, page 64-17 for information.

Step 1 In the ASA's Identity Certificate area, click **Generate and Export ASA's Identity Certificate**.

An information dialog boxes appear indicating that the enrollment seceded. In the Enrollment Status dialog box, click **OK**. The Export certificate dialog box appears.

Note

- If an identity certificate for the ASA has already been created, the button in this area appears as **Export ASA's Identity Certificate** and the Export certificate dialog box immediately appears.
- When using the wizard to configure the Cisco Intercompany Media Engine Proxy, the wizard only supports installing self-signed certificates.

Step 2 Export the identity certificate generated by the wizard for the ASA. See Exporting an Identity Certificate, page 64-23.

Step 3 In the Local Unified CM's Certificate area, click **Install Local Unified CM's Certificate**. The Install Certificate dialog appears.

Step 4 Locate the file containing the certificate from the Cisco Unified Communications Manager server or paste the certificate details in the dialog box. See Installing a Certificate, page 64-23. You must install the certificate from each Cisco Unified Communications Manager server in the cluster.

Step 5 Click **Next**.

Note See the Cisco Intercompany Media Engine server documentation for information on how to export the certificate for this server.

Configuring the Remote-Side Certificates for the Cisco Intercompany Media Engine Proxy

Establishing a trust relationship cross enterprises or across administrative domains is key. Cross enterprises you must use a trusted third-party CA (such as, VeriSign). The ASA obtains a certificate with the FQDN of the Cisco Unified Communications Manager server (certificate impersonation).

For the TLS handshake, the two entities could validate the peer certificate via a certificate chain to trusted third-party certificate authorities. Both entities enroll with the CAs. The ASA as the TLS proxy must be trusted by both entities. The ASA is always associated with one of the enterprises. Within that enterprise, the entity and the ASA could authenticate each other via a local CA, or by using self-signed certificates.

To establish a trusted relationship between the ASA and the remote entity, the ASA can enroll with the CA on behalf of the local enterprise. In the enrollment request, the local Cisco UCM identity (domain name) is used.

To establish the trust relationship, the ASA enrolls with the third party CA by using the Cisco Unified Communications Manager server FQDN as if the security appliance is the Cisco UCM.

Note If the ASA already has a signed identity certificate, you can skip Step 1 in this procedure and proceed directly to Step 3.

Step 1 In the ASA's Identity Certificate area, click **Generate CSR**. The CSR parameters dialog box appears.

For information about specifying additional parameters for the certificate signing request (CSR), see Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy, page 64-24.

Information dialog boxes appear indicating that the wizard is delivering the settings to the ASA and retrieving the certificate key pair information. The Identity Certificate Request dialog box appears.

For information about saving the CSR that was generated and submitting it to a CA, see Saving the Identity Certificate Request, page 64-25.

Step 2 In the ASA's Identity Certificate area, click **Install ASA's Identity Certificate**. Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers, page 64-26.

Step 3 In the Remote Server's CA's Certificate area, click **Install Remote Server's CA's Certificate**. Installing the root certificates of the CA for the remote servers is necessary so that the ASA can determine that the remote servers are trusted.

The Install Certificate dialog box appears. Install the certificate. See Installing a Certificate, page 64-23.

Note You must install the root certificates only when the root certificates for the remote servers are received from a CA other than the one that provided the identity certificate for the ASA

Step 4 Click **Next**.

The wizard completes by displaying a summary of the configuration created for the Cisco Intercompany Media Engine.

Working with Certificates in the Unified Communication Wizard

This section includes the following topics:

- Exporting an Identity Certificate, page 64-23
- Installing a Certificate, page 64-23
- Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy, page 64-24
- Saving the Identity Certificate Request, page 64-25
- Installing the ASA Identity Certificate on the Mobility Advantage Server, page 64-26
- Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers, page 64-26

Exporting an Identity Certificate

The Cisco Mobility Advantage Proxy, Cisco Presence Federation Proxy, or Cisco Intercompany Media Engine Proxy require that you export the ASA identity certificate to install on the Cisco Mobility Advantage server, Cisco Presence Federation server, and Cisco Unified Communications server, respectfully.

You use the wizard to export a self-signed identity certificate. The identity certificate has all associated keys and is in PKCS12 format, which is the public key cryptography standard. When configuring a Unified Communications proxy by using the wizard, you click the Generate and Export ASA's Identify Certificate button while in the local-side or server-side certificate management step of the wizard. The Export certificate dialog box appears.

From the Export certificate dialog box, perform these steps:

Step 1 Enter the name of the PKCS12 format file to use in exporting the certificate configuration. Alternatively, click Browse to display the Export ID Certificate File dialog box to find the file to which you want to export the certificate configuration.

Step 2 Click Export Certificate to export the certificate configuration.

An information dialog box appears informing you that the certificate configuration file has been successfully exported to the location that you specified.

You complete the configuration of the Cisco Mobility Advantage Proxy, Cisco Presence Federation Proxy, or Cisco Intercompany Media Engine Proxy, you must import the generated ASA identify certificate in to the Cisco Mobility Advantage server, Cisco Presence Federation server, and Cisco Unified Communications server, respectfully, depending on which proxy you are configuring.

See the documentation for the for each of these products for information about importing an identity certificate into each.

Installing a Certificate

When configuring certificates for the Phone Proxy, Cisco Mobility Advantage Proxy, the Cisco Presence Federation Proxy, and Cisco Intercompany Media Engine Proxy, you must install the certificates from the Cisco Unified Communications Manager servers, the Cisco Mobility Advantage server, the Cisco

Presence Federation server, and the Cisco Unified Communications Manager servers, respectively, on the ASA. See the documentation for each of these products for information about obtaining the identity certificates from each.

When configuring the Cisco Phone Proxy, if LSC provisioning is required or you have LSC enabled IP phones, you must install the CAPF certificate from the Cisco UCM on the ASA. If the Cisco UCM has more than one CAPF certificate, you must import all of them to the ASA. See Enabling Certificate Authority Proxy Function (CAPF) for IP Phones, page 64-8.

Additionally, when configuring the Cisco Mobility Advantage Proxy, you use the Install Certificate dialog box to install the root certificate received from the certificate authority. The root certificate from the certificate authority is used to sign other certificates. The root certificate is used by the ASA to authenticate your signed identity certificate received from the certificate authority.

Note When using the wizard to configure the Unified Communications proxies, the wizard only supports installing self-signed certificates.

From the Install Certificate dialog box, perform these steps:

Step 1 Perform one of the following actions:

- To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting). Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.
- To enroll manually, click the **Paste certificate in PEM format** radio button. Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided.

Step 2 Click **Install Certificate**.

An information dialog box appears informing you that the certificate was installed on the ASA successfully.

Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy

When configuring certificates for the Cisco Mobility Advantage Proxy, Cisco Presence Federation Proxy, or Cisco Intercompany Media Engine Proxy, you must generate and identity certificate request for the ASA.

Note If the ASA already has a signed identity certificate, you do not need to generate a CSR and can proceed directly to installing this certificate on the ASA. See Installing the ASA Identity Certificate on the Mobility Advantage Server, page 64-26 and Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers, page 64-26 for the steps to install the identity certificate.

The identify certificate that you receive is presented to the following entities for each of the Unified Communication Proxies:

- Unified Mobile Communicator clients for the Cisco Mobility Advantage Proxy

- Remote Presence Federation servers for the Cisco Presence Federation Proxy
- The remote ASAfor the Cisco Intercompany Media Engine Proxy

Before generating the CSR, you can enter additional parameters.

When configuring a Unified Communications proxy by using the wizard, you click the Generate CSR button while in the client-side or remote-side certificate management step of the wizard. The CSR Parameters dialog box appears.

In the CSR Parameters dialog box, perform the following steps:

Step 1 From the Key Pair Size drop-down list, choose the size required for you certificate.

The key size that you select depends on the level of security that you want to configure and on any limitations imposed by the CA from which you are obtaining the certificate. The larger the number that you select, the higher the security level will be for the certificate. Most CAs recommend 2048 for the key modulus size; however, GoDaddy requires a key modulus size of 2048.

Step 2 (Cisco Intercompany Media Engine Proxy only) In the CN field, enter the domain name used by your enterprise or network. The subject DN you configure for the Cisco Intercompany Media Engine Proxy must match the domain name that set in the local Cisco Unified Communications Manager server.

Note For the Cisco Mobility Advantage Proxy and Cisco Presence Federation Proxy, the wizard provides the common name (CN), which is the FQDN of the Cisco Mobility Advantage server or Cisco Unified Presence server, respectively.

Step 3 In the Additional DN Attributes field, enter an attribute.

Or

Click **Select** to display the Additional DN Attributes dialog box.

a. In the Additional DN Attributes dialog box, choose an attribute from the drop-down list.
b. Enter a value for the attribute.
c. Click Add. The attribute appears in the list.
d. Click OK to return to the CSR Parameters dialog box.

The value you added appears in the Additional DN Attributes field in the CSR Parameters dialog box.

Step 4 Click **OK**.

Saving the Identity Certificate Request

After successfully generating the identity certificate request for one of the Unified Communications proxies, the Identity Certificate Request dialog box appears and prompts you to save the request.

Step 1 In the Save CSR to File field, enter the CSR file name and path; for example, c:\asa-csr.txt.

Step 2 Click **OK**. An information dialog box appears indicating the CSR was saved successfully.

Step 3 Click **OK** to close the dialog and return to the wizard.

Submit the CSR to the certificate authority (CA), for example, by pasting the CSR text into the CSR enrollment page on the CA website.

When the CA returns the signed identity certificate, rerun the Unified Communications Wizard. From the client-side or remote-side certificate management step of the wizard, click **Install ASA's Identity Certificate**. See Installing the ASA Identity Certificate on the Mobility Advantage Server, page 64-26 and Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers, page 64-26 for the steps to install the identity certificate.

Installing the ASA Identity Certificate on the Mobility Advantage Server

When configuring certificates for the Cisco Mobility Advantage Proxy, you must install the ASA identity certificate on the Cisco Mobility Advantage server.

Typically, a certificate authority returns two certificates: your signed identity certificate and the certificate authority's certificate (referred to as the root certificate). However, some certificate authorities (for example, VeriSign) might also send you an intermediate certificate.

The root certificate from the certificate authority is used to sign other certificates. The root certificate is used by the ASA to authenticate your signed identity certificate received from the certificate authority.

If the certificate authority provided an intermediate certificate, you must enter the certificate text in the Intermediate Certificate (If Applicable) area of the Install ASA's Identity Certificate dialog box.

For the Cisco Mobility Advantage Proxy, you install the root certificate in another dialog box. See Installing a Certificate, page 64-23 for the steps to install the root certificate.

Step 1 In the Intermediate Certificate (If Applicable) area, perform on of the following actions:

- To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting). Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.
- To enroll manually, click the **Paste the certificate data in base-64 format** radio button. Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided.

Step 2 In the ASA's Identity Certificate area, perform on of the following actions:

- To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting). Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.
- To enroll manually, click the **Paste the certificate data in base-64 format** radio button. Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided.

Step 3 Click **Install Certificate**.

Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers

When configuring certificates for the Cisco Presence Federation Proxy and Cisco Intercompany Media Engine Proxy, you must install the ASA identity certificate and the root certificate on the Cisco Presence Federation server and Cisco Intercompany Media Engine server, respectively.

Typically, a certificate authority returns two certificates: your signed identity certificate and the certificate authority's certificate (referred to as the root certificate). The root certificate from the certificate authority is used to sign other certificates. The root certificate is used by the ASA to authenticate your signed identity certificate received from the certificate authority.

Step 1 In the Root CA's Certificate area, perform on of the following actions:

- To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting). Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.
- To enroll manually, click the **Paste the certificate data in base-64 format** radio button. Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided.

Step 2 In the ASA's Identity Certificate area, perform on of the following actions:

- To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting). Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.
- To enroll manually, click the **Paste the certificate data in base-64 format** radio button. Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided.

Step 3 Click **Install Certificate**.

Configuring the Cisco Phone Proxy

This chapter describes how to configure the adaptive security appliance for Cisco Phone Proxy feature.

This chapter includes the following sections:

- Information About the Cisco Phone Proxy, page 65-1
- Licensing Requirements for the Phone Proxy, page 65-4
- Prerequisites for the Phone Proxy, page 65-6
- Phone Proxy Guidelines and Limitations, page 65-12
- Configuring the Phone Proxy, page 65-14
- Feature History for the Phone Proxy, page 65-22

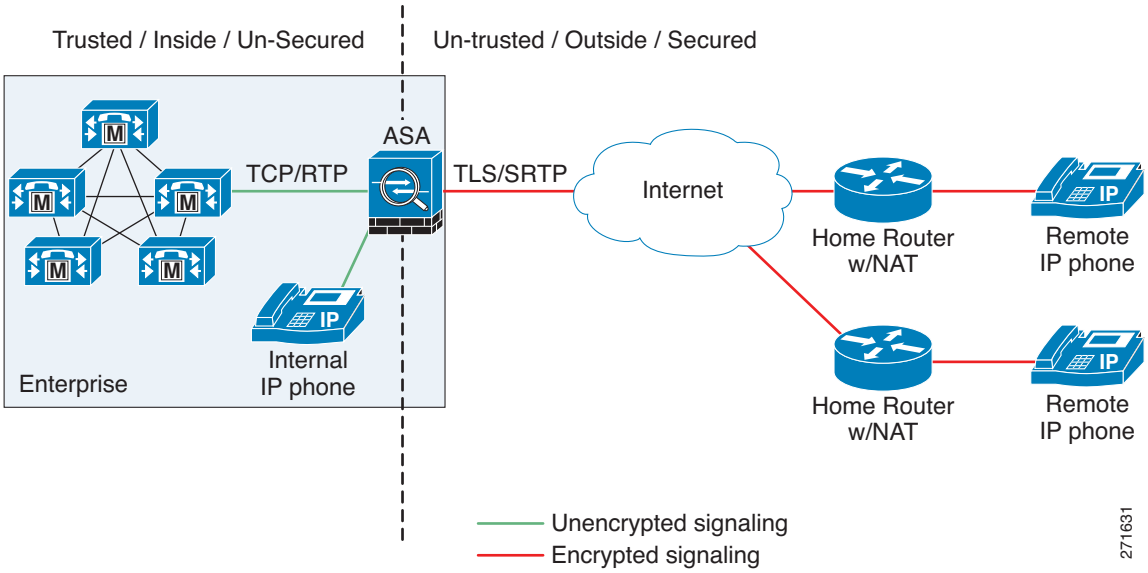
Information About the Cisco Phone Proxy

The Cisco Phone Proxy on the ASA bridges IP telephony between the corporate IP telephony network and the Internet in a secure manner by forcing data from remote phones on an untrusted network to be encrypted.

Phone Proxy Functionality

Telecommuters can connect their IP phones to the corporate IP telephony network over the Internet securely via the phone proxy without the need to connect over a VPN tunnel as illustrated by Figure 65-1.

Figure 65-1 Phone Proxy Secure Deployment



The phone proxy supports a Cisco UCM cluster in mixed mode or nonsecure mode. Regardless of the cluster mode, the remote phones that are capable of encryption are always forced to be in encrypted mode. TLS (signaling) and SRTP (media) are always terminated on the ASA. The ASA can also perform NAT, open pinholes for the media, and apply inspection policies for the SCCP and SIP protocols. In a nonsecure cluster mode or a mixed mode where the phones are configured as nonsecure, the phone proxy behaves in the following ways:

- The TLS connections from the phones are terminated on the ASA and a TCP connection is initiated to the Cisco UCM.
- SRTP sent from external IP phones to the internal network IP phone via the ASA is converted to RTP.

In a mixed mode cluster where the internal IP phones are configured as authenticated, the TLS connection is not converted to TCP to the Cisco UCM but the SRTP is converted to RTP.

In a mixed mode cluster where the internal IP phone is configured as encrypted, the TLS connection remains a TLS connection to the Cisco UCM and the SRTP from the remote phone remains SRTP to the internal IP phone.

Since the main purpose of the phone proxy is to make the phone behave securely while making calls to a nonsecure cluster, the phone proxy performs the following major functions:

- Creates the certificate trust list (CTL) file, which is used to perform certificate based authentication with remote phones.
- Modifies the IP phone configuration file when it is requested via TFTP, changes security fields from nonsecure to secure, and signs all files sent to the phone. These modifications secure remote phones by forcing the phones to perform encrypted signaling and media.
- Terminates TLS signaling from the phone and initiates TCP or TLS to Cisco UCM
- Inserts itself into the media path by modifying the Skinny and SIP signaling messages.
- Terminates SRTP and initiates RTP/SRTP to the called party.

Note As an alternative to authenticating remote IP phones through the TLS handshake, you can configure authentication via LSC provisioning. With LSC provisioning you create a password for each remote IP phone user and each user enters the password on the remote IP phones to retrieve the LSC.

Because using LSC provisioning to authenticate remote IP phones requires the IP phones first register in nonsecure mode, Cisco recommends LSC provisioning be done inside the corporate network before giving the IP phones to end-users. Otherwise, having the IP phones register in nonsecure mode requires the Administrator to open the nonsecure signaling port for SIP and SCCP on the ASA.

See also the Cisco Unified Communications Manager Security Guide for information on Using the Certificate Authority Proxy Function (CAPF) to install a locally significant certificate (LSC).

Supported Cisco UCM and IP Phones for the Phone Proxy

Cisco Unified Communications Manager

The following release of the Cisco Unified Communications Manager are supported with the phone proxy:

- Cisco Unified CallManager Version 4.*x*
- Cisco Unified CallManager Version 5.0
- Cisco Unified CallManager Version 5.1
- Cisco Unified Communications Manager 6.1
- Cisco Unified Communications Manager 7.0

Cisco Unified IP Phones

The phone proxy supports these IP phone features:

- Enterprise features like conference calls on remote phones connected through the phone proxy
- XML services

The following IP phones in the Cisco Unified IP Phones 7900 Series are supported with the phone proxy:

- Cisco Unified IP Phone 7975
- Cisco Unified IP Phone 7971
- Cisco Unified IP Phone 7970
- Cisco Unified IP Phone 7965
- Cisco Unified IP Phone 7962
- Cisco Unified IP Phone 7961
- Cisco Unified IP Phone 7961G-GE
- Cisco Unified IP Phone 7960 (SCCP protocol support only)
- Cisco Unified IP Phone 7945
- Cisco Unified IP Phone 7942
- Cisco Unified IP Phone 7941
- Cisco Unified IP Phone 7941G-GE

- Cisco Unified IP Phone 7940 (SCCP protocol support only)
- Cisco Unified Wireless IP Phone 7921
- Cisco Unified Wireless IP Phone 7925

Note To support Cisco Unified Wireless IP Phone 7925, you must also configure MIC or LSC on the IP phone so that it properly works with the phone proxy.

- CIPC for softphones (CIPC versions with Authenticated mode only)

Note The Cisco IP Communicator is supported with the phone proxy VLAN Traversal in authenticated TLS mode. We do not recommend it for remote access because SRTP/TLS is not supported currently on the Cisco IP Communicator.

Note The ASA supports inspection of traffic from Cisco IP Phones running SCCP protocol version 19 and earlier.

Licensing Requirements for the Phone Proxy

The Cisco Phone Proxy feature supported by the ASA require a Unified Communications Proxy license.

The following table shows the Unified Communications Proxy license details by platform:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement[1]
ASA 5505	Base License and Security Plus License: 2 sessions. *Optional license: 24 sessions.*
ASA 5510	Base License and Security Plus License: 2 sessions. *Optional licenses: 24, 50, or 100 sessions.*
ASA 5520	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5540	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5550	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5580	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASA 5512-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*

Model	License Requirement[1]
ASA 5515-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5525-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5545-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5555-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-10	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-20, -40, or -60	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASASM	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]

1. The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit:
   - Phone Proxy
   - Presence Federation Proxy
   - Encrypted Voice Inspection

   Other applications that use TLS proxy sessions do not count towards the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license).

   Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used.

   You independently set the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. When you apply a UC license that is higher than the default TLS proxy limit, the ASA automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license.

   Note: For license part numbers ending in “K8” (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in “K9” (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.

   Note: If you clear the configuration, then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the to raise the limit again (in ASDM, use the **TLS Proxy** pane). If you use failover and use **File > Save Running Configuration to Standby Unit** on the primary unit to force a configuration synchronization, the **clear configure all** command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning.

   You might also use SRTP encryption sessions for your connections:
   - For K8 licenses, SRTP sessions are limited to 250.
   - For K9 licenses, there is not limit.

   Note: Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.
2. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

For more information about licensing, see Chapter 5, “Managing Feature Licenses.”

Prerequisites for the Phone Proxy

This section contains the following topics:

- Media Termination Instance Prerequisites, page 65-6
- Certificates from the Cisco UCM, page 65-7
- DNS Lookup Prerequisites, page 65-7
- Cisco Unified Communications Manager Prerequisites, page 65-7
- Access List Rules, page 65-7
- NAT and PAT Prerequisites, page 65-8
- Prerequisites for IP Phones on Multiple Interfaces, page 65-8
- 7960 and 7940 IP Phones Support, page 65-9
- Cisco IP Communicator Prerequisites, page 65-10
- Prerequisites for Rate Limiting TFTP Requests, page 65-10
- End-User Phone Provisioning, page 65-11

Media Termination Instance Prerequisites

The ASA must have a media termination instance that meets the following criteria:

- You must configure one media termination for each phone proxy on the ASA. Multiple media termination instances on the ASA are not supported.
- For the media termination instance, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces. However, you cannot use a global media-termination address and media-termination addresses configured for each interface at the same time.
- If you configure a media termination address for multiple interfaces, you must configure an address on each interface that the ASA uses when communicating with IP phones.

  For example, if you had three interfaces on the ASA (one internal interface and two external interfaces) and only one of the external interfaces were used to communicate with IP phones, you would configure two media termination addresses: one on the internal interface and one on the external interface that communicated with the IP phones.
- Only one media-termination address can be configured per interface.
- The IP addresses are publicly routable addresses that are unused IP addresses within the address range on that interface.
- The IP address on an interface cannot be the same address as that interface on the ASA.
- The IP addresses cannot overlap with existing static NAT pools or NAT rules.
- The IP addresses cannot be the same as the Cisco UCM or TFTP server IP address.
- For IP phones behind a router or gateway, you must also meet this prerequisite. On the router or gateway, add routes to the media termination address on the ASA interface that the IP phones communicate with so that the phone can reach the media termination address.

Certificates from the Cisco UCM

Import the following certificates which are stored on the Cisco UCM. These certificates are required by the ASA for the phone proxy.

- Cisco_Manufacturing_CA
- CAP-RTP-001
- CAP-RTP-002
- CAPF certificate (Optional)

If LSC provisioning is required or you have LSC enabled IP phones, you must import the CAPF certificate from the Cisco UCM. If the Cisco UCM has more than one CAPF certificate, you must import all of them to the ASA.

Note You can configure LSC provisioning for additional end-user authentication. See the Cisco Unified Communications Manager configuration guide for information.

For example, the CA Manufacturer certificate is required by the phone proxy to validate the IP phone certificate.

DNS Lookup Prerequisites

- If you have an fully qualified domain name (FQDN) configured for the Cisco UCM rather than an IP address, you must configure and enable DNS lookup on the ASA.
- After configuring the DNS lookup, make sure that the ASA can ping the Cisco UCM with the configured FQDN.
- You must configure DNS lookup when you have a CAPF service enabled and the Cisco UCM is not running on the Publisher but the Publisher is configured with a FQDN instead of an IP address.

Cisco Unified Communications Manager Prerequisites

- The TFTP server must reside on the same interface as the Cisco UCM.
- The Cisco UCM can be on a private network on the inside but you need to have a static mapping for the Cisco UCM on the ASA to a public routable address.
- If NAT is required for Cisco UCM, it must be configured on the ASA, not on the existing firewall.

Access List Rules

If the phone proxy is deployed behind an existing firewall, access-list rules to permit signaling, TFTP requests, and media traffic to the phone proxy must be configured.

If NAT is configured for the TFTP server or Cisco UCMs, the translated “global” address must be used in the access lists.

Table 65-1 lists the ports that are required to be configured on the existing firewall:

Table 65-1 Port Configuration Requirements

Address	Port	Protocol	Description
Media Termination	1024-65535	UDP	Allow incoming SRTP
TFTP Server	69	UDP	Allow incoming TFTP
Cisco UCM	2443	TCP	Allow incoming secure SCCP
Cisco UCM	5061	TCP	Allow incoming secure SIP
CAPF Service (on Cisco UCM)	3804	TCP	Allow CAPF service for LSC provisioning

Note All these ports are configurable on the Cisco UCM, except for TFTP. These are the default values and should be modified if they are modified on the Cisco UCM. For example, 3804 is the default port for the CAPF Service. This default value should be modified if it is modified on the Cisco UCM.

NAT and PAT Prerequisites

NAT Prerequisites

- If NAT is configured for the TFTP server, the NAT configuration must be configured prior to configuring the TFTP Server for the phone proxy.
- If NAT is configured for the TFTP server or Cisco UCMs, the translated “global” address must be used in the access lists.

PAT Prerequisites

- When the Skinny inspection global port is configured to use a non-default port, then you must configure the nonsecure port as the `global_sccp_port+443`.

  Therefore, if *global_sccp_port* is 7000, then the global secure SCCP port is 7443. Reconfiguring the port might be necessary when the phone proxy deployment has more than one Cisco UCM and they must share the interface IP address or a global IP address.

Note Both PAT configurations—for the nonsecure and secure ports—must be configured.

- When the IP phones must contact the CAPF on the Cisco UCM and the Cisco UCM is configured with static PAT (LCS provisioning is required), you must configure static PAT for the default CAPF port 3804.

Prerequisites for IP Phones on Multiple Interfaces

When IP phones reside on multiple interfaces, the phone proxy configuration must have the correct IP address set for the Cisco UCM in the CTL file.

See the following example topology for information about how to correctly set the IP address:

```
phones --- (dmz)-----|
                     |----- ASA PP --- (outside Internet) --- phones
phones --- (inside)--|
```

In this example topology, the following IP address are set:

- Cisco UCM on the inside interface is set to 10.0.0.5
- The DMZ network is 192.168.1.0/24
- The inside network is 10.0.0.0/24

The Cisco UCM is mapped with different global IP addresses from DMZ > outside and inside interfaces > outside interface.

In the CTL file, the Cisco UCM must have two entries because of the two different IP addresses. For example, if the static statements for the Cisco UCM are as follows:

```
object network obj-10.0.0.5-01
    host 10.0.0.5
    nat (inside,outside) static 209.165.202.129
object network obj-10.0.0.5-02
    host 10.0.0.5
    nat (inside,dmz) static 198.168.1.2
```

There must be two CTL file record entries for the Cisco UCM:

```
record-entry cucm trustpoint cucm_in_to_out address 209.165.202.129
record-entry cucm trustpoint cucm_in_to_dmz address 192.168.1.2
```

7960 and 7940 IP Phones Support

- An LSC must be installed on these IP phones because they do not come pre installed with a MIC. Install the LSC on each phone before using them with the phone proxy to avoid opening the nonsecure SCCP port for the IP phones to register in nonsecure mode with the Cisco UCM.

  See the following document for the steps to install an LSC on IP phones:

  http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/security/7_0_1/secugd/secucapf.html#wp1093518

Note If an IP phone already has an LSC installed on it from a different Cisco UCM cluster, delete the LSC from the different cluster and install an LSC from the current Cisco UCM cluster.

Note You can configure LSC provisioning for additional end-user authentication. See the Cisco Unified Communications Manager configuration guide for information.

- The CAPF certificate must be imported onto the ASA.
- The CTL file created on the ASA must be created with a CAPF record-entry.
- The phone must be configured to use only the SCCP protocol because the SIP protocol does not support encryption on these IP phones.
- If LSC provisioning is done via the phone proxy, you must add an ACL to allow the IP phones to register with the Cisco UCM on the nonsecure port 2000.

Cisco IP Communicator Prerequisites

To configure Cisco IP Communicator (CIPC) with the phone proxy, you must meet the following prerequisites:

- Go to Configuration > Firewall > Unified Communications > Phone Proxy and select the "Enable CICP security mode authentication" check box under the Call Manager and Phone Settings area.
- Create an ACL to allow CIPC to register with the Cisco UCM in nonsecure mode.
- Configure null-sha1 as one of the SSL encryption ciphers.

Current versions of Cisco IP Communicator (CIPC) support authenticated mode and perform TLS signaling but not voice encryption.

Because CIPC requires an LSC to perform the TLS handshake, CIPC needs to register with the Cisco UCM in nonsecure mode using cleartext signaling. To allow the CIPC to register, create an ACL that allows the CIPC to connect to the Cisco UCM on the nonsecure SIP/SCCP signalling ports (5060/2000).

Note You can configure LSC provisioning for additional end-user authentication. See the Cisco Unified Communications Manager configuration guide for information.

CIPC uses a different cipher when doing the TLS handshake and requires the null-sha1 cipher and SSL encryption be configured. To add the null-shal cipher, use the show run all ssl command to see the output for the ssl encryption command and add null-shal to the end of the SSL encryption list.

Note When used with CIPC, the phone proxy does not support end-users resetting their device name in CIPC (Preferences > Network tab > Use this Device Name field) or Administrators resetting the device name in Cisco Unified CM Administration console (Device menu > Phone Configuration > Device Name field). To function with the phone proxy, the CIPC configuration file must be in the format: SEP<mac_address>.cnf.xml. If the device name does not follow this format (SEP<mac_address>), CIPC cannot retrieve its configuration file from Cisco UMC via the phone proxy and CIPC will not function.

Prerequisites for Rate Limiting TFTP Requests

In a remote access scenario, we recommend that you configure rate limiting of TFTP requests because any IP phone connecting through the Internet is allowed to send TFTP requests to the TFTP server.

To configure rate limiting of TFTP requests, configure the **police** command in the Modular Policy Framework. See the command reference for information about using the **police** command.

Policing is a way of ensuring that no traffic exceeds the maximum rate (in bits/second) that you configure, thus ensuring that no one traffic flow can take over the entire resource. When traffic exceeds the maximum rate, the ASA drops the excess traffic. Policing also sets the largest single burst of traffic allowed.

Rate Limiting Configuration Example

The following example describes how you configure rate limiting for TFTP requests by using the **police** command and the Modular Policy Framework.

Begin by determining the conformance rate that is required for the phone proxy. To determine the conformance rate, use the following formula:

```
X * Y * 8
```

Where

X = requests per second

Y = size of each packet, which includes the L2, L3, and L4 plus the payload

Therefore, if a rate of 300 TFTP requests/second is required, then the conformance rate would be calculated as follows:

```
300 requests/second * 80 bytes * 8 = 192000
```

To control which hosts can ping the media termination address, create an ICMP rule. Go to Configuration > Device Management > Management Access > ICMP and click the Add button.

End-User Phone Provisioning

The phone proxy is a transparent proxy with respect to the TFTP and signaling transactions. If NAT is not configured for the Cisco UCM TFTP server, then the IP phones need to be configured with the Cisco UCM cluster TFTP server address.

If NAT is configured for the Cisco UCM TFTP server, then the Cisco UCM TFTP server global address is configured as the TFTP server address on the IP phones.

Ways to Deploy IP Phones to End Users

In both options, deploying a remote IP phone behind a commercial Cable/DSL router with NAT capabilities is supported.

Option 1 (Recommended)

Stage the IP phones at corporate headquarters before sending them to the end users:

- The phones register inside the network. IT ensures there are no issues with the phone configurations, image downloads, and registration.
- If Cisco UCM cluster was in mixed mode, the CTL file should be erased before sending the phone to the end user.

Advantages of this option are:

- Easier to troubleshoot and isolate problems with the network or phone proxy because you know whether the phone is registered and working with the Cisco UCM.
- Better user experience because the phone does not have to download firmware from over a broadband connection, which can be slow and require the user to wait for a longer time.

Option 2

Send the IP phone to the end user. When using option 2, the user must be provided instructions to change the settings on phones with the appropriate Cisco UCM and TFTP server IP address.

Note As an alternative to authenticating remote IP phones through the TLS handshake, you can configure authentication via LSC provisioning. With LSC provisioning you create a password for each remote IP phone user and each user enters the password on the remote IP phones to retrieve the LSC.

Because using LSC provisioning to authenticate remote IP phones requires the IP phones first register

in nonsecure mode, Cisco recommends LSC provisioning be done inside the corporate network before giving the IP phones to end-users. Otherwise, having the IP phones register in nonsecure mode requires the Administrator to open the nonsecure signaling port for SIP and SCCP on the ASA.

See also the Cisco Unified Communications Manager Security Guide for information on Using the Certificate Authority Proxy Function (CAPF) to install a locally significant certificate (LSC).

Phone Proxy Guidelines and Limitations

This section includes the following topics:

- General Guidelines and Limitations, page 65-12
- Media Termination Address Guidelines and Limitations, page 65-13

General Guidelines and Limitations

The phone proxy has the following general limitations:

- Only one phone proxy instance can be configured on the ASA by using the **phone-proxy** command. See the command reference for information about the **phone-proxy** command. See also Creating the Phone Proxy Instance, page 65-18.
- The phone proxy only supports one Cisco UCM cluster. See Creating the CTL File, page 65-14 for the steps to configure the Cisco UCM cluster for the phone proxy.
- The phone proxy is not supported when the ASA is running in transparent mode or multiple context mode.
- When a remote IP phone calls an invalid internal or external extension, the phone proxy does not support playing the annunciator message from the Cisco UCM. Instead, the remote IP phone plays a fast busy signal instead of the annunciator message "Your call cannot be completed ..." However, when an internal IP phone dials in invalid extension, the annunciator messages plays "Your call cannot be completed ..."
- Packets from phones connecting to the phone proxy over a VPN tunnel are not inspected by the ASA inspection engines.
- The phone proxy does not support IP phones sending Real-Time Control Protocol (RTCP) packets through the ASA. Disable RTCP packets in the Cisco Unified CM Administration console from the Phone Configuration page. See your Cisco Unified Communications Manager (CallManager) documentation for information about setting this configuration option.
- When used with CIPC, the phone proxy does not support end-users resetting their device name in CIPC (Preferences > Network tab > Use this Device Name field) or Administrators resetting the device name in Cisco Unified CM Administration console (Device menu > Phone Configuration > Device Name field). To function with the phone proxy, the CIPC configuration file must be in the format: SEP<mac_address>.cnf.xml. If the device name does not follow this format (SEP<mac_address>), CIPC cannot retrieve its configuration file from Cisco UMC via the phone proxy and CIPC will not function.
- The phone proxy does not support IP phones sending SCCP video messages using Cisco VT Advantage because SCCP video messages do not support SRTP keys.
- For mixed-mode clusters, the phone proxy does not support the Cisco Unified Call Manager using TFTP to send encrypted configuration files to IP phones through the ASA.

- Multiple IP phones behind one NAT device must be configured to use the same security mode.

  When the phone proxy is configured for a mixed-mode cluster and multiple IP phones are behind one NAT device and registering through the phone proxy, all the SIP and SCCP IP phones must be configured as authenticated or encrypted, or all as non-secure on the Unified Call Manager.

  For example, if there are four IP phones behind one NAT device where two IP phones are configured using SIP and two IP phones are configured using SCCP, the following configurations on the Unified Call Manager are acceptable:

  – Two SIP IP phones: one IP phone in authenticated mode and one in encrypted mode, both in authenticated mode, or both in encrypted mode

    Two SCCP IP phones: one IP phone in authenticated mode and one in encrypted mode, both in authenticated mode, or both in encrypted mode

  – Two SIP IP phones: both in non-secure mode

    Two SCCP IP phones: one IP phone in authenticated mode and one in encrypted mode, both in authenticated mode, both in encrypted mode

  – Two SIP IP phones: one IP phone in authenticated mode and one in encrypted mode, both in authenticated mode, both in encrypted mode

    Two SCCP IP phones: both in non-secure mode

  This limitation results from the way the application-redirect rules (rules that convert TLS to TCP) are created for the IP phones.

Media Termination Address Guidelines and Limitations

The phone proxy has the following limitations relating to configuring the media-termination address:

- When configuring the media-termination address, the phone proxy does not support having internal IP phones (IP phones on the inside network) being on a different network interface from the Cisco UCM unless the IP phones are forced to use the non-secure Security mode.

  When internal IP phones are on a different network interface than the Cisco UCM, the IP phones signalling sessions still go through ASA; however, the IP phone traffic does not go through the phone proxy. Therefore, Cisco recommends that you deploy internal IP phones on the same network interface as the Cisco UMC.

  If the Cisco UMC and the internal IP phones must be on different network interfaces, you must add routes for the internal IP phones to access the network interface of the media-termination address where Cisco UMC resides.

  When the phone proxy is configured to use a global media-termination address, all IP phones see the same global address, which is a public routable address.

- If you decide to configure a media-termination address on interfaces (rather than using a global interface), you must configure a media-termination address on at least two interfaces (the inside and an outside interface) before applying the phone-proxy service policy. Otherwise, you will receive an error message when enabling the Phone Proxy with SIP and Skinny Inspection.

- The phone proxy can use only one type of media termination instance at a time; for example, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces. However, you cannot use a global media-termination address and media-termination addresses configured for each interface at the same time.

Configuring the Phone Proxy

This section includes the following topics:

- Task Flow for Configuring the Phone Proxy, page 65-14
- Creating the CTL File, page 65-14
- Adding or Editing a Record Entry in a CTL File, page 65-16
- Creating the Media Termination Instance, page 65-17
- Creating the Phone Proxy Instance, page 65-18
- Adding or Editing the TFTP Server for a Phone Proxy, page 65-20
- Configuring Linksys Routers with UDP Port Forwarding for the Phone Proxy, page 65-21

Task Flow for Configuring the Phone Proxy

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Configuring the Phone Proxy requires the following steps:

Step 1: Create the CTL file. See Creating the CTL File, page 65-14.

Step 2: Create the TLS Proxy instance to handle the encrypted signaling. See Adding a TLS Proxy Instance, page 66-9.

Step 3: Create the Phone Proxy instance. See the "Creating the Phone Proxy Instance" section on page 65-18.

Step 4: Configure the media termination address for the Phone Proxy. See Creating the Media Termination Instance, page 65-17.

Note Before you enable SIP and Skinny inspection for the Phone Proxy (which is done by applying the Phone Proxy to a service policy rule), the Phone Proxy must have an MTA instance, TLS Proxy, and CTL file assigned to it before the Phone Proxy can be applied to a service policy. Additionally, once a Phone Proxy is applied to a service policy rule, the Phone Proxy cannot be changed or removed.

Step 5: Enable the Phone Proxy with SIP and Skinny inspection. See SIP Inspection, page 59-20 and Skinny (SCCP) Inspection, page 59-31.

Creating the CTL File

Create a Certificate Trust List (CTL) file that is required by the Phone Proxy. Specify the certificates needed by creating a new CTL file or by specifying the path of an exiting CTL file to parse from Flash memory.

Create trustpoints and generate certificates for each entity in the network (CUCM, CUCM and TFTP, TFTP server, CAPF) that the IP phones must trust. The certificates are used in creating the CTL file. You need to create trustpoints for each CUCM (primary and secondary if a secondary CUCM is used) and TFTP server in the network. The trustpoints need to be in the CTL file for the phones to trust the CUCM.

Create the CTL File that will be presented to the IP phones during the TFTP. The address must be the translated or global address of the TFTP server or CUCM if NAT is configured.

When the file is created, it creates an internal trustpoint used by the Phone Proxy to sign the TFTP files. The trustpoint is named **_internal_PP**_*ctl-instance_filename*.

Note When a CTL file instance is assigned to the Phone Proxy, you cannot modify it in the CTL File pane and the pane is disabled. To modify a CTL File that is assigned to the Phone Proxy, go to the Phone Proxy pane (Configuration > Firewall > Unified Communications > Phone Proxy), and deselect the Use the Certificate Trust List File generated by the CTL instance check box.

Use the Create a Certificate Trust List (CTL) File pane to create a CTL file for the Phone Proxy. This pane creates the CTL file that is presented to the IP phones during the TFTP handshake with the ASA. For a detailed overview of the CTL file used by the Phone Proxy, see the "Creating the CTL File" section on page 65-14.

The Create a Certificate Trust List (CTL) File pane is used to configure the attributes for generating the CTL file. The name of the CTL file instance is generated by the ASDM. When the user tries to edit the CTL file instance configuration, the ASDM automatically generates the **shutdown** CLI command first and the **no shutdown** CLI command as the last command.

This pane is available from the Configuration > Firewall > Unified Communications > CTL File pane.

Step 1 Open the Configuration > Firewall > Unified Communications > CTL File pane.

Step 2 Check the Enable Certificate Trust List File check box to enable the feature.

Step 3 To specify the CTL file to use for the Phone Proxy, perform one of the following:

- If there is an existing CTL file available, download the CTL file to Flash memory by using the File Management Tool in the ASDM Tools menu. Select the Use certificates present in the CTL stored in flash radio button and specify the CTL file name and path in the text box.

  Use an existing CTL file to install the trustpoints for each entity in the network (CUCM, CUCM and TFTP, TFTP server, CAPF) that the IP phones must trust. If you have an existing CTL file that contains the correct IP addresses of the entities (namely, the IP address that the IP phones use for the CUCM or TFTP servers), you can be use it to create a new CTL file. Store a copy of the existing CTL file to Flash memory and rename it something other than `CTLFile.tlv`

- If there is no existing CTL file available, select Create new CTL file radio button.

  Add Record entries for each entity in the network such as CUCM, TFTP, and CUCM-TFTP option by clicking **Add**. The Add Record Entry dialog box opens. See Adding or Editing a Record Entry in a CTL File, page 65-16.

Step 4 Specify the number SAST certificate tokens required. The default is 2. maximum allowed is 5.

Because the Phone Proxy generates the CTL file, it needs to create the System Administrator Security Token (SAST) key to sign the CTL file itself. This key can be generated on the ASA. A SAST is created as a self-signed certificate. Typically, a CTL file contains more than one SAST. In case a SAST is not recoverable, the other one can be used to sign the file later.

Step 5 Click **Apply** to save the CTL file configuration settings.

Adding or Editing a Record Entry in a CTL File

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Use the Add/Edit Record Entry dialog box to specify the trustpoints to be used for the creation of the CTL file.

Note You can edit an entry in the CTL file by using the Edit Record Entry dialog box; however, changing a setting in this dialog box does not change related settings for the phone proxy. For example, editing the IP address for the CUCM or TFTP servers in this dialog changes the setting only in the CTL file and does not change the actual addresses of those servers or update the address translations required by the phone proxy.
To modify CTL file settings, we strongly recommend you re-run the Unified Communications Wizard to edit CTL file settings and ensure proper synchronization with all phone proxy settings.

Add additional record-entry configurations for each entity that is required in the CTL file.

Step 1 Open the Configuration > Firewall > Unified Communications > CTL File pane.

Step 2 Check the Enable Certificate Trust List File check box to enable the feature.

Step 3 In the Type field, specify the type of trustpoint to create:

- cucm: Specifies the role of this trustpoint to be CCM. Multiple CCM trustpoints can be configured.
- cucm-tftp: Specifies the role of this trustpoint to be CCM+TFTP. Multiple CCM+TFTP trustpoints can be configured.
- tftp: Specifies the role of this trustpoint to be TFTP. Multiple TFTP trustpoints can be configured.
- capf: Specifies the role of this trustpoint to be CAPF. Only one CAPF trustpoint can be configured.

Step 4 In the Host field, specify the IP address of the trustpoint. The IP address you specify must be the global address of the TFTP server or CUCM if NAT is configured. The global IP address is the IP address as seen by the IP phones because it will be the IP address used for the CTL record for the trustpoint.

Step 5 In the Certificate field, specify the Identity Certificate for the record entry in the CTL file. You can create a new Identity Certificate by clicking **Manage**. The Manage Identify Certificates dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22.

You can add an Identity Certificate by generating a self-signed certificate, obtaining the certificate through SCEP enrollment, or by importing a certificate in PKCS-12 format. Choose the best option based on the requirements for configuring the CTL file.

Step 6 (Optional) In the Domain Name field, specify the domain name of the trustpoint used to create the DNS field for the trustpoint. This is appended to the Common Name field of the Subject DN to create the DNS Name. The domain name should be configured when the FQDN is not configured for the trustpoint. Only one domain-name can be specified.

Note If you are using domain names for your CUCM and TFTP server, you must configure DNS lookup on the ASA. Add an entry for each of the outside interfaces on the ASA into your DNS server, if such entries are not already present. Each ASA outside IP address should have a DNS entry associated with it for

lookups. These DNS entries must also be enabled for Reverse Lookup. Additionally, define your DNS server IP address on the ASA; for example: `dns name-server 10.2.3.4` (IP address of your DNS server).

Creating the Media Termination Instance

Create the media termination instance that you will use in the phone proxy.

The media termination address you configure must meet the requirements as described in Media Termination Instance Prerequisites, page 65-6.

Note In versions before 8.2(1), you configured one media-termination address (MTA) on the outside interface of the adaptive security appliance where the remote Cisco IP phones were located. In Version 8.2(1) and later, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces.

As a result of this enhancement, the old configuration has been deprecated. You can continue to use the old configuration if desired. However, if you need to change the configuration at all, only the new configuration method is accepted; you cannot later restore the old configuration. If you need to maintain downgrade compatibility, you should keep the old configuration as is.

Step 1 Open the Configuration > Firewall > Unified Communications > Media Termination Address pane.

Step 2 Check the Enable Media Termination Address check box to enable the feature.

Step 3 In the Media Termination Address Settings area, specify whether to configure a media-termination address (MTA) per interface or to configure a global MTA. You can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces.

- To configure an MTA per interface, click the Configure MTA per Interface radio button and click the **Add** button. In the dialog box that appears, specify the interface name and enter an IP address or hostname.

  If you configure a media termination address for multiple interfaces, you must configure an address on each interface that the ASA uses when communicating with IP phones. The IP addresses are publicly routable addresses that are unused IP addresses within the address range on that interface.

  See Media Termination Instance Prerequisites, page 65-6 for the complete list of requirements that you must follow when creating the media termination instance and configuring the media termination addresses.

- To configure a global MTA, click the Configure global MTA on interface radio button and enter the IP address in the text box. See Media Termination Instance Prerequisites, page 65-6 for the complete list of requirements that you must follow when configuring a global media termination address.

Step 4 Specify the minimum and maximum values for the RTP port range for the media termination instance. The minimum port and the maximum port can be a value from 1024 to 65535.

Step 5 Click **Apply** to save the media termination address configuration settings.

Creating the Phone Proxy Instance

Create the phone proxy instance. To have a fully functional phone proxy, you must also complete additional tasks, such as creating the MTA and enabling SIP and SCCP (Skinny) inspection. See Task Flow for Configuring the Phone Proxy, page 65-14 for the complete list of tasks.

Prerequisites

You must have already created the CTL file and TLS proxy instance for the phone proxy.

See Creating the CTL File, page 65-14 and Adding a TLS Proxy Instance, page 66-9.

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Use the Configure Phone Proxy pane to add a Phone Proxy.

This pane is available from the Configuration > Firewall > Unified Communications > Phone Proxy pane.

Step 1 Open the Configuration > Firewall > Unified Communications > Phone Proxy pane.

Step 2 Check the Enable Phone Proxy check box to enable the feature.

Step 3 Check the Apply MTA instance to Phone Proxy check box to add the media termination address to the Phone Proxy instance. You must have a media termination address instance configured. The configured address is added to the Phone Proxy instance.

Note To configure the media termination address, click the Configure MTA button. The Media Termination Address dialog box appears. Once you click the Add MTA instance to Phone Proxy check box, the media termination address instance cannot be modified and the button changes to View MTA Configuration. To change the media termination address, uncheck the Add MTA instance to Phone Proxy check box.

Step 4 If necessary, add a TFTP server for the Phone Proxy. To add a new TFTP server for the Phone Proxy, click **Add**. The Add TFTP Server dialog box opens. See Adding or Editing the TFTP Server for a Phone Proxy, page 65-20.

Note The TFTP server must reside on the same interface as the Cisco Unified Call Manager. Additionally, If NAT is configured for the TFTP server, the NAT configuration must be configured prior to configuring the specifying the TFTP server while creating the Phone Proxy instance.

Step 5 Specify the CTL File to use for the Phone Proxy by doing one of the following:

- To use an existing CTL File, check the Use the Certificate Trust List File generated by the CTL instance check box.
- To create a new CTL file for the Phone Proxy, click the link Generate Certificate Trust List File. The Create a Certificate Trust List (CTL) File pane opens. See "Creating the CTL File" section on page 65-14.

Step 6 To specify the security mode of the CUCM cluster, click one of the following options in the CUCM Cluster Mode field:

- Non-secure—Specifies the cluster mode to be in nonsecure mode when configuring the Phone Proxy feature.
- Mixed—Specifies the cluster mode to be in mixed mode when configuring the Phone Proxy feature.

Step 7 To configure the idle timeout after which the secure-phone entry is removed from the Phone Proxy database (the default is 5 minutes), enter a value in the format *hh*:*mm*:*ss*.

Since secure phones always request a CTL file upon bootup, the Phone Proxy creates a database that marks the phone as secure. The entries in the secure phone database are removed after a specified configured timeout. The entry timestamp is updated for each registration refresh the Phone Proxy receives for SIP phones and KeepAlives for SCCP phones.

Specify a value that is greater than the maximum timeout value for SCCP KeepAlives and SIP Register refresh. For example, if the SCCP KeepAlives are configured for 1 minute intervals and the SIP Register Refresh is configured for 3 minutes, configure this timeout value greater than 3 minutes.

Step 8 To preserve Call Manager configuration on the IP phones, check the Preserve the Call Manager's configuration on the phone... check box. When this check box is uncheck, the following service settings are disabled on the IP phones:

- PC Port
- Gratuitous ARP
- Voice VLAN access
- Web Access
- Span to PC Port

Step 9 To force Cisco IP Communicator (CIPC) softphones to operate in authenticated mode when CIPC softphones are deployed in a voice and data VLAN scenario, check the Enable CIPC security mode authentication check box.

Because CIPC requires an LSC to perform the TLS handshake, CIPC needs to register with the CUCM in nonsecure mode using cleartext signaling. To allow the CIPC to register, create an ACL that allows the CIPC to connect to the CUCM on the nonsecure SIP/SCCP signalling ports (5060/2000).

CIPC uses a different cipher when doing the TLS handshake and requires the null-sha1 cipher and SSL encryption be configured. To add the null-shal cipher, go to Configuration > Device Management > Advanced > SSL Settings > Encryption section. Select the null-shal SSL encryption type and add it to the Available Algorithms.

Current versions of Cisco IP Communicator (CIPC) support authenticated mode and perform TLS signaling but not voice encryption.

Step 10 To configure an HTTP proxy for the Phone Proxy feature that is written into the IP phone's configuration file under the <proxyServerURL> tag, do the following:

a. Check the Configure a http-proxy which would be written into the phone's config file... check box.

b. In the IP Address field, type the IP address of the HTTP proxy and the listening port of the HTTP proxy.

The IP address you enter should be the global IP address based on where the IP phone and HTTP proxy server is located. You can enter a hostname in the IP Address field when that hostname can be resolved to an IP address by the ASA (for example, DNS lookup is configured) because the ASA will resolve the hostname to an IP address. If a port is not specified, the default will be 8080.

c. In the Interface field, select the interface on which the HTTP proxy resides on the ASA.

Setting the proxy server configuration option for the Phone Proxy allows for an HTTP proxy on the DMZ or external network in which all the IP phone URLs are directed to the proxy server for services on the phones. This setting accommodates nonsecure HTTP traffic, which is not allowed back into the corporate network.

Step 11 Click **Apply** to save the Phone Proxy configuration settings.

Note After creating the Phone Proxy instance, you enable it with SIP and Skinny inspection. See SIP Inspection, page 59-20 and Skinny (SCCP) Inspection, page 59-31.

However, before you enable SIP and Skinny inspection for the Phone Proxy (which is done by applying the Phone Proxy to a service policy rule), the Phone Proxy must have an MTA instance, TLS Proxy, and CTL file assigned to it before the Phone Proxy can be applied to a service policy. Additionally, once a Phone Proxy is applied to a service policy rule, the Phone Proxy cannot be changed or removed.

Adding or Editing the TFTP Server for a Phone Proxy

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Note You can edit the TFTP server setting by using the Edit TFTP Server dialog box; however, changing a setting in this dialog box does not change related settings for the phone proxy. For example, editing the IP address for the TFTP server in this dialog does not change the setting in the CTL file and does not update the address translations required by the phone proxy.
To modify TFTP server settings, we strongly recommend you re-run the Unified Communications Wizard to ensure proper synchronization with all phone proxy settings.

Step 1 Open the Configuration > Firewall > Unified Communications > Phone Proxy pane.

Step 2 Check the Enable Phone Proxy check box to enable the feature.

Step 3 To add or edit the TFTP Server information for the phone proxy, click the **Add** or **Edit** button. The Add/Edit TFTP Server dialog box appears.

Use the Add/Edit TFTP Server dialog box to specify the IP address of the TFTP server and the interface on which the TFTP server resides.

The Phone Proxy must have at least one CUCM TFTP server configured. Up to five TFTP servers can be configured for the Phone Proxy.

The TFTP server is assumed to be behind the firewall on the trusted network; therefore, the Phone Proxy intercepts the requests between the IP phones and TFTP server.

Note If NAT is configured for the TFTP server, the NAT configuration must be configured prior to specifying the TFTP server while creating the Phone Proxy instance.

Step 4 In the TFTP Server IP Address field, specify the address of the TFTP server. Create the TFTP server using the actual internal IP address.

Step 5 (Optional) In the Port field, specify the port the TFTP server is listening in on for the TFTP requests. This should be configured if it is not the default TFTP port 69.

Step 6 In the Interface field, specify the interface on which the TFTP server resides. The TFTP server must reside on the same interface as the Cisco Unified Call Manager (CUCM).

Step 7 Click OK to apply the settings.

Configuring Linksys Routers with UDP Port Forwarding for the Phone Proxy

When IP phones are behind a NAT-capable router, the router can be configured to forward the UDP ports to the IP address of the IP phone. Specifically, configure the router for UDP port forwarding when an IP phone is failing during TFTP requests and the failure is due to the router dropping incoming TFTP data packets. Configure the router to enable UDP port forwarding on port 69 to the IP phone.

As an alternative of explicit UDP forwarding, some Cable/DSL routers require you to designate the IP phone as a DMZ host. For Cable/DSL routers, this host is a special host that receives all incoming connections from the public network.

When configuring the phone proxy, there is no functional difference between an IP phone that has UDP ports explicitly forwarded or an IP phone designated as a DMZ host. The choice is entirely dependent upon the capabilities and preference of the end user.

Configuring Your Router

Your firewall/router needs to be configured to forward a range of UDP ports to the IP phone. This will allow the IP phone to receive audio when you make/receive calls.

Note Different Cable/DSL routers have different procedures for this configuration. Furthermore most NAT-capable routers will only allow a given port range to be forwarded to a single IP address

The configuration of each brand/model of firewall/router is different, but the task is the same. For specific instructions for your brand and model of router, please contact the manufacturer's website.

Linksys Routers

Step 1 From your web browser, connect to the router administrative web page. For Linksys, this is typically something like `http://192.168.1.1`.

Step 2 Click Applications & Gaming or the Port Forwarding tab (whichever is present on your router).

Step 3 Locate the table containing the port forwarding data and add an entry containing the following values:

Table 65-2 Port Forwarding Values to Add to Router

Application	Start	End	Protocol	IP Address	Enabled
IP phone	1024	65535	UDP	*Phone IP address*	**Checked**
TFTP	69	69	UDP	*Phone IP address*	**Checked**

Step 4 Click Save Settings. Port forwarding is configured.

Feature History for the Phone Proxy

Table 65-3 lists the release history for this feature.

Table 65-3 Feature History for Cisco Phone Proxy

Feature Name	Releases	Feature Information
Cisco Phone Proxy	8.0(4)	The phone proxy feature was introduced. The Phone Proxy feature was accessible in ASDM by choosing the following options: Configuration > Firewall > Advanced > Encrypted Traffic Inspection > Phone Proxy pane
NAT for the media termination address	8.1(2)	The Media Termination fields were removed from the Phone Proxy pane and added to the Media Termination pane: Configuration > Firewall > Advanced > Encrypted Traffic Inspection > Media Termination Address pane

Configuring the TLS Proxy for Encrypted Voice Inspection

This chapter describes how to configure the adaptive security appliance for the TLS Proxy for Encrypted Voice Inspection feature.

This chapter includes the following sections:

- Information about the TLS Proxy for Encrypted Voice Inspection, page 66-1
- Licensing for the TLS Proxy, page 66-4
- Prerequisites for the TLS Proxy for Encrypted Voice Inspection, page 66-6
- Configuring the TLS Proxy for Encrypted Voice Inspection, page 66-6
- Feature History for the TLS Proxy for Encrypted Voice Inspection, page 66-17

Information about the TLS Proxy for Encrypted Voice Inspection

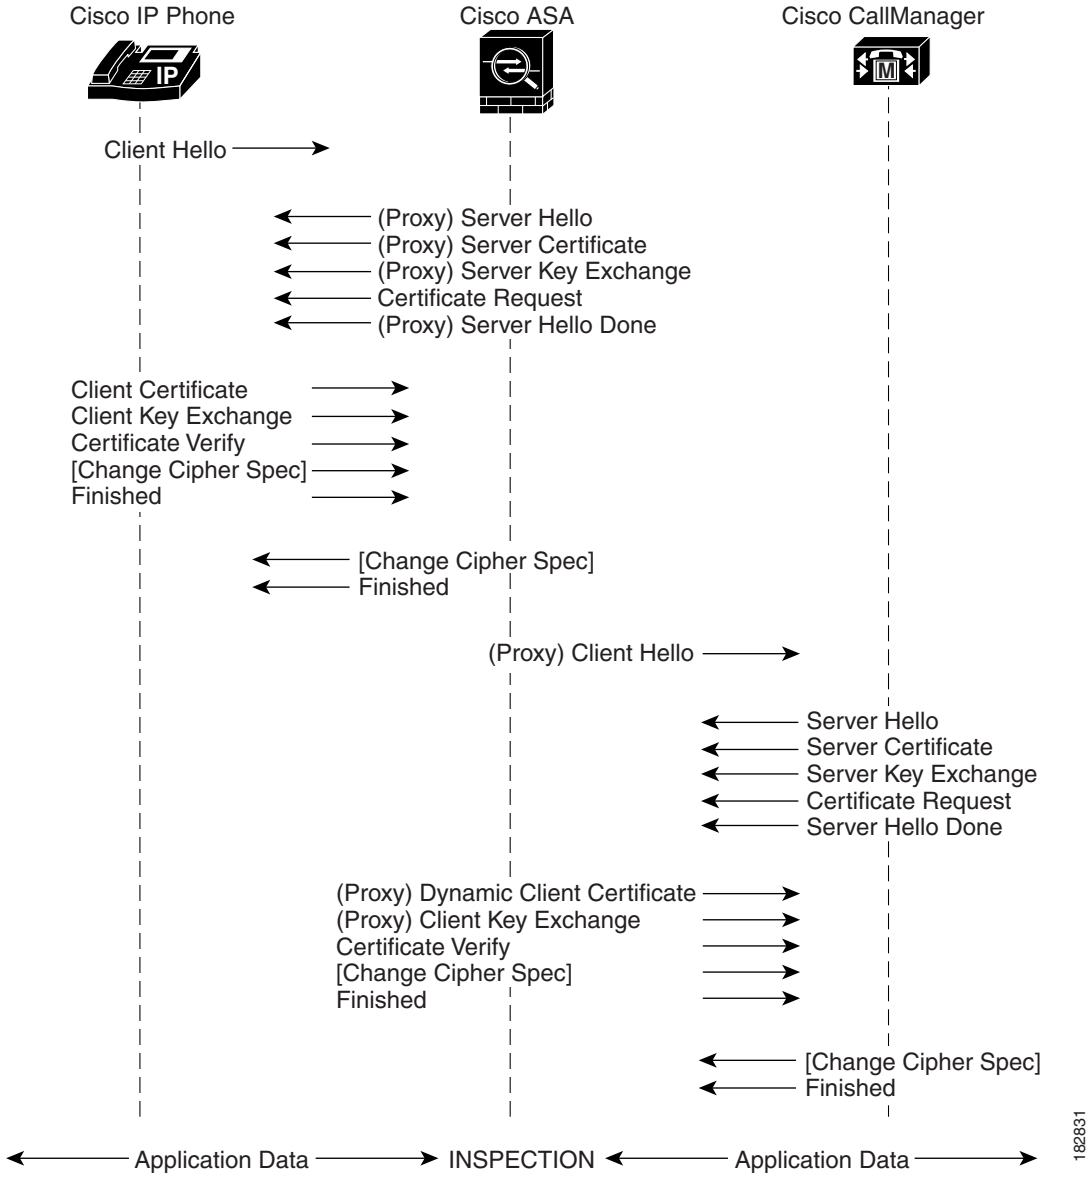
End-to-end encryption often leaves network security appliances “blind” to media and signaling traffic, which can compromise access control and threat prevention security functions. This lack of visibility can result in a lack of interoperability between the firewall functions and the encrypted voice, leaving businesses unable to satisfy both of their key security requirements.

The ASA is able to intercept and decrypt encrypted signaling from Cisco encrypted endpoints to the Cisco Unified Communications Manager (Cisco UCM), and apply the required threat protection and access control. It can also ensure confidentiality by re-encrypting the traffic onto the Cisco UCM servers.

Typically, the ASA TLS Proxy functionality is deployed in campus unified communications network. This solution is ideal for deployments that utilize end to end encryption and firewalls to protect Unified Communications Manager servers.

The security appliance in Figure 66-1 serves as a proxy for both client and server, with Cisco IP Phone and Cisco UCM interaction.

Figure 66-1 TLS Proxy Flow



Decryption and Inspection of Unified Communications Encrypted Signaling

With encrypted voice inspection, the security appliance decrypts, inspects and modifies (as needed, for example, performing NAT fixup), and re-encrypts voice signaling traffic while all of the existing VoIP inspection functions for Skinny and SIP protocols are preserved. Once voice signaling is decrypted, the plaintext signaling message is passed to the existing inspection engines.

The security appliance acts as a TLS proxy between the Cisco IP Phone and Cisco UCM. The proxy is transparent for the voice calls between the phone and theCisco UCM. Cisco IP Phones download a Certificate Trust List from the Cisco UCM before registration which contains identities (certificates) of the devices that the phone should trust, such as TFTP servers and Cisco UCM servers. To support server

proxy, the CTL file must contain the certificate that the security appliance creates for the Cisco UCMs. To proxy calls on behalf of the Cisco IP Phone, the security appliance presents a certificate that the Cisco UCM can verify, which is a Local Dynamic Certificate for the phone, issued by the certificate authority on the security appliance.

TLS proxy is supported by the Cisco Unified CallManager Release 5.1 and later. You should be familiar with the security features of the Cisco UCM. For background and detailed description of Cisco UCM security, see the Cisco Unified CallManager document:

http://www.cisco.com/univercd/cc/td/doc/product/voice/c_callmg/5_0/sec_vir/ae/sec504/index.htm

TLS proxy applies to the encryption layer and must be configured with an application layer protocol inspection. You should be familiar with the inspection features on the ASA, especially Skinny and SIP inspection.

Supported Cisco UCM and IP Phones for the TLS Proxy

Cisco Unified Communications Manager

The following releases of the Cisco Unified Communications Manager are supported with the TLS proxy:

- Cisco Unified CallManager Version 4.*x*
- Cisco Unified CallManager Version 5.0
- Cisco Unified CallManager Version 5.1
- Cisco Unified Communications Manager 6.1
- Cisco Unified Communications Manager 7.0
- Cisco Unified Communications Manager 8.0

Cisco Unified IP Phones

The following IP phones in the Cisco Unified IP Phones 7900 Series are supported with the TLS proxy:

- Cisco Unified IP Phone 7985
- Cisco Unified IP Phone 7975
- Cisco Unified IP Phone 7971
- Cisco Unified IP Phone 7970
- Cisco Unified IP Phone 7965
- Cisco Unified IP Phone 7962
- Cisco Unified IP Phone 7961
- Cisco Unified IP Phone 7961G-GE
- Cisco Unified IP Phone 7960
- Cisco Unified IP Phone 7945
- Cisco Unified IP Phone 7942
- Cisco Unified IP Phone 7941
- Cisco Unified IP Phone 7941G-GE
- Cisco Unified IP Phone 7940
- Cisco Unified Wireless IP Phone 7921

- Cisco Unified Wireless IP Phone 7925
- Cisco IP Communicator (CIPC) for softphones

Licensing for the TLS Proxy

The TLS proxy for encrypted voice inspection feature supported by the ASA require a Unified Communications Proxy license.

The following table shows the Unified Communications Proxy license details by platform:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement[1]
ASA 5505	Base License and Security Plus License: 2 sessions. *Optional license: 24 sessions.*
ASA 5510	Base License and Security Plus License: 2 sessions. *Optional licenses: 24, 50, or 100 sessions.*
ASA 5520	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5540	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5550	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5580	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASA 5512-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5515-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5525-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5545-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5555-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-10	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*

Model	License Requirement[1]
ASA 5585-X with SSP-20, -40, or -60	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASASM	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]

1. The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit:
   - Phone Proxy
   - Presence Federation Proxy
   - Encrypted Voice Inspection

   Other applications that use TLS proxy sessions do not count towards the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license).

   Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used.

   You independently set the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. When you apply a UC license that is higher than the default TLS proxy limit, the ASA automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license.

   Note: For license part numbers ending in "K8" (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in "K9" (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.

   Note: If you clear the configuration, then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the to raise the limit again (in ASDM, use the **TLS Proxy** pane). If you use failover and use **File > Save Running Configuration to Standby Unit** on the primary unit to force a configuration synchronization, the **clear configure all** command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning.

   You might also use SRTP encryption sessions for your connections:
   - For K8 licenses, SRTP sessions are limited to 250.
   - For K9 licenses, there is not limit.

   Note: Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.
2. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

Table 66-1 shows the default and maximum TLS session details by platform.

Table 66-1 Default and Maximum TLS Sessions on the Security Appliance

Security Appliance Platform	Default TLS Sessions	Maximum TLS Sessions
ASA 5505	10	80
ASA 5510	100	200
ASA 5520	300	1200
ASA 5540	1000	4500
ASA 5550	2000	4500
ASA 5580	4000	13,000

For more information about licensing, see Chapter 5, "Managing Feature Licenses."

Prerequisites for the TLS Proxy for Encrypted Voice Inspection

Before configuring TLS proxy, the following prerequisites are required:

- You must set clock on the security appliance before configuring TLS proxy. To set the clock manually and display clock, use the **clock set** and **show clock** commands. We recommend that the security appliance use the same NTP server as the Cisco Unified CallManager cluster. TLS handshake may fail due to certificate validation failure if clock is out of sync between the security appliance and the Cisco Unified CallManager server.
- 3DES-AES license is needed to interoperate with the Cisco Unified CallManager. AES is the default cipher used by the Cisco Unified CallManager and Cisco IP Phone.
- Import the following certificates which are stored on the Cisco UCM. These certificates are required by the ASA for the phone proxy.
  - Cisco_Manufacturing_CA
  - CAP-RTP-001
  - CAP-RTP-002
  - CAPF certificate (Optional)

    If LSC provisioning is required or you have LSC enabled IP phones, you must import the CAPF certificate from the Cisco UCM. If the Cisco UCM has more than one CAPF certificate, you must import all of them to the ASA.

  See Chapter 65, "Configuring the Cisco Phone Proxy."For example, the CA Manufacturer certificate is required by the phone proxy to validate the IP phone certificate.

Configuring the TLS Proxy for Encrypted Voice Inspection

This section includes the following topics:

- Configure TLS Proxy Pane, page 66-8
- Adding a TLS Proxy Instance, page 66-9
- Add TLS Proxy Instance Wizard – Server Configuration, page 66-9
- Add TLS Proxy Instance Wizard – Client Configuration, page 66-10
- Add TLS Proxy Instance Wizard – Other Steps, page 66-12
- Edit TLS Proxy Instance – Server Configuration, page 66-13
- Edit TLS Proxy Instance – Client Configuration, page 66-14

CTL Provider

Use the CTL Provider option to configure Certificate Trust List provider service.

The CTL Provider pane lets you define and configure Certificate Trust List provider service to enable inspection of encrypted traffic.

Fields

- CTL Provider Name—Lists the CTL Provider name.

- Client Details—Lists the name and IP address of the client.
  - Interface Name—Lists the defined interface name.
  - IP Address—Lists the defined interface IP address.
- Certificate Name—Lists the certificate to be exported.
- Add—Adds a CTL Provider.
- Edit—Edits a CTL Provider.
- Delete—Deletes a CTL Provider.

Add/Edit CTL Provider

The Add/Edit CTL Provider dialog box lets you define the parameters for the CTL Provider.

Fields

- CTL Provider Name—Specifies the CTL Provider name.
- Certificate to be Exported—Specifies the certificate to be exported to the client.
  - Certificate Name—Specifies the name of the certificate to be exported to the client.
  - Manage—Manages identity certificates.
- Client Details—Specifies the clients allowed to connect.
  - Client to be Added—Specifies the client interface and IP address to add to the client list.

    Interface—Specifies client interface.

    IP Address—Specifies the client IP address.

    Add—Adds the new client to the client list.

    Delete—Deletes the selected client from the client list.
- More Options—Specifies the available and active algorithms to be announced or matched during the TLS handshake.
  - Parse the CTL file provided by the CTL Client and install trustpoints—Trustpoints installed by this option have names prefixed with "_internal_CTL_." If disabled, each Call Manager server and CAPF certificate must be manually imported and installed.
  - Port Number—Specifies the port to which the CTL provider listens. The port must be the same as the one listened to by the CallManager servers in the cluster (as configured under Enterprise Parameters on the CallManager administration page). The default is 2444.
  - Authentication—Specifies the username and password that the client authenticates with the provider.

    Username—Client username.

    Password—Client password.

    Confirm Password—Client password.

Configure TLS Proxy Pane

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

You can configure the TLS Proxy from the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Configuring a TLS Proxy lets you use the TLS Proxy to enable inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and enable the ASA for the Cisco Unified Communications features:

- TLS Proxy for the Cisco Unified Presence Server (CUPS), part of Presence Federation
- TLS Proxy for the Cisco Unified Mobility Advantage (CUMA) server, part of Mobile Advantage
- Phone Proxy

Fields

- TLS Proxy Name—Lists the TLS Proxy name.
- Server Proxy Certificate—Lists the trustpoint, which is either self-signed or enrolled with a certificate server.
- Local Dynamic Certificate Issuer—Lists the local certificate authority to issue client or server dynamic certificates.
- Client Proxy Certificate—Lists the proxy certificate for the TLS client. The ASA uses the client proxy certificate to authenticate the TLS client during the handshake between the proxy and the TLS client. The certificate can be either self-signed, enrolled with a certificate authority, or issued by the third party.
- Add—Adds a TLS Proxy by launching the Add TLS Proxy Instance Wizard. See Adding a TLS Proxy Instance, page 66-9 for the steps to create a TLS Proxy instance.
- Edit—Edits a TLS Proxy. The fields in the Edit panel area identical to the fields displayed when you add a TLS Proxy instance. See Edit TLS Proxy Instance – Server Configuration, page 66-13 and Edit TLS Proxy Instance – Client Configuration, page 66-14.
- Delete—Deletes a TLS Proxy.
- Maximum Sessions—Lets you specify the maximum number of TLS Proxy sessions to support.
  - Specify the maximum number of TLS Proxy sessions that the ASA needs to support.
  - Maximum number of sessions—The minimum is 1. The maximum is dependent on the platform:

    Cisco ASA 5505 security appliance: 10

    Cisco ASA 5510 security appliance: 100

    Cisco ASA 5520 security appliance: 300

    Cisco ASA 5540 security appliance: 1000

    Cisco ASA 5550 security appliance: 2000

    Cisco ASA 5580 security appliance: 4000

Note The maximum number of sessions is global to all TLS proxy sessions.

Adding a TLS Proxy Instance

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Use the Add TLS Proxy Instance Wizard to add a TLS Proxy to enable inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and to support the Cisco Unified Communications features on the ASA.

This wizard is available from the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 1 Open the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 2 To add a new TLS Proxy Instance, click **Add**.

The Add TLS Proxy Instance Wizard opens.

Step 3 In the TLS Proxy Name field, type the TLS Proxy name.

Step 4 Click **Next**.

The Add TLS Proxy Instance Wizard – Server Configuration dialog box opens. In this step of the wizard, configure the server proxy parameters for original TLS Server—the Cisco Unified Call Manager (CUCM) server, the Cisco Unified Presence Server (CUPS), or the Cisco Unified Mobility Advantage (CUMA) server. See Add TLS Proxy Instance Wizard – Server Configuration, page 66-9.

After configuring the server proxy parameters, the wizard guides you through configuring client proxy parameters (see Add TLS Proxy Instance Wizard – Client Configuration, page 66-10) and provides instructions on the steps to complete outside the ASDM to make the TLS Proxy fully functional (see Add TLS Proxy Instance Wizard – Other Steps, page 66-12).

Add TLS Proxy Instance Wizard – Server Configuration

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Use the Add TLS Proxy Instance Wizard to add a TLS Proxy to enable inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and to support the Cisco Unified Communications features on the ASA.

The Add TLS Proxy Instance Wizard is available from the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 1 Complete the first step of the Add TLS Proxy Instance Wizard. See Adding a TLS Proxy Instance, page 66-9.

The Add TLS Proxy Instance Wizard – Server Configuration dialog box opens.

Step 2 Specify the server proxy certificate by doing one of the following:

- To add a new certificate, click **Manage**. The Manage Identify Certificates dialog box opens.

When the Phone Proxy is operating in a mixed-mode CUCM cluster, you must import the CUCM certificate by clicking **Add** in the Manage Identify Certificates dialog box. See the "Configuring Identity Certificates Authentication" section on page 49-22.

- To select an existing certificate, select one from the drop-down list.

  When you are configuring the TLS Proxy for the Phone Proxy, select the certificate that has a filename beginning with **_internal_PP_**. When you create the CTL file for the Phone Proxy, the ASA, creates an internal trustpoint used by the Phone Proxy to sign the TFTP files. The trustpoint is named **_internal_PP**_*ctl-instance_filename*.

The server proxy certificate is used to specify the trustpoint to present during the TLS handshake. The trustpoint can be self-signed or enrolled locally with the certificate service on the proxy. For example, for the Phone Proxy, the server proxy certificate is used by the Phone Proxy during the handshake with the IP phones.

Step 3 To install the TLS server certificate in the ASA trust store, so that the ASA can authenticate the TLS server during TLS handshake between the proxy and the TLS server, click **Install TLS Server's Certificate**.

The Manage CA Certificates dialog box opens. See the "Guidelines and Limitations" section on page 49-9. Click **Add** to open the Install Certificate dialog box. See the "Adding or Installing a CA Certificate" section on page 49-11.

When you are configuring the TLS Proxy for the Phone Proxy, click **Install TLS Server's Certificate** and install the Cisco Unified Call Manager (CUCM) certificate so that the proxy can authenticate the IP phones on behalf of the CUCM server.

Step 4 To require the ASA to present a certificate and authenticate the TLS client during TLS handshake, check the Enable client authentication during TLS Proxy handshake check box.

When adding a TLS Proxy Instance for Mobile Advantage (the CUMC client and CUMA server), disable the check box when the client is incapable of sending a client certificate.

Step 5 Click **Next**.

The Add TLS Proxy Instance Wizard – Client Configuration dialog box opens. In this step of the wizard, configure the client proxy parameters for original TLS Client—the CUMC client for Mobile Advantage, CUP or MS LCS/OCS client for Presence Federation, or the IP phone for the Phone Proxy. See Add TLS Proxy Instance Wizard – Client Configuration, page 66-10.

After configuring the client proxy parameters, the wizard provides instructions on the steps to complete outside the ASDM to make the TLS Proxy fully functional (see Add TLS Proxy Instance Wizard – Other Steps, page 66-12).

Add TLS Proxy Instance Wizard – Client Configuration

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

Use the Add TLS Proxy Instance Wizard to add a TLS Proxy to enable inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and to support the Cisco Unified Communications features on the ASA.

This wizard is available from the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 1 Complete the first two steps of the Add TLS Proxy Instance Wizard. See Adding a TLS Proxy Instance, page 66-9 and Add TLS Proxy Instance Wizard – Client Configuration, page 66-10.

The Add TLS Proxy Instance Wizard – Client Configuration dialog box opens.

Step 2 To specify a client proxy certificate to use for the TLS Proxy, perform the following. Select this option when the client proxy certificate is being used between two servers; for example, when configuring the TLS Proxy for Presence Federation, which uses the Cisco Unified Presence Server (CUPS), both the TLS client and TLS server are both servers.

a. Check the Specify the proxy certificate for the TLS Client... check box.

b. Select a certificate from the drop-down list.

Or

To create a new client proxy certificate, click **Manage**. The Manage Identify Certificates dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22.

Note When you are configuring the TLS Proxy for the Phone Proxy and it is using the mixed security mode for the CUCM cluster, you must configure the LDC Issuer. The LDC Issuer lists the local certificate authority to issue client or server dynamic certificates.

Step 3 To specify an LDC Issuer to use for the TLS Proxy, perform the following. When you select and configure the LDC Issuer option, the ASA acts as the certificate authority and issues certificates to TLS clients.

a. Click the Specify the internal Certificate Authority to sign the local dynamic certificate for phones... check box.

b. Click the Certificates radio button and select a self-signed certificate from the drop-down list or click **Manage** to create a new LDC Issuer. The Manage Identify Certificates dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22.

Or

Click the Certificate Authority radio button to specify a Certificate Authority (CA) server. When you specify a CA server, it needs to be created and enabled in the ASA. To create and enable the CA server, click **Manage**. The Edit CA Server Settings dialog box opens. See the "Authenticating Using the Local CA" section on page 49-29.

Note To make configuration changes after the local certificate authority has been configured for the first time, disable the local certificate authority.

c. In the Key-Pair Name field, select a key pair from the drop-list. The list contains the already defined RSA key pair used by client dynamic certificates. To see the key pair details, including generation time, usage, modulus size, and key data, click **Show**.

Or

To create a new key pair, click **New**. The Add Key Pair dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22 for details about the Key Pair fields.

Step 4 In the Security Algorithms area, specify the available and active algorithms to be announced or matched during the TLS handshake.

- Available Algorithms—Lists the available algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1.

Add—Adds the selected algorithm to the active list.

Remove—Removes the selected algorithm from the active list.

- Active Algorithms—Lists the active algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1. For client proxy (acting as a TLS client to the server), the user-defined algorithms replace the original ones from the hello message for asymmetric encryption method between the two TLS legs. For example, the leg between the proxy and Call Manager may be NULL cipher to offload the Call Manager.

  Move Up—Moves an algorithm up in the list.

  Move Down—Moves an algorithm down in the list.

Step 5 Click **Next**.

The Add TLS Proxy Instance Wizard – Other Steps dialog box opens. The Other Steps dialog box provides instructions on the steps to complete outside the ASDM to make the TLS Proxy fully functional (see Add TLS Proxy Instance Wizard – Other Steps, page 66-12).

Add TLS Proxy Instance Wizard – Other Steps

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

The last dialog box of the Add TLS Proxy Instance Wizard specifies the additional steps required to make TLS Proxy fully functional. In particular, you need to perform the following tasks to complete the TLS Proxy configuration:

- Export the local CA certificate or LDC Issuer and install them on the original TLS server.

  To export the LDC Issuer, go to Configuration > Firewall > Advanced > Certificate Management > Identity Certificates > Export. See the "Exporting an Identity Certificate" section on page 49-25.

- For the TLS Proxy, enable Skinny and SIP inspection between the TLS server and TLS clients. See SIP Inspection, page 59-20 and Skinny (SCCP) Inspection, page 59-31. When you are configuring the TLS Proxy for Presence Federation (which uses CUP), you only enable SIP inspection because the feature supports only the SIP protocol.
- For the TLS Proxy for CUMA, enable MMP inspection.
- When using the internal Certificate Authority of the ASA to sign the LDC Issuer for TLS clients, perform the following:
  - Use the Cisco CTL Client to add the server proxy certificate to the CTL file and install the CTL file on the ASA.

    For information on the Cisco CTL Client, see "Configuring the Cisco CTL Client" in *Cisco Unified CallManager Security Guide*.

    http://www.cisco.com/en/US/docs/voice_ip_comm/cucm/security/5_0_4/secuauth.html

    To install the CTL file on the ASA, go to Configuration > Firewall > Unified Communications > CTL Provider > Add. The Add CTL Provider dialog box opens. For information on using this dialog box to install the CTL file, see Add/Edit CTL Provider, page 66-7.
  - Create a CTL provider instance for connections from the CTL clients. See Add/Edit CTL Provider, page 66-7.

Edit TLS Proxy Instance – Server Configuration

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

The TLS Proxy enables inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and to support the Cisco Unified Communications features on the ASA.

Use the Edit TLS Proxy – Server Configuration tab to edit the server proxy parameters for the original TLS Server—the Cisco Unified Call Manager (CUCM) server, the Cisco Unified Presence Server (CUPS), or the Cisco Unified Mobility Advantage (CUMA) server.

Step 1 Open the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 2 To edit a TLS Proxy Instance, click **Edit**.

The Edit TLS Proxy Instance dialog box opens.

Step 3 If necessary, click the **Server Configuration** tab.

Step 4 Specify the server proxy certificate by doing one of the following:

- To add a new certificate, click **Manage**. The Manage Identify Certificates dialog box opens.

  When the Phone Proxy is operating in a mixed-mode CUCM cluster, you must import the CUCM certificate by clicking **Add** in the Manage Identify Certificates dialog box. See the "Configuring CA Certificate Authentication" section on page 49-11.

- To select an existing certificate, select one from the drop-down list.

  When you are configuring the TLS Proxy for the Phone Proxy, select the certificate that has a filename beginning with **_internal_PP_**. When you create the CTL file for the Phone Proxy, the ASA, creates an internal trustpoint used by the Phone Proxy to sign the TFTP files. The trustpoint is named **_internal_PP**_*ctl-instance_filename*.

The server proxy certificate is used to specify the trustpoint to present during the TLS handshake. The trustpoint can be self-signed or enrolled locally with the certificate service on the proxy. For example, for the Phone Proxy, the server proxy certificate is used by the Phone Proxy during the handshake with the IP phones.

Step 5 To install the TLS server certificate in the ASA trust store, so that the ASA can authenticate the TLS server during TLS handshake between the proxy and the TLS server, click **Install TLS Server's Certificate**.

The Manage CA Certificates dialog box opens. See the "Guidelines and Limitations" section on page 49-9. Click **Add** to open the Install Certificate dialog box. See the "Configuring CA Certificate Authentication" section on page 49-11.

When you are configuring the TLS Proxy for the Phone Proxy, click **Install TLS Server's Certificate** and install the Cisco Unified Call Manager (CUCM) certificate so that the proxy can authenticate the IP phones on behalf of the CUCM server.

Step 6 To require the ASA to present a certificate and authenticate the TLS client during TLS handshake, check the Enable client authentication during TLS Proxy handshake check box.

When adding a TLS Proxy Instance for Mobile Advantage (the CUMC client and CUMA server), disable the check box when the client is incapable of sending a client certificate.

Step 7 Click **Apply** to save the changes.

Edit TLS Proxy Instance – Client Configuration

Note This feature is not supported for the Adaptive Security Appliance version 8.1.2.

The TLS Proxy enables inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco Call Manager and to support the Cisco Unified Communications features on the ASA.

The fields in the Edit TLS Proxy dialog box are identical to the fields displayed when you add a TLS Proxy instance. Use the Edit TLS Proxy – Client Configuration tab to edit the client proxy parameters for the original TLS Client, such as IP phones, CUMA clients, the Cisco Unified Presence Server (CUPS), or the Microsoft OCS server.

Step 1 Open the Configuration > Firewall > Unified Communications > TLS Proxy pane.

Step 2 To edit a TLS Proxy Instance, click **Edit**.

The Edit TLS Proxy Instance dialog box opens.

Step 3 If necessary, click the **Client Configuration** tab.

Step 4 To specify a client proxy certificate to use for the TLS Proxy, perform the following. Select this option when the client proxy certificate is being used between two servers; for example, when configuring the TLS Proxy for Presence Federation, which uses the Cisco Unified Presence Server (CUPS), both the TLS client and TLS server are both servers.

a. Check the Specify the proxy certificate for the TLS Client... check box.

b. Select a certificate from the drop-down list.

Or

To create a new client proxy certificate, click **Manage**. The Manage Identify Certificates dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22.

Note When you are configuring the TLS Proxy for the Phone Proxy and it is using the mixed security mode for the CUCM cluster, you must configure the LDC Issuer. The LDC Issuer lists the local certificate authority to issue client or server dynamic certificates.

Step 5 To specify an LDC Issuer to use for the TLS Proxy, perform the following. When you select and configure the LDC Issuer option, the ASA acts as the certificate authority and issues certificates to TLS clients.

a. Click the Specify the internal Certificate Authority to sign the local dynamic certificate for phones... check box.

b. Click the Certificates radio button and select a self-signed certificate from the drop-down list or click **Manage** to create a new LDC Issuer. The Manage Identify Certificates dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22.

Or

Click the Certificate Authority radio button to specify a Certificate Authority (CA) server. When you specify a CA server, it needs to be created and enabled in the ASA. To create and enable the CA server, click **Manage**. The Edit CA Server Settings dialog box opens. See the "Authenticating Using the Local CA" section on page 49-29.

Note To make configuration changes after the local certificate authority has been configured for the first time, disable the local certificate authority.

c. In the Key-Pair Name field, select a key pair from the drop-list. The list contains the already defined RSA key pair used by client dynamic certificates. To see the key pair details, including generation time, usage, modulus size, and key data, click **Show**.

Or

To create a new key pair, click **New**. The Add Key Pair dialog box opens. See the "Configuring Identity Certificates Authentication" section on page 49-22 for details about the Key Pair fields.

Step 6 In the Security Algorithms area, specify the available and active algorithms to be announced or matched during the TLS handshake.

- Available Algorithms—Lists the available algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1.

  Add—Adds the selected algorithm to the active list.

  Remove—Removes the selected algorithm from the active list.

- Active Algorithms—Lists the active algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1. For client proxy (acting as a TLS client to the server), the user-defined algorithms replace the original ones from the hello message for asymmetric encryption method between the two TLS legs. For example, the leg between the proxy and Call Manager may be NULL cipher to offload the Call Manager.

  Move Up—Moves an algorithm up in the list.

  Move Down—Moves an algorithm down in the list.

Step 7 Click **Apply** to save the changes.

TLS Proxy

This feature is supported only for ASA versions 8.0.x prior to 8.0.4 and for version 8.1.

Note This feature is not supported for the Adaptive Security Appliance versions prior to 8.0.4 and for version 8.1.2.

Use the TLS Proxy option to enable inspection of SSL encrypted VoIP signaling, namely Skinny and SIP, interacting with Cisco CallManager.

The TLS Proxy pane lets you define and configure Transaction Layer Security Proxy to enable inspection of encrypted traffic.

Fields

- TLS Proxy Name—Lists the TLS Proxy name.
- Server—Lists the trustpoint, which is either self-signed or enrolled with a certificate server.
- Local Dynamic Certificate Issuer—Lists the local certificate authority to issue client or server dynamic certificates.

- Local Dynamic Certificate Key Pair—Lists the RSA key pair used by client or server dynamic certificates.
- Add—Adds a TLS Proxy.
- Edit—Edits a TLS Proxy.
- Delete—Deletes a TLS Proxy.
- Maximum Sessions—Lets you specify the maximum number of TLS Proxy sessions to support.
  - Specify the maximum number of TLS Proxy sessions that the ASA needs to support. By default, ASA supports 300 sessions.—Enables maximum number of sessions option.
  - Maximum number of sessions:—The minimum is 1. The maximum is dependent on the platform. The default is 300.

Add/Edit TLS Proxy

Note This feature is not supported for the Adaptive Security Appliance versions prior to 8.0.4 and for version 8.1.2.

The Add/Edit TLS Proxy dialog box lets you define the parameters for the TLS Proxy.

Fields

- TLS Proxy Name—Specifies the TLS Proxy name.
- Server Configuration—Specifies the proxy certificate name.
  - Server—Specifies the trustpoint to be presented during the TLS handshake. The trustpoint could be self-signed or enrolled locally with the certificate service on the proxy.
- Client Configuration—Specifies the local dynamic certificate issuer and key pair.
  - Local Dynamic Certificate Issuer—Lists the local certificate authority to issue client or server dynamic certificates.

    Certificate Authority Server—Specifies the certificate authority server.

    Certificate—Specifies a certificate.

    Manage—Configures the local certificate authority. To make configuration changes after it has been configured for the first time, disable the local certificate authority.
  - Local Dynamic Certificate Key Pair—Lists the RSA key pair used by client dynamic certificates.

    Key-Pair Name—Specifies a defined key pair.

    Show—Shows the key pair details, including generation time, usage, modulus size, and key data.

    New—Lets you define a new key pair.
- More Options—Specifies the available and active algorithms to be announced or matched during the TLS handshake.
  - Available Algorithms—Lists the available algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1.

    Add—Adds the selected algorithm to the active list.

    Remove—Removes the selected algorithm from the active list.

– Active Algorithms—Lists the active algorithms to be announced or matched during the TLS handshake: des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, and null-sha1. For client proxy (acting as a TLS client to the server), the user-defined algorithms replace the original ones from the hello message for asymmetric encryption method between the two TLS legs. For example, the leg between the proxy and CallManager may be NULL cipher to offload the CallManager.

  Move Up—Moves an algorithm up in the list.

  Move Down—Moves an algorithm down in the list.

Feature History for the TLS Proxy for Encrypted Voice Inspection

Table 66-2 lists the release history for this feature.

Table 66-2 Feature History for Cisco Phone Proxy

Feature Name	Releases	Feature Information
TLS Proxy	8.0(2)	The TLS proxy feature was introduced.

Configuring Cisco Mobility Advantage

This chapter describes how to configure the adaptive security appliance for Cisco Unified Communications Mobility Advantage Proxy features.

This chapter includes the following sections:

- Information about the Cisco Mobility Advantage Proxy Feature, page 67-1
- Licensing for the Cisco Mobility Advantage Proxy Feature, page 67-6
- Configuring Cisco Mobility Advantage, page 67-6
- Feature History for Cisco Mobility Advantage, page 67-7

Information about the Cisco Mobility Advantage Proxy Feature

This section contains the following topics:

- Cisco Mobility Advantage Proxy Functionality, page 67-1
- Mobility Advantage Proxy Deployment Scenarios, page 67-2
- Trust Relationships for Cisco UMA Deployments, page 67-4

Cisco Mobility Advantage Proxy Functionality

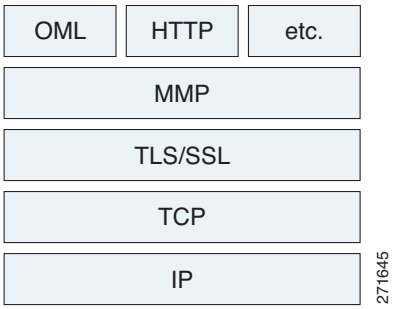
To support Cisco UMA for the Cisco Mobility Advantage solution, the mobility advantage proxy (implemented as a TLS proxy) includes the following functionality:

- The ability to allow no client authentication during the handshake with clients.
- Allowing an imported PKCS-12 certificate to server as a proxy certificate.

The ASA includes an inspection engine to validate the Cisco UMA Mobile Multiplexing Protocol (MMP).

MMP is a data transport protocol for transmitting data entities between Cisco UMA clients and servers. As shown in Figure 67-1, MMP must be run on top of a connection-oriented protocol (the underlying transport) and is intended to be run on top of a secure transport protocol such as TLS. The Orative Markup Language (OML) protocol is intended to be run on top of MMP for the purposes of data synchronization, as well as the HTTP protocol for uploading and downloading large files.

Figure 67-1 MMP Stack



The TCP/TLS default port is 5443. There are no embedded NAT or secondary connections.

Cisco UMA client and server communications can be proxied via TLS, which decrypts the data, passes it to the inspect MMP module, and re-encrypt the data before forwarding it to the endpoint. The inspect MMP module verifies the integrity of the MMP headers and passes the OML/HTTP to an appropriate handler. The ASA takes the following actions on the MMP headers and data:

- Verifies that client MMP headers are well-formed. Upon detection of a malformed header, the TCP session is terminated.
- Verifies that client to server MMP header lengths are not exceeded. If an MMP header length is exceeded (4096), then the TCP session is terminated.
- Verifies that client to server MMP content lengths are not exceeded. If an entity content length is exceeded (4096), the TCP session is terminated.

Note 4096 is the value currently used in MMP implementations.

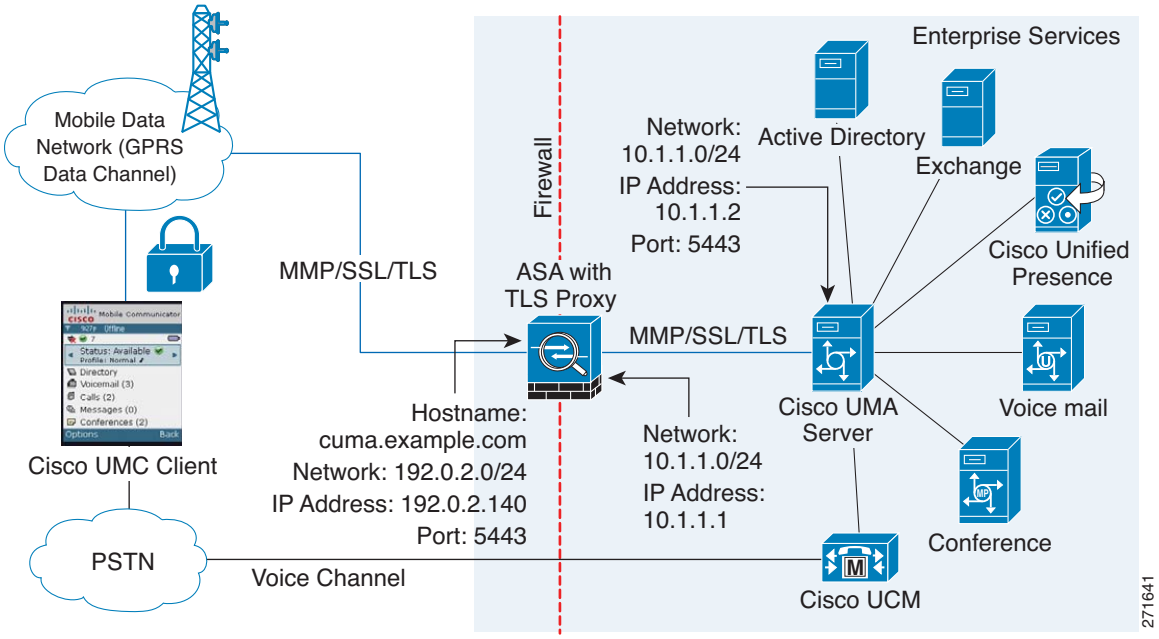
Because MMP headers and entities can be split across packets, the ASA buffers data to ensure consistent inspection. The SAPI (stream API) handles data buffering for pending inspection opportunities. MMP header text is treated as case insensitive and a space is present between header text and values. Reclaiming of MMP state is performed by monitoring the state of the TCP connection.

Mobility Advantage Proxy Deployment Scenarios

Figure 67-2 and Figure 67-3 show the two deployment scenarios for the TLS proxy used by the Cisco Mobility Advantage solution. In scenario 1 (the recommended deployment architecture), the ASA functions as both the firewall and TLS proxy. In scenario 2, the ASA functions as the TLS proxy only and works with an existing firewall. In both scenarios, the clients connect from the Internet.

In the scenario 1 deployment, the ASA is between a Cisco UMA client and a Cisco UMA server. The Cisco UMA client is an executable that is downloaded to each smartphone. The Cisco UMA client applications establishes a data connection, which is a TLS connection, to the corporate Cisco UMA server. The ASA intercepts the connections and inspects the data that the client sends to the Cisco UMA server.

Figure 67-2 The TLS proxy for the Cisco Mobility Advantage solution does not support client authentication because the Cisco UMA client cannot present a certificate. ***Security Appliance as Firewall with Mobility Advantage Proxy and MMP Inspection***



In Figure 67-2, the ASA performs static NAT by translating the Cisco UMA server 10.1.1.2 IP address to 192.0.2.140.

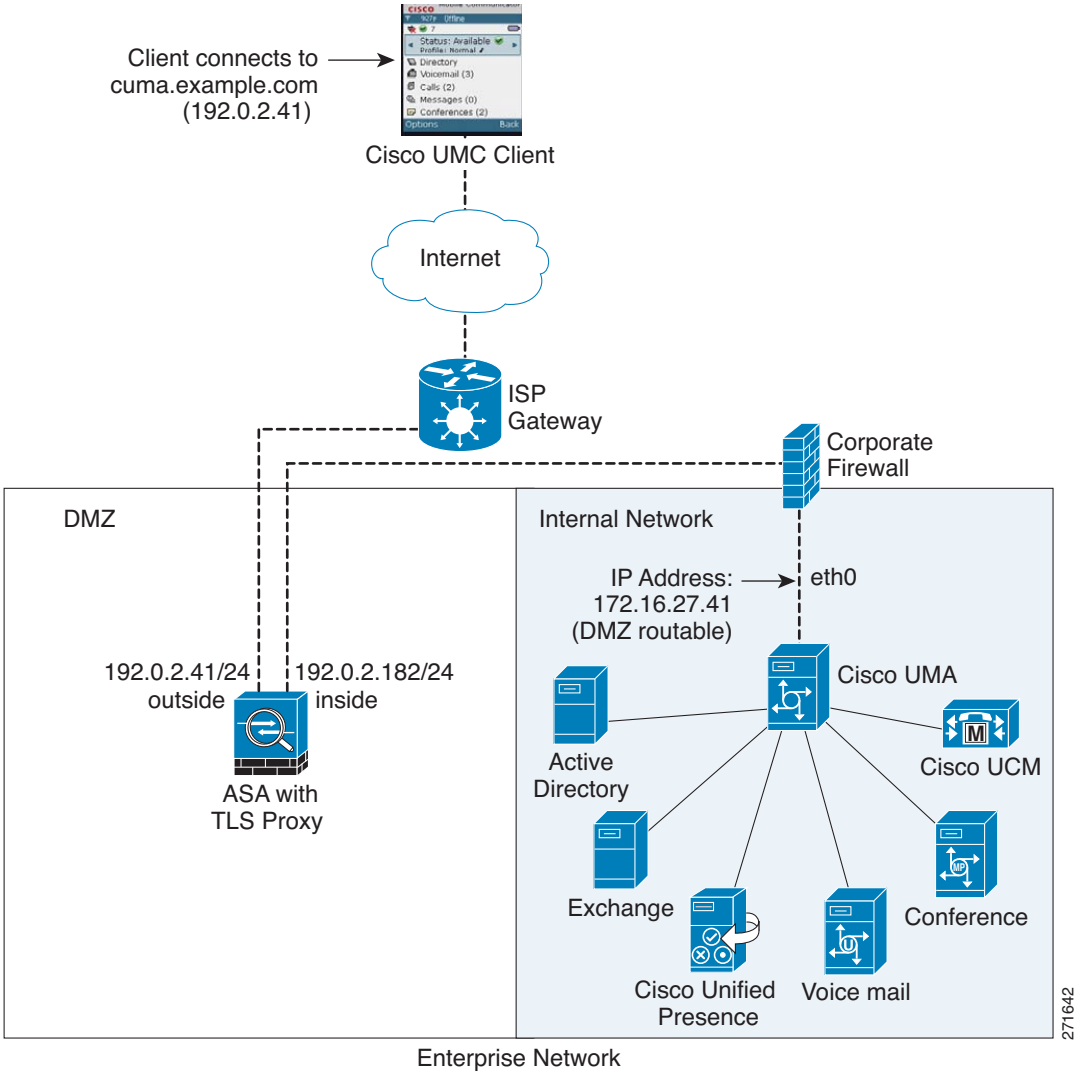
Figure 67-3 shows deployment scenario 2, where the ASA functions as the TLS proxy only and does not function as the corporate firewall. In this scenario, the ASA and the corporate firewall are performing NAT. The corporate firewall will not be able to predict which client from the Internet needs to connect to the corporate Cisco UMA server. Therefore, to support this deployment, you can take the following actions:

- Set up a NAT rule for inbound traffic that translates the destination IP address 192.0.2.41 to 172.16.27.41.
- Set up an interface PAT rule for inbound traffic translating the source IP address of every packet so that the corporate firewall does not need to open up a wildcard pinhole. The Cisco UMA server receives packets with the source IP address 192.0.12.183.

  See Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)" and Chapter 41, "Configuring Twice NAT (ASA 8.3 and Later)" for information.

Note This interface PAT rule converges the Cisco UMA client IP addresses on the outside interface of the ASA into a single IP address on the inside interface by using different source ports. Performing this action is often referred as "outside PAT". "Outside PAT" is not recommended when TLS proxy for Cisco Mobility Advantage is enabled on the same interface of the ASA with phone proxy, Cisco Unified Presence, or any other features involving application inspection. "Outside PAT" is not supported completely by application inspection when embedded address translation is needed.

Figure 67-3 Cisco UMC/Cisco UMA Architecture – Scenario 2: Security Appliance as Mobility Advantage Proxy Only



Mobility Advantage Proxy Using NAT/PAT

In both scenarios (Figure 67-2 and Figure 67-3), NAT can be used to hide the private address of the Cisco UMA servers.

In scenario 2 (Figure 67-3), PAT can be used to converge all client traffic into one source IP, so that the firewall does not have to open up a wildcard pinhole for inbound traffic.

Trust Relationships for Cisco UMA Deployments

To establish a trust relationship between the Cisco UMC client and the ASA, the ASA uses the Cisco UMA server certificate and keypair or the ASA obtains a certificate with the Cisco UMA server FQDN (certificate impersonation). Between the ASA and the Cisco UMA server, the ASA and Cisco UMA server use self-signed certificates or certificates issued by a local certificate authority.

Figure 67-4 shows how you can import the Cisco UMA server certificate onto the ASA. When the Cisco UMA server has already enrolled with a third-party CA, you can import the certificate with the private key onto the ASA. Then, the ASA has the full credentials of the Cisco UMA server. When a Cisco UMA client connects to the Cisco UMA server, the ASA intercepts the handshake and uses the Cisco UMA server certificate to perform the handshake with the client. The ASA also performs a handshake with the server.

Figure 67-4 How the Security Appliance Represents Cisco UMA – Private Key Sharing

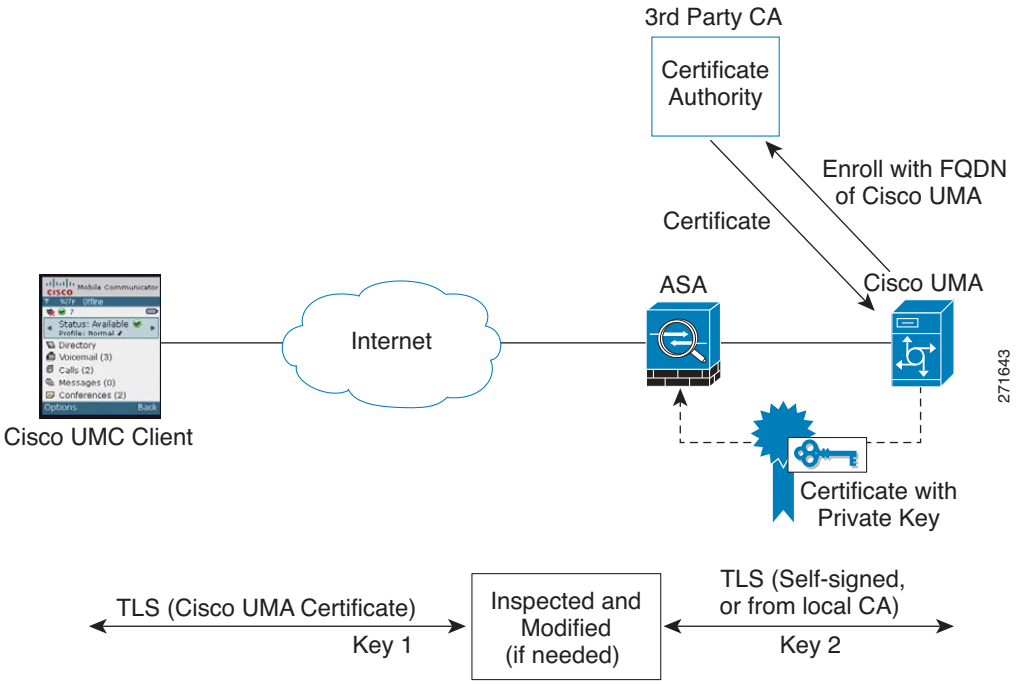


Figure 67-5 shows another way to establish the trust relationship. Figure 67-5 shows a green field deployment, because each component of the deployment has been newly installed. The ASA enrolls with the third-party CA by using the Cisco UMA server FQDN as if the ASA is the Cisco UMA server. When the Cisco UMA client connects to the ASA, the ASA presents the certificate that has the Cisco UMA server FQDN. The Cisco UMA client believes it is communicating to with the Cisco UMA server.

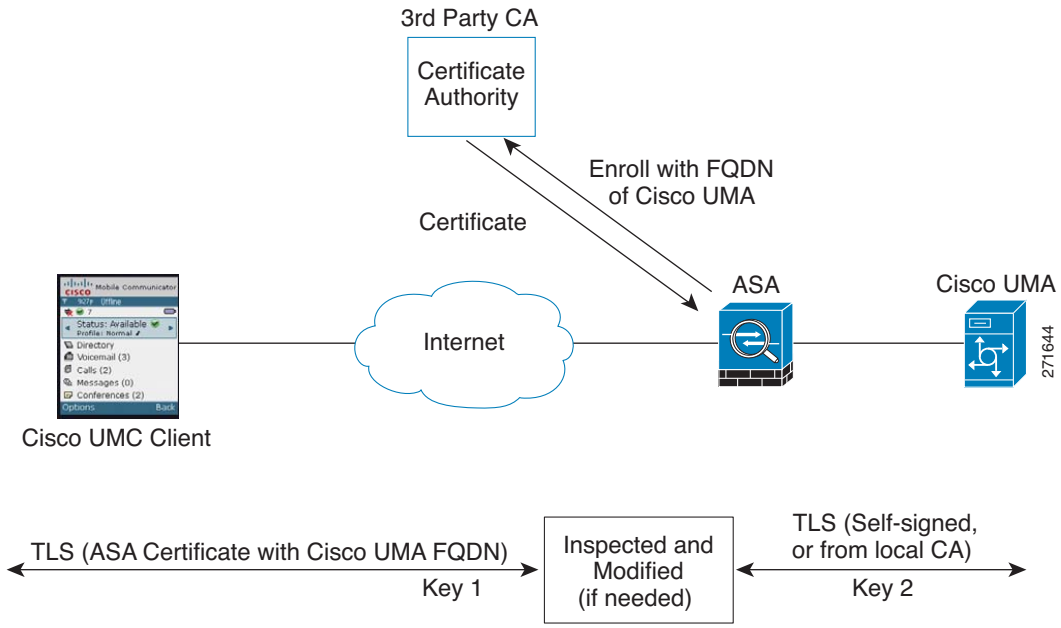
Figure 67-5 How the Security Appliance Represents Cisco UMA – Certificate Impersonation



A trusted relationship between the ASA and the Cisco UMA server can be established with self-signed certificates. The ASA's identity certificate is exported, and then uploaded on the Cisco UMA server truststore. The Cisco UMA server certificate is downloaded, and then uploaded on the ASA truststore by creating a trustpoint and using the **crypto ca authenticate** command.

Licensing for the Cisco Mobility Advantage Proxy Feature

The Cisco Unified Communications proxy features (Cisco Phone Proxy, TLS proxy for encrypted voice inspection, and the Cisco Presence Federation Proxy) supported by the ASA require a Unified Communications Proxy license. However, in Version 8.2(2) and later, the Mobility Advantage proxy no longer requires a Unified Communications Proxy license.

The following table shows the licensing requirements for the Mobility Advantage proxy:

Model	License Requirement
All models	Base License.

For more information about licensing, see Chapter 5, “Managing Feature Licenses.”

Configuring Cisco Mobility Advantage

This section includes the following topic:

- Task Flow for Configuring Cisco Mobility Advantage, page 67-7

Task Flow for Configuring Cisco Mobility Advantage

To configure for the ASA to perform TLS proxy and MMP inspection as shown in Figure 67-2 and Figure 67-3, perform the following tasks.

It is assumed that self-signed certificates are used between the ASA and the Cisco UMA server.

To configure the Cisco Mobility Advantage Proxy by using ASDM, choose Wizards > Unified Communications Wizard from the menu. The Unified Communications Wizard opens. From the first page, select the Cisco Mobility Advantage Proxy option under the Remote Access section.

The wizard automatically creates the necessary TLS proxy, then guides you through creating the Unified Presence Proxy instance, importing and installing the required certificates, and finally enables the MMP inspection for the Mobility Advantage traffic automatically.

The wizard guides you through four steps to create the Mobility Advantage Proxy:

Step 1 Select the Mobility Advantage Proxy option.

Step 2 Specify setting to define the proxy topology, such the IP address of the Mobility Advantage server.

Step 3 Configure the server-side certificate management, namely the certificates that are exchanged between the local Mobility Advantage server and the ASA.

Step 4 Configure the client-side certificate management, namely the certificates that are exchanged between the Unified Mobile Communicator and the ASA

The wizard completes by displaying a summary of the configuration created for Mobility Advantage Proxy. See Chapter 64, "Using the Cisco Unified Communication Wizard" for more information.

Feature History for Cisco Mobility Advantage

Table 67-1 lists the release history for this feature.

Table 67-1 Feature History for Cisco Phone Proxy

Feature Name	Releases	Feature Information
Cisco Mobility Advantage Proxy	8.0(4)	The Cisco Mobility Advantage Proxy feature was introduced.
Cisco Mobility Advantage Proxy	8.3(1)	The Unified Communications Wizard was added to ASDM. By using the wizard, you can configure the Cisco Mobility Advantage Proxy.

Configuring Cisco Unified Presence

This chapter describes how to configure the adaptive security appliance for Cisco Unified Presence.

This chapter includes the following sections:

- Information About Cisco Unified Presence, page 68-1
- Licensing for Cisco Unified Presence, page 68-7
- Configuring Cisco Unified Presence Proxy for SIP Federation, page 68-8
- Feature History for Cisco Unified Presence, page 68-9

Information About Cisco Unified Presence

This section includes the following topics:

- Architecture for Cisco Unified Presence for SIP Federation Deployments, page 68-1
- Trust Relationship in the Presence Federation, page 68-4
- Security Certificate Exchange Between Cisco UP and the Security Appliance, page 68-5
- XMPP Federation Deployments, page 68-5
- Configuration Requirements for XMPP Federation, page 68-6

Architecture for Cisco Unified Presence for SIP Federation Deployments

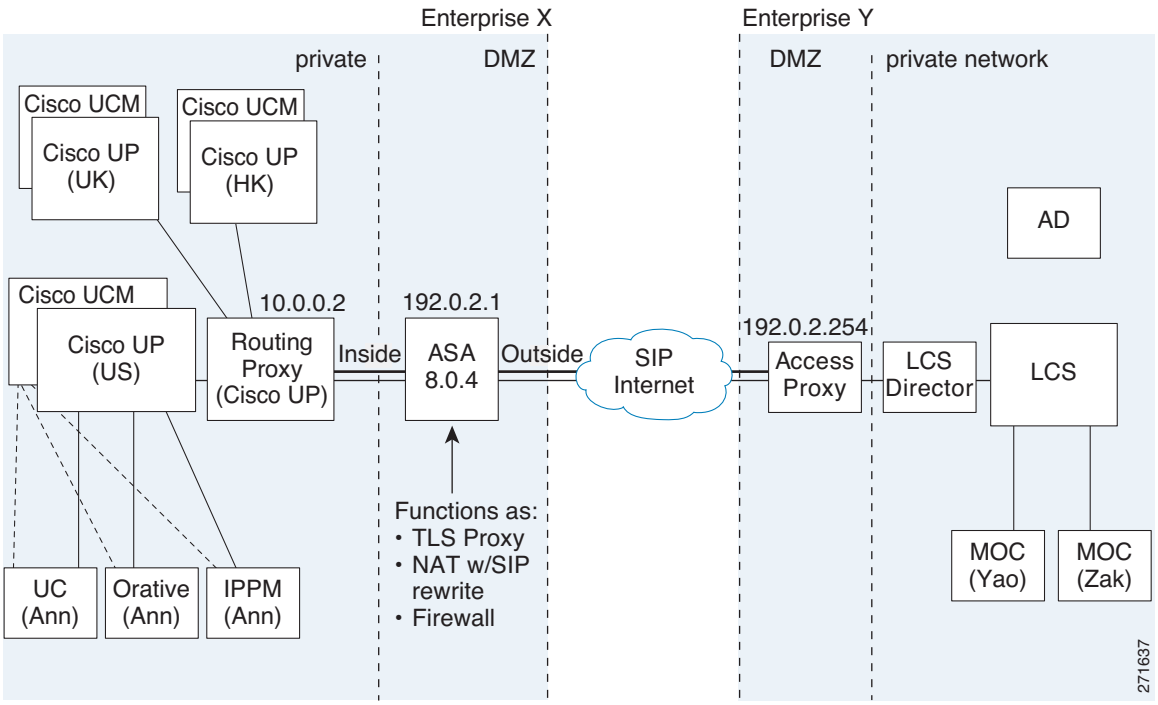
Figure 68-1 depicts a Cisco Unified Presence/LCS Federation scenario with the ASA as the presence federation proxy (implemented as a TLS proxy). The two entities with a TLS connection are the "Routing Proxy" (a dedicated Cisco UP) in Enterprise X and the Microsoft Access Proxy in Enterprise Y. However, the deployment is not limited to this scenario. Any Cisco UP or Cisco UP cluster could be deployed on the left side of the ASA; the remote entity could be any server (an LCS, an OCS, or another Cisco UP).

The following architecture is generic for two servers using SIP (or other ASA inspected protocols) with a TLS connection.

Entity X: Cisco UP/Routing Proxy in Enterprise X

Entity Y: Microsoft Access Proxy/Edge server for LCS/OCS in Enterprise Y

Figure 68-1 Typical Cisco Unified Presence/LCS Federation Scenario



In the above architecture, the ASA functions as a firewall, NAT, and TLS proxy, which is the recommended architecture. However, the ASA can also function as NAT and the TLS proxy alone, working with an existing firewall.

Either server can initiate the TLS handshake (unlike IP Telephony or Cisco Unified Mobility, where only the clients initiate the TLS handshake). There are by-directional TLS proxy rules and configuration. Each enterprise can have an ASA as the TLS proxy.

In Figure 68-1, NAT or PAT can be used to hide the private address of Entity X. In this situation, static NAT or PAT must be configured for foreign server (Entity Y) initiated connections or the TLS handshake (inbound). Typically, the public port should be 5061. The following static PAT command is required for the Cisco UP that accepts inbound connections:

```
hostname(config)# object network obj-10.0.0.2-01
hostname(config-network-object)# host 10.0.0.2
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5061
5061
```

The following static PAT must be configured for each Cisco UP that could initiate a connection (by sending SIP SUBSCRIBE) to the foreign server.

For Cisco UP with the address 10.0.0.2, enter the following command:

```
hostname(config)# object network obj-10.0.0.2-02
hostname(config-network-object)# host 10.0.0.2
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5062
5062
hostname(config)# object network obj-10.0.0.2-03
hostname(config-network-object)# host 10.0.0.2
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service udp 5070
5070
hostname(config)# object network obj-10.0.0.2-04
hostname(config-network-object)# host 10.0.0.2
```

```
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5060
5060
```

For another Cisco UP with the address 10.0.0.3, you must use a different set of PAT ports, such as 45062 or 45070:

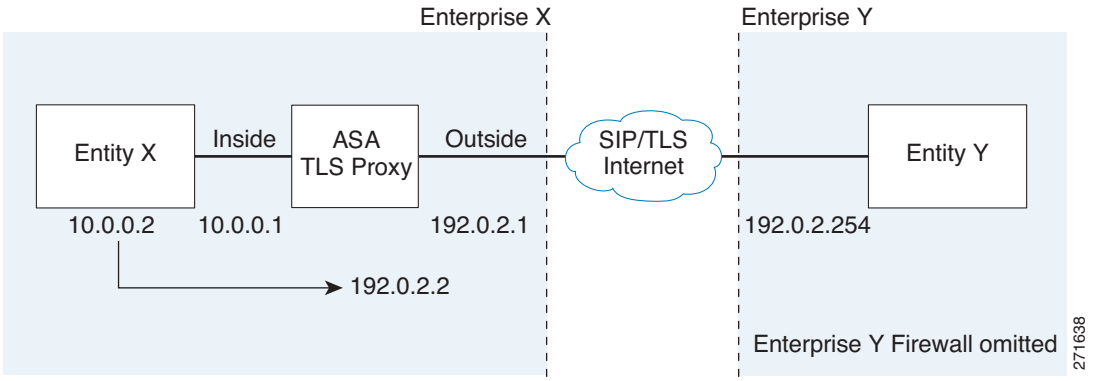
```
hostname(config)# object network obj-10.0.0.3-01
hostname(config-network-object)# host 10.0.0.3
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5061
45061
hostname(config)# object network obj-10.0.0.3-02
hostname(config-network-object)# host 10.0.0.3
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5062
45062
hostname(config)# object network obj-10.0.0.3-03
hostname(config-network-object)# host 10.0.0.3
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service udp 5070
5070
hostname(config)# object network obj-10.0.0.2-03
hostname(config-network-object)# host 10.0.0.2
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5070
45070
hostname(config)# object network obj-10.0.0.3-04
hostname(config-network-object)# host 10.0.0.3
hostname(config-network-object)# nat (inside,outside) static 192.0.2.1 service tcp 5060
45060
```

Dynamic NAT or PAT can be used for the rest of the outbound connections or the TLS handshake. The ASA SIP inspection engine takes care of the necessary translation (fixup).

```
hostname(config)# object network obj-0.0.0.0-01
hostname(config-network-object)# subnet 0.0.0.0 0.0.0.0
hostname(config-network-object)# nat (inside,outside) dynamic 192.0.2.1
```

Figure 68-2 illustrates an abstracted scenario with Entity X connected to Entity Y through the presence federation proxy on the ASA. The proxy is in the same administrative domain as Entity X. Entity Y could have another ASA as the proxy but this is omitted for simplicity.

Figure 68-2 Abstracted Presence Federation Proxy Scenario between Two Server Entities



For the Entity X domain name to be resolved correctly when the ASA holds its credential, the ASA could be configured to perform NAT for Entity X, and the domain name is resolved as the Entity X public address for which the ASA provides proxy service.

For further information about configuring Cisco Unified Presence Federation for SIP Federation, see the Integration Guide for Configuring Cisco Unified Presence for Interdomain Federation.:

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

Trust Relationship in the Presence Federation

Within an enterprise, setting up a trust relationship is achievable by using self-signed certificates or you can set it up on an internal CA.

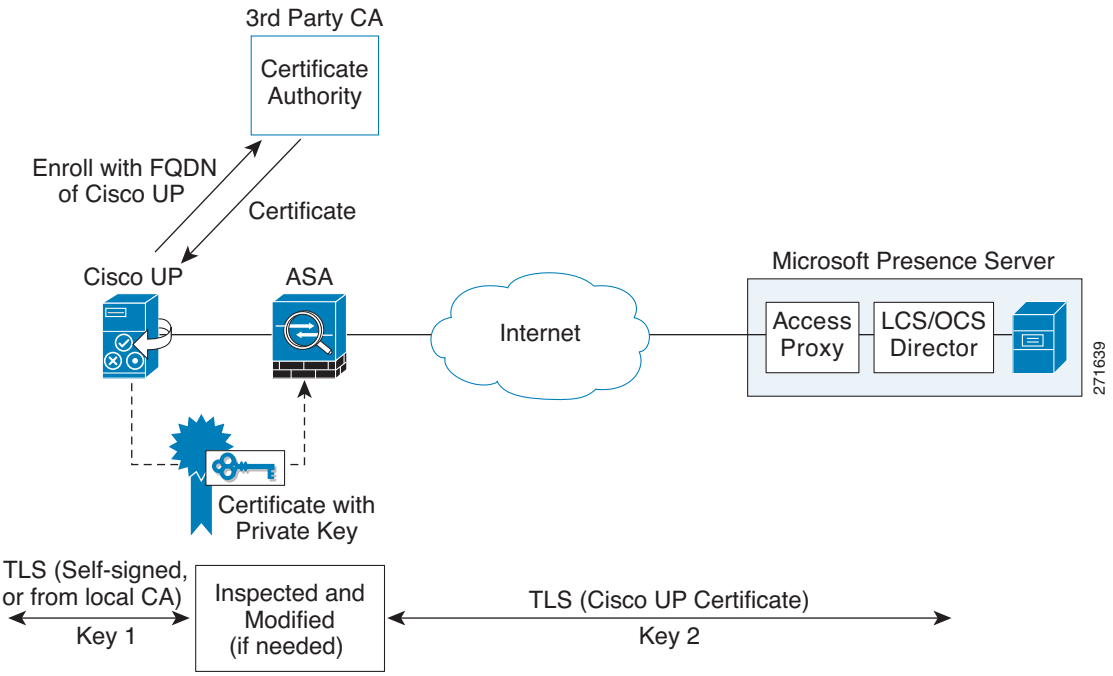
Establishing a trust relationship cross enterprises or across administrative domains is key for federation. Cross enterprises you must use a trusted third-party CA (such as, VeriSign). The ASA obtains a certificate with the FQDN of the Cisco UP (certificate impersonation).

For the TLS handshake, the two entities could validate the peer certificate via a certificate chain to trusted third-party certificate authorities. Both entities enroll with the CAs. The ASA as the TLS proxy must be trusted by both entities. The ASA is always associated with one of the enterprises. Within that enterprise (Enterprise X in Figure 68-1), the entity and the ASA could authenticate each other via a local CA, or by using self-signed certificates.

To establish a trusted relationship between the ASA and the remote entity (Entity Y), the ASA can enroll with the CA on behalf of Entity X (Cisco UP). In the enrollment request, the Entity X identity (domain name) is used.

Figure 68-3 shows the way to establish the trust relationship. The ASA enrolls with the third party CA by using the Cisco UP FQDN as if the ASA is the Cisco UP.

Figure 68-3 How the Security Appliance Represents Cisco Unified Presence – Certificate Impersonate



Security Certificate Exchange Between Cisco UP and the Security Appliance

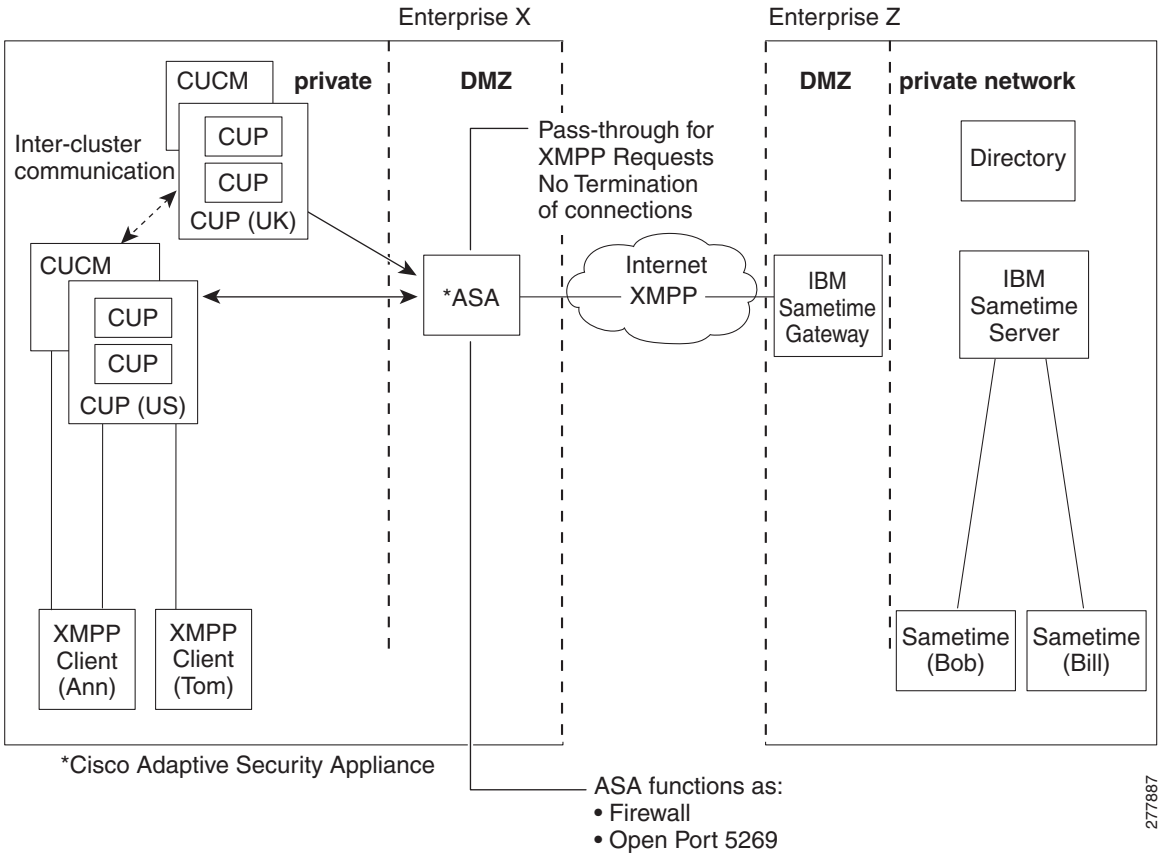
You need to generate the keypair for the certificate (such as `cup_proxy_key`) used by the ASA, and configure a trustpoint to identify the self-signed certificate sent by the ASA to Cisco UP (such as `cup_proxy`) in the TLS handshake.

For the ASA to trust the Cisco UP certificate, you need to create a trustpoint to identify the certificate from the Cisco UP (such as `cert_from_cup`), and specify the enrollment type as terminal to indicate that you will paste the certificate received from the Cisco UP into the terminal.

XMPP Federation Deployments

Figure 68-4 provides an example of an XMPP federated network between Cisco Unified Presence enterprise deployment and an IBM Sametime enterprise deployment. TLS is optional for XMPP federation. ASA acts only as a firewall for XMPP federation; it does not provide TLS proxy functionality or PAT for XMPP federation.

Figure 68-4 Basic XMPP Federated Network between Cisco Unified Presence and IBM Sametime



There are two DNS servers within the internal Cisco Unified Presence enterprise deployment. One DNS server hosts the Cisco Unified Presence private address. The other DNS server hosts the Cisco Unified Presence public address and a DNS SRV records for SIP federation (_sipfederationtle), and XMPP federation (_xmpp-server) with Cisco Unified Presence. The DNS server that hosts the Cisco Unified Presence public address is located in the local DMZ.

For further information about configuring Cisco Unified Presence Federation for XMPP Federation, see the *Integration Guide for Configuring Cisco Unified Presence Release 8.0 for Interdomain Federation*:

http://www.cisco.com/en/US/products/ps6837/products_installation_and_configuration_guides_list.html

Configuration Requirements for XMPP Federation

For XMPP Federation, ASA acts as a firewall only. You must open port 5269 for both incoming and outgoing XMPP federated traffic on ASA.

These are sample access lists to open port 5269 on ASA.

Allow traffic from any address to any address on port 5269:

```
access-list ALLOW-ALL extended permit tcp any any eq 5269
```

Allow traffic from any address to any single node on port 5269:

```
access-list ALLOW-ALL extended permit tcp any host <private cup IP address> eq 5269
```

If you do not configure the access list above, and you publish additional XMPP federation nodes in DNS, you must configure access to each of these nodes, for example:

```
object network obj_host_<private cup ip address>
#host <private cup ip address>
object network obj_host_<private cup2 ip address>
#host <private cup2 ip address>
object network obj_host_<public cup ip address>
#host <public cup ip address>
....
```

Configure the following NAT commands:

```
nat (inside,outside) source static obj_host_<private cup1 IP> obj_host_<public cup IP>
service
obj_udp_source_eq_5269 obj_udp_source_eq_5269
nat (inside,outside) source static obj_host_<private cup1 IP> obj_host_<public cup IP>
service
obj_tcp_source_eq_5269 obj_tcp_source_eq_5269
```

If you publish a single public IP address in DNS, and use arbitrary ports, configure the following:

(This example is for two additional XMPP federation nodes)

```
nat (inside,outside) source static obj_host_<private cup2 ip> obj_host_<public cup IP>
service
obj_udp_source_eq_5269 obj_udp_source_eq_25269
nat (inside,outside) source static obj_host_<private cup2 ip> obj_host_<public cup IP>
service
obj_tcp_source_eq_5269 obj_tcp_source_eq_25269

nat (inside,outside) source static obj_host_<private cup3 ip> obj_host_<public cup IP>
service
obj_udp_source_eq_5269 obj_udp_source_eq_35269
nat (inside,outside) source static obj_host_<private cup3 ip> obj_host_<public cup IP>
service
obj_tcp_source_eq_5269 obj_tcp_source_eq_35269
```

If you publish multiple public IP addresses in DNS all using port 5269, configure the following:

(This example is for two additional XMPP federation nodes)

```
nat (inside,outside) source static obj_host_<private cup2 ip> obj_host_<public cup2 IP>
service
obj_udp_source_eq_5269 obj_udp_source_eq_5269
nat (inside,outside) source static obj_host_<private cup2 ip> obj_host_<public cup2 IP>
service
obj_tcp_source_eq_5269 obj_tcp_source_eq_5269

nat (inside,outside) source static obj_host_<private cup3 ip> obj_host_<public cup3 IP>
service
obj_udp_source_eq_5269 obj_udp_source_eq_5269
nat (inside,outside) source static obj_host_<private cup3 ip> obj_host_<public cup IP>
service
obj_tcp_source_eq_5269 obj_tcp_source_eq_5269
```

Licensing for Cisco Unified Presence

The Cisco Unified Presence feature supported by the ASA require a Unified Communications Proxy license.

The following table shows the Unified Communications Proxy license details by platform:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement[1]
ASA 5505	Base License and Security Plus License: 2 sessions. *Optional license: 24 sessions.*
ASA 5510	Base License and Security Plus License: 2 sessions. *Optional licenses: 24, 50, or 100 sessions.*
ASA 5520	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*
ASA 5540	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5550	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5580	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASA 5512-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5515-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, or 500 sessions.*
ASA 5525-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, or 1000 sessions.*

Model	License Requirement[1]
ASA 5545-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, or 2000 sessions.*
ASA 5555-X	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-10	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, or 3000 sessions.*
ASA 5585-X with SSP-20, -40, or -60	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]
ASASM	Base License: 2 sessions. *Optional licenses: 24, 50, 100, 250, 500, 750, 1000, 2000, 3000, 5000, or 10,000 sessions.*[2]

1. The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit:
   - Phone Proxy
   - Presence Federation Proxy
   - Encrypted Voice Inspection

   Other applications that use TLS proxy sessions do not count towards the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license).

   Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used.

   You independently set the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. When you apply a UC license that is higher than the default TLS proxy limit, the ASA automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license.

   Note: For license part numbers ending in "K8" (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in "K9" (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted.

   Note: If you clear the configuration, then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the to raise the limit again (in ASDM, use the **TLS Proxy** pane). If you use failover and use **File > Save Running Configuration to Standby Unit** on the primary unit to force a configuration synchronization, the **clear configure all** command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning.

   You might also use SRTP encryption sessions for your connections:
   - For K8 licenses, SRTP sessions are limited to 250.
   - For K9 licenses, there is not limit.

   Note: Only calls that require encryption/decryption for media are counted towards the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count towards the limit.
2. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

For more information about licensing, see Chapter 5, "Managing Feature Licenses."

Configuring Cisco Unified Presence Proxy for SIP Federation

This section contains the following topic:

- Task Flow for Configuring Cisco Unified Presence Federation Proxy for SIP Federation, page 68-9

Task Flow for Configuring Cisco Unified Presence Federation Proxy for SIP Federation

To configure a Cisco Unified Presence/LCS Federation scenario with the ASA as the TLS proxy where there is a single Cisco UP that is in the local domain and self-signed certificates are used between the Cisco UP and the ASA (like the scenario shown in Figure 68-1), perform the following tasks.

To configure the Cisco Unified Presence proxy by using ASDM, choose Wizards > Unified Communications Wizard from the menu. The Unified Communications Wizard opens. From the first page, select the Cisco Unified Presence Proxy option under the Business-to-Business section.

The wizard automatically creates the necessary TLS proxy, then guides you through creating the Unified Presence Proxy instance, importing and installing the required certificates, and finally enables the SIP and SCCP inspection for the Presence Federation traffic automatically.

The wizard guides you through four steps to create the Presence Federation Proxy:

Step 1 Select the Presence Federation Proxy option.

Step 2 Specify setting to define the proxy topology, such the IP address of the Presence Federation server.

Step 3 Configure the local-side certificate management, namely the certificates that are exchanged between the local Unified Presence Federation server and the ASA.

Step 4 Configure the remote-side certificate management, namely the certificates that are exchanged between the remote server and the ASA

The wizard completes by displaying a summary of the configuration created for Presence Federation. See the Unified Communications Wizard section in this documentation for more information.

Feature History for Cisco Unified Presence

Table 68-1 lists the release history for this feature.

Table 68-1 Feature History for Cisco Unified Presence

Feature Name	Releases	Feature Information
Cisco Presence Federation Proxy	8.0(4)	The Cisco Unified Presence proxy feature was introduced.
Cisco Presence Federation Proxy	8.3(1)	The Unified Communications Wizard was added to ASDM. By using the wizard, you can configure the Cisco Presence Federation Proxy. Support for XMPP Federation was introduced.

Configuring Cisco Intercompany Media Engine Proxy

This chapter describes how to configure the adaptive security appliance for Cisco Intercompany Media Engine Proxy.

This chapter includes the following sections:

- Information About Cisco Intercompany Media Engine Proxy, page 69-1
- Licensing for Cisco Intercompany Media Engine, page 69-8
- Guidelines and Limitations, page 69-9
- Configuring Cisco Intercompany Media Engine Proxy, page 69-11
- Feature History for Cisco Intercompany Media Engine Proxy, page 69-37

Information About Cisco Intercompany Media Engine Proxy

This section includes the following topics:

- Features of Cisco Intercompany Media Engine Proxy, page 69-1
- How the UC-IME Works with the PSTN and the Internet, page 69-2
- Tickets and Passwords, page 69-3
- Call Fallback to the PSTN, page 69-5
- Architecture and Deployment Scenarios for Cisco Intercompany Media Engine, page 69-5

Features of Cisco Intercompany Media Engine Proxy

Cisco Intercompany Media Engine enables companies to interconnect on-demand, over the Internet with advanced features made available by VoIP technologies. Cisco Intercompany Media Engine allows for business-to-business federation between Cisco Unified Communications Manager clusters in different enterprises by utilizing peer-to-peer, security, and SIP protocols to create dynamic SIP trunks between businesses. A collection of enterprises work together to end up looking like one large business with inter-cluster trunks between them.

The adaptive security appliance applies its existing TLS proxy, SIP Application Layer Gateway (ALG), and SIP verification features to the functioning of Cisco Intercompany Media Engine.

Cisco Intercompany Media Engine has the following key features:

- Works with existing phone numbers: Cisco Intercompany Media Engine works with the phone numbers an enterprise currently has and does not require an enterprise to learn new numbers or change providers to use Cisco Intercompany Media Engine.
- Works with existing IP phones: Cisco Intercompany Media Engine works with the existing IP phones within an enterprise. However, the feature set in business-to-business calls is limited to the capabilities of the IP phones.
- Does not require purchasing new services: Cisco Intercompany Media Engine does not require any new services from any service providers. Customers continue to use the PSTN connectivity they have and the Internet connectivity they have today. Cisco Intercompany Media Engine gradually moves calls off the PSTN and onto the Internet.
- Provides a full Cisco Unified Communications experience: Because Cisco Intercompany Media Engine creates inter-cluster SIP trunks between enterprises, any Unified Communication features that work over the SIP trunk and only require a SIP trunk work with the Cisco Intercompany Media Engine, thus providing a Unified Communication experience across enterprises.
- Works on the Internet: Cisco Intercompany Media Engine was designed to work on the Internet. It can also work on managed extranets.
- Provides worldwide reach: Cisco Intercompany Media Engine can connect to any enterprise anywhere in the world, as long as the enterprise is running Cisco Intercompany Media Engine technology. There are no regional limitations. This is because Cisco Intercompany Media Engine utilizes two networks that both have worldwide reach—the Internet and the PSTN.
- Allows for unlimited scale: Cisco Intercompany Media Engine can work with any number of enterprises.
- Is self-learning: The system is primarily self-learning. Customers do not have to enter information about other businesses: no phone prefixes, no IP address, no ports, no domain names, nor certificates. Customers need to configure information about their own networks, and provide policy information if they want to limit the scope of Cisco Intercompany Media Engine.
- Is secure: Cisco Intercompany Media Engine is secure, utilizing a large number of different technologies to accomplish this security.
- Includes anti-spam: Cisco Intercompany Media Engine prevents people from setting up software on the Internet that spams enterprises with phone calls. It provides an extremely high barrier to entry.
- Provides for QoS management: Cisco Intercompany Media Engine provides features that help customers manage the QoS on the Internet, such as the ability to monitor QoS of the RTP traffic in real-time and fallback to PSTN automatically if problems arise.

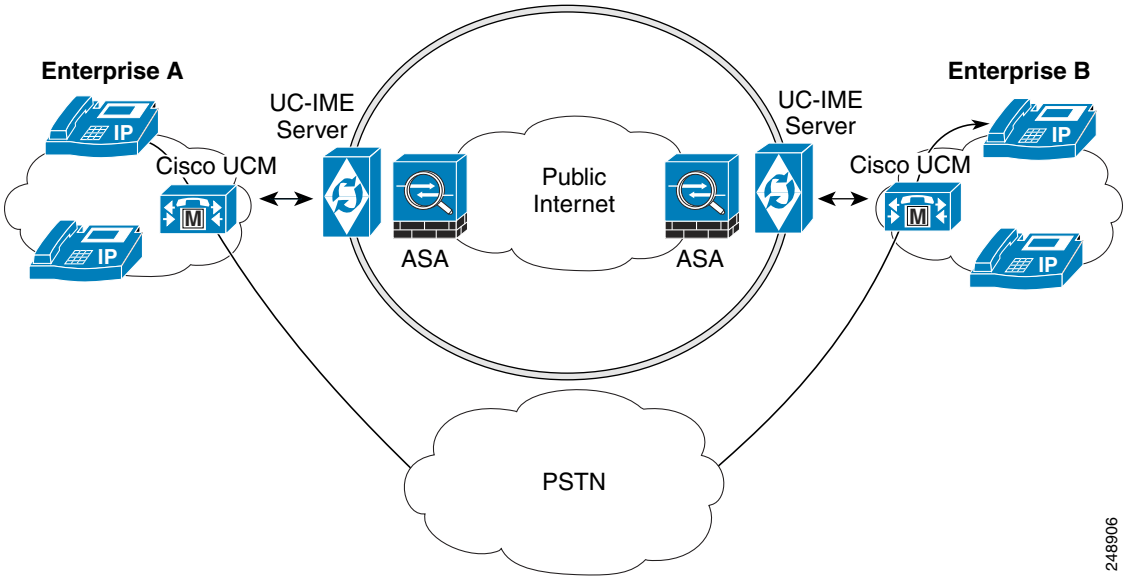
How the UC-IME Works with the PSTN and the Internet

The Cisco Intercompany Media Engine utilizes two networks that both have worldwide reach—the Internet and the PSTN. Customers continue to use the PSTN connectivity they have. The Cisco Intercompany Media Engine gradually moves calls off the PSTN and onto the Internet. However, if QoS problems arise, the Cisco Intercompany Media Engine Proxy monitors QoS of the RTP traffic in real-time and fallbacks to PSTN automatically.

The Cisco Intercompany Media Engine uses information from PSTN calls to validate that the terminating side owns the number that the originated side had called. After the PSTN call terminates, the enterprises involved in the call send information about the call to their Cisco IME server. The Cisco IME server on the originating side validates the call. Figure 69-1 shows the initial call flow through the PSTN.

On successful verification, the terminating side creates a ticket that grants permission to the call originator to make a Cisco IME call to a specific number. See Tickets and Passwords, page 69-3 for information.

Figure 69-1 Interaction of the UC-IME Proxy with the PSTN



Tickets and Passwords

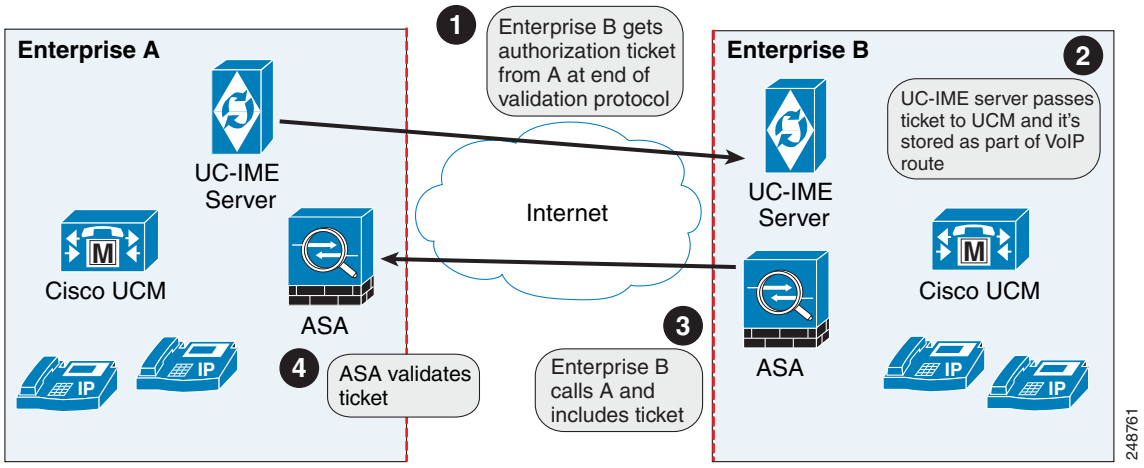
Cisco Intercompany Media Engine utilizes tickets and passwords to provide enterprise verification. Verification through the creation of tickets ensures an enterprise is not subject to denial-of-service (DOS) attacks from the Internet or endless VoIP spam calls. Ticket verification prevents spam and DOS attacks because it introduces a cost to the VoIP caller; namely, the cost of a PSTN call. A malicious user cannot set up just an open source asterisk PBX on the Internet and begin launching SIP calls into an enterprise running Cisco Intercompany Media Engine. Having the Cisco Intercompany Media Engine Proxy verify tickets allows incoming calls from a particular enterprise to a particular number only when that particular enterprise has previously called that phone number on the PSTN.

To send a spam VoIP call to every phone within an enterprise, an organization would have to purchase the Cisco Intercompany Media Engine and Cisco Unified Communications Manager and have called each phone number within the enterprise over the PSTN and completed each call successfully. Only then can it launch a VoIP call to each number.

The Cisco Intercompany Media Engine server creates tickets and the ASA validates them. The ASA and Cisco Intercompany Media Engine server share a password that is configured so that the ASA detects the ticket was created by a trusted Cisco Intercompany Media Engine server. The ticket contains information that indicates that the enterprise is authorized to call specific phone numbers at the target enterprise. See Figure 69-2 for the ticket verification process and how it operates between the originating and terminating-call enterprises.

Note Because the initial calls are over the PSTN, they are subject to any national regulations regarding telemarketing calling. For example, within the United States, they would be subject to the national do-not-call registry.

Figure 69-2 Ticket Verification Process with Cisco Intercompany Media Engine



As illustrated in Figure 69-2. Enterprise B makes a PSTN call to enterprise A. That call completes successfully. Later, Enterprise B Cisco Intercompany Media Engine server initiates validation procedures with Enterprise A. These validation procedures succeed. During the validation handshake, Enterprise B sends Enterprise A its domain name. Enterprise A verifies that this domain name is not on the blacklisted set of domains. Assuming it is not, Enterprise A creates a ticket.

Subsequently, someone in Enterprise B calls that number again. That call setup message from Enterprise B to Enterprise A includes the ticket in the X-Cisco-UC-IME-Ticket header field in the SIP INVITE message. This message arrives at the Enterprise A ASA. The ASA verifies the signature and computes several checks on the ticket to make sure it is valid. If the ticket is valid, the ASA forwards the request to Cisco UCM (including the ticket). Because the ASA drops requests that lack a valid ticket, unauthorized calls are never received by Cisco UCM.

The ticket password is a 128 bit random key, which can be thought of as a shared password between the adaptive security appliance and the Cisco Intercompany Media Engine server. This password is generated by the Cisco Intercompany Media Engine server and is used by a Cisco Intercompany Media Engine SIP trunk to generate a ticket to allow a call to be made between Cisco Intercompany Media Engine SIP trunks. A ticket is a signed object that contains a number of fields that grant permission to the calling domain to make a Cisco Intercompany Media Engine call to a specific number. The ticket is signed by the ticket password.

The Cisco Intercompany Media Engine also required that you configure an epoch for the password. The epoch contains an integer that updates each time that the password is changed. When the proxy is configured the first time and a password entered for the first time, enter 1 for the epoch integer. Each time you change the password, increment the epoch to indicate the new password. You must increment the epoch value each time your change the password.

Typically, you increment the epoch sequentially; however, the ASA allows you to choose any value when you update the epoch. If you change the epoch value, the tickets in use at remote enterprises become invalid. The incoming calls from the remote enterprises fallback to the PSTN until the terminating enterprise reissues tickets with the new epoch value and password.

The epoch and password that you configure on the ASA must match the epoch and password configured on the Cisco Intercompany Media Engine server. If you change the password or epoch on the ASA, you must update them on the Cisco Intercompany Media Engine server. See the Cisco Intercompany Media Engine server documentation for information.

Call Fallback to the PSTN

Cisco Intercompany Media Engine provides features that manage the QoS on the Internet, such as the ability to monitor QoS of the RTP traffic in real-time and fallback to PSTN automatically if problems arise. Call fallback from Internet VoIP calls to the public switched telephone network (PSTN) can occur for two reasons changes in connection quality and signal failure for the Cisco Intercompany Media Engine.

Internet connections can vary wildly in their quality and vary over time. Therefore, even if a call is sent over VoIP because the quality of the connection was good, the connection quality might worsen mid-call. To ensure an overall good experience for the end user, Cisco Intercompany Media Engine attempts to perform a mid-call fallback.

Performing a mid-call fallback requires the adaptive security appliance to monitor the RTP packets coming from the Internet and send information into an RTP Monitoring Algorithm (RMA) API, which will indicates to the adaptive security appliance whether fallback is required. If fallback is required, the adaptive security appliance sends a REFER message to Cisco UCM to tell it that it needs to fallback the call to PSTN.

The TLS signaling connections from the Cisco UCM are terminated on the adaptive security appliance and a TCP or TLS connection is initiated to the Cisco UCM. SRTP (media) sent from external IP phones to the internal network IP phone via the adaptive security appliance is converted to RTP. The adaptive security appliance inserts itself into the media path by modifying the SIP signaling messages that are sent over the SIP trunk between Cisco UCMs. TLS (signaling) and SRTP are always terminated on the adaptive security appliance.

If signaling problems occur, the call falls back to the PSTN; however, the Cisco UCM initiates the PSTN fall back and the adaptive security appliance does not send REFER message.

Architecture and Deployment Scenarios for Cisco Intercompany Media Engine

This section includes the following topics:

- Architecture, page 69-5
- Basic Deployment, page 69-6
- Off Path Deployment, page 69-7

Architecture

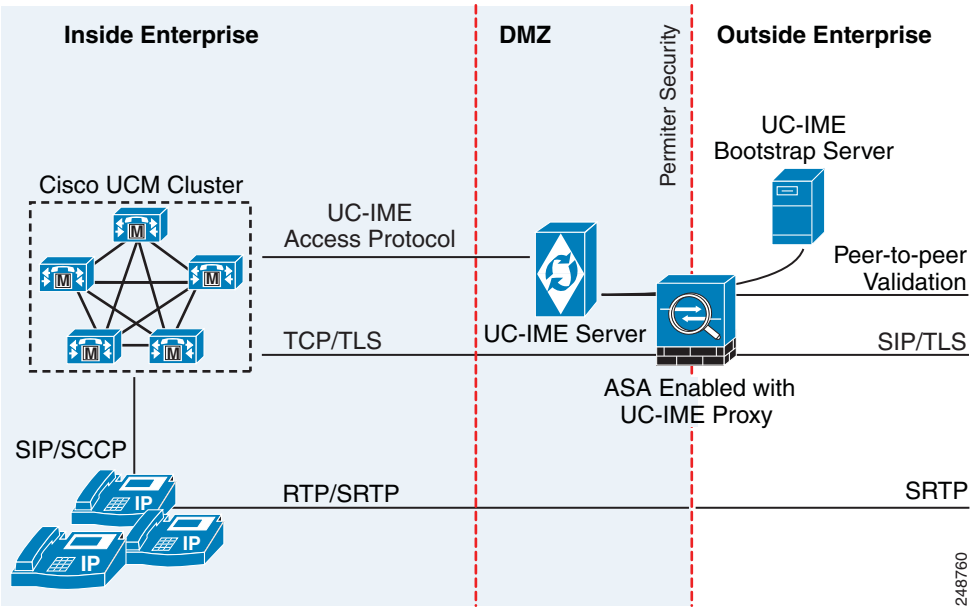
Within the enterprise, Cisco Intercompany Media Engine is deployed with the following components for the following purposes:

- The adaptive security appliance—Enabled with the Cisco Intercompany Media Engine Proxy, provides perimeter security functions and inspects SIP signaling between SIP trunks.
- Cisco Intercompany Media Engine (UC-IME) server— Located in the DMZ, provides an automated provisioning service by learning new VoIP routes to particular phone numbers, and recording those routes in Cisco UCM. The Cisco Intercompany Media Engine server does not perform call control.
- Cisco Unified Communications Manager (Cisco UCM)—Responsible for call control and processing. Cisco UCM connects to the Cisco Intercompany Media Engine server by using the Access Protocol to publish and exchange updates. The architecture can consist of a single Cisco UCM or a Cisco UCM cluster within the enterprise.

- Cisco Intercompany Media Engine (UC-IME) Bootstrap server—Provides a certificate required admission onto the public peer-to-peer network for Cisco Intercompany Media Engine.

Figure 69-3 illustrates the components of the Cisco Intercompany Media Engine in a basic deployment.

Figure 69-3 Cisco Intercompany Media Engine Architecture in a Basic Deployment

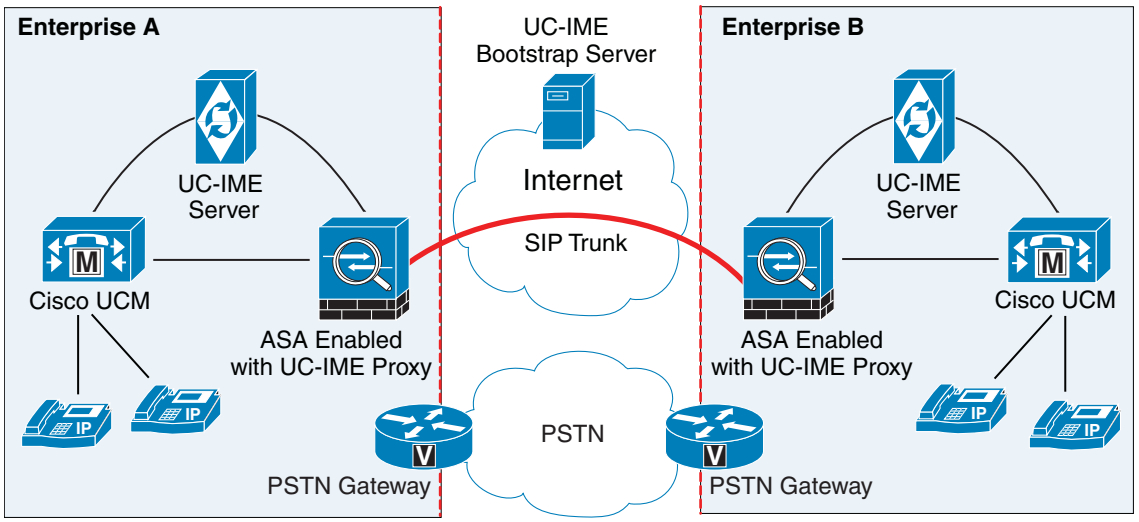


Basic Deployment

In a basic deployment, the Cisco Intercompany Media Engine Proxy sits in-line with the Internet firewall such that all Internet traffic traverses the adaptive security appliance. In this deployment, a single Cisco UCM or a Cisco UCM cluster is centrally deployed within the enterprise, along with a Cisco Intercompany Media Engine server (and perhaps a backup).

As shown in Figure 69-4, the adaptive security appliance sits on the edge of the enterprise and inspects SIP signaling by creating dynamic SIP trunks between enterprises.

Figure 69-4 Basic Deployment Scenario



Off Path Deployment

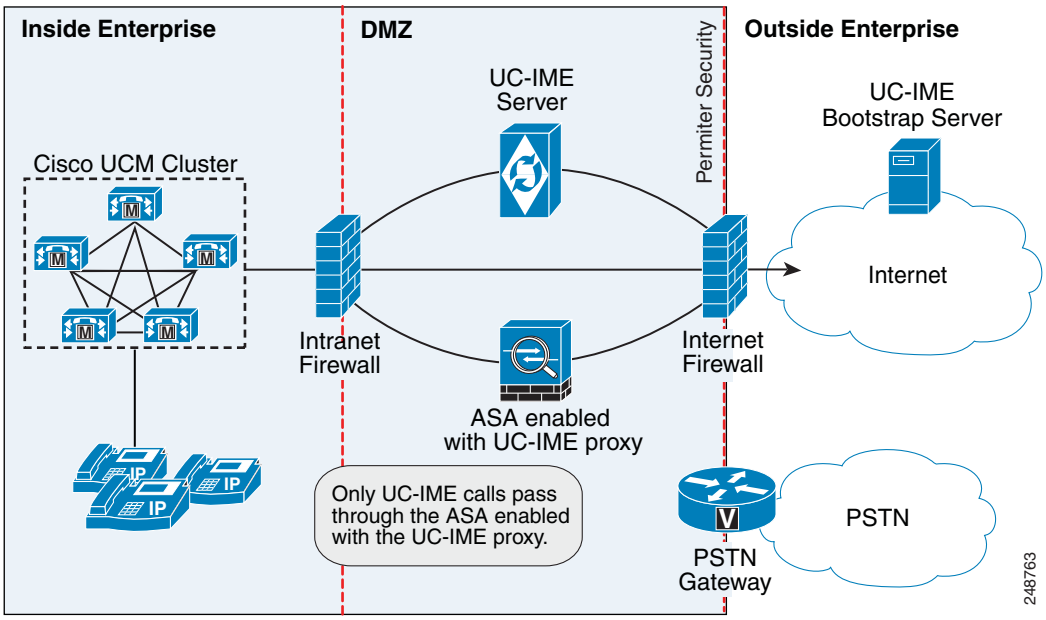
In an off path deployment, inbound and outbound Cisco Intercompany Media Engine calls pass through an adaptive security appliance enabled with the Cisco Intercompany Media Engine Proxy. The adaptive security appliance is located in the DMZ and is configured to support only the Cisco Intercompany Media Engine traffic (SIP signaling and RTP traffic). Normal Internet facing traffic does not flow through this adaptive security appliance.

For all inbound calls, the signaling is directed to the adaptive security appliance because destined Cisco UCMs are configured with the global IP address on the adaptive security appliance. For outbound calls, the called party could be any IP address on the Internet; therefore, the adaptive security appliance is configured with a mapping service that dynamically provides an internal IP address on the adaptive security appliance for each global IP address of the called party on the Internet.

Cisco UCM sends all outbound calls directly to the mapped internal IP address on the adaptive security appliance instead of the global IP address of the called party on the Internet. The adaptive security appliance then forwards the calls to the global IP address of the called party.

Figure 69-5 illustrates the architecture of the Cisco Intercompany Media Engine in an off path deployment.

Figure 69-5 Off Path Deployment of the Adaptive Security Appliance



Licensing for Cisco Intercompany Media Engine

The Cisco Intercompany Media Engine feature supported by the ASA require a Unified Communications Proxy license.

The following table shows the details of the Unified Communications Proxy license:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement
All models	Intercompany Media Engine license. When you enable the Intercompany Media Engine (IME) license, you can use TLS proxy sessions up to the configured TLS proxy limit. If you also have a Unified Communications (UC) license installed that is higher than the default TLS proxy limit, then the ASA sets the limit to be the UC license limit plus an additional number of sessions depending on your model. You can manually configure the TLS proxy limit using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. If you also install the UC license, then the TLS proxy sessions available for UC are also available for IME sessions. For example, if the configured limit is 1000 TLS proxy sessions, and you purchase a 750-session UC license, then the first 250 IME sessions do not affect the sessions available for UC. If you need more than 250 sessions for IME, then the remaining 750 sessions of the platform limit are used on a first-come, first-served basis by UC and IME. • For a license part number ending in "K8", TLS proxy sessions are limited to 1000. • For a license part number ending in "K9", the TLS proxy limit depends on your configuration and the platform model. **Note** K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted. You might also use SRTP encryption sessions for your connections: • For a K8 license, SRTP sessions are limited to 250. • For a K9 license, there is no limit. **Note** Only calls that require encryption/decryption for media are counted toward the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count toward the limit.

For more information about licensing, see Chapter 5, "Managing Feature Licenses."

Guidelines and Limitations

Context Mode Guidelines

Supported in single context mode only.

Firewall Mode Guidelines

Supported in routed firewall mode only.

IPv6 Guidelines

Does not support IPv6 addresses.

Additional Guidelines and Limitations

Cisco Intercompany Media Engine has the following limitations:

- Fax is not supported. Fax capability needs to be disabled on the SIP trunk.
- Stateful failover of Cisco Unified Intercompany Media Engine is not supported. During failover, existing calls traversing the Cisco Intercompany Media Engine Proxy disconnect; however, new calls successfully traverse the proxy after the failover completes.

- Having Cisco UCMs on more than one of the ASA interfaces is not supported with the Cisco Intercompany Media Engine Proxy. Having the Cisco UCMs on one trusted interface is especially necessary in an off path deployment because the ASA requires that you specify the listening interface for the mapping service and the Cisco UCMs must be connected on one trusted interface.
- Multipart MIME is not supported.
- Only existing SIP features and messages are supported.
- H.264 is not supported.
- RTCP is not supported. The ASA drops any RTCP traffic sent from the inside interface to the outside interface. The ASA does not convert RTCP traffic from the inside interface into SRTP traffic.
- The Cisco Intercompany Media Engine Proxy configured on the ASA creates a dynamic SIP trunk for each connection to a remote enterprise. However, you cannot configure a unique subject name for each SIP trunk. The Cisco Intercompany Media Engine Proxy can have only one subject name configured for the proxy.

  Additionally, the subject DN you configure for the Cisco Intercompany Media Engine Proxy match the domain name that has been set for the local Cisco UCM.
- If a service policy rule for the Cisco Intercompany Media Engine Proxy is removed (by using the no service policy command) and reconfigured, the first call traversing the ASA will fail. The call fails over to the PSTN because the Cisco UCM does not know the connections are cleared and tries to use the recently cleared IME SIP trunk for the signaling.

  To resolve this issue, you must additionally enter the **clear connection all** command and restart the ASA. If the failure is due to failover, the connections from the primary ASA are not synchronized to the standby ASA.
- After the **clear connection all** command is issued on an ASA enabled with a UC-IME Proxy and the IME call fails over to the PSTN, the next IME call between an originating and terminating SCCP IP phone completes but does not have audio and is dropped after the signaling session is established.

  An IME call between SCCP IP phones use the IME SIP trunk in both directions. Namely, the signaling from the calling to called party uses the IME SIP trunk. Then, the called party uses the reverse IME SIP trunk for the return signaling and media exchange. However, this connection is already cleared on the ASA, which causes the IME call to fail.

  The next IME call (the third call after the **clear connection all** command is issued), will be completely successful.

  Note This limitation does not apply when the originating and terminating IP phones are configured with SIP.

- The ASA must be licensed and configured with enough TLS proxy sessions to handle the IME call volume. See Licensing for Cisco Intercompany Media Engine for information about the licensing requirements for TLS proxy sessions.

  This limitation occurs because an IME call cannot fall back to the PSTN when there are not enough TLS proxy sessions left to complete the IME call. An IME call between two SCCP IP phones requires the ASA to use two TLS proxy sessions to successfully complete the TLS handshake.

  Assume for example, the ASA is configured to have a maximum of 100 TLS proxy sessions and IME calls between SCCP IP phones establish 101 TLS proxy sessions. In this example, the next IME call is initiated successfully by the originating SCCP IP phone but fails after the call is accepted by the terminating SCCP IP phone. The terminating IP phone rings and on answering the call, the call hangs due to an incomplete TLS handshake. The call does not fall back to the PSTN.

Configuring Cisco Intercompany Media Engine Proxy

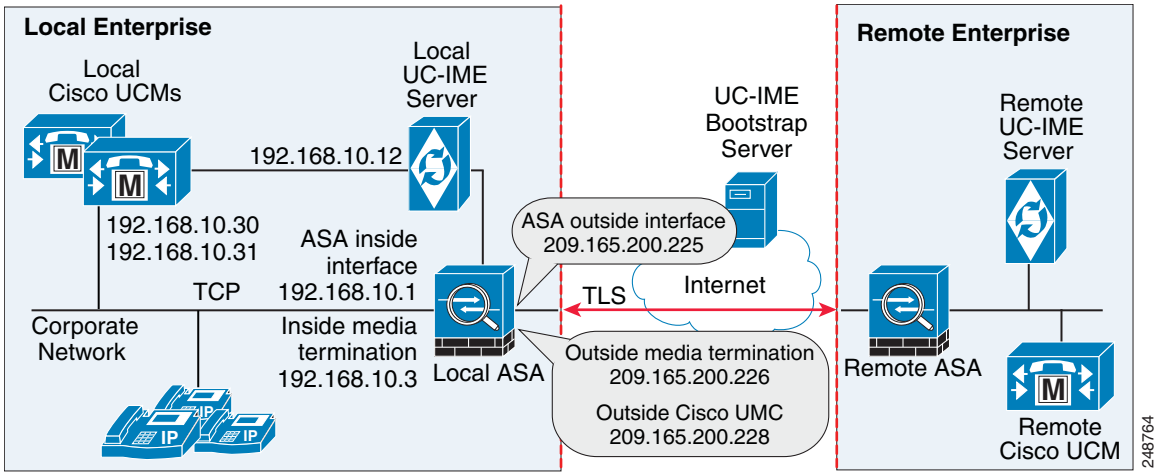
This section contains the following topics:

- Task Flow for Configuring Cisco Intercompany Media Engine, page 69-11
- Configuring NAT for Cisco Intercompany Media Engine Proxy, page 69-12
- Configuring PAT for the Cisco UCM Server, page 69-14
- Creating Access Lists for Cisco Intercompany Media Engine Proxy, page 69-16
- Creating the Media Termination Instance, page 69-17
- Creating the Cisco Intercompany Media Engine Proxy, page 69-18
- Creating Trustpoints and Generating Certificates, page 69-21
- Creating the TLS Proxy, page 69-24
- Enabling SIP Inspection for the Cisco Intercompany Media Engine Proxy, page 69-25
- (Optional) Configuring TLS within the Local Enterprise, page 69-27
- (Optional) Configuring Off Path Signaling, page 69-30

Task Flow for Configuring Cisco Intercompany Media Engine

Figure 69-6 provides an example for a basic deployment of the Cisco Intercompany Media Engine. The following tasks include command line examples based on Figure 69-6.

Figure 69-6 Example for Basic (in-line) Deployment Tasks



Note Step 1 through Step 8 apply to both basic (in-line) and off path deployments and Step 9 applies only to off path deployment.

To configure a Cisco Intercompany Media Engine for a basic deployment, perform the following tasks.

Step 1 Configure static NAT for Cisco UCM. See Configuring NAT for Cisco Intercompany Media Engine Proxy, page 69-12.

Or

Configure PAT for the UCM server. See Configuring PAT for the Cisco UCM Server, page 69-14.

Step 2 Create access lists for Cisco Intercompany Media Engine Proxy. See Creating Access Lists for Cisco Intercompany Media Engine Proxy, page 69-16.

Step 3 Create the media termination address instance for Cisco Intercompany Media Engine Proxy. See Creating the Media Termination Instance, page 69-17.

Step 4 Create the Cisco Intercompany Media Engine Proxy. See Creating the Cisco Intercompany Media Engine Proxy, page 69-18.

Step 5 Create trustpoints and generate certificates for the Cisco Intercompany Media Engine Proxy. See Creating Trustpoints and Generating Certificates, page 69-21.

Step 6 Create the TLS proxy. See Creating the TLS Proxy, page 69-24.

Step 7 Configure SIP inspection for the Cisco Intercompany Media Engine Proxy. See Enabling SIP Inspection for the Cisco Intercompany Media Engine Proxy, page 69-25.

Step 8 (Optional) Configure TLS within the enterprise. See (Optional) Configuring TLS within the Local Enterprise, page 69-27.

Step 9 (Optional) Configure off path signaling. See (Optional) Configuring Off Path Signaling, page 69-30.

Note You only perform Step 9 when you are configuring the Cisco Intercompany Media Engine Proxy in an off path deployment.

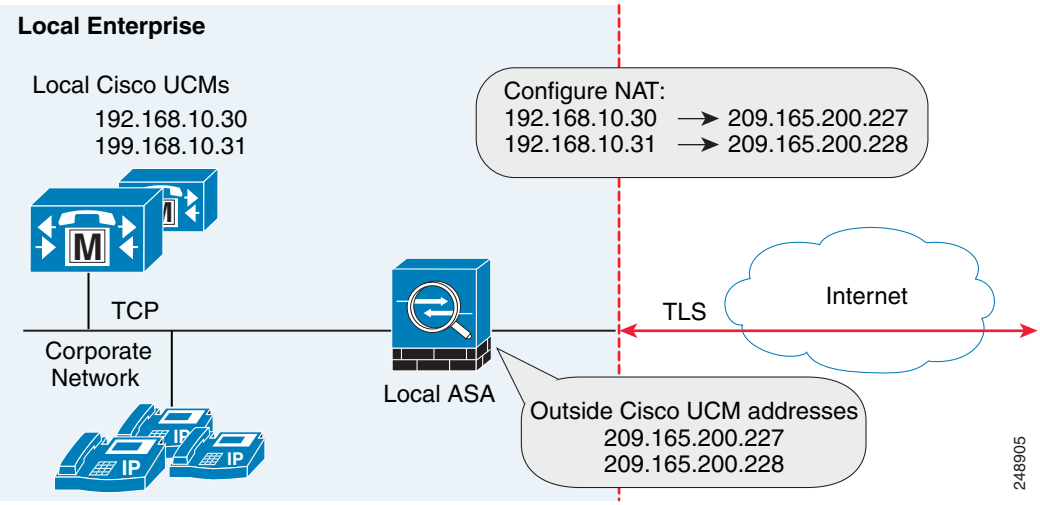
Configuring NAT for Cisco Intercompany Media Engine Proxy

To configure auto NAT, you first configure an object; then use the **nat** command in the object configuration mode.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

Alternatively, you can configure PAT for the Cisco Intercompany Media Engine Proxy. See Configuring PAT for the Cisco UCM Server, page 69-14.

Figure 69-7 Example for Configuring NAT for a Deployment



To configure auto NAT rules for the Cisco UCM server, perform the following steps:

	Command	Purpose

Step 1	`hostname(config)# object network name`
	Examples:
	`hostname(config)# object network ucm_real_192.168.10.30`
	`hostname(config)# object network ucm_real_192.168.10.31`
		Configures a network object for the real address of Cisco UCM that you want to translate.

Step 2	`hostname(config-network-object)# host ip_address`
	Examples:
	`hostname(config-network-object)# host 192.168.10.30`
	`hostname(config-network-object)# host 192.168.10.31`
		Specifies the real IP address of the Cisco UCM host for the network object.

Step 3	(Optional)
	`hostname(config-network-object)# description string`
	Example:
	`hostname(config-network-object)# description "Cisco UCM Real Address"`
		Provides a description of the network object.

Step 4	`hostname(config-network-object)# exit`	Exits from the objects configuration mode.

Step 5	`hostname(config)# object network name`
	Example:
	`hostname(config)# object network ucm_map_209.165.200.228`
		Configures a network object for the mapped address of the Cisco UCM.

Step 6	`hostname(config-network-object)# host ip_address`
	Example:
	`hostname(config-network-object)# host 209.165.200.228`
		Specifies the mapped IP address of the Cisco UCM host for the network object.

Step 7	(Optional)
	`hostname(config-network-object)# description string`
	Example:
	`hostname(config-network-object)# description "Cisco UCM Mapped Address"`
		Provides a description of the network object.

	Command	Purpose
Step 8	`hostname(config-network-object)# exit`	Exits from the objects configuration mode.

Step 9	`hostname(config)# nat (inside,outside) source static` *real_obj mapped_obj*
	Examples:
	`hostname(config)# nat (inside,outside) source static ucm_real_192.168.10.30 ucm_209.165.200.228`
	`hostname(config)# nat (inside,outside) source static ucm_real_192.168.10.31 ucm_209.165.200.228`
		Specifies the address translation on the network objects created in this procedure.
		Where *real_obj* is the *name* that you created in Step 1 in this task.
		Where *mapped_obj* is the *name* that you created in Step 5 in this task.

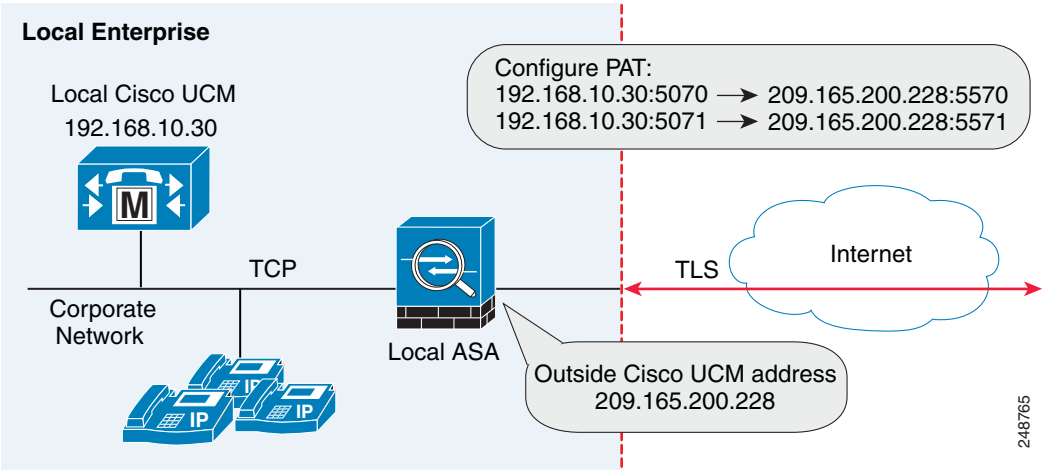
What to Do Next

Create the access lists for the Cisco Intercompany Media Engine Proxy. See Creating Access Lists for Cisco Intercompany Media Engine Proxy, page 69-16.

Configuring PAT for the Cisco UCM Server

Perform this task as an alternative to configuring NAT for the Cisco Intercompany Media Engine Proxy.

Figure 69-8 Example for Configuring PAT for a Deployment



Note You only perform this step when NAT is not configured for the Cisco UCM server.

To configure PAT for the Cisco UCM server, perform the following steps:

	Command	Purpose
Step 1	hostname(config)# **object network** *name* **Examples:** hostname(config)# object network ucm-pat-209.165.200.228	Configures a network object for the outside IP address of Cisco UCM that you want to translate.
Step 2	hostname(config-network-object)# **host** *ip_address* **Example:** hostname(config-network-object)# host 209.165.200.228	Specifies the real IP address of the Cisco UCM host for the network object.
Step 3	hostname(config-network-object)# **exit**	Exits from the objects configuration mode.
Step 4	hostname(config)# **object service** *name* **Examples:** hostname(config)# object service tcp_5070 hostname(config)# object service tcp_5071	Creates a service object for the outside Cisco Intercompany Media Engine port.
Step 5	hostname(config-service-object)# **tcp source eq** *port* **Examples:** hostname(config-service-object)# tcp source eq 5070 hostname(config-service-object)# tcp source eq 5071	Specifies the port number.
Step 6	hostname(config-service-object)# **exit**	Exits from the objects configuration mode.
Step 7	hostname(config)# **object network** *name* **Examples:** hostname(config)# object network ucm-real-192.168.10.30 hostname(config)# object network ucm-real-192.168.10.31	Configures a network object to represent the real IP address of Cisco UCM.
Step 8	hostname(config-network-object)# **host** *ip_address* **Examples:** hostname(config-network-object)# host 192.168.10.30 hostname(config-network-object)# host 192.168.10.31	Specifies the real IP address of the Cisco UCM host for the network object.
Step 9	hostname(config-network-object)# **exit**	Exits from the objects configuration mode.
Step 10	hostname(config)# **object service** *name* **Examples:** hostname(config)# object service tcp_5570 hostname(config)# object service tcp_5571	Creates a service objects for Cisco UCM SIP port.
Step 11	hostname(config-service-object)# **tcp source eq** *port* **Example:** hostname(config-service-object)# tcp source eq 5570 hostname(config-service-object)# tcp source eq 5571	Specifies the port number.
Step 12	hostname(config-service-object)# **exit**	Exits from the objects configuration mode.
Step 13	hostname(config)# **nat (inside,outside) source static** *real_obj mapped_obj* **service** *real_port mapped_port* **Examples:** hostname(config)# nat (inside,outside) source static ucm-real-192.168.10.30 ucm-pat-209.165.200.228 service tcp_5070 tcp_5570 hostname(config)# nat (inside,outside) source static ucm-real-192.168.10.31 ucm-pat-128.106.254.5 service tcp_5071 tcp_5571	Creates a static mapping for Cisco UCM. *Where real_obj is the name that you created in Step 1 in this task.* *Where mapped_obj is the name that you created in Step 7 in this task.* *Where real_port is the name that you created in Step 4 in this task.* *Where mapped_obj is the name that you created in Step 10 in this task.*

Creating Access Lists for Cisco Intercompany Media Engine Proxy

To configure access lists for the Cisco Intercompany Media Engine Proxy to reach the Cisco UCM server, perform the following steps.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

	Command	Purpose
Step 1	hostname(config)# **access-list** *id* **extended permit tcp any host** *ip_address* **eq** *port* **Example:** hostname(config)# access-list incoming extended permit tcp any host 192.168.10.30 eq 5070	Adds an Access Control Entry (ACE). An access list is made up of one or more ACEs with the same access list ID. This ACE provides access control by allowing incoming access for Cisco Intercompany Media Engine connections on the specified port. In the *ip_address* argument, provide the real IP address of Cisco UCM.
Step 2	hostname(config)# **access-group** *access-list* **in interface** *interface_name* **Example:** hostname(config)# access-group incoming in interface outside	Binds the access list to an interface.
Step 3	hostname(config)# **access-list** *id* **extended permit tcp any host** *ip_address* **eq** *port* **Example:** hostname(config)# access-list ime-inbound-sip extended permit tcp any host 192.168.10.30 eq 5070	Adds an ACE. This ACE allows the ASA to allow inbound SIP traffic for Cisco Intercompany Media Engine. This entry is used to classify traffic for the class and policy map. **Note** The port that you configure here must match the trunk settings configured on Cisco UCM. See the Cisco Unified Communications Manager documentation for information about this configuration setting.
Step 4	hostname(config)# **access-list** *id* **extended permit tcp** *ip_address mask* **any range** *range* **Example:** hostname(config)# access-list ime-outbound-sip extended permit tcp 192.168.10.30 255.255.255.255 any range 5000 6000	Adds an ACE. This ACE allows the ASA to allow outbound SIP traffic for Cisco Intercompany Media Engine (in the example, any TCP traffic with source as 192.168.10.30 and destination port range between 5000 and 6000). This entry is used to classify traffic for the class and policy map. **Note** Ensure that TCP traffic between Cisco UCM and the Cisco Intercompany Media Engine server does not use this port range (if that connection goes through the ASA).
Step 5	hostname(config)# **access-list** *id* **permit tcp any host** *ip_address* **eq 6084** **Example:** hostname(config)# access-list ime-traffic permit tcp any host 192.168.10.12 eq 6084	Adds an ACE. This ACE allows the ASA to allow traffic from the Cisco Intercompany Media Engine server to remote Cisco Intercompany Media Engine servers.
Step 6	hostname(config)# **access-list** *id* **permit tcp any host** *ip_address* **eq 8470** **Example:** hostname(config)# access-list ime-bootserver-traffic permit tcp any host 192.168.10.12 eq 8470	Adds an ACE. This ACE allows the ASA to allow traffic from the Cisco Intercompany Media Engine server to the Bootstrap server for the Cisco Intercompany Media Engine.

What to Do Next

Create the media termination instance on the ASA for the Cisco Intercompany Media Engine Proxy. See Creating the Media Termination Instance, page 69-17.

Creating the Media Termination Instance

Guidelines

The media termination address you configure must meet these requirements:

- If you decide to configure a media-termination address on interfaces (rather than using a global interface), you must configure a media-termination address on at least two interfaces (the inside and an outside interface) before applying the service policy for the Cisco Intercompany Media Engine Proxy. Otherwise, you will receive an error message when enabling the proxy with SIP inspection.

Note Cisco recommends that you configure the media-termination address for the Cisco Intercompany Media Engine Proxy on interfaces rather than configuring a global media-termination address.

- The Cisco Intercompany Media Engine Proxy can use only one type of media termination instance at a time; for example, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces. However, you cannot use a global media-termination address and media-termination addresses configured for each interface at the same time.

Note If you change any Cisco Intercompany Media Engine Proxy settings after you create the media-termination address for the proxy, you must reconfigure the media-termination address by using the **no media-termination** command, and then reconfiguring it as described in this procedure.

Procedure

Create the media termination instance to use with the Cisco Intercompany Media Engine Proxy.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

To create the media termination instance for the Cisco Intercompany Media Engine Proxy, perform the following steps:

	Command	Purpose
Step 1	hostname(config)# **media-termination** *instance_name* **Example:** hostname(config)# **media-termination** *uc-ime-media-term*	Creates the media termination instance that you attach to the Cisco Intercompany Media Engine Proxy.
Step 2	hostname(config-media-termination)# **address** *ip_address* **interface** *intf_name* **Examples:** hostname(config-media-termination)# address 209.165.200.228 interface outside	Configures the media-termination address used by the outside interface of the ASA. The outside IP address must be a publicly routable address that is an unused IP address within the address range on that interface. See Creating the Cisco Intercompany Media Engine Proxy, page 69-18 for information about the UC-IME proxy settings. See CLI configuration guide for information about the **no service-policy** command.
Step 3	hostname(config-media-termination)# **address** *ip_address* **interface** *intf_name* **Examples:** hostname(config-media-termination)# address 192.168.10.3 interface inside	Configures a media termination address used by the inside interface of the ASA. **Note** The IP address must be an unused IP address within the same subnet on that interface.
Step 4	(Optional) hostname(config-media-termination)# ***rtp-min-port*** *port1* ***rtp-maxport*** *port2* **Examples:** hostname(config-media-termination)# rtp-min-port 1000 rtp-maxport 2000	Configures the rtp-min-port and rtp-max-port limits for the Cisco Intercompany Media Engine Proxy. Configure the RTP port range for the media termination point when you need to scale the number of calls that the Cisco Intercompany Media Engine supports. Where *port1* specifies the minimum value for the RTP port range for the media termination point, where port1 can be a value from 1024 to 65535. By default, the value for *port1* is 16384. Where *port2* specifies the maximum value for the RTP port range for the media termination point, where port2 can be a value from 1024 to 65535. By default, the value for *port2* is 32767.

What To Do Next

Once you have created the media termination instance, create the Cisco Intercompany Media Engine Proxy. See Creating the Cisco Intercompany Media Engine Proxy, page 69-18.

Creating the Cisco Intercompany Media Engine Proxy

To create the Cisco Intercompany Media Engine Proxy, perform the following steps.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

Note You cannot change any of the configuration settings for the Cisco Intercompany Media Engine Proxy described in this procedure when the proxy is enabled for SIP inspection. Remove the Cisco Intercompany Media Engine Proxy from SIP inspection before changing any of the settings described in this procedure.

	Command	Purpose

Step 1	`hostname(config)# uc-ime uc_ime_name`
	Example:
	`hostname(config)# uc-ime local-ent-ime`
		Configures the Cisco Intercompany Media Engine Proxy.
		Where *uc_ime_name* is the name of the Cisco Intercompany Media Engine Proxy. The name is limited to 64 characters.
		Only one Cisco Intercompany Media Engine Proxy can be configured on the ASA.

Step 2	`hostname(config-uc-ime)# media-termination mta_instance_name`
	Example:
	`hostname(config-uc-ime)# media-termination ime-media-term`
		Specifies the media termination instance used by the Cisco Intercompany Media Engine Proxy.
		Note You must create the media termination instance before you specify it in the Cisco Intercompany Media Engine Proxy.
		Where *mta_instance_name* is the *instance_name* that you created in Step 1 of Creating the Media Termination Instance.
		See Creating the Media Termination Instance, page 69-17 for the steps to create the media termination instance.

Step 3	`hostname(config-uc-ime)# ucm address ip_address trunk-security-mode [nonsecure | secure]`
	Example:
	`hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure`
		Specifies the Cisco UCM server in the enterprise. You must specify the real IP address of the Cisco UCM server. Do not specify a mapped IP address for the server.
		Note You must include an entry for each Cisco UCM in the cluster with Cisco Intercompany Media Engine that has a SIP trunk enabled.
		Where the **nonsecure** and **secure** options specify the security mode of the Cisco UCM or cluster of Cisco UCMs.
		Note Specifying **secure** for Cisco UCM or Cisco UCM cluster indicates that Cisco UCM or Cisco UCM cluster is initiating TLS; therefore, you must configure TLS for components. See (Optional) Configuring TLS within the Local Enterprise, page 69-27.
		You can specify the **secure** option in this task or you can update it later while configuring TLS for the enterprise. See Step 11 in (Optional) Configuring TLS within the Local Enterprise, page 69-27.

	Command	Purpose
Step 4	hostname(config-uc-ime)# **ticket epoch** *n* **password** *password* **Example:** hostname(config-uc-ime)# ticket epoch 1 password password1234	Configures the ticket epoch and password for Cisco Intercompany Media Engine. Where *n* is an integer from 1-255. The epoch contains an integer that updates each time that the password is changed. When the proxy is configured the first time and a password entered for the first time, enter 1 for the epoch integer. Each time you change the password, increment the epoch to indicate the new password. You must increment the epoch value each time your change the password. Typically, you increment the epoch sequentially; however, the ASA allows you to choose any value when you update the epoch. If you change the epoch value, the current password is invalidated and you must enter a new password. Where *password* contains a minimum of 10 and a maximum of 64 printable character from the US-ASCII character set. The allowed characters include 0x21 to 0x73 inclusive, and exclude the space character. We recommend a password of at least 20 characters. Only one password can be configured at a time. The ticket password is stored onto flash. The output of the **show running-config uc-ime** command displays ***** instead of the password string. **Note** The epoch and password that you configure on the ASA must match the epoch and password configured on the Cisco Intercompany Media Engine server. See the Cisco Intercompany Media Engine server documentation for information.

	Command	Purpose

Step 5	(Optional)
	`hostname(config-uc-ime)# fallback monitoring timer timer_millisec | hold-down timer timer_sec`
	Examples:
	`hostname(config-uc-ime)# fallback monitoring timer 120`
	`hostname(config-uc-ime)# fallback hold-down timer 30`
		Specifies the fallback timers for Cisco Intercompany Media Engine.
		Specifying **monitoring timer** sets the time between which the ASA samples the RTP packets received from the Internet. The ASA uses the data sample to determine if fallback to the PSTN is needed for a call.
		Where *timer_millisec* specifies the length of the monitoring timer. By default, the length is 100 milliseconds for the monitoring timer and the allowed range is 10-600 ms.
		Specifying **hold-down timer** sets the amount of time that ASA waits before notifying Cisco UCM whether to fall back to PSTN.
		Where *timer_sec* specifies the length of the hold-down timer. By default, the length is 20 seconds for the hold-down timer and the allowed range is 10-360 seconds.
		If you do not use this command to specify fallback timers, the ASA uses the default settings for the fallback timers.

Step 6	(Optional)
	`hostname(config-uc-ime)# fallback sensitivity-file file_name`
	Example:
	`hostname(config-uc-ime)# fallback sensitivity-file ime-fallback-sensitvity.fbs`
		Specifies the file to use for mid-call PSTN fallback.
		Where *file_name* must be the name of a file on disk that includes the .fbs file extension.
		The fallback file is used to determine whether the QoS of the call is poor enough for the Cisco Intercompany Media Engine to move the call to the PSTN.

What to Do Next

Install the certificate on the local entity truststore. You could also enroll the certificate with a local CA trusted by the local entity.

Creating Trustpoints and Generating Certificates

You need to generate the keypair for the certificate used by the ASA, and configure a trustpoint to identify the certificate sent by the ASA in the TLS handshake.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

Note This task instructs you on how to create trustpoints for the local enterprise and the remote enterprise and how to exchange certificates between these two enterprises. This task does not provide steps for creating trustpoints and exchanging certificates between the local Cisco UCM and the local ASA. However, if you require additional security within the local enterprise, you must perform the optional task (Optional)

Configuring TLS within the Local Enterprise, page 69-27. Performing that task allows for secure TLS connections between the local Cisco UCM and the local ASA. The instructions in that task describe how to create trustpoints between the local Cisco UCM and the local ASA.

Prerequisites for Installing Certificates

To create a proxy certificate on the ASA that is trusted by the remote entity, obtain a certificate from a trusted CA or export it from the remote enterprise ASA.

To export the certificate from the remote enterprise, you enter the following command on the remote ASA:

hostname(config)# **crypto ca export trustpoint identity-certificate**

The ASA prompts displays the certificate in the terminal screen. Copy the certificate from the terminal screen. You will need the certificate text in Step 5 of this task.

Procedure

To create the trustpoints and generate certificates, perform the following steps:

	Command	Purpose
Step 1	hostname(config)# **crypto key generate rsa label** *key-pair-label* **modulus** *size* **Example:** hostname(config)# crypto key generate rsa label local-ent-key modulus 2048	On the local ASA, creates the RSA keypair that can be used for the trustpoints. This is the keypair and trustpoint for the local entities signed certificate. The modulus key size that you select depends on the level of security that you want to configure and on any limitations imposed by the CA from which you are obtaining the certificate. The larger the number that you select, the higher the security level will be for the certificate. Most CAs recommend 2048 for the key modulus size; however, **Note** GoDaddy requires a key modulus size of 2048.
Step 2	hostname(config)# **crypto ca trustpoint** *trustpoint_name* **Example:** hostname(config)# crypto ca trustpoint local_ent	Enters the trustpoint configuration mode for the specified trustpoint so that you can create the trustpoint for the local entity. A trustpoint represents a CA identity and possibly a device identity, based on a certificate issued by the CA. Maximum name length is 128 characters.
Step 3	hostname(config-ca-trustpoint)# **subject-name** *X.500_name* **Example:** hostname(config-ca-trustpoint)# subject-name cn=Ent-local-domain-name**	Includes the indicated subject DN in the certificate during enrollment. **Note** The domain name that you enter here must match the domain name that has been set for the local Cisco UCM. For information about how to configure the domain name for Cisco UCM, see the Cisco Unified Communications Manager documentation for information.

	Command	Purpose

Step 4	`hostname(config-ca-trustpoint)# keypair keyname`
	Example:
	`hostname(config-ca-trustpoint)# keypair local-ent-key`
		Specifies the key pair whose public key is to be certified.

Step 5	`hostname(config-ca-trustpoint)# enroll terminal`	Specifies that you will use the "copy and paste" method of enrollment with this trustpoint (also known as manual enrollment).
Step 6	`hostname(config-ca-trustpoint)# exit`	Exits from the CA Trustpoint configuration mode.

Step 7	`hostname(config)# crypto ca enroll trustpoint`
	Example:
	`hostname(config)# crypto ca enroll remote-ent`
	`%`
	`% Start certificate enrollment ...`
	`% The subject name in the certificate will be:`
	`% cn=enterpriseA`
	`% The fully-qualified domain name in the certificate will`
	`@ be: ciscoasa`
	`% Include the device serial number in the subject name?`
	`[yes/no]: no`
	`Display Certificate Request to terminal? [yes/no]: yes`
		Starts the enrollment process with the CA.
		Where *trustpoint* is the same as the value you entered for *trustpoint_name* in Step 2.
		When the trustpoint is configured for manual enrollment (**enroll terminal** command), the ASA writes a base-64-encoded PKCS10 certification request to the console and then displays the CLI prompt. Copy the text from the prompt.
		Submit the certificate request to the CA, for example, by pasting the text displayed at the prompt into the certificate signing request enrollment page on the CA website.
		When the CA returns the signed identity certificate, proceed to Step 8 in this procedure.

Step 8	`hostname(config)# crypto ca import trustpoint certificate`
	Example:
	`hostname(config)# crypto ca import remote-ent certificate`
		Imports the signed certificate received from the CA in response to a manual enrollment request.
		Where *trustpoint* specifies the trustpoint you created in Step 2.
		The ASA prompts you to paste the base-64 formatted signed certificate onto the terminal.

Step 9	`hostname(config)# crypto ca authenticate trustpoint`
	Example:
	`hostname(config)# crypto ca authenticate remote-ent`
		Authenticates the third-party identity certificate received from the CA. The identity certificate is associated with a trustpoint created for the remote enterprise.
		The ASA prompts you to paste the base-64 formatted identity certificate from the CA onto the terminal.

What to Do Next

Create the TLS proxy for the Cisco Intercompany Media Engine. See the "Creating the TLS Proxy" section on page 69-24.

Creating the TLS Proxy

Because either enterprise, namely the local or remote Cisco UCM servers, can initiate the TLS handshake (unlike IP Telephony or Cisco Mobility Advantage, where only the clients initiate the TLS handshake), you must configure by-directional TLS proxy rules. Each enterprise can have an ASA as the TLS proxy.

Create TLS proxy instances for the local and remote entity initiated connections respectively. The entity that initiates the TLS connection is in the role of "TLS client." Because the TLS proxy has a strict definition of "client" and "server" proxy, two TLS proxy instances must be defined if either of the entities could initiate the connection.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

To create the TLS proxy, perform the following steps:

	Command	Purpose

Step 1	`hostname(config)# tls-proxy proxy_name`
	Example:
	`hostname(config)# tls-proxy local_to_remote-ent`
		Creates the TLS proxy for the outbound connections.

Step 2	`hostname(config-tlsp)# client trust-point proxy_trustpoint`
	Example:
	`hostname(config-tlsp)# client trust-point local-ent`
		For **outbound** connections, specifies the trustpoint and associated certificate that the adaptive security appliance uses in the TLS handshake when the adaptive security appliance assumes the role of the TLS client. The certificate must be owned by the adaptive security appliance (identity certificate).
		Where *proxy_trustpoint* specifies the trustpoint defined by the **crypto ca trustpoint** command in Step 2 in "Creating Trustpoints and Generating Certificates" section on page 69-21.

Step 3	`hostname(config-tlsp)# client cipher-suite cipher_suite`
	Example:
	`hostname(config-tlsp)# client cipher-suite aes128-sha1 aes256-sha1 3des-sha1 null-sha1`
		For outbound connections, controls the TLS handshake parameter for the cipher suite.
		Where `cipher_suite` includes des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, or null-sha1.
		For client proxy (the proxy acts as a TLS client to the server), the user-defined cipher suite replaces the default cipher suite, or the one defined by the **ssl encryption** command. Use this command to achieve difference ciphers between the two TLS sessions. You should use AES ciphers with the Cisco UCM server.

Step 4	`hostname(config-tlsp)# exit`	Exits from the TLS proxy configuration mode.

Step 5	`hostname(config)# tls-proxy proxy_name`
	Example:
	`hostname(config)# tls-proxy remote_to_local-ent`
		Create the TLS proxy for inbound connections.

	Command	Purpose

Step 6	`hostname(config-tlsp)# server trust-point proxy_trustpoint`
	Example:
	`hostname(config-tlsp)# server trust-point local-ent`
		For **inbound** connections, specifies the proxy trustpoint certificate presented during TLS handshake. The certificate must be owned by the adaptive security appliance (identity certificate).
		Where *proxy_trustpoint* specifies the trustpoint defined by the **crypto ca trustpoint** command in Step 2 in "Creating Trustpoints and Generating Certificates" section on page 69-21.
		Because the TLS proxy has strict definition of client proxy and server proxy, two TLS proxy instances must be defined if either of the entities could initiate the connection.

Step 7	`hostname(config-tlsp)# client cipher-suite cipher_suite`
	Example:
	`hostname(config-tlsp)# client cipher-suite aes128-sha1 aes256-sha1 3des-sha1 null-sha1`
		For inbound connections, controls the TLS handshake parameter for the cipher suite.
		Where *cipher_suite* includes des-sha1, 3des-sha1, aes128-sha1, aes256-sha1, or null-sha1.

Step 8	`hostname(config-tlsp)# exit`	Exits from the TSL proxy configuration mode.
Step 9	`hostname(config)# ssl encryption 3des-sha1 aes128-sha1 [algorithms]`	Specifies the encryption algorithms that the SSL/TLS protocol uses. Specifying the 3des-shal and aes128-shal is required. Specifying other algorithms is optional. **Note** The Cisco Intercompany Media Engine Proxy requires that you use strong encryption. You must specify this command when the proxy is licensed using a K9 license.

What to Do Next

Once you have created the TLS proxy, enable it for SIP inspection.

Enabling SIP Inspection for the Cisco Intercompany Media Engine Proxy

Enable the TLS proxy for SIP inspection and define policies for both entities that could initiate the connection.

The example command lines in this task are based on a basic (in-line) deployment. See Figure 69-6 on page 69-11 for an illustration explaining the example command lines in this task.

Note If you want to change any Cisco Intercompany Media Engine Proxy settings after you enable SIP inspection, you must enter the **no service-policy** command, and then reconfigure the service policy as described in this procedure. Removing and reconfiguring the service policy does not affect existing calls; however, the first call traversing the Cisco Intercompany Media Engine Proxy will fail. Enter the **clear connection** command and restart the ASA.

To enable SIP inspection for the Cisco Intercompany Media Engine Proxy, perform the following steps:

	Command	Purpose
Step 1	hostname(config)# **class-map** *class_map_name* **Examples:** hostname(config)# class-map ime-inbound-sip	Defines a class for the inbound Cisco Intercompany Media Engine SIP traffic.
Step 2	hostname(config-cmap)# **match access-list** *access_list_name* **Examples:** hostname(config-cmap)# match access-list ime-inbound-sip	Identifies the SIP traffic to inspect. Where the *access_list_name* is the access list you created in Step 3, page 69-16 of the task Creating Access Lists for Cisco Intercompany Media Engine Proxy.
Step 3	hostname(config-cmap)# **exit**	Exits from the class map configuration mode.
Step 4	hostname(config)# **class-map** *class_map_name* **Examples:** hostname(config)# class-map ime-outbound-sip	Defines a class for the outbound SIP traffic from Cisco Intercompany Media Engine.
Step 5	hostname(config)# **match access-list** *access_list_name* **Examples:** hostname(config-cmap)# match access-list ime-outbound-sip	Identifies which outbound SIP traffic to inspect. Where the *access_list_name* is the access list you created in Step 4, page 69-16 of the task Creating Access Lists for Cisco Intercompany Media Engine Proxy.
Step 6	hostname(config-cmap)# **exit**	Exits from the class map configuration mode.
Step 7	hostname(config)# **policy-map** *name* **Examples:** hostname(config)# policy-map ime-policy	Defines the policy map to which to attach the actions for the class of traffic.
Step 8	hostname(config-pmap)# **class** *classmap_name* **Examples:** hostname(config-pmap)# class ime-outbound-sip	Assigns a class map to the policy map so that you can assign actions to the class map traffic. Where *classmap_name* is the name of the SIP class map that you created in Step 1 in this task.
Step 9	hostname(config-pmap-c)# **inspect sip** [*sip_map*] **tls-proxy** *proxy_name* **uc-ime** *uc_ime_map* **Examples:** hostname(config-pmap-c)# inspect sip tls-proxy local_to_remote-ent uc-ime local-ent-ime	Enables the TLS proxy and Cisco Intercompany Media Engine Proxy for the specified SIP inspection session.
Step 10	hostname(config-cmap-c)# **exit**	Exits from the policy map class configuration mode.
Step 11	hostname(config-pmap)# **class** *class_map_name* **Examples:** hostname(config-pmap)# class ime-inbound-sip	Assigns a class map to the policy map so that you can assign actions to the class map traffic. Where *classmap_name* is the name of the SIP class map that you created in Step 4 in this task.
Step 12	hostname(config-pmap-c)# **inspect sip** [*sip_map*] **tls-proxy** *proxy_name* **uc-ime** *uc_ime_map* **Examples:** hostname(config-pmap-c)# inspect sip tls-proxy remote-to-local-ent uc-ime local-ent-ime	Enables the TLS proxy and Cisco Intercompany Media Engine Proxy for the specified SIP inspection session.
Step 13	hostname(config-pmap-c)# **exit**	Exits from the policy map class configuration mode.

	Command	Purpose
Step 14	`hostname(config-pmap)# exit`	Exits from the policy map configuration mode.

Step 15	`hostname(config)# service-policy policymap_name global`
	Examples:
	`hostname(config)# service-policy ime-policy global`
		Enables the service policy for SIP inspection for all interfaces.
		Where *policymap_name* is the name of the policy map you created in Step 7 of this task.
		See Creating the Cisco Intercompany Media Engine Proxy, page 69-18 for information about the UC-IME proxy settings. See CLI configuration guide for information about the **no service-policy** command.

What to Do Next

Once you have enabled the TLS proxy for SIP inspection, if necessary, configure TLS within the enterprise. See (Optional) Configuring TLS within the Local Enterprise, page 69-27.

(Optional) Configuring TLS within the Local Enterprise

This task is not required if TCP is allowable within the inside network.

TLS within the enterprise refers to the security status of the Cisco Intercompany Media Engine trunk as seen by the ASA.

Note If the transport security for the Cisco Intercompany Media Engine trunk changes on Cisco UCM, it must be changed on the ASA as well. A mismatch will result in call failure. The ASA does not support SRTP with non-secure IME trunks. The ASA assumes SRTP is allowed with secure trunks. So 'SRTP Allowed' must be checked for IME trunks if TLS is used. The ASA supports SRTP fallback to RTP for secure IME trunk calls.

Prerequisites

On the local Cisco UCM, download the Cisco UCM certificate. See the Cisco Unified Communications Manager documentation for information. You will need this certificate when performing Step 6 of this procedure.

Procedure

To configure TLS within the local enterprise, perform the following steps on the local ASA:

	Commands	Purpose
Step 1	hostname(config)# **crypto key generate rsa label** *key-pair-label* hostname(config)# **crypto ca trustpoint** *trustpoint_name* hostname(config-ca-trustpoint)# **enroll self** hostname(config-ca-trustpoint)# **keypair** *keyname* hostname(config-ca-trustpoint)# **subject-name** *x.500_name* **Example:** hostname(config)# crypto key generate rsa label local-ent-key hostname(config)# crypto ca trustpoint local-asa hostname(config-ca-trustpoint)# enroll self hostname(config-ca-trustpoint)# keypair key-local-asa hostname(config-ca-trustpoint)# subject-name *cn=Ent-local-domain-name***., o="Example Corp"	Creates an RSA key and trustpoint for the self-signed certificate. Where *key-pair-label* is the RSA key for the local ASA. Where *trustpoint_name* is the trustpoint for the local ASA. Where *keyname* is key pair for the local ASA. Where *x.500_name* includes the X.500 distinguished name of the local ASA; for example, *cn=Ent-local-domain-name***. **Note** The domain name that you enter here must match the domain name that has been set for the local Cisco UCM. For information about how to configure the domain name for Cisco UCM, see the Cisco Unified Communications Manager documentation for information.
Step 2	hostname(config-ca-trustpoint)# **exit**	Exits from Trustpoint Configuration mode.
Step 3	hostname(config)# **crypto ca export** *trustpoint* **identity-certificate** **Example:** hostname(config)# crypto ca export local-asa identity-certificate	Exports the certificate you created in Step 1. The certificate contents appear on the terminal screen. Copy the certificate from the terminal screen. This certificate enables Cisco UCM to validate the certificate that the ASA sends in the TLS handshake. On the local Cisco UCM, upload the certificate into the Cisco UCM trust store. See the Cisco Unified Communications Manager documentation for information. **Note** The subject name you enter while uploading the certificate to the local Cisco UCM is compared with the X.509 Subject Name field entered on the SIP Trunk Security Profile on Cisco UCM. For example, "Ent-local-domain-name" was entered in Step 1 of this task; therefore, "Ent-local-domain-name" should be entered in the Cisco UCM configuration.
Step 4	hostname(config)# **crypto ca trustpoint** *trustpoint_name* hostname(config-ca-trustpoint)# **enroll terminal** **Example:** hostname(config)# crypto ca trustpoint local-ent-ucm hostname(config-ca-trustpoint)# enroll terminal	Creates a trustpoint for local Cisco UCM. Where *trustpoint_name* is the trustpoint for the local Cisco UCM.
Step 5	hostname(config-ca-trustpoint)# **exit**	Exits from Trustpoint Configuration mode.

	Commands	Purpose
Step 6	hostname(config)# **crypto ca authenticate** *trustpoint* **Example:** hostname(config)# crypto ca authenticate local-ent-ucm	Imports the certificate from local Cisco UCM. Where *trustpoint* is the trustpoint for the local Cisco UCM. Paste the certificate downloaded from the local Cisco UCM. This certificate enables the ASA to validate the certificate that Cisco UCM sends in the TLS handshake.
Step 7	hostname(config)# **tls-proxy** *proxy_name* hostname(config-tlsp)# **server trust-point** *proxy_trustpoint* hostname(config-tlsp)# **client trust-point** *proxy_trustpoint* hostname(config-tlsp)# **client cipher-suite** aes128-sha1 aes256-sha1 3des-sha1 null-sha1 **Example:** hostname(config)# tls-proxy local_to_remote-ent hostname(config-tlsp)# server trust-point local-ent-ucm hostname(config-tlsp)# client trust-point local-ent hostname(config-tlsp)# client cipher-suite aes128-sha1 aes256-sha1 3des-sha1 null-sha1	Updates the TLS proxy for **outbound** connections. Where *proxy_name* is the name you entered in Step 1 of the task Creating the TLS Proxy. Where *proxy_trustpoint* for the **server trust-point** command is the name you entered in Step 4 of this procedure. Where *proxy_trustpoint* for the **client trust-point** command is the name you entered in Step 2 of the task Creating Trustpoints and Generating Certificates. **Note** In this step, you are creating different trustpoints for the client and the server.
Step 8	hostname(config-tlsp)# **exit**	Exits from TLS Proxy Configuration mode.
Step 9	hostname(config)# **tls-proxy** proxy_name hostname(config-tlsp)# **server trust-point** *proxy_trustpoint* hostname(config-tlsp)# **client trust-point** *proxy_trustpoint* hostname(config-tlsp)# **client cipher-suite** aes128-sha1 aes256-sha1 3des-sha1 null-sha1 **Example:** hostname(config)# tls-proxy remote_to_local-ent hostname(config-tlsp)# server trust-point local-ent hostname(config-tlsp)# client trust-point local-ent-ucm hostname(config-tlsp)# client cipher-suite aes128-sha1 aes256-sha1 3des-sha1 null-sha1	Updates the TLS proxy for **inbound** connections. Where *proxy_name* is the name you entered in Step 5 of the task Creating the TLS Proxy. Where *proxy_trustpoint* for the **server trust-point** command is the name you entered in Step 2 of the task Creating Trustpoints and Generating Certificates. Where *proxy_trustpoint* for the **client trust-point** command is the name you entered in Step 4 of this procedure.
Step 10	hostname(config-tlsp)# **exit**	Exits from TLS Proxy Configuration mode.
Step 11	hostname(config)# **uc-ime** *uc_ime_name* hostname(config-uc-ime)# **ucm address** *ip_address* **trunk-security-mode secure** **Example:** hostname(config)# uc-ime local-ent-ime hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode secure	Updates the Cisco Intercompany Media Engine Proxy for trunk-security-mode. Where *uc_ime_name* is the name you entered in Step 1 of the task Creating the Cisco Intercompany Media Engine Proxy. Only perform this step if you entered nonsecure in Step 3 of the task Creating the Cisco Intercompany Media Engine Proxy.

What to Do Next

Once you have configured the TLS within the enterprise, if necessary, configure off path signaling for an off path deployment. See (Optional) Configuring Off Path Signaling, page 69-30.

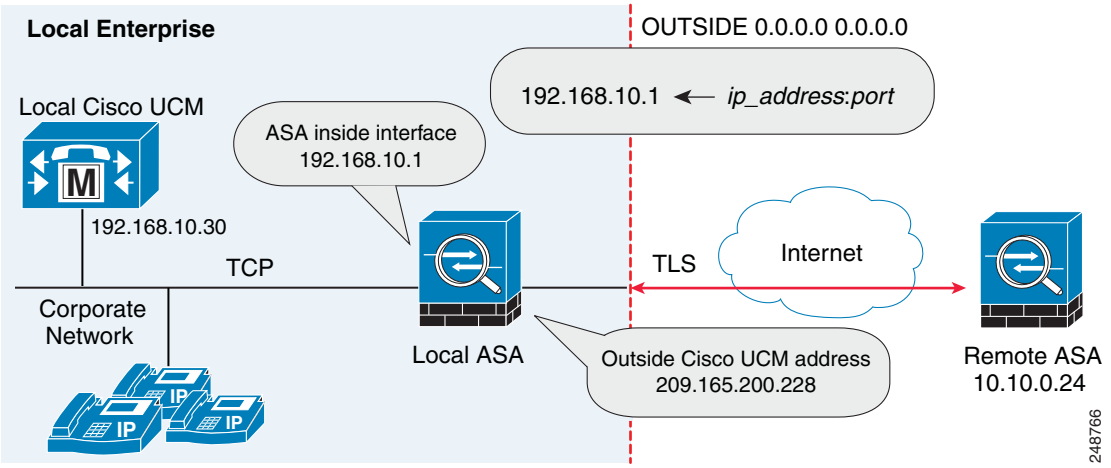
(Optional) Configuring Off Path Signaling

Perform this task only when you are configuring the Cisco Intercompany Media Engine Proxy as part of an off path deployment. You might choose to have an off path deployment when you want to use the Cisco Intercompany Media Engine but do not want to replace your existing Internet firewall with an ASA enabled with the Cisco Intercompany Media Engine Proxy.

In an off path deployment, the existing firewall that you have deployed in your environment is not capable of transmitting Cisco Intercompany Media Engine traffic.

Off path signaling requires that outside IP addresses translate to an inside IP address. The inside interface address can be used for this mapping service configuration. For the Cisco Intercompany Media Engine Proxy, the ASA creates dynamic mappings for external addresses to the internal IP address; therefore, using the dynamic NAT configuration on outbound calls, Cisco UCM sends SIP traffic to this internal IP address, and the ASA uses that mapping to determine the real destination on inbound calls. The static NAT or PAT mapping is used for inbound calls in an off path configuration.

Figure 69-9 Example for Configuring Off Path Signaling in an Off Path Deployment



After you configure off path signaling, the ASA mapping service listens on interface “inside” for requests. When it receives a request, it creates a dynamic mapping for the “outside” as the destination interface.

To configure off path signaling for the Cisco Intercompany Media Engine Proxy, perform the following steps:

	Command	Purpose
Step 1	`hostname(config)# object network` *name* **Example:** `hostname(config)# object network outside-any`	For the off path ASA, creates a network object to represent all outside addresses.
Step 2	`hostname(config-network-object)# subnet` *ip_address* **Example:** `hostname(config-network-object)# subnet 0.0.0.0 0.0.0.0`	Specifies the IP address of the subnet.
Step 3	`hostname(config-network-object)# nat (outside,inside) dynamic interface inside`	Creates a mapping for the Cisco UCM of remote enterprises.
Step 4	`hostname(config-network-object)# exit`	Exits from the objects configuration mode.

	Command	Purpose

Step 5	`hostname(config)# uc-ime uc_ime_name`
	Example:
	`hostname(config)# uc-ime local-ent-ime`
		Specifies the Cisco Intercompany Media Engine Proxy that you created in the task Creating the Cisco Intercompany Media Engine Proxy, page 69-18.
		Where *uc_ime_name* is the name you specified in Step 1 of Creating the Cisco Intercompany Media Engine Proxy, page 69-18.

Step 6	`hostname(config)# mapping-service listening-interface interface_name [listening-port port] uc-ime-interface uc-ime-interface_name`
	Example:
	`hostname(config-uc-ime)# mapping-service listening-interface inside listening-port 8060 uc-ime-interface outside`
		For the off path ASA, adds the mapping service to the Cisco Intercompany Media Engine Proxy.
		Specifies the interface and listening port for the ASA mapping service.
		You can only configure one mapping server for the Cisco Intercompany Media Engine Proxy.
		Where *interface_name* is the name of the interface on which the ASA listens for the mapping requests.
		Where port is the TCP port on which the ASA listens for the mapping requests. The port number must be between 1024 and 65535 to avoid conflicts with other services on the device, such as Telnet or SSH. By default, the port number is TCP 8060.
		Where *uc-ime-interface_name* is the name of the interface that connects to the remote Cisco UCM.

This section contains the following sections:

- Configuring the Cisco UC-IMC Proxy by using the UC-IME Proxy Pane, page 69-31
- Configuring the Cisco UC-IMC Proxy by using the Unified Communications Wizard, page 69-33

Configuring the Cisco UC-IMC Proxy by using the UC-IME Proxy Pane

Use the Configure Cisco Intercompany Media Engine (UC-IME) proxy pane to add or edit a Cisco Intercompany Media Engine Proxy instance.

Note The Cisco Intercompany Media Engine Proxy does not appear as an option under the Unified Communications section of the navigation pane unless the license required for this proxy is installed on the ASA.

Use this pane to create the proxy instance; however, for the UC-IME proxy to be fully functionally, you must complete additional tasks, such as create the required NAT statements, access lists, and MTA, set up the certificates, create the TLS Proxy, and enable SIP inspection.

Depending on whether the UC-IME proxy is deployed off path or in-line of Internet traffic, you must create the appropriate network objects with embedded NAT/PAT statements for the Cisco UCMs.

This pane is available from the Configuration > Firewall > Unified Communications > UC-IME Proxy.

Step 1 Open the Configuration > Firewall > Unified Communications > UC-IME Proxy pane.

Step 2 Check the Enable Cisco UC-IME proxy check box to enable the feature.

Step 3 In the Unified CM Servers area, enter an IP address or hostname for the Cisco Unified Communications Manager (Cisco UCM) or click the ellipsis to open a dialog and browse for an IP address or hostname.

Step 4 In the Trunk Security Mode field, click a security option. Specifying **secure** for Cisco UCM or Cisco UCM cluster indicates that Cisco UCM or Cisco UCM cluster is initiating TLS.

Step 5 Click **Add** to add the Cisco UCM for the Cisco Intercompany Media Engine Proxy. You must include an entry for each Cisco UCM in the cluster with Cisco Intercompany Media Engine that has a SIP trunk enabled.

Step 6 In the Ticket Epoch field, enter an integer from 1-255.

The epoch contains an integer that updates each time that the password is changed. When the proxy is configured the first time and a password entered for the first time, enter 1 for the epoch integer. Each time you change the password, increment the epoch to indicate the new password. You must increment the epoch value each time your change the password.

Typically, you increment the epoch sequentially; however, the ASA allows you to choose any value when you update the epoch.

If you change the epoch value, the current password is invalidated and you must enter a new password.

Note The epoch and password that you configure in this step on the ASA must match the epoch and password that you configure on the Cisco Intercompany Media Engine server. See the Cisco Intercompany Media Engine server documentation for information.

Step 7 In the Ticket Password field, enter a minimum of 10 printable character from the US-ASCII character set. The allowed characters include 0x21 to 0x73 inclusive, and exclude the space character. The ticket password can be up to 64 characters. Confirm the password you entered. Only one password can be configured at a time.

Step 8 Check the Apply MTA to UC-IME Link proxy check box to associate the media termination address with the Cisco Intercompany Media Engine Proxy.

Note You must create the media termination instance before you associate it with the Cisco Intercompany Media Engine Proxy. If necessary, click the Configure MTA button to configure a media termination address instance.

Step 9 If the Cisco Intercompany Media Engine Proxy is being configured as part of off path deployment, check the Enable off path address mapping service checkbox and configure the off path deployment settings:

a. From the Listening Interface field, select an ASA interface. This is the interface on which the ASA listens for the mapping requests.

b. In the Port field, enter a number between 1024 and 65535 as the TCP port on which the ASA listens for the mapping requests. The port number must be 1024 or higher to avoid conflicts with other services on the device, such as Telnet or SSH. By default, the port number is TCP 8060.

c. From the UC-IME Interface field, select an interface from the list. This is the interface that the ASA uses to connect to the remote Cisco UCM.

Note In an off path deployment any existing ASA that you have deployed in your environment are not capable of transmitting Cisco Intercompany Media Engine traffic. Off-path signaling requires that outside addresses are translated (using NAT) to an inside IP address. The inside interface address can be used for this mapping service configuration. For the Cisco Intercompany Media Engine Proxy, the ASA creates dynamic mappings for external addresses to the internal IP address.

Step 10 In the Fallback area, configure the fallback timer for the Cisco Intercompany Media Engine by specifying the following settings:

a. In the Fallback Sensitivity File field, enter the path to a file in flash memory that the ASA uses for mid-call PSTN fallback. The file name that you enter must be the name of a file on disk that includes the .fbs file extension. Alternatively, click the Browse Flash button to locate and select the file from flash memory.

b. In the Call Quality Evaluation Interval field, enter a number between 10-600 (in milliseconds). This number controls the frequency at which the ASA samples the RTP packets received from the Internet. The ASA uses the data sample to determine if fallback to the PSTN is needed for a call. By default, the length is 100 milliseconds for the timer.

c. In the Notification Interval field, enter a number between 10-360 (in seconds). This number controls the amount of time that the ASA waits before notifying Cisco UCM whether to fall back to PSTN. By default, the length is 20 seconds for this timer.

Note When you change the fallback timer for the Cisco Intercompany Media Engine Proxy, ASDM automatically removes the proxy from SIP inspection and then reapplies SIP inspection when the proxy is re-enabled.

Step 11 Click Apply to save the configuration changes for the Cisco Intercompany Media Engine Proxy.

Configuring the Cisco UC-IMC Proxy by using the Unified Communications Wizard

To configure the Cisco Intercompany Media Engine Proxy by using ASDM, choose Wizards > Unified Communications Wizard from the menu. The Unified Communications Wizard opens. From the first page, select the Cisco Intercompany Media Engine Proxy option under the Business-to-Business section.

The wizard automatically creates the necessary TLS proxy, then guides you through creating the Intercompany Media Engine proxy, importing and installing the required certificates, and finally enables the SIP inspection for the Intercompany Media Engine traffic automatically.

The wizard guides you through these steps to create the Cisco Intercompany Media Engine Proxy:

Step 1 Select the Intercompany Media Engine Proxy option.

Step 2 Select the topology of the Cisco Intercompany Media Engine Proxy, namely whether the ASA is an edge firewall with all Internet traffic flowing through it or whether the ASA is off the path of the main Internet traffic (referred to as an off path deployment).

Step 3 Specify private network settings such as the Cisco UCM IP addresses and the ticket settings.

Step 4 Specify the public network settings.

Step 5 Specify the media termination address settings of Cisco UCM.

Step 6 Configure the local-side certificate management, namely the certificates that are exchanged between the local Cisco Unified Communications Manager servers and the ASA. The identity certificate that the wizard generates in this step needs to be installed on each Cisco Unified Communications Manager (UCM) server in the cluster with the proxy and each identity certificate from the Cisco UCMs need to be installed on the ASA. The certificates are used by the ASA and the Cisco UCMs to authenticate each other, respectively, during TLS handshakes. The wizard only supports self-signed certificates for this step.

Step 7 Configure the remote-side certificate management, namely the certificates that are exchanged between the remote server and the ASA. In this step, the wizard generates a certificate signing request (CSR). After successfully generating the identity certificate request for the proxy, the wizard prompts you to save the file.

You must send the CSR text file to a certificate authority (CA), for example, by pasting the text file into the CSR enrollment page on the CA website. When the CA returns the Identity Certificate, you must install it on the ASA. This certificate is presented to remote servers so that they can authenticate the ASA as a trusted server.

Finally, this step of the wizard assists you in installing the root certificates of the CA from the remote servers so that the ASA can determine that the remote servers are trusted.

The wizard completes by displaying a summary of the configuration created for Cisco Intercompany Media Engine. See the Unified Communications Wizard section in this documentation for more information.

This section describes how to certain options of the **show uc-ime** command to obtain troubleshooting information for the Cisco Intercompany Media Engine Proxy. See the command reference for detailed information about the syntax for these commands.

show uc-ime signaling-sessions

Displays the corresponding SIP signaling sessions stored by the Cisco Intercompany Media Engine Proxy. Use this command to troubleshoot media or signaling failure. The command also displays the fallback parameters extracted from the SIP message headers, whether RTP monitoring is enabled or disabled, and whether SRTP keys are set.

Through the use of the Cisco Intercompany Media Engine Proxy, not only signaling but also media is secured for communication. It provides signaling encryption and SRTP/RTP conversion with SRTP enforced on the Internet side. The Cisco Intercompany Media Engine Proxy inserts itself into the media path by modifying the SIP signaling messages from Cisco UCMs.The Cisco Intercompany Media Engine Proxy sits on the edge of the enterprise and inspects SIP signaling between SIP trunks created between enterprises. It terminates TLS signaling from the Internet and initiates TCP or TLS to the local Cisco UCM.

```
hostname# show uc-ime signaling-sessions
 1 in use, 3 most used
 inside 192.168.10.30:39608 outside 10.194.108.118:5070
   Local Media (audio) conn: 10.194.108.119/29824 to 10.194.108.109/21558
     Local SRTP key set : Remote SRTP key set
   Remote Media (audio) conn: 192.168.10.51/19520 to 192.168.10.3/30930
   Call-ID: ab6d7980-a7d11b08-50-1e0aa8c0@192.168.10.30
   FB Sensitivity: 3
   Session ID: 2948-32325449-0@81a985c9-f3a1-55a0-3b19-96549a027259
```

```
SIP Trunk URI: 81a985c9-f3a1-55a0-3b19-9654@UCM-30;maddr=192.168.10.30
Codec-name: G722
Payload type: 9
```

Note If calls are not going through the Cisco Intercompany Media Engine, you can also use the **show tls-proxy session** command to troubleshoot the success of the TLS handshake between the components in the Cisco Intercompany Media Engine system. See the command reference for information about this command.

show uc-ime signaling-sessions statistics

Displays statistical information about corresponding signaling sessions stored by Cisco Intercompany Media Engine Proxy. Failure of signaling sessions in the Cisco Intercompany Media Engine can occur for different call-related reasons; such as failure of ticket verification or domain name verification, or offering RTP over the Internet.

```
hostname# show uc-ime signaling-sessions statistics
10 in use, 20 most used
15 terminated
  Ticket integrity check failed: 2
  Ticket decode failed: 1
  Ticket epoch mismatch: 1
  Ticket DID mismatch: 0
  Ticket timestamp invalid: 4
  Ticket domain check failed: 2
  Ticket not found: 0
  Route domain name check failed: 1
  RTP over UC-IME: 2
```

Note Call-related failures, for example, can be due to the service policy rule being reconfigured or the primary ASA operating in failover mode. If a service policy rule for the Cisco Intercompany Media Engine Proxy is removed (by using the **no service policy** command) and reconfigured, the first call trasversing the ASA will fail. To resolve this issue, you must additionally enter the **clear connection** command and restart the ASA. If the failure is due to failover, the connections from the primary ASA are not synchronized to the standby ASA.

show uc-ime media-sessions detail

Displays the details about all active media sessions (calls) stored for the Cisco Intercompany Media Engine Proxy. Use this command to display output from successful calls. Additionally, use this command to troubleshoot problems with IP phone audio, such as one-way audio. If no calls are currently up, this output will be blank.

```
hostname(config)# show uc-ime media-sessions detail

 Call ID: N/A
   Lcl RTP conn 192.168.10.3/30930 to 192.168.10.51/19520 tx_pkts 20201 rx_pkts 20203
```

show uc-ime fallback-notification statistics

Displays statistics about the PSTN fallback notifications to the Cisco UMC. Even if a call is sent over VoIP because the quality of the connection was good, the connection quality might worsen mid-call. To ensure an overall good experience for the end user, Cisco Intercompany Media Engine attempts to perform a mid-call fallback. Performing a mid-call fallback requires the adaptive security appliance to monitor the RTP packets coming from the Internet. If fallback is required, the adaptive security appliance sends a REFER message to Cisco UCM to tell it that it needs to fallback the call to PSTN.

Cisco Intercompany Media Engine uses a configurable hold-down timer to set the amount of time that adaptive security appliance waits before notifying Cisco UCM whether to fall back to PSTN.

```
hostname# show uc-ime fallback-notification statistics
UCM address: 172.23.32.37
 Total Notifications Sent: 10
```

show uc-ime mapping-service-sessions

When the Cisco Intercompany Media Engine Proxy is configured for an off path deployment, displays mapping-service requests and replies between the proxy and the local Cisco UMC. A TCP port on the ASA is configured to listen for mapping requests.

The port number must be 1024 or higher to avoid conflicts with other services on the device, such as Telnet or SSH. By default, the port number is TCP 8060.

```
Hostname# show uc-b2blink mapping-service-sessions
Total active sessions:  2
Session client (IP:Port)      Idle time
192.168.1.10:2001             0:01:01
192.168.1.20:3001             0:10:20
```

show uc-ime mapping-service-sessions statistics

Displays statistical information about the Cisco Intercompany Media Engine Proxy mapping service used in off path signaling.

```
Hostname# show uc-ime mapping-service-sessions statistics
Total active sessions:  2
Session client      Total       Responses   Failed      Pending     Idle
(IP:Port)           requests    sent        requests    responses   time
192.168.1.10:2001   10          9           1           0           0:01:01
192.168.1.20:3001   19          19          0           0           0:10:20
```

Feature History for Cisco Intercompany Media Engine Proxy

Table 69-1 lists the release history for this feature.

Table 69-1 Feature History for Cisco Phone Proxy

Feature Name	Releases	Feature Information
Cisco Intercompany Media Engine Proxy	8.3(1)	The Cisco Intercompany Media Engine Proxy was introduced. The following pane was added to the ASDM: Configuration > Firewall > Unified Communications > UC-IME Proxy The following wizard was added to ASDM, which allows you to configure the Unified Communication proxies (including the Cisco Intercompany Media Engine Proxy): Wizards > Unified Communications Wizard

PART 12

Configuring Connection Settings and QoS

Configuring Connection Settings

This chapter describes how to configure connection settings for connections that go through the ASA, or for management connections, that go to the ASA. Connection settings include:

- Maximum connections (TCP and UDP connections, embryonic connections, per-client connections)
- Connection timeouts
- Dead connection detection
- TCP sequence randomization
- TCP normalization customization
- TCP state bypass
- Global timeouts

This chapter includes the following sections:

- Information About Connection Settings, page 71-1
- Licensing Requirements for Connection Settings, page 71-4
- Guidelines and Limitations, page 71-5
- Default Settings, page 71-5
- Configuring Connection Settings, page 71-5
- Feature History for Connection Settings, page 71-11

Information About Connection Settings

This section describes why you might want to limit connections and includes the following topics:

- TCP Intercept and Limiting Embryonic Connections, page 71-2
- Disabling TCP Intercept for Management Packets for Clientless SSL Compatibility, page 71-2
- Dead Connection Detection (DCD), page 71-2
- TCP Sequence Randomization, page 71-3
- TCP Normalization, page 71-3
- TCP State Bypass, page 71-3

TCP Intercept and Limiting Embryonic Connections

Limiting the number of embryonic connections protects you from a DoS attack. The ASA uses the per-client limits and the embryonic connection limit to trigger TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. TCP Intercept uses the SYN cookies algorithm to prevent TCP SYN-flooding attacks. A SYN-flooding attack consists of a series of SYN packets usually originating from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests. When the embryonic connection threshold of a connection is crossed, the ASA acts as a proxy for the server and generates a SYN-ACK response to the client SYN request. When the ASA receives an ACK back from the client, it can then authenticate the client and allow the connection to the server.

Note When you use TCP SYN cookie protection to protect servers from SYN attacks, you must set the embryonic connection limit lower than the TCP SYN backlog queue on the server that you want to protect. Otherwise, valid clients can nolonger access the server during a SYN attack.

To view TCP Intercept statistics, including the top 10 servers under attack, see Chapter 77, “Configuring Threat Detection.”

Disabling TCP Intercept for Management Packets for Clientless SSL Compatibility

By default, TCP management connections have TCP Intercept always enabled. When TCP Intercept is enabled, it intercepts the 3-way TCP connection establishment handshake packets and thus deprives the ASA from processing the packets for clientless SSL. Clientless SSL requires the ability to process the 3-way handshake packets to provide selective ACK and other TCP options for clientless SSL connections. To disable TCP Intercept for management traffic, you can set the embryonic connection limit; only after the embryonic connection limit is reached is TCP Intercept enabled.

Dead Connection Detection (DCD)

DCD detects a dead connection and allows it to expire, without expiring connections that can still handle traffic. You configure DCD when you want idle, but valid connections to persist.

When you enable DCD, idle timeout behavior changes. With idle timeout, DCD probes are sent to each of the two end-hosts to determine the validity of the connection. If an end-host fails to respond after probes are sent at the configured intervals, the connection is freed, and reset values, if configured, are sent to each of the end-hosts. If both end-hosts respond that the connection is valid, the activity timeout is updated to the current time and the idle timeout is rescheduled accordingly.

Enabling DCD changes the behavior of idle-timeout handling in the TCP normalizer. DCD probing resets the idle timeout on the connections seen in the **show conn** command. To determine when a connection that has exceeded the configured timeout value in the timeout command but is kept alive due to DCD probing, the **show service-policy** command includes counters to show the amount of activity from DCD.

TCP Sequence Randomization

Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predecting the next ISN for a new connection and potentially hijacking the new session.

TCP initial sequence number randomization can be disabled if required. For example:

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.

TCP Normalization

The TCP normalization feature identifies abnormal packets that the ASA can act on when they are detected; for example, the ASA can allow, drop, or clear the packets. TCP normalization helps protect the ASA from attacks. TCP normalization is always enabled, but you can customize how some features behave.

The TCP normalizer includes non-configurable actions and configurable actions. Typically, non-configurable actions that drop or clear connections apply to packets that are always bad. Configurable actions (as detailed in "Customizing the TCP Normalizer with a TCP Map" section on page 71-6) might need to be customized depending on your network needs.

See the following guidelines for TCP normalization:

- The normalizer does not protect from SYN floods. The ASA includes SYN flood protection in other ways.
- The normalizer always sees the SYN packet as the first packet in a flow unless the ASA is in loose mode due to failover.

TCP State Bypass

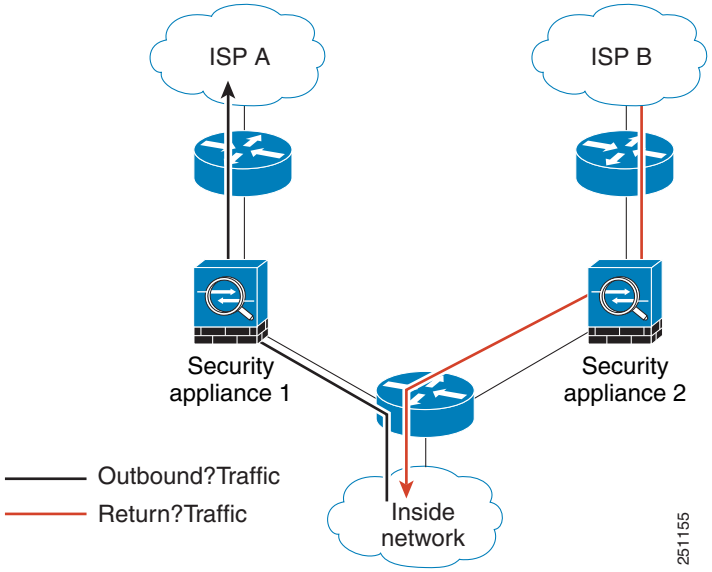
By default, all traffic that goes through the ASA is inspected using the Adaptive Security Algorithm and is either allowed through or dropped based on the security policy. The ASA maximizes the firewall performance by checking the state of each packet (is this a new connection or an established

connection?) and assigning it to either the session management path (a new connection SYN packet), the fast path (an established connection), or the control plane path (advanced inspection). See the "Stateful Inspection Overview" section on page 1-24 for more detailed information about the stateful firewall.

TCP packets that match existing connections in the fast path can pass through the ASA without rechecking every aspect of the security policy. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), can stand in the way of asymmetrical routing solutions: both the outbound and inbound flow of a connection must pass through the same ASA.

For example, a new connection goes to ASA 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through ASA 1, then the packets will match the entry in the fast path, and are passed through. But if subsequent packets go to ASA 2, where there was not a SYN packet that went through the session management path, then there is no entry in the fast path for the connection, and the packets are dropped. Figure 71-1 shows an asymmetric routing example where the outbound traffic goes through a different ASA than the inbound traffic:

Figure 71-1 Asymmetric Routing



If you have asymmetric routing configured on upstream routers, and traffic alternates between two ASAs, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic much as it treats a UDP connection: when a non-SYN packet matching the specified networks enters the ASA, and there is not an fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Licensing Requirements for Connection Settings

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the following guidelines and limitations:

- TCP State Bypass Guidelines and Limitations, page 71-5

TCP State Bypass Guidelines and Limitations

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent mode.

Failover Guidelines

Failover is supported.

Unsupported Features

The following features are not supported when you use TCP state bypass:

- Application inspection—Application inspection requires both inbound and outbound traffic to go through the same ASA, so application inspection is not supported with TCP state bypass.
- AAA authenticated sessions—When a user authenticates with one ASA, traffic returning via the other ASA will be denied because the user did not authenticate with that ASA.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The ASA does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- SSM and SSC functionality—You cannot use TCP state bypass and any application running on an SSM or SSC, such as IPS or CSC.

NAT Guidelines

Because the translation session is established separately for each ASA, be sure to configure static NAT on both ASAs for TCP state bypass traffic; if you use dynamic NAT, the address chosen for the session on ASA 1 will differ from the address chosen for the session on ASA 2.

Default Settings

TCP State Bypass

TCP state bypass is disabled by default.

Configuring Connection Settings

This section includes the following topics:

- Customizing the TCP Normalizer with a TCP Map, page 71-6
- Configuring Connection Settings, page 71-8
- Configuring Global Timeouts, page 71-9

Task Flow For Configuring Configuration Settings (Except Global Timeouts)

Step 1 For TCP normalization customization, create a TCP map according to the "Customizing the TCP Normalizer with a TCP Map" section on page 71-6.

Step 2 For all connection settings except for global timeouts, configure a service policy according to Chapter 44, "Configuring a Service Policy."

Step 3 Configure connection settings according to the "Configuring Connection Settings" section on page 71-8.

Customizing the TCP Normalizer with a TCP Map

To customize the TCP normalizer, first define the settings using a TCP map.

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Objects > TCP Maps** pane, and click **Add**.

The Add TCP Map dialog box appears.

Step 2 In the TCP Map Name field, enter a name.

Step 3 In the Queue Limit field, enter the maximum number of out-of-order packets, between 0 and 250 packets.

The Queue Limit sets the maximum number of out-of-order packets that can be buffered and put in order for a TCP connection. The default is 0, which means this setting is disabled and the default system queue limit is used depending on the type of traffic:

- Connections for application inspection, IPS, and TCP check-retransmission have a queue limit of 3 packets. If the ASA receives a TCP packet with a different window size, then the queue limit is dynamically changed to match the advertised setting.
- For other TCP connections, out-of-order packets are passed through untouched.

If you set the Queue Limit to be 1 or above, then the number of out-of-order packets allowed for all TCP traffic matches this setting. For example, for application inspection, IPS, and TCP check-retransmission traffic, any advertised settings from TCP packets are ignored in favor of the Queue Limit setting. For other TCP traffic, out-of-order packets are now buffered and put in order instead of passed through untouched.

Step 4 In the Timeout field, set the maximum amount of time that out-of-order packets can remain in the buffer, between 1 and 20 seconds.

If they are not put in order and passed on within the timeout period, then they are dropped. The default is 4 seconds. You cannot change the timeout for any traffic if the Queue Limit is set to 0; you need to set the limit to be 1 or above for the Timeout to take effect.

Step 5 In the Reserved Bits area, click **Clear and allow**, **Allow only**, or **Drop**.

Allow only allows packets with the reserved bits in the TCP header.

Clear and allow clears the reserved bits in the TCP header and allows the packet.

Drop drops the packet with the reserved bits in the TCP header.

Step 6 Check any of the following options:

- Clear urgent flag—Clears the URG flag through the ASA. The URG flag is used to indicate that the packet contains information that is of higher priority than other data within the stream. The TCP RFC is vague about the exact interpretation of the URG flag, therefore end systems handle urgent offsets in different ways, which may make the end system vulnerable to attacks.
- Drop connection on window variation—Drops a connection that has changed its window size unexpectedly. The window size mechanism allows TCP to advertise a large window and to subsequently advertise a much smaller window without having accepted too much data. From the TCP specification, "shrinking the window" is strongly discouraged. When this condition is detected, the connection can be dropped.
- Drop packets that exceed maximum segment size—Drops packets that exceed MSS set by peer.
- Check if transmitted data is the same as original—Enables the retransmit data checks.
- Drop packets which have past-window sequence—Drops packets that have past-window sequence numbers, namely the sequence number of a received TCP packet is greater than the right edge of the TCP receiving window. If you do not check this option, then the Queue Limit must be set to 0 (disabled).
- Drop SYN Packets with data—Drops SYN packets with data.
- Enable TTL Evasion Protection—Enables the TTL evasion protection offered by the ASA. Do not enable this option if you want to prevent attacks that attempt to evade security policy.
- For example, an attacker can send a packet that passes policy with a very short TTL. When the TTL goes to zero, a router between the ASA and the endpoint drops the packet. It is at this point that the attacker can send a malicious packet with a long TTL that appears to the ASA to be a retransmission and is passed. To the endpoint host, however, it is the first packet that has been received by the attacker. In this case, an attacker is able to succeed without security preventing the attack.
- Verify TCP Checksum—Enables checksum verification.
- Drop SYNACK Packets with data—Drops TCP SYNACK packets that contain data.
- Drop packets with invalid ACK—Drops packets with an invalid ACK. You might see invalid ACKs in the following instances:
  - In the TCP connection SYN-ACK-received status, if the ACK number of a received TCP packet is not exactly same as the sequence number of the next TCP packet sending out, it is an invalid ACK.
  - Whenever the ACK number of a received TCP packet is greater than the sequence number of the next TCP packet sending out, it is an invalid ACK.

Note TCP packets with an invalid ACK are automatically allowed for WAAS connections.

Step 7 To set TCP options, check any of the following options:

- Clear Selective Ack—Sets whether the selective-ack TCP option is allowed or cleared.
- Clear TCP Timestamp—Sets whether the TCP timestamp option is allowed or cleared.
- Clear Window Scale—Sets whether the window scale timestamp option is allowed or cleared.
- Range—Sets the valid TCP options ranges, which should fall within 6-7 and 9-255. The lower bound should be less than or equal to the upper bound. Choose **Allow** or **Drop** for each range.

Step 8 Click **OK**.

Configuring Connection Settings

To set connection settings, perform the following steps.

Guidelines and Limitations

Depending on the number of CPU cores on your ASA model, the maximum concurrent and embryonic connections may exceed the configured numbers due to the way each core manages connections. In the worst case scenario, the ASA allows up to *n*-1 extra connections and embryonic connections, where *n* is the number of cores. For example, if your model has 4 cores, if you configure 6 concurrent connections and 4 embryonic connections, you could have an additional 3 of each type. To determine the number of cores for your model, enter the **show cpu core** command.

Detailed Steps

Step 1 Configure a service policy on the Configuration > Firewall > Service Policy Rules pane according to Chapter 44, "Configuring a Service Policy."

You can configure connection limits as part of a new service policy rule, or you can edit an existing service policy.

Step 2 On the Rule Actions dialog box, click the **Connection Settings** tab.

Step 3 To set maximum connections, configure the following values in the Maximum Connections area:

- TCP & UDP Connections—Specifies the maximum number of simultaneous TCP and UDP connections for all clients in the traffic class, up to 2000000. The default is 0 for both protocols, which means the maximum possible connections are allowed.
- Embryonic Connections—Specifies the maximum number of embryonic connections per host up to 2000000. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is **0**, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.
- Per Client Connections—Specifies the maximum number of simultaneous TCP and UDP connections for each client up to 2000000. When a new connection is attempted by a client that already has opened the maximum per-client number of connections, the ASA rejects the connection and drops the packet.
- Per Client Embryonic Connections—Specifies the maximum number of simultaneous TCP embryonic connections for each client up to 2000000. When a new TCP connection is requested by a client that already has the maximum per-client number of embryonic connections open through the ASA, the ASA proxies the request to the TCP Intercept feature, which prevents the connection.

Step 4 To configure connection timeouts, configure the following values in the TCP Timeout area:

- Connection Timeout—Specifies the idle time until a connection slot (of *any* protocol, not just TCP) is freed. Enter 0:0:0 to disable timeout for the connection. This duration must be at least 5 minutes. The default is 1 hour.
- Send reset to TCP endpoints before timeout—Specifies that the ASA should send a TCP reset message to the endpoints of the connection before freeing the connection slot.
- Embryonic Connection Timeout—Specifies the idle time until an embryonic connection slot is freed. Enter 0:0:0 to disable timeout for the connection. The default is 30 seconds.
- Half Closed Connection Timeout—Specifies the idle time until a half closed connection slot is freed. Enter 0:0:0 to disable timeout for the connection. This duration must be at least 5 minutes. The default is 10 minutes.

Step 5 To disable randomized sequence numbers, uncheck **Randomize Sequence Number**.

TCP initial sequence number randomization can be disabled if another in-line firewall is also randomizing the initial sequence numbers, because there is no need for both firewalls to be performing this action. However, leaving ISN randomization enabled on both firewalls does not affect the traffic.

Each TCP connection has two ISNs: one generated by the client and one generated by the server. The security appliance randomizes the ISN of the TCP SYN passing in the outbound direction. If the connection is between two interfaces with the same security level, then the ISN will be randomized in the SYN in both directions.

Randomizing the ISN of the protected host prevents an attacker from predecting the next ISN for a new connection and potentially hijacking the new session.

Step 6 To configure TCP normalization, check **Use TCP Map**. Choose an existing TCP map from the drop-down list (if available), or add a new one by clicking **New**.

The Add TCP Map dialog box appears. See the "Customizing the TCP Normalizer with a TCP Map" section on page 71-6.

Step 7 Click **OK**.

Step 8 To set the time to live, check **Decrement time to live for a connection**.

Step 9 To enable TCP state bypass, in the Advanced Options area, check **TCP State Bypass**.

Step 10 Click **OK** or **Finish**.

Configuring Global Timeouts

The Configuration > Firewall > Advanced > Global Timeouts pane lets you set the timeout durations for use with the ASA. All durations are displayed in the format *hh*:*mm*:*ss*. It sets the idle time for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool. TCP connection slots are freed approximately 60 seconds after a normal connection close sequence.

Fields

In all cases, except for Authentication absolute and Authentication inactivity, unchecking the check boxes means there is no timeout value. For those two cases, clearing the check box means to reauthenticate on every new connection.

- Connection—Modifies the idle time until a connection slot is freed. Enter 0:0:0 to disable timeout for the connection. This duration must be at least 5 minutes. The default is 1 hour.

- Half-closed—Modifies the idle time until a TCP half-closed connection closes. The minimum is 5 minutes. The default is 10 minutes. Enter 0:0:0 to disable timeout for a half-closed connection.
- UDP—Modifies the idle time until a UDP protocol connection closes. This duration must be at least 1 minute. The default is 2 minutes. Enter 0:0:0 to disable timeout.
- ICMP—Modifies the idle time after which general ICMP states are closed.
- H.323—Modifies the idle time until an H.323 media connection closes. The default is 5 minutes. Enter 0:0:0 to disable timeout.
- H.225—Modifies the idle time until an H.225 signaling connection closes. The H.225 default timeout is 1 hour (1:0:0). Setting the value of 0:0:0 means never close this connection. To close this connection immediately after all calls are cleared, a value of 1 second (0:0:1) is recommended.
- MGCP—Modifies the timeout value for MGCP which represents the idle time after which MGCP media ports are closed. The MGCP default timeout is 5 minutes (0:5:0). Enter 0:0:0 to disable timeout.
- MGCP PAT—Modifies the idle time after which an MGCP PAT translation is removed. The default is 5 minutes (0:5:0). The minimum time is 30 seconds. Uncheck the check box to return to the default value.
- TCP Proxy Reassembly—Configures the idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
- Floating Connection—When multiple static routes exist to a network with different metrics, the ASA uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To take advantage of this feature, change the timeout to a new value between 0:1:0 and 1193:0:0.
- SUNRPC—Modifies the idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes. Enter 0:0:0 to disable timeout.
- SIP—Modifies the idle time until an SIP signalling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.
- SIP Media—Modifies the idle time until an SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- SIP Provisional Media—Modifies the timeout value for SIP provisional media connections, between 0:1:0 and 1193:0:0. The default is 2 minutes.
- SIP Invite—Modifies the idle time after which pinholes for PROVISIONAL responses and media xlates will be closed. The minimum value is 0:1:0, the maximum value is 0:30:0. The default value is 0:3:0.
- SIP Disconnect—Modifies the idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message. The minimum value is 0:0:1, the maximum value is 0:10:0. The default value is 0:2:0.
- Authentication absolute—Modifies the duration until the authentication cache times out and you have to reauthenticate a new connection. This duration must be shorter than the Translation Slot value. The system waits until you start a new connection to prompt you again. Enter 0:0:0 to disable caching and reauthenticate on every new connection.

Note Do not set this value to 0:0:0 if passive FTP is used on the connections.

Note When Authentication Absolute = 0, HTTPS authentication may not work. If a browser initiates multiple TCP connections to load a web page after HTTPS authentication, the first connection is permitted through, but subsequent connections trigger authentication. As a result, users are continuously presented with an authentication page, even after successful authentication. To work around this, set the authentication absolute timeout to 1 second. This workaround opens a 1-second window of opportunity that might allow non-authenticated users to go through the firewall if they are coming from the same source IP address.

- Authentication inactivity—Modifies the idle time until the authentication cache times out and users have to reauthenticate a new connection. This duration must be shorter than the Translation Slot value.
- Translation Slot—Modifies the idle time until a translation slot is freed. This duration must be at least 1 minute. The default is 3 hours. Enter 0:0:0 to disable the timeout.
- (8.4(3) and later, not including 8.5(1) and 8.6(1)) PAT Translation Slot—Modifies the idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.

Feature History for Connection Settings

Table 71-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 71-1 Feature History for Connection Settings

Feature Name	Platform Releases	Feature Information
TCP state bypass	8.2(1)	This feature was introduced. The following command was introduced: **set connection advanced-options tcp-state-bypass**.
Connection timeout for all protocols	8.2(2)	The idle timeout was changed to apply to all protocols, not just TCP. The following screen was modified: Configuration > Firewall > Service Policies > Rule Actions > Connection Settings.
Timeout for connections using a backup static route	8.2(5)/8.4(2)	When multiple static routes exist to a network with different metrics, the ASA uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To take advantage of this feature, change the timeout to a new value. We modified the following screen: Configuration > Firewall > Advanced > Global Timeouts.

Table 71-1 Feature History for Connection Settings (continued)

Feature Name	Platform Releases	Feature Information
Configurable timeout for PAT xlate	8.4(3)	When a PAT xlate times out (by default after 30 seconds), and the ASA reuses the port for a new translation, some upstream routers might reject the new connection because the previous connection might still be open on the upstream device. The PAT xlate timeout is now configurable, to a value between 30 seconds and 5 minutes. We modified the following screen: Configuration > Firewall > Advanced > Global Timeouts. *This feature is not available in 8.5(1) or 8.6(1).*
Increased maximum connection limits for service policy rules	9.0(1)	The maximum number of connections for service policy rules was increased from 65535 to 2000000. We modified the following screen: Configuration > Firewall > Service Policy Rules > Connection Settings.

Configuring QoS

Have you ever participated in a long-distance phone call that involved a satellite connection? The conversation might be interrupted with brief, but perceptible, gaps at odd intervals. Those gaps are the time, called the latency, between the arrival of packets being transmitted over the network. Some network traffic, such as voice and video, cannot tolerate long latency times. Quality of service (QoS) is a feature that lets you give priority to critical traffic, prevent bandwidth hogging, and manage network bottlenecks to prevent packet drops.

Note For the ASASM, we suggest performing QoS on the switch instead of the ASASM. Switches have more capability in this area.

This chapter describes how to apply QoS policies and includes the following sections:

- Information About QoS, page 72-1
- Licensing Requirements for QoS, page 72-5
- Guidelines and Limitations, page 72-5
- Configuring QoS, page 72-6
- Monitoring QoS, page 72-11
- Feature History for QoS, page 72-14

Information About QoS

You should consider that in an ever-changing network environment, QoS is not a one-time deployment, but an ongoing, essential part of network design.

This section describes the QoS features supported by the ASA and includes the following topics:

- Supported QoS Features, page 72-2
- What is a Token Bucket?, page 72-2
- Information About Policing, page 72-3
- Information About Priority Queuing, page 72-3
- Information About Traffic Shaping, page 72-4
- DSCP and DiffServ Preservation, page 72-5

Supported QoS Features

The ASA supports the following QoS features:

- Policing—To prevent individual flows from hogging the network bandwidth, you can limit the maximum bandwidth used per flow. See the "Information About Policing" section on page 72-3 for more information.
- Priority queuing—For critical traffic that cannot tolerate latency, such as Voice over IP (VoIP), you can identify traffic for Low Latency Queuing (LLQ) so that it is always transmitted ahead of other traffic. See the "Information About Priority Queuing" section on page 72-3 for more information.
- Traffic shaping—If you have a device that transmits packets at a high speed, such as a ASA with Fast Ethernet, and it is connected to a low speed device such as a cable modem, then the cable modem is a bottleneck at which packets are frequently dropped. To manage networks with differing line speeds, you can configure the ASA to transmit packets at a fixed slower rate. See the "Information About Traffic Shaping" section on page 72-4 for more information.

What is a Token Bucket?

A token bucket is used to manage a device that regulates the data in a flow. For example, the regulator might be a traffic policer or a traffic shaper. A token bucket itself has no discard or priority policy. Rather, a token bucket discards tokens and leaves to the flow the problem of managing its transmission queue if the flow overdrives the regulator.

A token bucket is a formal definition of a rate of transfer. It has three components: a burst size, an average rate, and a time interval. Although the average rate is generally represented as bits per second, any two values may be derived from the third by the relation shown as follows:

average rate = burst size / time interval

Here are some definitions of these terms:

- Average rate—Also called the committed information rate (CIR), it specifies how much data can be sent or forwarded per unit time on average.
- Burst size—Also called the Committed Burst (Bc) size, it specifies in bits or bytes per burst how much traffic can be sent within a given unit of time to not create scheduling concerns. (For traffic shaping, it specifies bits per burst; for policing, it specifies bytes per burst.)
- Time interval—Also called the measurement interval, it specifies the time quantum in seconds per burst.

In the token bucket metaphor, tokens are put into the bucket at a certain rate. The bucket itself has a specified capacity. If the bucket fills to capacity, newly arriving tokens are discarded. Each token is permission for the source to send a certain number of bits into the network. To send a packet, the regulator must remove from the bucket a number of tokens equal in representation to the packet size.

If not enough tokens are in the bucket to send a packet, the packet either waits until the bucket has enough tokens (in the case of traffic shaping) or the packet is discarded or marked down (in the case of policing). If the bucket is already full of tokens, incoming tokens overflow and are not available to future packets. Thus, at any time, the largest burst a source can send into the network is roughly proportional to the size of the bucket.

Note that the token bucket mechanism used for traffic shaping has both a token bucket and a data buffer, or queue; if it did not have a data buffer, it would be a policer. For traffic shaping, packets that arrive that cannot be sent immediately are delayed in the data buffer.

For traffic shaping, a token bucket permits burstiness but bounds it. It guarantees that the burstiness is bounded so that the flow will never send faster than the token bucket capacity, divided by the time interval, plus the established rate at which tokens are placed in the token bucket. See the following formula:

(token bucket capacity in bits / time interval in seconds) + established rate in bps = maximum flow speed in bps

This method of bounding burstiness also guarantees that the long-term transmission rate will not exceed the established rate at which tokens are placed in the bucket.

Information About Policing

Policing is a way of ensuring that no traffic exceeds the maximum rate (in bits/second) that you configure, thus ensuring that no one traffic flow or class can take over the entire resource. When traffic exceeds the maximum rate, the ASA drops the excess traffic. Policing also sets the largest single burst of traffic allowed.

Information About Priority Queuing

LLQ priority queuing lets you prioritize certain traffic flows (such as latency-sensitive traffic like voice and video) ahead of other traffic.

The ASA supports two types of priority queuing:

- Standard priority queuing—Standard priority queuing uses an LLQ priority queue on an interface (see the "Configuring the Standard Priority Queue for an Interface" section on page 72-8), while all other traffic goes into the "best effort" queue. Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped. This is called *tail drop*. To avoid having the queue fill up, you can increase the queue buffer size. You can also fine-tune the maximum number of packets allowed into the transmit queue. These options let you control the latency and robustness of the priority queuing. Packets in the LLQ queue are always transmitted before packets in the best effort queue.
- Hierarchical priority queuing—Hierarchical priority queuing is used on interfaces on which you enable a traffic shaping queue. A subset of the shaped traffic can be prioritized. The standard priority queue is not used. See the following guidelines about hierarchical priority queuing:
  - Priority packets are always queued at the head of the shape queue so they are always transmitted ahead of other non-priority queued packets.
  - Priority packets are never dropped from the shape queue unless the sustained rate of priority traffic exceeds the shape rate.
  - For IPsec-encrypted packets, you can only match traffic based on the DSCP or precedence setting.
  - IPsec-over-TCP is not supported for priority traffic classification.

Information About Traffic Shaping

Traffic shaping is used to match device and link speeds, thereby controlling packet loss, variable delay, and link saturation, which can cause jitter and delay.

Note Traffic shaping is not supported on the ASA 5580.

- Traffic shaping must be applied to all outgoing traffic on a physical interface or in the case of the ASA 5505 or ASASM, on a VLAN. You cannot configure traffic shaping for specific types of traffic.
- Traffic shaping is implemented when packets are ready to be transmitted on an interface, so the rate calculation is performed based on the actual size of a packet to be transmitted, including all the possible overhead such as the IPsec header and L2 header.
- The shaped traffic includes both through-the-box and from-the-box traffic.
- The shape rate calculation is based on the standard token bucket algorithm. The token bucket size is twice the Burst Size value. See the "What is a Token Bucket?" section on page 72-2.
- When bursty traffic exceeds the specified shape rate, packets are queued and transmitted later. Following are some characteristics regarding the shape queue (for information about hierarchical priority queuing, see the "Information About Priority Queuing" section on page 72-3):
  - The queue size is calculated based on the shape rate. The queue can hold the equivalent of 200-milliseconds worth of shape rate traffic, assuming a 1500-byte packet. The minimum queue size is 64.
  - When the queue limit is reached, packets are tail-dropped.
  - Certain critical keep-alive packets such as OSPF Hello packets are never dropped.
  - The time interval is derived by *time_interval* = *burst_size* / *average_rate*. The larger the time interval is, the burstier the shaped traffic might be, and the longer the link might be idle. The effect can be best understood using the following exaggerated example:

    Average Rate = 1000000

    Burst Size = 1000000

    In the above example, the time interval is 1 second, which means, 1 Mbps of traffic can be bursted out within the first 10 milliseconds of the 1-second interval on a 100 Mbps FE link and leave the remaining 990 milliseconds idle without being able to send any packets until the next time interval. So if there is delay-sensitive traffic such as voice traffic, the Burst Size should be reduced compared to the average rate so the time interval is reduced.

How QoS Features Interact

You can configure each of the QoS features alone if desired for the ASA. Often, though, you configure multiple QoS features on the ASA so you can prioritize some traffic, for example, and prevent other traffic from causing bandwidth problems.

See the following supported feature combinations per interface:

- Standard priority queuing (for specific traffic) + Policing (for the rest of the traffic).

  You cannot configure priority queuing and policing for the same set of traffic.
- Traffic shaping (for all traffic on an interface) + Hierarchical priority queuing (for a subset of traffic).

You cannot configure traffic shaping and standard priority queuing for the same interface; only hierarchical priority queuing is allowed. For example, if you configure standard priority queuing for the global policy, and then configure traffic shaping for a specific interface, the feature you configured last is rejected because the global policy overlaps the interface policy.

Typically, if you enable traffic shaping, you do not also enable policing for the same traffic, although the ASA does not restrict you from configuring this.

DSCP and DiffServ Preservation

- DSCP markings are preserved on all traffic passing through the ASA.
- The ASA does not locally mark/remark any classified traffic, but it honors the Expedited Forwarding (EF) DSCP bits of every packet to determine if it requires “priority” handling and will direct those packets to the LLQ.
- DiffServ marking is preserved on packets when they traverse the service provider backbone so that QoS can be applied in transit (QoS tunnel pre-classification).

Licensing Requirements for QoS

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single context mode only. Does not support multiple context mode.

Firewall Mode Guidelines

Supported in routed firewall mode only. Does not support transparent firewall mode.

IPv6 Guidelines

Does not support IPv6.

Model Guidelines

- (Multi-processor models, such as the ASA 5500-X, ASA 5580, ASA 5585-X, and ASASM) Traffic shaping is not supported.
- (ASA 5580) You cannot create a standard priority queue for a Ten Gigabit Ethernet interface. **Note**: For the ASA 5585-X, standard priority queuing is supported on a Ten Gigabit Interface.

- (ASA 5512-X through ASA 5555-X) Priority queuing is not supported on the Management 0/0 interface.
- (ASASM) Only policing is supported.

Additional Guidelines and Limitations

- QoS is applied unidirectionally; only traffic that enters (or exits, depending on the QoS feature) the interface to which you apply the policy map is affected. See the "Feature Directionality" section on page 38-3 for more information.
- For traffic shaping, you can only use the **class-default** class map, which is automatically created by the ASA, and which matches all traffic.
- For priority traffic, you cannot use the **class-default** class map.
- For hierarchical priority queuing, for encrypted VPN traffic, you can only match traffic based on the DSCP or precedence setting; you cannot match a tunnel group.
- For hierarchical priority queuing, IPsec-over-TCP traffic is not supported.
- You cannot configure traffic shaping and standard priority queuing for the same interface; only hierarchical priority queuing is allowed.
- For standard priority queuing, the queue must be configured for a physical interface or, for the ASA 5505 or ASASM, a VLAN.
- For policing, to-the-box traffic is not supported.
- For policing, traffic to and from a VPN tunnel bypass interface is not supported.
- For policing, when you match a tunnel group class map, only outbound policing is supported.

Configuring QoS

This section includes the following topics:

- Determining the Queue and TX Ring Limits for a Standard Priority Queue, page 72-7
- Configuring the Standard Priority Queue for an Interface, page 72-8
- Configuring a Service Rule for Standard Priority Queuing and Policing, page 72-9
- Configuring a Service Rule for Traffic Shaping and Hierarchical Priority Queuing, page 72-10

Determining the Queue and TX Ring Limits for a Standard Priority Queue

To determine the priority queue and TX ring limits, use the worksheets below.

Table 72-1 shows how to calculate the priority queue size. Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped (called *tail drop*). To avoid having the queue fill up, you can adjust the queue buffer size according to the "Configuring the Standard Priority Queue for an Interface" section on page 72-8.

Table 72-1 Queue Limit Worksheet

Step 1	_____ *Outbound bandwidth (Mbps or Kbps)*[1]	Mbps	x	**125**	=	_____ *# of bytes/ms*		
		Kbps	x	**.125**	=	_____ *# of bytes/ms*		
Step 2	_____ *# of bytes/ms from Step 1*	÷	_____ *Average packet size (bytes)*[2]	x	_____ *Delay (ms)*[3]	=	_____ *Queue limit (# of packets)*	

1. For example, DSL might have an uplink speed of 768 Kbps. Check with your provider.
2. Determine this value from a codec or sampling size. For example, for VoIP over VPN, you might use 160 bytes. We recommend 256 bytes if you do not know what size to use.
3. The delay depends on your application. For example, the recommended maximum delay for VoIP is 200 ms. We recommend 500 ms if you do not know what delay to use.

Table 72-2 shows how to calculate the TX ring limit. This limit determines the maximum number of packets allowed into the Ethernet transmit driver before the driver pushes back to the queues on the interface to let them buffer packets until the congestion clears. This setting guarantees that the hardware-based transmit ring imposes a limited amount of extra latency for a high-priority packet.

Table 72-2 TX Ring Limit Worksheet

Step 1	_____ *Outbound bandwidth (Mbps or Kbps)*[1]	Mbps	x	**125**	=	_____ *# of bytes/ms*		
		Kbps	x	**0.125**	=	_____ *# of bytes/ms*		
Step 2	_____ *# of bytes/ms from Step 1*	÷	_____ *Maximum packet size (bytes)*[2]	x	_____ *Delay (ms)*[3]	=	_____ *TX ring limit (# of packets)*	

1. For example, DSL might have an uplink speed of 768 Kbps.Check with your provider.

2. Typically, the maximum size is 1538 bytes, or 1542 bytes for tagged Ethernet. If you allow jumbo frames (if supported for your platform), then the packet size might be larger.
3. The delay depends on your application. For example, to control jitter for VoIP, you should use 20 ms.

Configuring the Standard Priority Queue for an Interface

If you enable standard priority queuing for traffic on a physical interface, then you need to also create the priority queue on each interface. Each physical interface uses two queues: one for priority traffic, and the other for all other traffic. For the other traffic, you can optionally configure policing.

Note The standard priority queue is not required for hierarchical priority queuing with traffic shaping; see the "Information About Priority Queuing" section on page 72-3 for more information.

Restrictions

- (ASASM) The ASASM does not support priority queuing.
- (ASA 5580) You cannot create a standard priority queue for a Ten Gigabit Ethernet interface. **Note**: For the ASA 5585-X, standard priority queuing is supported on a Ten Gigabit Interface.
- (ASA 5512-X through ASA 5555-X) Priority queuing is not supported on the Management 0/0 interface.

Detailed Steps

Step 1 Go to Configuration > Device Management > Advanced > Priority Queue, and click **Add**.

The Add Priority Queue dialog box displays.

Step 2 From the Interface drop-down list, choose the physical interface name on which you want to enable the priority queue, or for the ASA 5505 or ASASM, the VLAN interface name.

Step 3 To change the size of the priority queues, in the Queue Limit field, enter the number of average, 256-byte packets that the specified interface can transmit in a 500-ms interval.

A packet that stays more than 500 ms in a network node might trigger a timeout in the end-to-end application. Such a packet can be discarded in each network node.

Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped (called *tail drop*). To avoid having the queue fill up, you can use this option to increase the queue buffer size.

The upper limit of the range of values for this option is determined dynamically at run time. The key determinants are the memory needed to support the queues and the memory available on the device.

The Queue Limit that you specify affects both the higher priority low-latency queue and the best effort queue.

Step 4 To specify the depth of the priority queues, in the Transmission Ring Limit field, enter the number of maximum 1550-byte packets that the specified interface can transmit in a 10-ms interval.

This setting guarantees that the hardware-based transmit ring imposes no more than 10-ms of extra latency for a high-priority packet.

This option sets the maximum number of low-latency or normal priority packets allowed into the Ethernet transmit driver before the driver pushes back to the queues on the interface to let them buffer packets until the congestion clears.

The upper limit of the range of values is determined dynamically at run time. The key determinants are the memory needed to support the queues and the memory available on the device.

The Transmission Ring Limit that you specify affects both the higher priority low-latency queue and the best-effort queue.

Configuring a Service Rule for Standard Priority Queuing and Policing

You can configure standard priority queuing and policing for different class maps within the same policy map. See the "How QoS Features Interact" section on page 72-4 for information about valid QoS configurations.

To create a policy map, perform the following steps.

Restrictions

- You cannot use the **class-default** class map for priority traffic.
- You cannot configure traffic shaping and standard priority queuing for the same interface; only hierarchical priority queuing is allowed.
- (ASASM) The ASASM only supports policing.
- For policing, to-the-box traffic is not supported.
- For policing, traffic to and from a VPN tunnel bypass interface is not supported.
- For policing, when you match a tunnel group class map, only outbound policing is supported.

Guidelines

- For priority traffic, identify only latency-sensitive traffic.
- For policing traffic, you can choose to police all other traffic, or you can limit the traffic to certain types.

Detailed Steps

Step 1 To configure priority queuing, configure a service policy rule in the Configuration > Firewall > Service Policy Rules pane according to Chapter 44, "Configuring a Service Policy."

You can configure QoS as part of a new service policy rule, or you can edit an existing service policy.

Step 2 In the Rule Actions dialog box, click the **QoS** tab.

Step 3 Click **Enable priority for this flow**.

If this service policy rule is for an individual interface, ASDM automatically creates the priority queue for the interface (Configuration > Device Management > Advanced > Priority Queue; for more information, see the "Configuring the Standard Priority Queue for an Interface" section on page 72-8). If this rule is for the global policy, then you need to manually add the priority queue to one or more interfaces *before* you configure the service policy rule.

Step 4 Click **Finish**. The service policy rule is added to the rule table.

Step 5 To configure policing, configure a service policy rule for the same interface in the Configuration > Firewall > Service Policy Rules pane according to Chapter 44, "Configuring a Service Policy."

For policing traffic, you can choose to police all traffic that you are not prioritizing, or you can limit the traffic to certain types.

Step 6 In the Rule Actions dialog box, click the **QoS** tab.

Step 7 Click **Enable policing**, then check the **Input policing** or **Output policing** (or both) check boxes to enable the specified type of traffic policing. For each type of traffic policing, configure the following fields:

- Committed Rate—The rate limit for this traffic flow; this is a value in the range 8000-2000000000, specifying the maximum speed (bits per second) allowed.
- Conform Action—The action to take when the rate is less than the conform-burst value. Values are transmit or drop.
- Exceed Action—Take this action when the rate is between the conform-rate value and the conform-burst value. Values are transmit or drop.
- Burst Rate—A value in the range 1000-512000000, specifying the maximum number of instantaneous bytes allowed in a sustained burst before throttling to the conforming rate value.

Step 8 Click **Finish**. The service policy rule is added to the rule table.

Step 9 Click **Apply** to send the configuration to the device.

Configuring a Service Rule for Traffic Shaping and Hierarchical Priority Queuing

You can configure traffic shaping for all traffic on an interface, and optionally hierarchical priority queuing for a subset of latency-sensitive traffic.

Guidelines

- One side-effect of priority queuing is packet re-ordering. For IPsec packets, out-of-order packets that are not within the anti-replay window generate warning syslog messages. These warnings are false alarms in the case of priority queuing. You can configure the IPsec anti-replay window size to avoid possible false alarms. See the Configuration > VPN > IPsec > IPsec Rules > Enable Anti-replay window size option in the "Adding Crypto Maps" section on page 86-10.
- For hierarchical priority queuing, you do not need to create a priority queue on an interface.

Restrictions

- For hierarchical priority queuing, for encrypted VPN traffic, you can only match traffic based on the DSCP or precedence setting; you cannot match a tunnel group.
- For hierarchical priority queuing, IPsec-over-TCP traffic is not supported.
- Traffic shaping is not supported on the ASA 5580.
- For traffic shaping, you can only use the **class-default** class map, which is automatically created by the ASA, and which matches all traffic.

- You cannot configure traffic shaping and standard priority queuing for the same interface; only hierarchical priority queuing is allowed. See the "How QoS Features Interact" section on page 72-4 for information about valid QoS configurations.
- You cannot configure traffic shaping in the global policy.

Detailed Steps

Step 1 Configure a service policy on the Configuration > Firewall > Service Policy Rules pane according to Chapter 44, "Configuring a Service Policy."

You can configure QoS as part of a new service policy rule, or you can edit an existing service policy.

Step 2 In the Rule Actions dialog box, click the **QoS** tab.

Step 3 Click **Enable traffic shaping**, and configure the following fields:

- Average Rate—Sets the average rate of traffic in bits per second over a given fixed time period, between 64000 and 154400000. Specify a value that is a multiple of 8000.
- Burst Size—Sets the average burst size in bits that can be transmitted over a given fixed time period, between 2048 and 154400000. Specify a value that is a multiple of 128. If you do not specify the Burst Size, the default value is equivalent to 4-milliseconds of traffic at the specified Average Rate. For example, if the average rate is 1000000 bits per second, 4 ms worth = 1000000 * 4/1000 = 4000.

Step 4 (Optional) To configure priority queuing for a subset of shaped traffic:

a. Click **Enforce priority to selected shape traffic**.

b. Click **Configure** to identify the traffic that you want to prioritize.

You are prompted to identify the traffic for which you want to apply priority queuing.

c. After you identify the traffic (see the "Adding a Service Policy Rule for Through Traffic" section on page 44-8), click **Next**.

d. Click **Enable priority for this flow**.

e. Click **Finish**.

You return to the QoS tab.

Step 5 Click **Finish**. The service policy rule is added to the rule table.

Step 6 Click **Apply** to send the configuration to the device.

Monitoring QoS

To monitor QoS in ASDM, you can enter commands at the Command Line Interface tool. This section includes the following topics:

- Viewing QoS Police Statistics, page 72-12
- Viewing QoS Standard Priority Statistics, page 72-12
- Viewing QoS Shaping Statistics, page 72-12
- Viewing QoS Standard Priority Queue Statistics, page 72-13

Viewing QoS Police Statistics

To view the QoS statistics for traffic policing, use the **show service-policy** command with the **police** keyword:

```
hostname# show service-policy police
```

The following is sample output for the **show service-policy police** command:

```
hostname# show service-policy police

Global policy:
    Service-policy: global_fw_policy

Interface outside:
    Service-policy: qos
        Class-map: browse
            police Interface outside:
                cir 56000 bps, bc 10500 bytes
                conformed 10065 packets, 12621510 bytes; actions: transmit
                exceeded 499 packets, 625146 bytes; actions: drop
                conformed 5600 bps, exceed 5016 bps
        Class-map: cmap2
            police Interface outside:
                cir 200000 bps, bc 37500 bytes
                conformed 17179 packets, 20614800 bytes; actions: transmit
                exceeded 617 packets, 770718 bytes; actions: drop
                conformed 198785 bps, exceed 2303 bps
```

Viewing QoS Standard Priority Statistics

To view statistics for service policies implementing the **priority** command, use the **show service-policy** command with the **priority** keyword:

```
hostname# show service-policy priority
```

The following is sample output for the **show service-policy priority** command:

```
hostname# show service-policy priority
Global policy:
    Service-policy: global_fw_policy
Interface outside:
    Service-policy: qos
        Class-map: TG1-voice
            Priority:
                Interface outside: aggregate drop 0, aggregate transmit 9383
```

Note "Aggregate drop" denotes the aggregated drop in this interface; "aggregate transmit" denotes the aggregated number of transmitted packets in this interface.

Viewing QoS Shaping Statistics

To view statistics for service policies implementing the **shape** command, use the **show service-policy** command with the **shape** keyword:

```
hostname# show service-policy shape
```

The following is sample output for the **show service-policy shape** command:

```
hostname# show service-policy shape
Interface outside
  Service-policy: shape
    Class-map: class-default

      Queueing
      queue limit 64 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0

      shape (average) cir 2000000, bc 8000, be 8000
```

The following is sample output of the **show service policy shape** command, which includes service policies that include the **shape** command and the **service-policy** command that calls the hierarchical priority policy and the related statistics:

```
hostname# show service-policy shape

Interface outside:
  Service-policy: shape
    Class-map: class-default

      Queueing
      queue limit 64 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0

      shape (average) cir 2000000, bc 16000, be 16000

      Service-policy: voip
        Class-map: voip

          Queueing
          queue limit 64 packets
          (queue depth/total drops/no-buffer drops) 0/0/0
          (pkts output/bytes output) 0/0
        Class-map: class-default

          queue limit 64 packets
          (queue depth/total drops/no-buffer drops) 0/0/0
          (pkts output/bytes output) 0/0
```

Viewing QoS Standard Priority Queue Statistics

To display the priority-queue statistics for an interface, use the **show priority-queue statistics** command in privileged EXEC mode. The results show the statistics for both the best-effort (BE) queue and the low-latency queue (LLQ). The following example shows the use of the **show priority-queue statistics** command for the interface named test, and the command output.

```
hostname# show priority-queue statistics test

Priority-Queue Statistics interface test

Queue Type         = BE
Packets Dropped    = 0
Packets Transmit   = 0
Packets Enqueued   = 0
```

```
Current Q Length  = 0
Max Q Length      = 0

Queue Type        = LLQ
Packets Dropped   = 0
Packets Transmit  = 0
Packets Enqueued  = 0
Current Q Length  = 0
Max Q Length      = 0
hostname#
```

In this statistical report, the meaning of the line items is as follows:

- "Packets Dropped" denotes the overall number of packets that have been dropped in this queue.
- "Packets Transmit" denotes the overall number of packets that have been transmitted in this queue.
- "Packets Enqueued" denotes the overall number of packets that have been queued in this queue.
- "Current Q Length" denotes the current depth of this queue.
- "Max Q Length" denotes the maximum depth that ever occurred in this queue.

Feature History for QoS

Table 72-3 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 72-3 Feature History for QoS

Feature Name	Platform Releases	Feature Information
Priority queuing and policing	7.0(1)	We introduced QoS priority queuing and policing. We introduced the following screens: Configuration > Device Management > Advanced > Priority Queue Configuration > Firewall > Service Policy Rules
Shaping and hierarchical priority queuing	7.2(4)/8.0(4)	We introduced QoS shaping and hierarchical priority queuing. We modified the following screen: Configuration > Firewall > Service Policy Rules.
Ten Gigabit Ethernet support for a standard priority queue on the ASA 5585-X	8.2(3)/8.4(1)	We added support for a standard priority queue on Ten Gigabit Ethernet interfaces for the ASA 5585-X.

Troubleshooting Connections and Resources

This chapter describes how to troubleshoot the ASA and includes the following sections:

- Testing Your Configuration, page 73-1
- Monitoring Performance, page 73-8
- Monitoring System Resources, page 73-9
- Monitoring Connections, page 73-11
- Monitoring Per-Process CPU Usage, page 73-12

Testing Your Configuration

This section describes how to test connectivity for the single mode ASA or for each security context, how to ping the ASA interfaces, and how to allow hosts on one interface to ping through to hosts on another interface.

This section includes the following topics:

- Pinging ASA Interfaces, page 73-1
- Verifying ASA Configuration and Operation, and Testing Interfaces Using Ping, page 73-3
- Determining Packet Routing with Traceroute, page 73-6
- Tracing Packets with Packet Tracer, page 73-7

Pinging ASA Interfaces

To test whether the ASA interfaces are up and running and that the ASA and connected routers are operating correctly, you can ping the ASA interfaces.

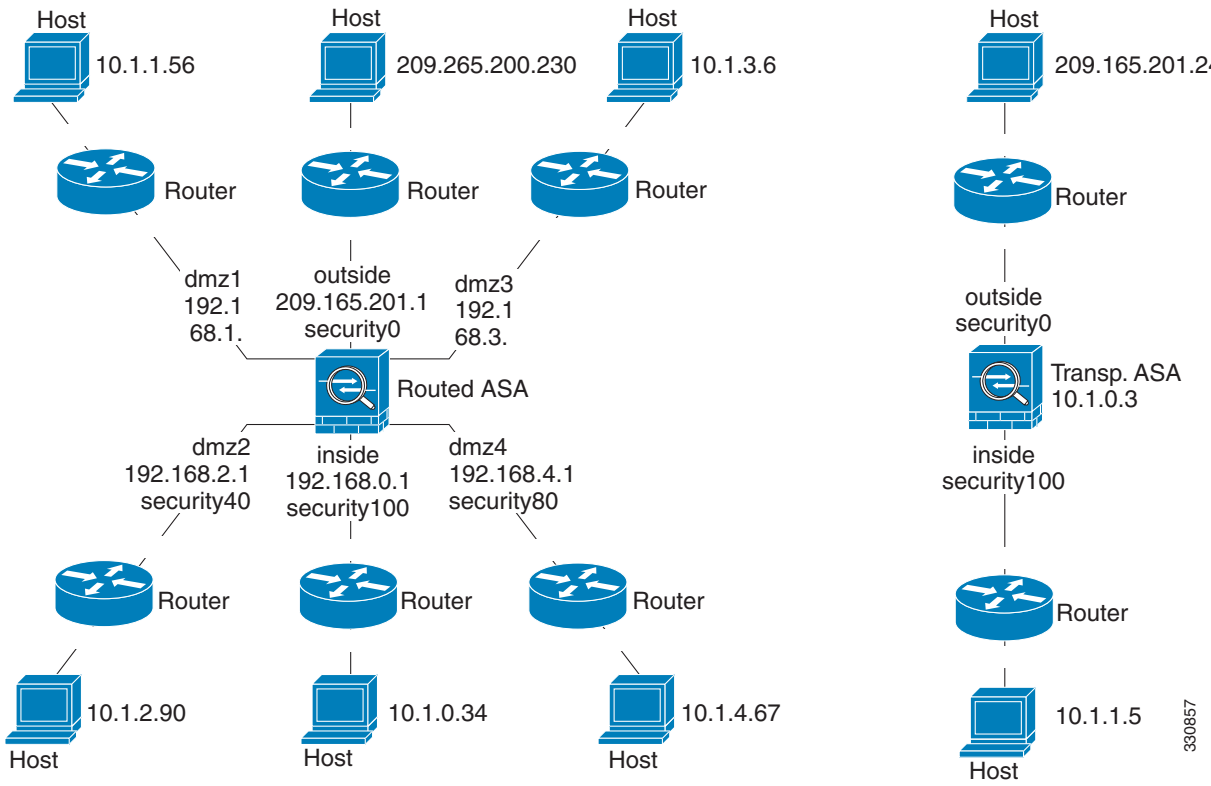
To ping the ASA interfaces, perform the following steps:

Step 1 Draw a diagram of your single-mode ASA or security context that shows the interface names, security levels, and IP addresses.

Note Although this procedure uses IP addresses, the **ping** command also supports DNS names and names that are assigned to a local IP address with the **name** command.

The diagram should also include any directly connected routers and a host on the other side of the router from which you will ping the ASA. (See Figure 73-1.)

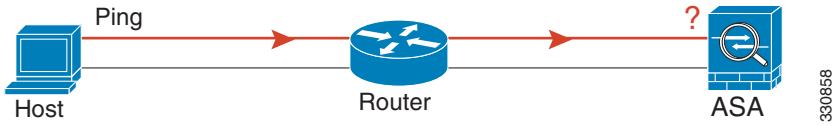
Figure 73-1 Network Diagram with Interfaces, Routers, and Hosts



Step 2 Ping each ASA interface from the directly connected routers. For transparent mode, ping the management IP address. This test ensures that the ASA interfaces are active and that the interface configuration is correct.

A ping might fail if the ASA interface is not active, the interface configuration is incorrect, or if a switch between the ASA and a router is down (see Figure 73-2). In this case, no debugging messages or syslog messages appear, because the packet never reaches the ASA.

Figure 73-2 Ping Failure at the ASA Interface

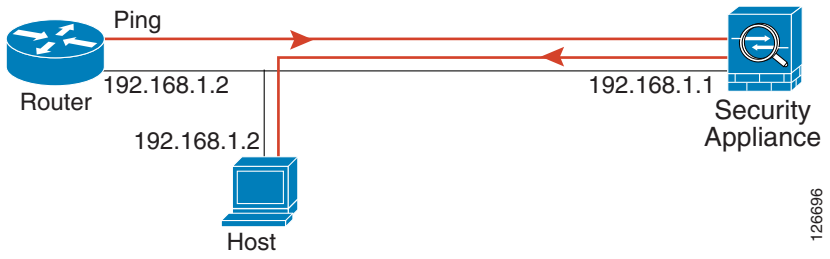


If the ping reaches the ASA, and it responds, debugging messages similar to the following appear:

```
ICMP echo reply (len 32 id 1 seq 256) 209.165.201.1 > 209.165.201.2
ICMP echo request (len 32 id 1 seq 512) 209.165.201.2 > 209.165.201.1
```

If the ping reply does not return to the router, then a switch loop or redundant IP addresses may exist (see Figure 73-3).

Figure 73-3 Ping Failure Because of IP Addressing Problems



Step 3 Ping each ASA interface from a remote host. For transparent mode, ping the management IP address. This test checks whether the directly connected router can route the packet between the host and the ASA, and whether the ASA can correctly route the packet back to the host.

A ping might fail if the ASA does not have a return route to the host through the intermediate router (see Figure 73-4). In this case, the debugging messages show that the ping was successful, but syslog message 110001 appears, indicating a routing failure has occurred.

Figure 73-4 Ping Failure Because the ASA Has No Return Route

Verifying ASA Configuration and Operation, and Testing Interfaces Using Ping

The Ping tool is useful for verifying the configuration and operation of the ASA and surrounding communications links, as well as for testing other network devices.

This section includes the following topics:

- Information About Ping, page 73-3
- Pinging From an ASA Interface, page 73-4
- Pinging to an ASA Interface, page 73-4
- Pinging Through the ASA Interface, page 73-4
- Troubleshooting the Ping Tool, page 73-4
- Using the Ping Tool, page 73-5

Information About Ping

A ping is sent to an IP address and it returns a reply. This process enables network devices to discover, identify, and test each other.

The Ping tool uses ICMP (as described in RFC 777 and RFC 792) to define an echo request-and-reply transaction between two network devices. The echo request packet is sent to the IP address of a network device. The receiving device reverses the source and destination address and sends the packet back as the echo reply.

Administrators can use the ASDM Ping interactive diagnostic tool in these ways:

- Loopback testing of two interfaces—A ping may be initiated from one interface to another on the same ASA, as an external loopback test to verify basic "up" status and operation of each interface.
- Pinging to an ASA—The Ping tool can ping an interface on another ASA to verify that it is up and responding.
- Pinging through an ASA—Ping packets originating from the Ping tool may pass through an intermediate ASA on their way to a device. The echo packets will also pass through two of its interfaces as they return. This procedure can be used to perform a basic test of the interfaces, operation, and response time of the intermediate unit.
- Pinging to test questionable operation of a network device—A ping may be initiated from an ASA interface to a network device that is suspected of functioning incorrectly. If the interface is configured correctly and an echo is not received, there may be problems with the device.
- Pinging to test intermediate communications—A ping may be initiated from an ASA interface to a network device that is known to be functioning correctly and returning echo requests. If the echo is received, the correct operation of any intermediate devices and physical connectivity is confirmed.

Pinging From an ASA Interface

For basic testing of an interface, you can initiate a ping from an ASA interface to a network device that you know is functioning correctly and returning replies through the intermediate communications path. For basic testing, make sure you do the following:

- Verify receipt of the ping from the ASA interface by the "known good" device. If the ping is not received, a problem with the transmitting hardware or interface configuration may exist.
- If the ASA interface is configured correctly and it does not receive an echo reply from the "known good" device, problems with the interface hardware receiving function may exist. If a different interface with "known good" receiving capability can receive an echo after pinging the same "known good" device, the hardware receiving problem of the first interface is confirmed.

Pinging to an ASA Interface

When you try to ping to an ASA interface, verify that the pinging response (ICMP echo reply*)* is enabled for that interface by choosing **Tools > Ping**. When pinging is disabled, the ASA cannot be detected by other devices or software applications, and does not respond to the ASDM Ping tool.

Pinging Through the ASA Interface

To verify that other types of network traffic from "known good" sources are being passed through the ASA, choose **Monitoring > Interfaces > Interface Graphs** or an SNMP management station.

To enable internal hosts to ping external hosts, configure ICMP inspection. Choose **Configuration > Firewall > Service Policies**.

Troubleshooting the Ping Tool

When pings fail to receive an echo, it may be the result of a configuration or operational error in an ASA, and not necessarily because of no response from the IP address being pinged. Before using the Ping tool to ping from, to, or through an ASA interface, perform the following basic checks:

- Verify that interfaces are configured. Choose **Configuration > Device Setup > Interfaces**.

- Verify that devices in the intermediate communications path, such as switches or routers, are correctly delivering other types of network traffic.
- Make sure that traffic of other types from "known good" sources is being passed. Choose **Monitoring > Interfaces > Interface Graphs**.

Using the Ping Tool

To use the Ping tool, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Ping**.

The Ping dialog box appears.

Step 2 Enter the destination IP address for the ICMP echo request packets in the IP Address field.

Ping also supports IPv6 addresses.

Note If a hostname has been assigned in the Configuration > Firewall > Objects > Service Objects/Groups pane, you can use the hostname in place of the IP address.

Step 3 (Optional) Choose the ASA interface that transmits the echo request packets from the drop-down list. If it is not specified, the ASA checks the routing table to find the destination address and uses the required interface.

Step 4 Click **Ping** to send an ICMP echo request packet from the specified or default interface to the specified IP address and start the response timer.

The response appears in the Ping Output area. Three attempts are made to ping the IP address, and results display the following fields:

- The IP address of the device pinged or a device name, if available. The name of the device, if assigned, may be displayed, even if NO response is the result.
- When the ping is transmitted, a millisecond timer starts with a specified maximum, or timeout value. This timer is useful for testing the relative response times of different routes or activity levels.
- Example Ping output:

```
Sending 5, 100-byte ICMP Echos to out-pc, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

If the ping fails, the output is as follows:

```
Sending 5, 100-byte ICMP Echos to 10.132.80.101, timeout is 2 seconds:
?????
Success rate is 0 percent (0/5)
```

Step 5 To enter a new IP address, click **Clear Screen** to remove the previous response from the Ping output area.

Determining Packet Routing with Traceroute

The Traceroute tool helps you to determine the route that packets will take to their destination. The tool prints the result of each probe sent. Every line of output corresponds to a TTL value in increasing order. The following table lists the output symbols printed by this tool.

Output Symbol	Description
*	No response was received for the probe within the timeout period.
nn msec	For each node, the round-trip time (in milliseconds) for the specified number of probes.
!N.	ICMP network unreachable.
!H	ICMP host unreachable.
!P	ICMP unreachable.
!A	ICMP administratively prohibited.
?	Unknown ICMP error.

To use the Traceroute tool, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Traceroute**.

The Traceroute dialog box appears.

Step 2 Enter hostname or IP address to which the route is traced. If the hostname is given, define it by choosing **Configuration > Firewall > Objects > Service Objects/Groups**, or configure a DNS server to enable this tool to resolve the hostname to an IP address.

Step 3 Enter the amount of time in seconds to wait for a response before the connection times out. The default is three seconds.

Step 4 Type the destination port used by the UDP probe messages. The default is 33434.

Step 5 Enter the number of probes to be sent at each TTL level. The default is three.

Step 6 Specify the minimum and maximum TTL values for the first probes. The minimum default is one, but it can be set to a higher value to suppress the display of known hops. The maximum default is 30. The traceroute terminates when the packet reaches the destination or when the maximum value is reached.

Step 7 Check the **Specify source interface or IP address** check box. Choose the source interface or IP address for the packet trace from the drop-down list. This IP address must be the IP address of one of the interfaces. In transparent mode, it must be the management IP address of the ASA.

Step 8 Check the **Reverse Resolve** check box to have the output display the names of hops encountered if name resolution is configured. Leave this check box unchecked to have the output display IP addresses.

Step 9 Check the **Use ICMP** check box to specify the use of ICMP probe packets instead of UDP probe packets.

Step 10 Click **Trace Route** to start the traceroute.

The Traceroute Output area displays detailed messages about the traceroute results.

Step 11 Click **Clear Output** to start a new traceroute.

Tracing Packets with Packet Tracer

The packet tracer tool provides packet tracing for packet sniffing and network fault isolation, as well as detailed information about the packets and how they are processed by the ASA. If a configuration command did not cause the packet to drop, the packet tracer tool can provide information about the cause in an easily readable format.

In addition, you can trace the lifespan of a packet through the ASA to see whether the packet is operating correctly with the packet tracer tool. This tool enables you to do the following:

- Debug all packet drops in a production network.
- Verify the configuration is working as intended.
- Show all rules applicable to a packet, along with the CLI commands that caused the rule addition.
- Show a time line of packet changes in a data path.
- Inject tracer packets into the data path.
- Search for an IPv4 or IPv6 address based on the user identity and the FQDN.

To use the packet tracer, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Packet Tracer**.

The Cisco ASDM Packet Tracer dialog box appears.

Step 2 Choose the source interface for the packet trace from the drop-down list.

Step 3 Specify the protocol type for the packet trace. Available protocol types include ICMP, IP, TCP, and UDP.

Step 4 In the Source drop-down list, select one of the following options:

- IP Address
- User
- FQDN
- Security Tag
- Security Name

  Select the Security Tag or Security Name options when you want to trace packets sent by the ASA when integrated with the Cisco TrustSec solution. Security names are created on the Cisco ISE and provide user-friendly names for security groups.

  If a security policy is configured on the ASA with that security tags or security names, the ASA enforces the policy. (You can create security policies on the ASA that contain security tags or security names. To enforce policies based on security group names, the ASA needs the security group table to map security names to security tags.)

  See Configuring the ASA to Integrate with Cisco TrustSec, page 48-1 for information about configuring the ASA to integrate with the Cisco TrustSec solution.

Step 5 Based on the option you selected from the Source drop-down list, enter the corresponding text for the item you want to trace; for example, enter the source IP address for the packet trace in the Source IP Address field.

Step 6 For TCP and UDP only, choose the source port for the packet trace from the drop-down list.

Step 7 In the Destination drop-down list, select one of the following options:

- IP Address
- FQDN

- Security Tag
- Security Name

Step 8 Based on the option you selected from the Destination drop-down list, enter the corresponding text for the item you want to trace; for example, enter the source IP address for the packet trace in the Destination IP Address field.

Step 9 For TCP and UDP only, choose the destination port for the packet trace from the drop-down list.

Step 10 For ICMP only, choose the type of packet trace from the Type drop-down list. Then enter the trace code and trace ID in the appropriate fields.

Step 11 For IP only, enter the protocol number in the Protocol field. Valid values range from 0 to 255.

Step 12 Click **Start** to trace the packet.

The Information Display Area shows detailed messages about the results of the packet trace.

Note To display a graphical representation of the packet trace, check the **Show animation** check box.

Step 13 Click **Clear** to start a new packet trace.

Monitoring Performance

To view ASA performance information in a graphical or tabular format, perform the following steps:

Step 1 In the ASDM main window, choose **Monitoring > Properties > Connection Graphs > Perfmon**.

Step 2 Select one or more entries from the Available Graphs list, then click **Add** to move them to the Selected Graphs list. To remove an entry from the Selected Graphs list, click **Remove**. The available options are the following:

- AAA Perfmon—Displays the ASA AAA performance information.
- Inspection Perfmon—Displays the ASA inspection performance information.
- Web Perfmon—Displays the ASA web performance information, including URL access and URL server requests.
- Connections Perfmon—Displays the ASA connections performance information.
- Xlate Perfmon—Displays the ASA NAT performance information.

You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Step 3 To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title in the Graph Window Title field.

Step 4 Click **Show Graphs** to view performance statistics in a new or updated graph window.

Step 5 Click the **Table** tab to view the same performance statistics in a tabular format.

Step 6 From the View drop-down list on either tab, choose to display updates to information in the following time periods: Real-time, data every 10 sec; Last 10 minutes, data every 10 sec; Last 60 minutes, data every 1 min; Last 12 hours, data every 12 minutes; or Last 5 days, data every two hours.

Step 7 (Optional) Click **Export** to display the Export Graph Data dialog box. The selected performance statistics to export are already checked.

Step 8 (Optional) Click **Export** again to display the Save dialog box.

Step 9 (Optional) Click **Save** to save the performance statistics to a text file (.txt) on your local drive for future reference.

Step 10 (Optional) Click **Print** to display the Print Graph dialog box.

Step 11 (Optional) Choose the graph or table name from the drop-down list, then click **Print** to display the Print dialog box.

Step 12 (Optional) Click **OK** to print the selected performance statistics.

Monitoring System Resources

This section includes the following topics:

- Blocks, page 73-9
- CPU, page 73-10
- Memory, page 73-10

Blocks

To view the free and used memory blocks, perform the following steps:

Step 1 In the ASDM main window, choose **Monitoring > Properties > System Resources Graphs > Blocks**.

Step 2 Select one or more entries from the Available Graphs list, then click **Add** to move them to the Selected Graphs list. To remove an entry from the Selected Graphs list, click **Remove**. The available options are the following:

- Blocks Used—Displays the ASA used memory blocks.
- Blocks Free—Displays the ASA free memory blocks.

You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Step 3 To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title in the Graph Window Title field.

Step 4 Click **Show Graphs** to view system resource statistics in a new or updated graph window.

Step 5 Click the **Table** tab to view the same performance statistics in a tabular format.

Step 6 From the View drop-down list on either tab, choose to display updates to information in the following time periods: Real-time, data every 10 sec; Last 10 minutes, data every 10 sec; Last 60 minutes, data every 1 min; Last 12 hours, data every 12 minutes; or Last 5 days, data every two hours.

Step 7 (Optional) Click **Export** to display the Export Graph Data dialog box. The selected memory block statistics to export are already checked.

Step 8 (Optional) Click **Export** again to display the Save dialog box.

Step 9 (Optional) Click **Save** to save the memory block statistics to a text file (.txt) on your local drive for future reference.

Step 10 (Optional) Click **Print** to display the Print Graph dialog box.

Step 11 (Optional) Choose the graph or table name from the drop-down list, then click **Print** to display the Print dialog box.

Step 12 (Optional) Click **OK** to print the selected memory block statistics.

CPU

To view the CPU utilization, perform the following steps:

Step 1 In the ASDM main window, choose **Monitoring > Properties > System Resources Graphs > CPU**.

Step 2 Select one or more entries from the Available Graphs list, then click **Add** to move them to the Selected Graphs list. To remove an entry from the Selected Graphs list, click **Remove**.

You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Step 3 To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title in the Graph Window Title field.

Step 4 Click **Show Graphs** to view system resource statistics in a new or updated graph window.

Step 5 Click the **Table** tab to view the same performance statistics in a tabular format.

Step 6 From the View drop-down list on either tab, choose to display updates to information in the following time periods: Real-time, data every 10 sec; Last 10 minutes, data every 10 sec; Last 60 minutes, data every 1 min; Last 12 hours, data every 12 minutes; or Last 5 days, data every two hours.

Step 7 (Optional) Click **Export** to display the Export Graph Data dialog box. The selected CPU utilization statistics to export are already checked.

Step 8 (Optional) Click **Export** again to display the Save dialog box.

Step 9 (Optional) Click **Save** to save the CPU utilization statistics to a text file (.txt) on your local drive for future reference.

Step 10 (Optional) Click **Print** to display the Print Graph dialog box.

Step 11 (Optional) Choose the graph or table name from the drop-down list, then click **Print** to display the Print dialog box.

Step 12 (Optional) Click **OK** to print the selected CPU utilization statistics.

Memory

To view the memory utilization, perform the following steps:

Step 1 In the ASDM main window, choose **Monitoring > Properties > System Resources Graphs > Blocks**.

Step 2 Select one or more entries from the Available Graphs list, then click **Add** to move them to the Selected Graphs list. To remove an entry from the Selected Graphs list, click **Remove**. The available options are the following:

- Free Memory—Displays the ASA free memory.
- Used Memory—Displays the ASA used memory.

You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Step 3 To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title in the Graph Window Title field.

Step 4 Click **Show Graphs** to view system resource statistics in a new or updated graph window.

Step 5 Click the **Table** tab to view the same performance statistics in a tabular format.

Step 6 From the View drop-down list on either tab, choose to display updates to information in the following time periods: Real-time, data every 10 sec; Last 10 minutes, data every 10 sec; Last 60 minutes, data every 1 min; Last 12 hours, data every 12 minutes; or Last 5 days, data every two hours.

Step 7 (Optional) Click **Export** to display the Export Graph Data dialog box. The selected memory utilization statistics to export are already checked.

Step 8 (Optional) Click **Export** again to display the Save dialog box.

Step 9 (Optional) Click **Save** to save the memory utilization statistics to a text file (.txt) on your local drive for future reference.

Step 10 (Optional) Click **Print** to display the Print Graph dialog box.

Step 11 (Optional) Choose the graph or table name from the drop-down list, then click **Print** to display the Print dialog box.

Step 12 (Optional) Click **OK** to print the selected memory utilization statistics.

Monitoring Connections

To view current connections in a tabular format, in the ASDM main window, choose **Monitoring > Properties > Connections**. Each connection is identified by the following parameters:

- Protocol
- Source:
  - Security ID
  - Security Name
  - IP address
  - Port
- Destination:
  - Security ID
  - Security Name
  - IP address
  - Port

- Idle time since the last packet was sent or received
- Amount of sent and received traffic on the connection

Monitoring Per-Process CPU Usage

You can monitor the processes that run on the CPU. You can obtain information about the percentage of CPU that is used by a certain process. CPU usage statistics are sorted in descending order to display the highest consumer at the top. Also included is information about the load on the CPU per process, at 5 seconds, 1 minute, and 5 minutes before the log time. This information is updated automatically every 5 seconds to provide real-time statistics. In ASDM, it is updated every 30 seconds.

To view CPU usage on a per-process basis, perform the following steps:

Step 1 In the ASDM main window, choose **Monitoring > Properties > Per-Process CPU Usage**.

Step 2 To pause the auto-refresh of the screen, click **Stop auto-refresh**.

Step 3 To save the information on the screen to a local text file, click **Save log to local file**.

The Save dialog box appears.

Step 4 Enter the name of the text file, then click **Save**.

To color code processes according to their CPU usage range, click **Configure CPU usage**.

The Color Settings dialog box appears.

Step 5 Choose one of the following range options: 49% and below, 50% to 79%, and 80% and above.

Step 6 Click the foreground or background cell to display the Pick a Color dialog box, and select the foreground and background colors for the given ranges.

Step 7 Click one of the following tabs to pick the color palette: **Swatches**, **HSB**, or **RGB**. When you are done, click **OK**.

Step 8 Click **OK** to view the color-coded entries.

Step 9 Click **Refresh** to refresh the data manually at any time.

PART 13

Configuring Advanced Network Protection

CHAPTER 75

Configuring the ASA for Cisco Cloud Web Security

Cisco Cloud Web Security provides web security and web filtering services through the Software-as-a-Service (SaaS) model. Enterprises with the ASA in their network can use Cloud Web Security services without having to install additional hardware.

When Cloud Web Security is enabled on the ASA, the ASA transparently redirects selected HTTP and HTTPS traffic to the Cloud Web Security proxy servers. The Cloud Web Security proxy servers then scan the content and allow, block, or send a warning about the traffic based on the policy configured in Cisco ScanCenter to enforce acceptable use and to protect users from malware.

The ASA can optionally authenticate and identify users with Identity Firewall (IDFW) and AAA rules. The ASA encrypts and includes the user credentials (including usernames and/or user groups) in the traffic it redirects to Cloud Web Security. The Cloud Web Security service then uses the user credentials to match the traffic to the policy. It also uses these credentials for user-based reporting. Without user authentication, the ASA can supply an (optional) default username and/or group, although usernames and groups are not required for the Cloud Web Security service to apply policy.

You can customize the traffic you want to send to Cloud Web Security when you create your service policy rules. You can also configure a "whitelist" so that a subset of web traffic that matches the service policy rule instead goes directly to the originally requested web server and is not scanned by Cloud Web Security.

You can configure a primary and a backup Cloud Web Security proxy server, each of which the ASA polls regularly to check for availability.

Note This feature is also called "ScanSafe," so the ScanSafe name appears in some commands.

This chapter includes the following sections:

- Information About Cisco Cloud Web Security, page 75-2
- Licensing Requirements for Cisco Cloud Web Security, page 75-7
- Prerequisites for Cloud Web Security, page 75-7
- Guidelines and Limitations, page 75-7
- Default Settings, page 75-8
- Configuring Cisco Cloud Web Security, page 75-8
- Monitoring Cloud Web Security, page 75-26
- Related Documents, page 75-27
- Feature History for Cisco Cloud Web Security, page 75-27

Information About Cisco Cloud Web Security

This section includes the following topics:

- Redirection of Web Traffic to Cloud Web Security, page 75-2
- User Authentication and Cloud Web Security, page 75-2
- Authentication Keys, page 75-3
- ScanCenter Policy, page 75-4
- Cloud Web Security Actions, page 75-5
- Bypassing Scanning with Whitelists, page 75-5
- IPv4 and IPv6 Support, page 75-6
- Failover from Primary to Backup Proxy Server, page 75-6

Redirection of Web Traffic to Cloud Web Security

When an end user sends an HTTP or HTTPS request, the ASA receives it and optionally retrieves the user and/or group information. If the traffic matches an ASA service policy rule for Cloud Web Security, then the ASA redirects the request to the Cloud Web Security proxy servers. The ASA acts as an intermediary between the end user and the Cloud Web Security proxy server by redirecting the connection to the proxy server. The ASA changes the destination IP address and port in the client requests and adds Cloud Web Security-specific HTTP headers and then sends the modified request to the Cloud Web Security proxy server. The Cloud Web Security HTTP headers include various kinds of information, including the username and user group (if available).

User Authentication and Cloud Web Security

User identity can be used to apply policy in Cloud Web Security. User identity is also useful for Cloud Web Security reporting. User identity is not required to use Cloud Web Security. There are other methods to identify traffic for Cloud Web Security policy.

The ASA supports the following methods of determining the identity of a user, or of providing a default identity:

- AAA rules—When the ASA performs user authentication using a AAA rule, the username is retrieved from the AAA server or local database. Identity from AAA rules does not include group information. If configured, the default group is used. For information about configuring AAA rules, see Chapter 53, "Configuring AAA Rules for Network Access."
- IDFW—When the ASA uses IDFW with the Active Directory (AD), the username and group is retrieved from the AD agent when you activate a user and/or group by using an ACL in a feature such as an access rule or in your service policy, or by configuring the user identity monitor to download user identity information directly.

  For information about configuring IDFW, see Chapter 47, "Configuring the Identity Firewall."
- Default username and group—Without user authentication, the ASA uses an optional default username and/or group for all users that match a service policy rule for Cloud Web Security.

Authentication Keys

Each ASA must use an authentication key that you obtain from Cloud Web Security. The authentication key lets Cloud Web Security identify the company associated with web requests and ensures that the ASA is associated with valid customer.

You can use one of two types of authentication keys for your ASA: the company key or the group key.

- Company Authentication Key, page 75-3
- Group Authentication Key, page 75-3

Company Authentication Key

A Company authentication key can be used on multiple ASAs within the same company. This key simply enables the Cloud Web Security service for your ASAs. The administrator generates this key in ScanCenter (https://scancenter.scansafe.com/portal/admin/login.jsp); you have the opportunity to e-mail the key for later use. You cannot look up this key later in ScanCenter; only the last 4 digits are shown in ScanCenter. For more information, see the Cloud Web Security documentation: http://www.cisco.com/en/US/products/ps11720/products_installation_and_configuration_guides_list.html.

Group Authentication Key

A Group authentication key is a special key unique to each ASA that performs two functions:

- Enables the Cloud Web Security service for one ASA.
- Identifies all traffic from the ASA so you can create ScanCenter policy per ASA.

For information about using the Group authentication key for policy, see the "ScanCenter Policy" section on page 75-4).

The administrator generates this key in ScanCenter (https://scancenter.scansafe.com/portal/admin/login.jsp); you have the opportunity to e-mail the key for later use. You cannot look up this key later in ScanCenter; only the last 4 digits are shown in ScanCenter. For more information, see the Cloud Web Security documentation: http://www.cisco.com/en/US/products/ps11720/products_installation_and_configuration_guides_list.html.

ScanCenter Policy

In ScanCenter, traffic is matched against policy rules in order until a rule is matched. Cloud Web Security then applies the configured action for the rule. User traffic can match a policy rule in ScanCenter based on group association: a *directory group* or a *custom group*.

- Directory Groups, page 75-4
- Custom Groups, page 75-4
- How Groups and the Authentication Key Interoperate, page 75-5

Directory Groups

Directory groups define the group to which traffic belongs. The group, if present, is included in the HTTP header of the client request. The ASA includes the group in the HTTP header when you configure IDFW. If you do not use IDFW, you can configure a default group for traffic matching an ASA rule for Cloud Web Security inspection.

When you configure a directory group, you must enter the group name exactly.

- IDFW group names are sent in the following format:

  *domain-name**group-name*

  When the ASA learns the IDFW group name, the format on the ASA is *domain-name**group-name*. However, the ASA modifies the name to use only one backslash (\) to conform to typical ScanCenter notation.

- The default group name is sent in the following format:

  [*domain*\]*group-name*

  On the ASA, you need to configure the optional domain name to be followed by 2 backslashes (\\); however, the ASA modifies the name to use only one backslash (\) to conform to typical ScanCenter notation. For example, if you specify “Cisco\\Boulder1,” the ASA modifies the group name to be “Cisco\Boulder1” with only one backslash (\) when sending the group name to Cloud Web Security.

Custom Groups

Custom groups are defined using one or more of the following criteria:

- ScanCenter Group authentication key—You can generate a Group authentication key for a custom group. Then, if you identify this group key when you configure the ASA, all traffic from the ASA is tagged with the Group key.
- Source IP address—You can identify source IP addresses in the custom group. Note that the ASA service policy is based on source IP address, so you might want to configure any IP address-based policy on the ASA instead.
- Username—You can identify usernames in the custom group.
  - IDFW usernames are sent in the following format:

    *domain-name**username*
  - AAA usernames, when using RADIUS or TACACS+, are sent in the following format:

    LOCAL*username*
  - AAA usernames, when using LDAP, are sent in the following format:

    *domain-name**username*

– For the default username, it is sent in the following format:

[*domain-name*\]*username*

For example, if you configure the default username to be “Guest,” then the ASA sends “Guest.” If you configure the default username to be “Cisco\Guest,” then the ASA sends “Cisco\Guest.”

How Groups and the Authentication Key Interoperate

Unless you need the per-ASA policy that a custom group+group key provides, you will likely use a company key. Note that not all custom groups are associated with a group key. Non-keyed custom groups can be used to identify IP addresses or usernames, and can be used in your policy along with rules that use directory groups.

Even if you do want per-ASA policy and are using a group key, you can also use the matching capability provided by directory groups and non-keyed custom groups. In this case, you might want an ASA-based policy, with some exceptions based on group membership, IP address, or username. For example, if you want to exempt users in the America\Management group across all ASAs:

1. Add a directory group for America\Management.
2. Add an exempt rule for this group.
3. Add rules for each custom group+group key after the exempt rule to apply policy per-ASA.
4. Traffic from users in America\Management will match the exempt rule, while all other traffic will match the rule for the ASA from which it originated.

Many combinations of keys, groups, and policy rules are possible.

Cloud Web Security Actions

After applying the configured policies, Cloud Web Security either blocks, allows, or sends a warning about the user request:

- Allows—When Cloud Web Security allows the client request, it contacts the originally requested server and retrieves the data. It forwards the server response to the ASA, which then forwards it to the user.
- Blocks—When Cloud Web Security blocks the client request, it notifies the user that access has been blocked. It sends an HTTP 302 “Moved Temporarily” response that redirects the client application to a web page hosted by the Cloud Web Security proxy server showing the blocked error message. The ASA forwards the 302 response to the client.
- Warns—When the Cloud Web Security proxy server determines that a site may be in breach of the acceptable use policy, it displays a warning page about the site. You can choose to heed the warning and drop the request to connect, or you can click through the warning and proceed to the requested site.

You can also choose how the ASA handles web traffic when it cannot reach either the primary or backup Cloud Web Security proxy server. It can block or allow all web traffic. By default, it blocks web traffic.

Bypassing Scanning with Whitelists

If you use AAA rules or IDFW, you can configure the ASA so that web traffic from specific users or groups that otherwise match the service policy rule is not redirected to the Cloud Web Security proxy server for scanning. When you bypass Cloud Web Security scanning, the ASA retrieves the content

directly from the originally requested web server without contacting the proxy server. When it receives the response from the web server, it sends the data to the client. This process is called “whitelisting” traffic.

Although you can achieve the same results of exempting traffic based on user or group when you configure the class of traffic using ACLs to send to Cloud Web Security, you might find it more straightforward to use a whitelist instead. Note that the whitelist feature is only based on user and group, not on IP address.

IPv4 and IPv6 Support

Cloud Web Security currently supports only IPv4 addresses. If you use IPv6 internally, NAT 64 must be performed for any IPv6 flows that need to be sent to Cloud Web Security.

The following table shows the class map traffic that is supported by Cloud Web Security redirection:

Class Map Traffic	Cloud Web Security Inspection
From IPv4 to IPv4	Supported
From IPv6 to IPv4 (using NAT64)	Supported
From IPv4 to IPv6	Not Supported
From IPv6 to IPv6	Not Supported

Failover from Primary to Backup Proxy Server

When you subscribe to the Cisco Cloud Web Security service, you are assigned a primary Cloud Web Security proxy server and backup proxy server. These servers are routinely polled to check for their availability. If your ASA is unable to reach the Cloud Web Security proxy server (for example, if no SYN/ACK packets arrive from the proxy server), then the proxy server is polled through a TCP three-way handshake to check its availability. If the proxy server is unavailable after a configured number of retries (default is five), the server is declared as unreachable, and the backup proxy server becomes active.

The ASA automatically falls back to the primary Cloud Web Security proxy server from the backup server after continued polling shows that the primary server is active for two consecutive retry count periods. You can change this polling interval using the CLI or ASDM. For configuration information, see the “Configuring Communication with the Cloud Web Security Proxy Server” section on page 75-8.

Traffic Conditions Under Which Proxy Server Is Not Reachable	Server Timeout Calculation	Connection Timeout Result
High traffic	Client half open connection timeout + ASA TCP connection timeout	(30 + 30) = 60 seconds
Single connection failure	Client half open connection timeout + ((retry threshold - 1) x (ASA TCP connection timeout))	(30 + ((5-1) x (30)) = 150 seconds
Idle—No connections are passing	15 minutes + ((retry threshold) x (ASA TCP connection timeout))	900 + (5 x (30) = 1050 seconds

Licensing Requirements for Cisco Cloud Web Security

Model	License Requirement
All models	Strong Encryption (3DES/AES) License to encrypt traffic between the ASA and the Cloud Web Security server.

On the Cloud Web Security side, you must purchase a Cisco Cloud Web Security license and identify the number of users that the ASA handles. Then log into ScanCenter, and generate your authentication keys.

Prerequisites for Cloud Web Security

(Optional) User Authentication Prerequisites

To send user identity information to Cloud Web Security, configure one of the following on the ASA:

- AAA rules (username only)—See Chapter 53, "Configuring AAA Rules for Network Access."
- IDFW (username and group)—See Chapter 47, "Configuring the Identity Firewall."

(Optional) Fully Qualified Domain Name Prerequisites

If you use FQDNs in ACLs for your service policy rule, or for the Cloud Web Security server, you must configure a DNS server for the ASA according to the "Configuring the DNS Server" section on page 21-8.

Guidelines and Limitations

Context Mode Guidelines

Supported in single and multiple context modes.

In multiple context mode, the server configuration is allowed only in the system, and the service policy rule configuration is allowed only in the security contexts.

Each context can have its own authentication key, if desired.

Firewall Mode Guidelines

Supported in routed firewall mode only. Does not support transparent firewall mode.

IPv6 Guidelines

Does not support IPv6. See the "IPv4 and IPv6 Support" section on page 75-6.

Additional Guidelines

- Cloud Web Security is not supported with ASA clustering.
- Clientless SSL VPN is not supported with Cloud Web Security; be sure to exempt any clientless SSL VPN traffic from the ASA service policy for Cloud Web Security.

- When an interface to the Cloud Web Security proxy servers goes down, output from the **show scansafe server** command shows both servers up for approximately 15-25 minutes. This condition may occur because the polling mechanism is based on the active connection, and because that interface is down, it shows zero connection, and it takes the longest poll time approach.
- Cloud Web Security is not supported with the ASA CX module. If you configure both the ASA CX action and Cloud Web Security inspection for the same traffic, the ASA only performs the ASA CX action.
- Cloud Web Security inspection is compatibile with HTTP inspection for the same traffic. HTTP inspection is enabled by default as part of the default global policy.
- Cloud Web Security is not supported with extended PAT or any application that can potentially use the same source port and IP address for separate connections. For example, if two different connections (targeted to separate servers) use extended PAT, the ASA might reuse the same source IP and source port for both connection translations because they are differentiated by the separate destinations. When the ASA redirects these connections to the Cloud Web Security server, it replaces the destination with the Cloud Web Security server IP address and port (8080 by default). As a result, both connections now appear to belong to the same flow (same source IP/port and destination IP/port), and return traffic cannot be untranslated properly.
- The Default Inspection Traffic traffic class does not include the default ports for the Cloud Web Security inspection (80 and 443).

Default Settings

By default, Cisco Cloud Web Security is not enabled.

Configuring Cisco Cloud Web Security

- Configuring Communication with the Cloud Web Security Proxy Server, page 75-8
- (Multiple Context Mode) Allowing Cloud Web Security Per Security Context, page 75-9
- Configuring a Service Policy to Send Traffic to Cloud Web Security, page 75-10
- (Optional) Configuring Whitelisted Traffic, page 75-23
- Configuring the Cloud Web Security Policy, page 75-26

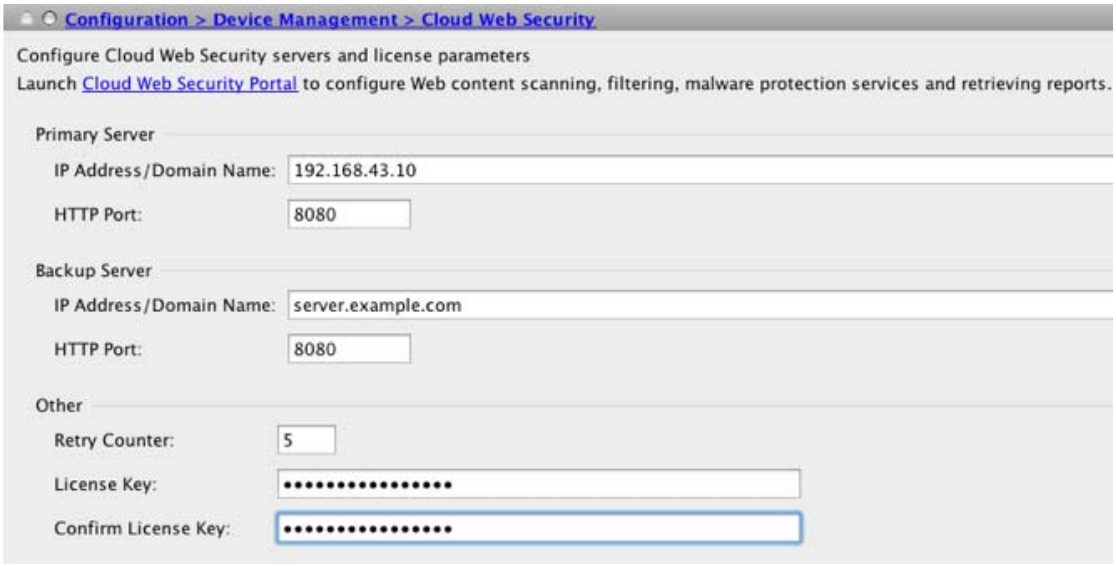
Configuring Communication with the Cloud Web Security Proxy Server

Guidelines

The public key is embedded in the ASA software, so there is no need for you to configure it.

Detailed Steps

Step 1 Choose **Configuration > Device Management > Cloud Web Security**.



Step 2 In the Primary Server area, enter the following:

- IP Address/Domain Name—Enter the IPv4 address or FQDN of the primary server.
- HTTP Port—Enter the HTTP port of the primary server (port to which traffic must be redirected). By default the port is 8080; do not change this value unless directed to do so.

Step 3 In the Backup Server area, enter the following:

- IP Address/Domain Name—Enter the IPv4 address or FQDN of the backup server.
- HTTP Port—Enter the HTTP port of the backup server (port to which traffic must be redirected). By default the port is 8080. Valid values are from 1 to 65535.

Step 4 In the Other area, enter the following:

- Retry Counter—Enter the retry counter. Valid values are from 2 to 100.
- License Key—Enter the license (authentication) key, which is a 16-byte hexidecimal key. See the "Authentication Keys" section on page 75-3.
- Confirm License Key—Confirm the authentication key.

Step 5 Click **Apply**.

(Multiple Context Mode) Allowing Cloud Web Security Per Security Context

In multiple context mode, you must allow Cloud Web Security per context. See the "Configuring a Security Context" section on page 9-20.

Configuring a Service Policy to Send Traffic to Cloud Web Security

Your service policy consists of multiple service policy rules, applied globally, or applied to each interface. Each service policy rule can either send traffic to Cloud Web Security (Match) or exempt traffic from Cloud Web Security (Do Not Match). Create rules for traffic destined for the Internet. The order of these rules is important. When the ASA decides whether to forward or exempt a packet, the ASA tests the packet with each rule in the order in which the rules are listed. After a match is found, no more rules are checked. For example, if you create a rule at the beginning of a policy that explicitly Matches all traffic, no further statements are ever checked. You can reorder the rules as needed after you add them.

See Chapter 44, "Configuring a Service Policy," for more information about service policy rules.

Prerequisites

(Optional) If you need to use a whitelist to exempt some traffic from being sent to Cloud Web Security, first create the whitelist according to the "(Optional) Configuring Whitelisted Traffic" section on page 75-23 so you can refer to the whitelist in your service policy rule.

Detailed Steps

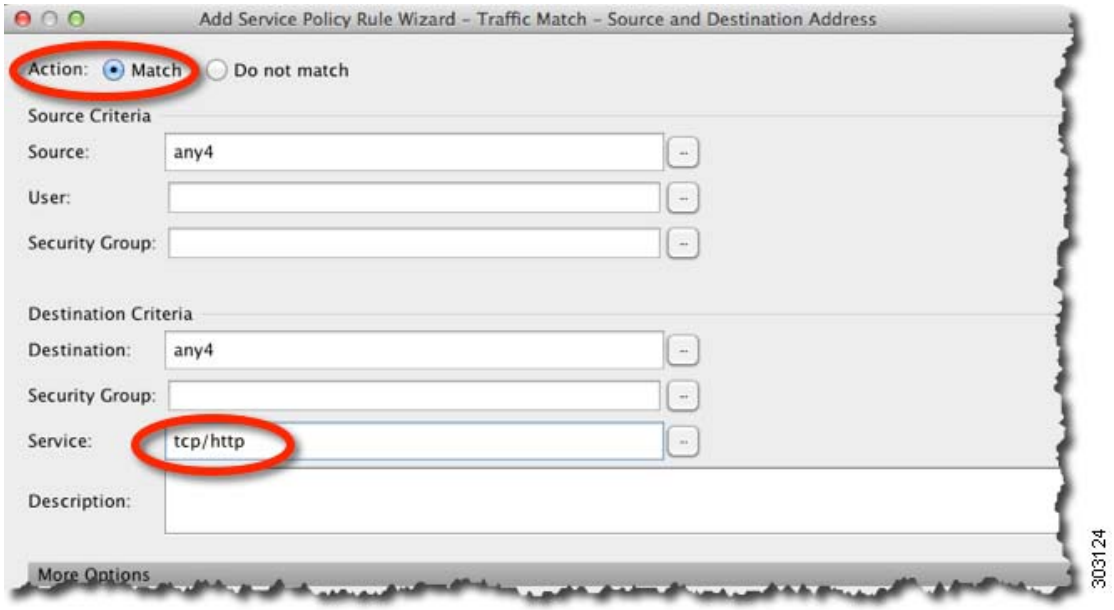
Step 1 Choose **Configuration > Firewall > Service Policy Rules**, and click **Add > Service Policy Rule** to add a service policy rule.

Step 2 On the Service Policy dialog box, you can configure Cloud Web Security as part of a new service policy, or you can edit an existing service policy. Click **Next**.

Step 3 On the Traffic Classification Criteria dialog box, name the traffic class (or accept the default name), keep the **Create a new traffic class** option selected, and click **Source and Destination IP address (Uses ACL)**, then click **Next**.

When you create a new traffic class of this type, you can only specify one access control entry (ACE) initially. After you finish adding the rule, you can add additional ACEs by adding a new rule to the same interface or global policy, and then specifying **Add rule to existing traffic class** on the Traffic Classification dialog box.

The Traffic Match - Source and Destination dialog box appears.



a. Click **Match** or **Do Not Match**.

   Match specifies that traffic matching the source and destination is sent to Cloud Web Security. **Do Not Match** exempts matching traffic from Cloud Web Security. You can later add additional rules to match or not match other traffic.

   When creating your rules, consider how you can match appropriate traffic that is destined for the Internet, but not match traffic that is destined for other internal networks. For example, to prevent inside traffic from being sent to Cloud Web Security when the destination is an internal server on the DMZ, be sure to add a deny ACE to the ACL that exempts traffic to the DMZ.

b. In the Source Criteria area, enter or browse for a Source IP address or network object, an optional IDFW Username or group, and an optional TrustSec Security Group.

c. In the Destination Criteria area, enter or browse for a Destination IP address or network object, and an optional TrustSec Security Group.

   FQDN network objects might be useful in matching or exempting traffic to specific servers.

d. In the Service field, enter **http** or **https**, and click **Next**.

Note Cloud Web Security only operates on HTTP and HTTPS traffic. Each type of traffic is treated separately by the ASA. Therefore, you need to create HTTP-only rules and HTTPS-only rules.

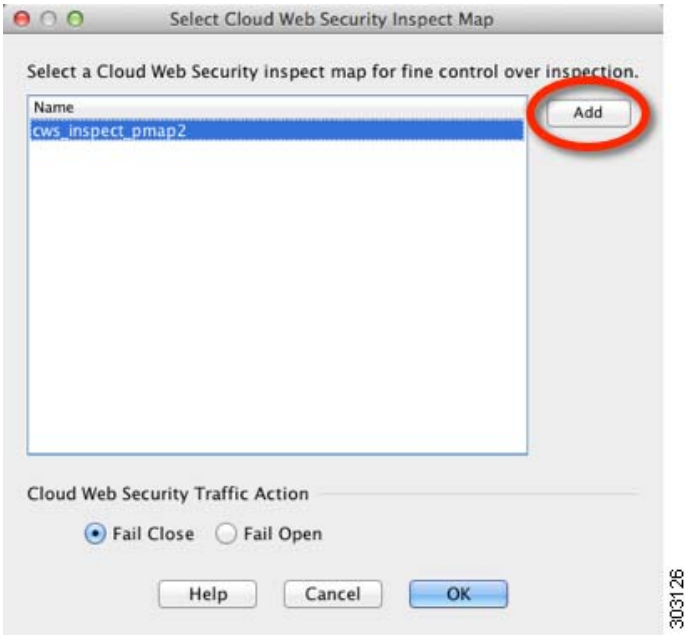
The Rule Actions dialog box appears.

Step 4 On the Protocol Inspection tab, check the **Cloud Web Security** check box.

Step 5 Click **Configure** to set the traffic action (fail open or fail close) and add the inspection policy map.

The inspection policy map configures essential parameters for the rule and also optionally identifies the whitelist. An inspection policy map is required for each class of traffic that you want to send to Cloud Web Security. You can also pre-configure inspection policy maps from the Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security pane.

The Select Cloud Web Security Inspect Map dialog box appears.

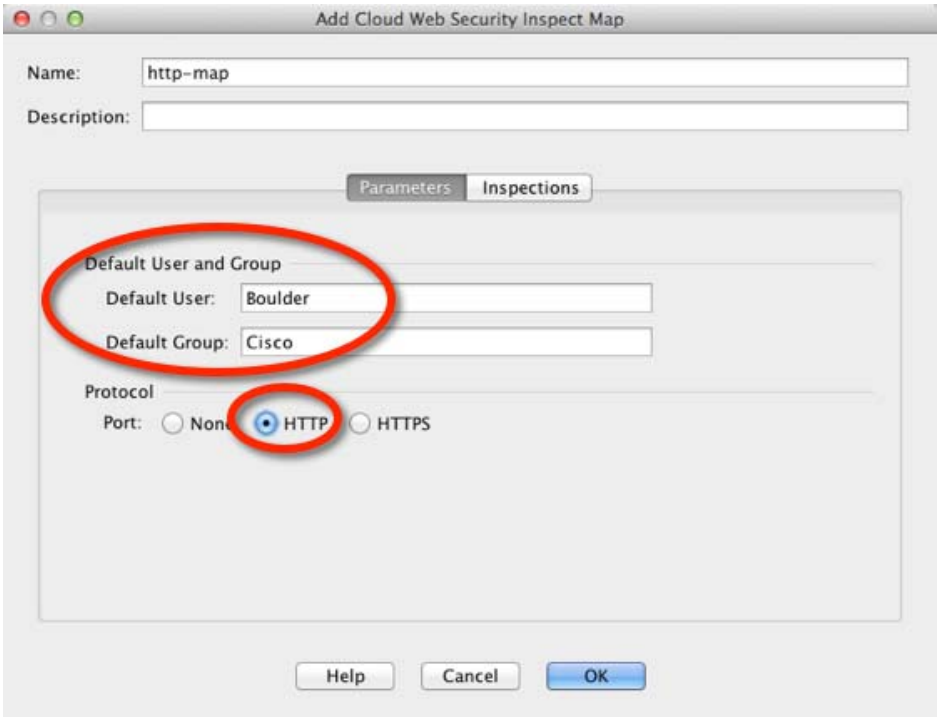


a. For the Cloud Web Security Traffic Action, choose one:
   - **Fail Close**—Drops all traffic if the Cloud Web Security servers are unavailable.
   - **Fail Open**—Allows traffic to pass through the ASA if the Cloud Web Security servers are unavailable.

b. Choose an existing inspection policy map, or add one using the **Add** button.

c. Click **Add** to add a new inspection policy map.

   The Add Cloud Web Security Inspect Map dialog box appears.



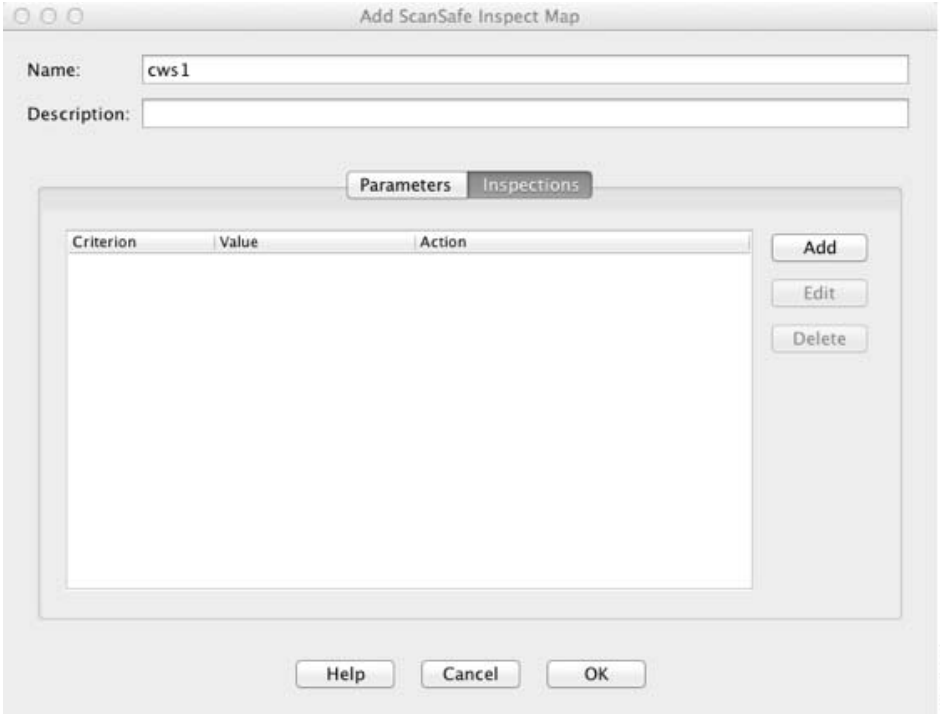
d. In the Name field, specify a name for the inspection policy map, up to 40 characters in length.

e. (Optional) Enter a description.

f. (Optional) On the Parameters tab, specify a Default User and/or a Default Group. If the ASA cannot determine the identity of the user coming into the ASA, then the default user and/or group is applied.

g. For the Protocol, click **HTTP** or **HTTPS**, to match the service you set in Step 3d. Cloud Web Security treats each type of traffic separately.

h. (Optional) To identify a whitelist, click the **Inspections** tab.



- Click **Add** to choose the inspection class map you created in the "(Optional) Configuring Whitelisted Traffic" section on page 75-23.

  The Add Cloud Web Security Match Criterion dialog box appears.
- From the Cloud Web Security Traffic Class drop-down menu, choose an inspection class map.

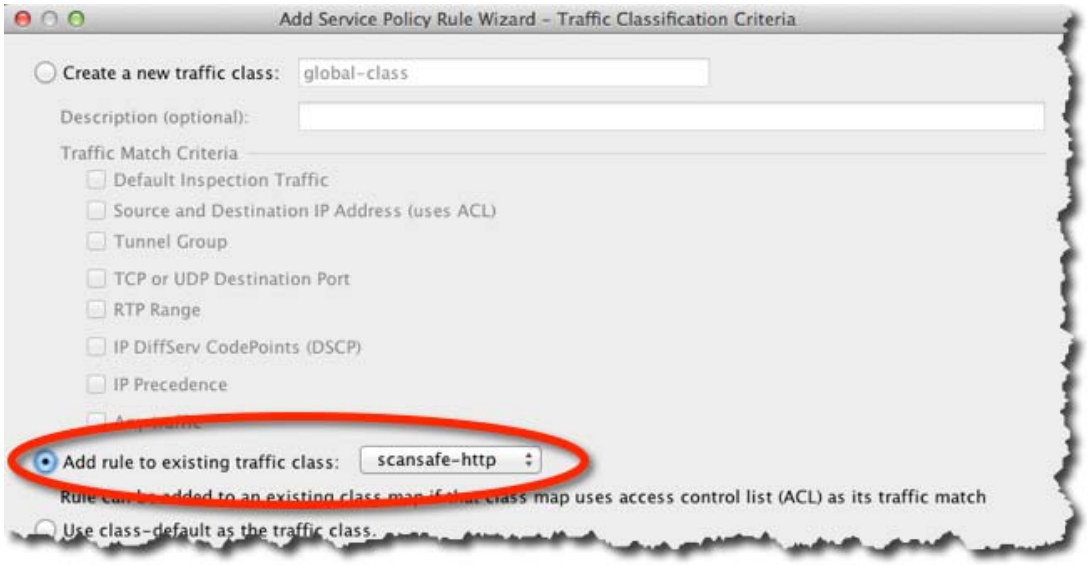
  To add or edit a class map, click **Manage**.
- For the Action, click **Whitelist**.
- Click **OK** to add the whitelist to the policy map.
- Click **OK**.

Step 6 Click **Finish**. The rule is added to the Service Policy Rules table.

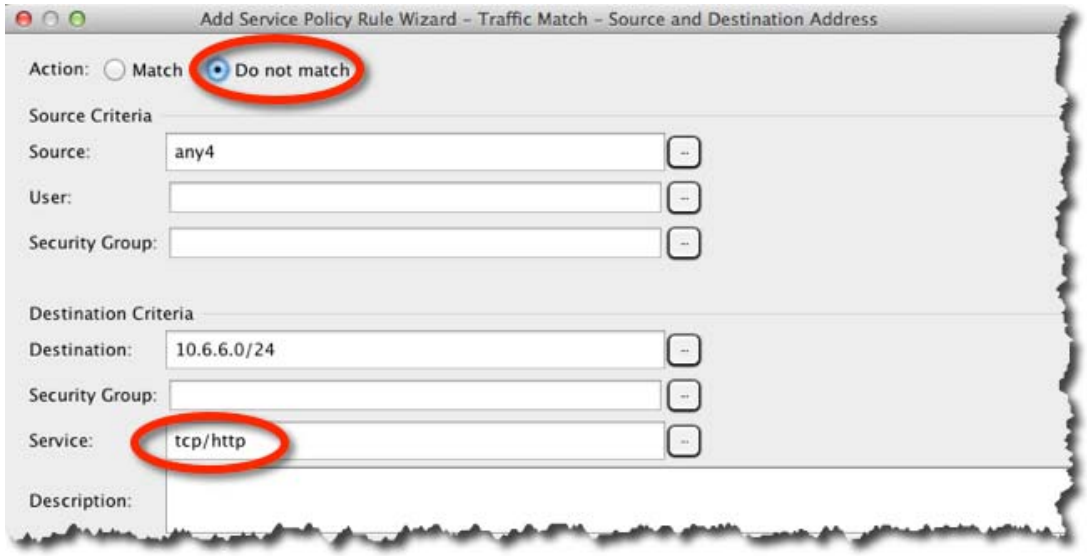
Step 7 To add additional sub-rules (ACEs) for this traffic class, to match or exempt additional traffic:

a. Choose **Configuration > Firewall > Service Policy Rules**, and click **Add > Service Policy Rule**.

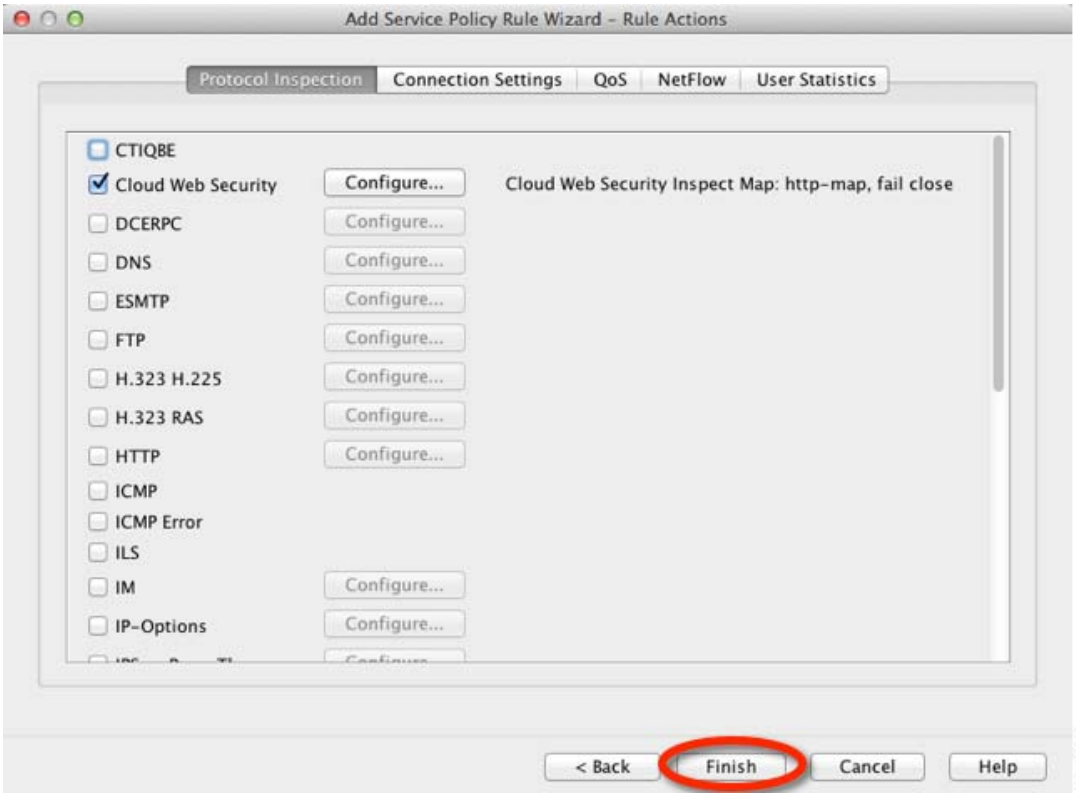
b. Choose the same service policy as Step 2. Click **Next**.



c. On the Traffic Classification Criteria dialog box, choose **Add Rule to Existing Traffic Class**, and choose the name you created in Step 3. Click **Next**.



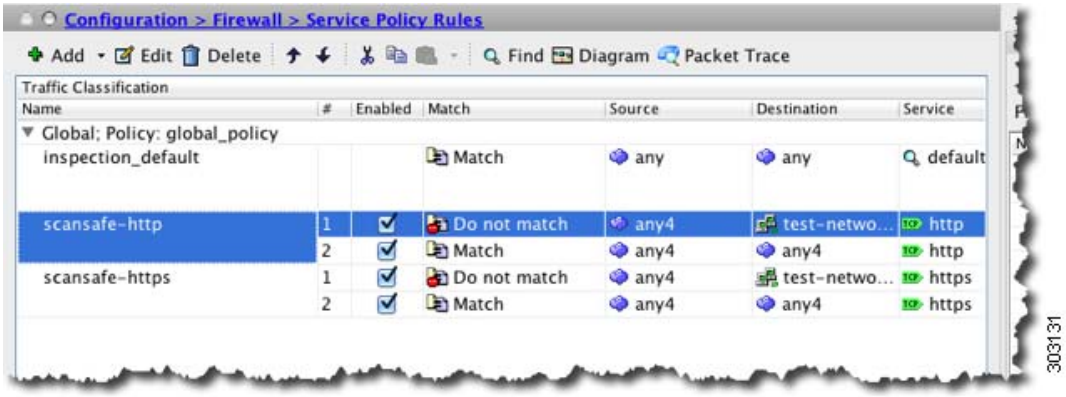
d. In the Traffic Match - Source and Destination dialog box, choose **Match** to add inspect additional traffic, or **Do Not Match** to exempt traffic from Cloud Web Security inspections. Be sure to set the service to match the previous rules in this class (HTTP or HTTPS); you cannot mix HTTP and HTTPS in the same traffic class for Cloud Web Security. Click **Next**.



e. On the Rule Actions dialog box, do not make any changes; click **Finish**. For this traffic class, you can have only one set of rule actions even if you add multiple ACEs, so the previously-specified actions are inherited.

Step 8 Repeat this entire procedure to create an additional traffic class, for example for HTTPS traffic. You can create as many rules and sub-rules as needed.

Step 9 Arrange the order of Cloud Web Security rules and sub-rules on the Service Policy Rules pane. See the "Managing the Order of Service Policy Rules" section on page 44-16 for information about changing the order of ACEs.

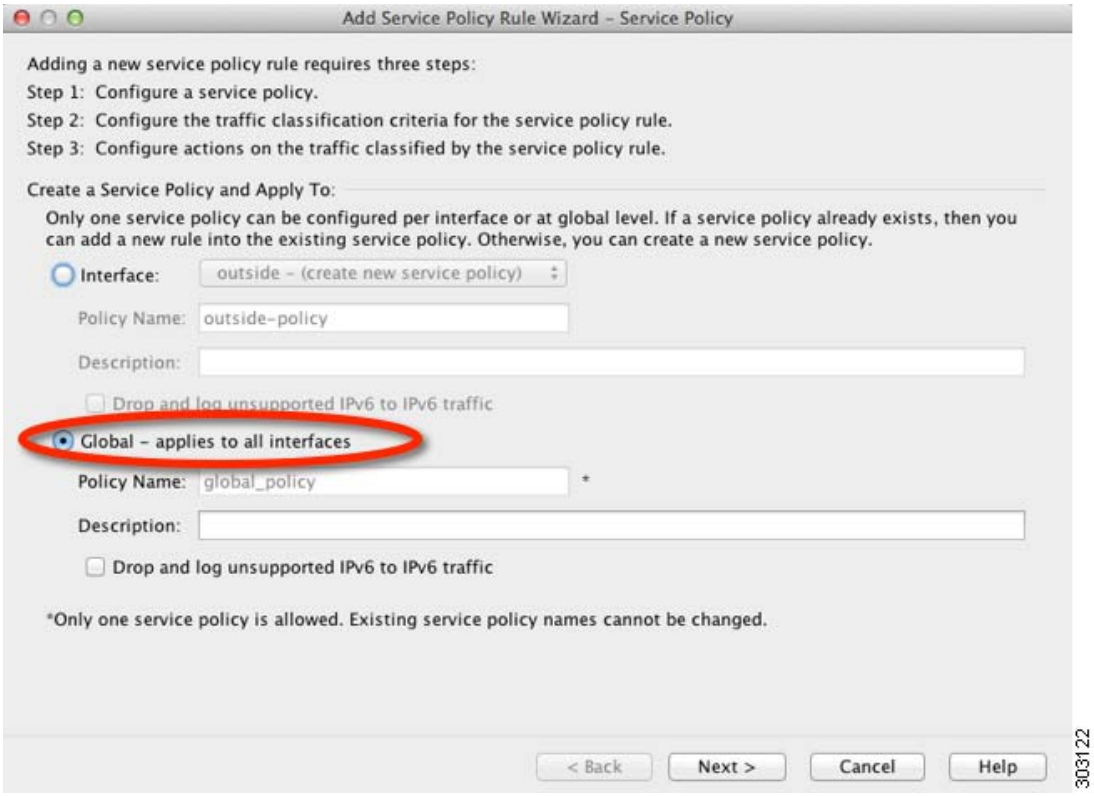


Step 10 Click **Apply**.

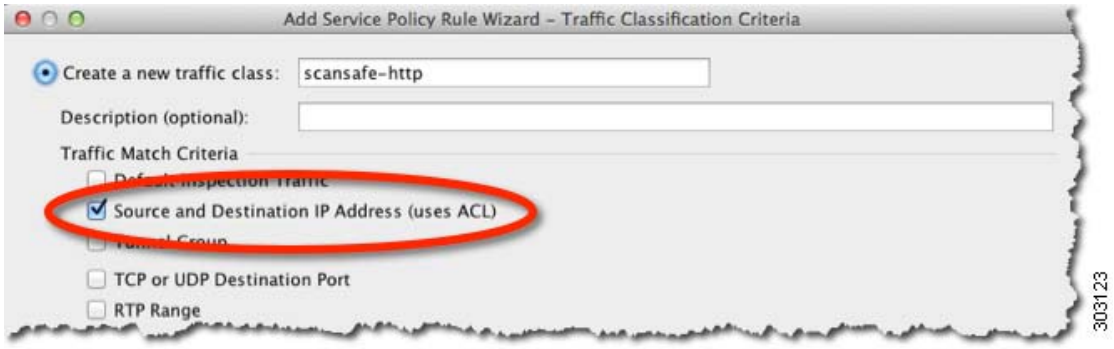
Examples

The following example exempts all IPv4 HTTP and HTTPS traffic going to the 10.6.6.0/24 (test_network), and sends all other HTTPS and HTTPS traffic to Cloud Web Security, and applies this service policy rule to all interfaces as part of the existing global policy. If the Cloud Web Security server is unreachable, the ASA drops all matching traffic (fail close). If a user is not have user identity information, the default user Boulder and group Cisco is used.

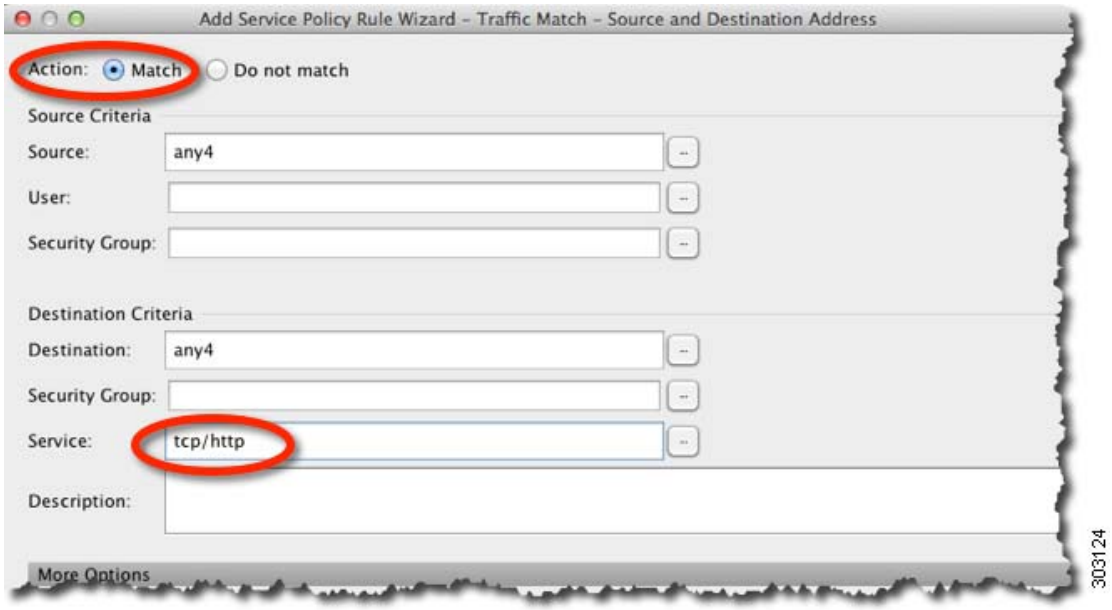
Step 1 Choose **Configuration > Firewall > Service Policy Rules**, and click **Add > Service Policy Rule**. Add this rule to the default global_policy:



Step 2 Add a new traffic class called “scansafe-http,” and specify an ACL for traffic matching:

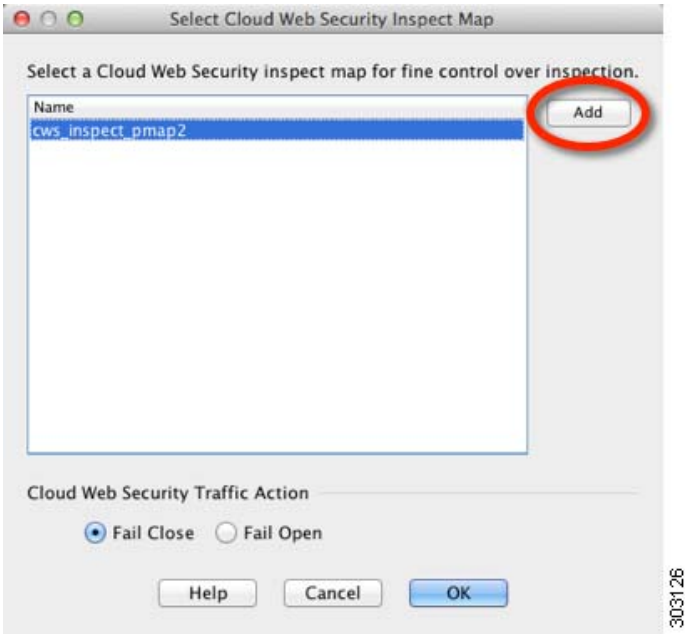


Step 3 Choose **Match**, and specify **any4** for the Source and Destination. Specify **tcp/http** for the Service.

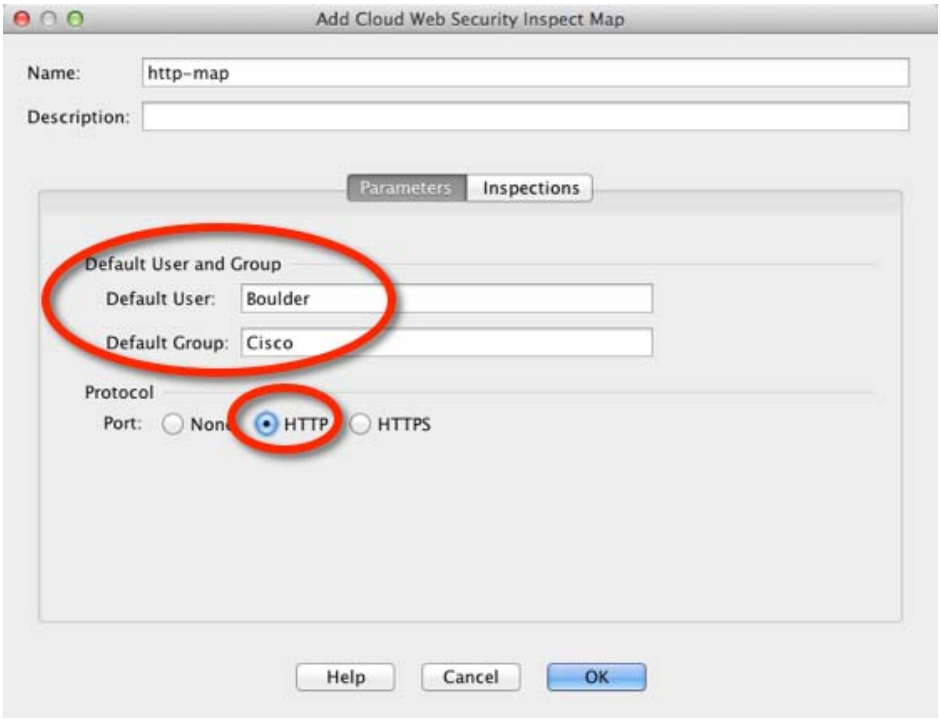


Step 4 Check **Cloud Web Security** and click **Configure**.

Step 5 Accept the default Fail Close action, and click **Add**.

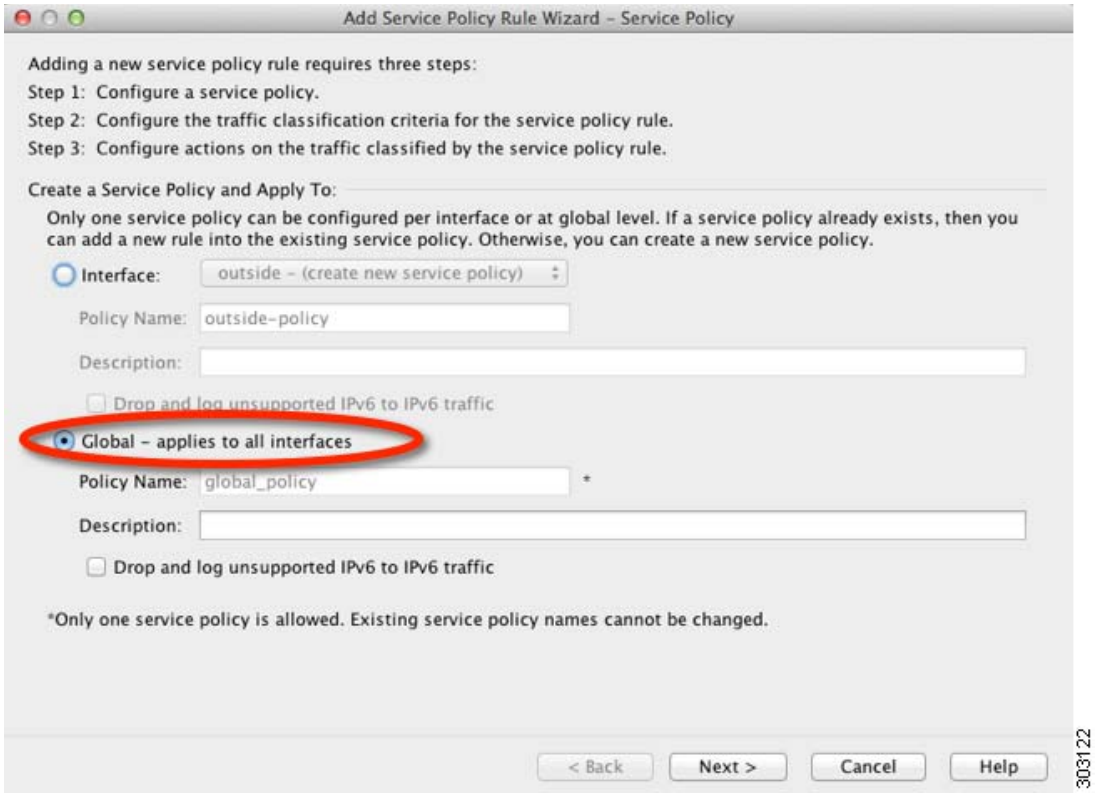


Step 6 Name the inspection policy map "http-map," set the Default User to Boulder and the default group to Cisco. Choose **HTTP**.

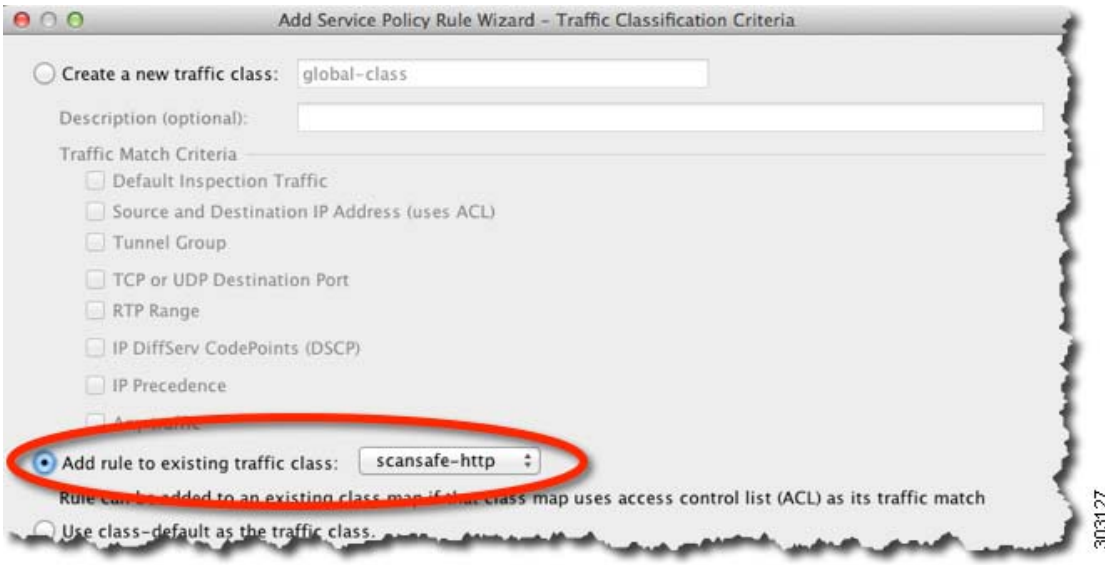


Step 7 Click **OK**, **OK**, and then **Finish**. The rule is added to the Service Policy Rules table.

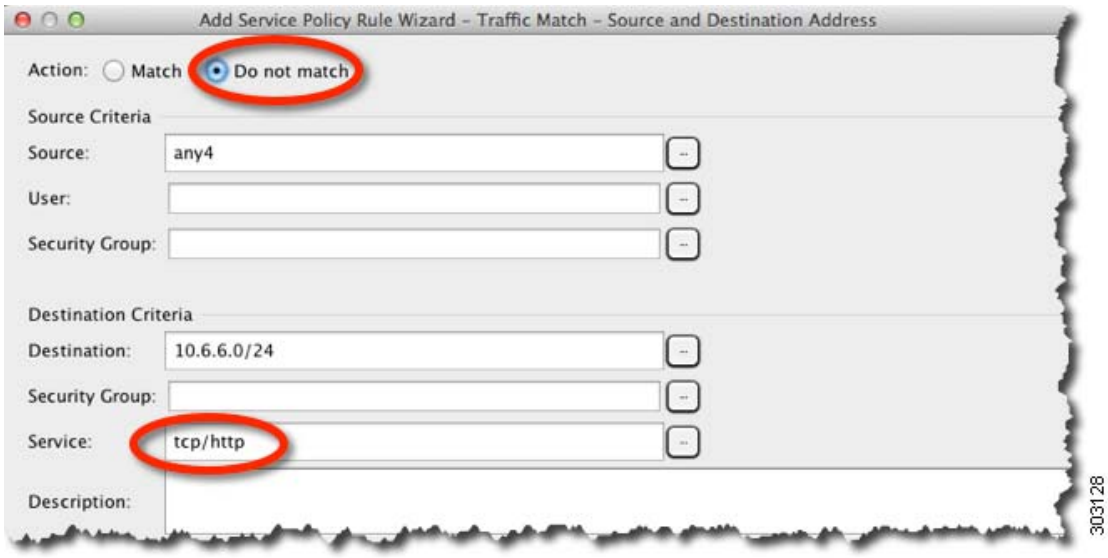
Step 8 Choose **Configuration > Firewall > Service Policy Rules**, and click **Add > Service Policy Rule**. Add the new rule to the default global_policy:



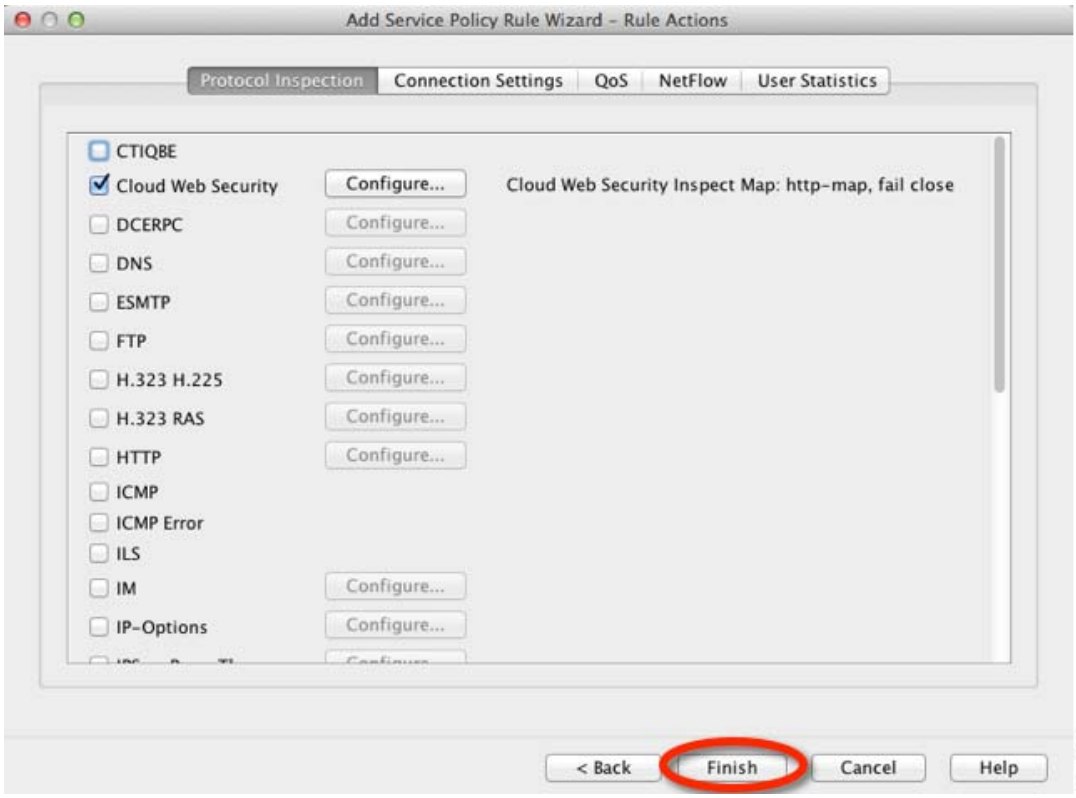
Step 9 Click **Add rule to existing traffic class**, and choose **scansafe-http**.



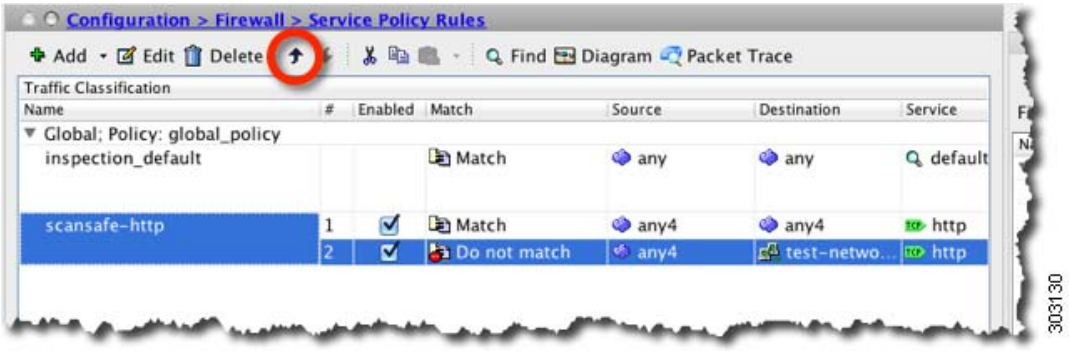
Step 10 Choose **Do not match**, set **any4** as the Source, and **10.6.6.0/24** as the Destination. Set the Service to **tcp/http**.



Step 11 Click **Finish**.

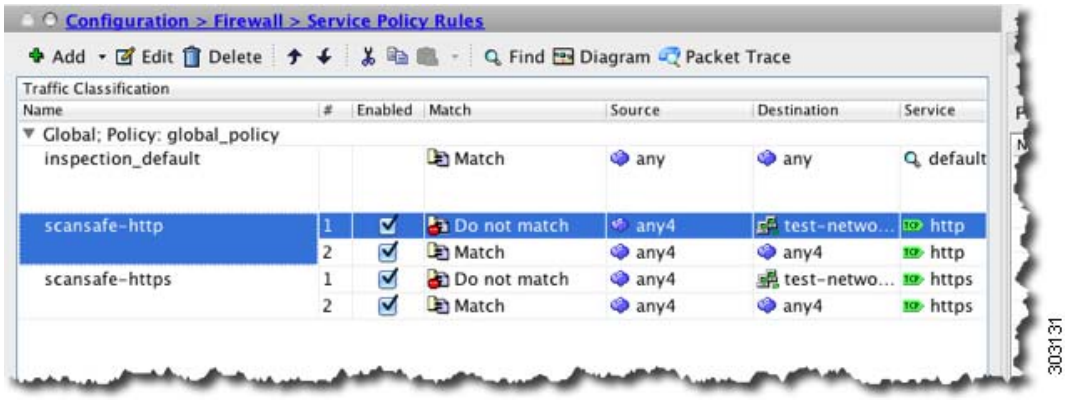


Step 12 Reorder the rules so the Do not match rule is above the Match rule.



User traffic is compared to these rules in order; if this Match rule is first in the list, then all traffic, including traffic to test_network, will match only that rule and the Do not match rule will never be hit. If you move the Do not match rule above the Match rule, then traffic to test_network will match the Do not match rule, and all other traffic will match the Match rule.

Step 13 Repeat the above steps with the following changes: add a new traffic class called "scansafe-https," and choose **HTTPS** for the inspection policy map.



Step 14 Click **Apply**.

(Optional) Configuring Whitelisted Traffic

If you use user authentication, you can exempt some traffic from being filtered by Cloud Web Security based on the username and/or groupname. When you configure your Cloud Web Security service policy rule, you can reference the whitelisting inspection class map. Both IDFW and AAA user credentials can be used with this feature.

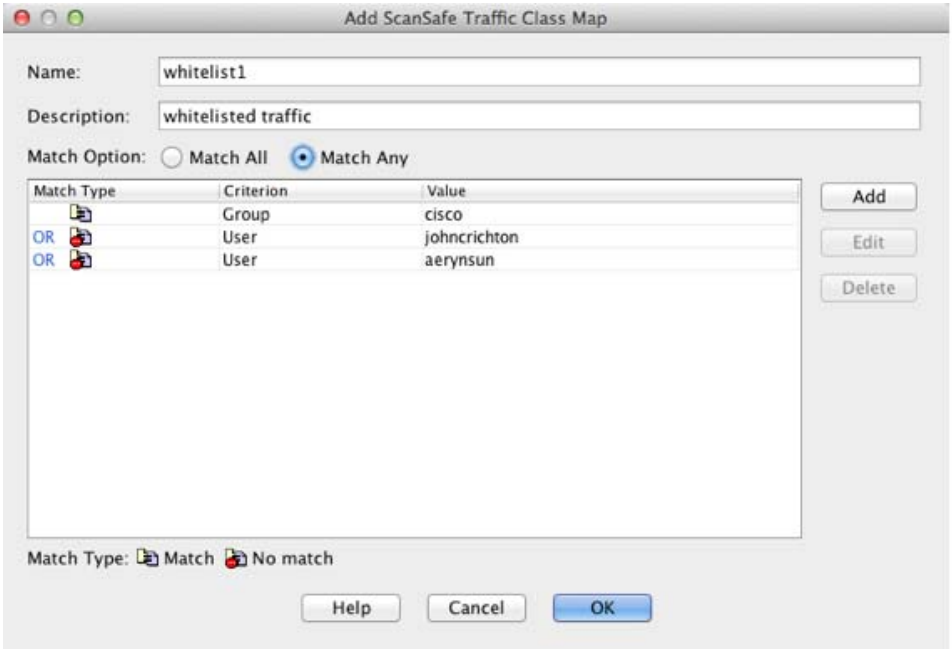
Although you can achieve the same results of exempting traffic based on user or group when you configure the service policy rule, you might find it more straightforward to use a whitelist instead. Note that the whitelist feature is only based on user and group, not on IP address.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Class Maps > Cloud Web Security**.

Step 2 Click **Add** to create a new class map.

The Add Cloud Web Security Traffic Class Map screen appears.



Step 3 In the Name field, enter the name of the new class map (40 characters or less).

Step 4 In the Description field, provide a description for the class map (200 characters or less).

Step 5 Choose the Match Option for the criteria you define when you click ADD:

- Match All—Specifies that traffic must match all criteria to match the class map.
- Match Any—Specifies that the traffic matches the class map if it matches at least one of the criteria.

Step 6 Click **Add**.

The Add Cloud Web Security Match Criterion Window appears.

Step 7 Choose the Match Type:

- Match—Specifies the user and/or group that you want to whitelist.
- No Match—Specifies the user and/or group that you do *not* want to whitelist; for example, if you whitelist the group “cisco,” but you want to scan traffic from users “johncrichton” and “aerynsun,” you can specify No Match for those users.

Step 8 Choose the Match Criterion:

- User—Specifies the user.
- Group—Specifies the group.
- User and Group—Specifies a user and group.

Step 9 Click **OK**.

Step 10 Continue to add match criteria as desired.

Step 11 Click **OK** to add the class map.

Step 12 Click **Apply**.

Step 13 Use the whitelist in the Cloud Web Security policy according to the "Configuring a Service Policy to Send Traffic to Cloud Web Security" section on page 75-10.

(Optional) Configuring the User Identity Monitor

When you use IDFW, the ASA only downloads user identity information from the AD server for users and groups included in active ACLs; the ACL must be used in a feature such as an access rule, AAA rule, service policy rule, or other feature to be considered active. Because Cloud Web Security can base its policy on user identity, you may need to download groups that are not part of an active ACL to get full IDFW coverage for all your users. For example, although you can configure your Cloud Web Security service policy rule to use an ACL with users and groups, thus activating any relevant groups, it is not required; you could use an ACL based entirely on IP addresses.The user identity monitor feature lets you download group information directly from the AD agent.

Restrictions

The ASA can only monitor a maximum of 512 groups, including those configured for the user identity monitor and those monitored through active ACLs.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Identity Options**, and scroll to the Cloud Web Security Configuration section.

Step 2 Click **Add**.

The Add Monitor User dialog box appears.

Step 3 To add a domain, click **Manage**, and then click **Add**. You can only monitor groups for domains you have pre-defined on the ASA.

The Configure Identity Domains dialog box appears. For detailed information about adding domains, see the "Configuring Identity Options" section on page 47-12.

Step 4 When you are finished adding domains, click **OK**.

Step 5 You can either type in a group name, or you can search for groups on the AD agent per domain.

- To type in a group name directly, enter the name in the bottom field in the following format, and click **OK**:

  *domain-name**group*

- To search for a group on the AD agent:

a. Choose the domain from the Domain drop-down list.

b. In the Find field, enter a text string to match group names, and click **Find**.

The ASA downloads names from the AD agent for the specified domain.

c. Double-click the name you want to monitor; it is added to the bottom field.

d. Click **OK**.

Repeat for additional groups.

Step 6 After you add the groups you want to monitor, click **Apply**.

Configuring the Cloud Web Security Policy

After you configure the ASA service policy rules, launch the ScanCenter Portal to configure Web content scanning, filtering, malware protection services, and reports.

Detailed Steps

Go to: https://scancenter.scansafe.com/portal/admin/login.jsp.

For more information, see the Cisco ScanSafe Cloud Web Security Configuration Guides:

http://www.cisco.com/en/US/products/ps11720/products_installation_and_configuration_guides_list.html

Monitoring Cloud Web Security

Command	Purpose
Monitoring > Properties > Cloud Web Security	Shows the status of the server, whether it is the current active server, the backup server, or unreachable. Shows total and current HTTP(S) connections. In multiple context mode, statistics are only shown within a context.
See the following URL: http://Whoami.scansafe.net	From a client, access this web site to determine if your traffic is going to the Cloud Web Security server.

Feature History for Cisco Cloud Web Security

Table 75-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 75-1 Feature History for Cloud Web Security

Feature Name	Platform Releases	Feature Information
Cloud Web Security	9.0(1)	This feature was introduced. Cisco Cloud Web Security provides content scanning and other malware protection service for web traffic. It can also redirect and report about web traffic based on user identity. We introduced or modified the following screens: Configuration > Device Management > Cloud Web Security Configuration > Firewall > Objects > Class Maps > Cloud Web Security Configuration > Firewall > Objects > Class Maps > Cloud Web Security > Add/Edit Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security > Add/Edit Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security > Add/Edit > Manage Cloud Web Security Class Maps Configuration > Firewall > Identity Options Configuration > Firewall > Service Policy Rules Monitoring > Properties > Cloud Web Security

Configuring the Botnet Traffic Filter

Malware is malicious software that is installed on an unknowing host. Malware that attempts network activity such as sending private data (passwords, credit card numbers, key strokes, or proprietary data) can be detected by the Botnet Traffic Filter when the malware starts a connection to a known bad IP address. The Botnet Traffic Filter checks incoming and outgoing connections against a dynamic database of known bad domain names and IP addresses (the *blacklist*), and then logs or blocks any suspicious activity.

You can also supplement the Cisco dynamic database with blacklisted addresses of your choosing by adding them to a static blacklist; if the dynamic database includes blacklisted addresses that you think should not be blacklisted, you can manually enter them into a static *whitelist*. Whitelisted addresses still generate syslog messages, but because you are only targeting blacklist syslog messages, they are informational.

Note If you do not want to use the Cisco dynamic database at all, because of internal requirements, you can use the static blacklist alone if you can identify all the malware sites that you want to target.

This chapter describes how to configure the Botnet Traffic Filter and includes the following sections:

- Information About the Botnet Traffic Filter, page 76-1
- Licensing Requirements for the Botnet Traffic Filter, page 76-6
- Guidelines and Limitations, page 76-6
- Default Settings, page 76-6
- Configuring the Botnet Traffic Filter, page 76-6
- Monitoring the Botnet Traffic Filter, page 76-14
- Where to Go Next, page 76-16
- Feature History for the Botnet Traffic Filter, page 76-16

Information About the Botnet Traffic Filter

This section includes information about the Botnet Traffic Filter and includes the following topics:

- Botnet Traffic Filter Address Types, page 76-2
- Botnet Traffic Filter Actions for Known Addresses, page 76-2
- Botnet Traffic Filter Databases, page 76-2

- How the Botnet Traffic Filter Works, page 76-5

Botnet Traffic Filter Address Types

Addresses monitored by the Botnet Traffic Filter include:

- Known malware addresses—These addresses are on the blacklist identified by the dynamic database and the static blacklist.
- Known allowed addresses—These addresses are on the whitelist. The whitelist is useful when an address is blacklisted by the dynamic database and also identified by the static whitelist.
- Ambiguous addresses—These addresses are associated with multiple domain names, but not all of these domain names are on the blacklist. These addresses are on the *greylist*.
- Unlisted addresses—These addresses are unknown, and not included on any list.

Botnet Traffic Filter Actions for Known Addresses

You can configure the Botnet Traffic Filter to log suspicious activity, and you can optionally configure it to block suspicious traffic automatically.

Unlisted addresses do not generate any syslog messages, but addresses on the blacklist, whitelist, and greylist generate syslog messages differentiated by type. See the "Botnet Traffic Filter Syslog Messaging" section on page 76-14 for more information.

Botnet Traffic Filter Databases

The Botnet Traffic Filter uses two databases for known addresses. You can use both databases together, or you can disable use of the dynamic database and use the static database alone. This section includes the following topics:

- Information About the Dynamic Database, page 76-2
- Information About the Static Database, page 76-3
- Information About the DNS Reverse Lookup Cache and DNS Host Cache, page 76-4

Information About the Dynamic Database

The Botnet Traffic Filter can receive periodic updates for the dynamic database from the Cisco update server. This database lists thousands of known bad domain names and IP addresses.

How the ASA Uses the Dynamic Database

The ASA uses the dynamic database as follows:

1. When the domain name in a DNS reply matches a name in the dynamic database, the Botnet Traffic Filter adds the name and IP address to the *DNS reverse lookup cache*.
2. When the infected host starts a connection to the IP address of the malware site, then the ASA sends a syslog message informing you of the suspicious activity and optionally drops the traffic if you configured the ASA to do so.

3. In some cases, the IP address itself is supplied in the dynamic database, and the Botnet Traffic Filter logs or drops any traffic to that IP address without having to inspect DNS requests.

Database Files

The database files are stored in running memory; they are not stored in flash memory. If you need to delete the database, use theConfiguration > Firewall > Botnet Traffic Filter > Botnet Database pane Purge Botnet Database button instead. Be sure to first disable use of the database by unchecking the **Use Botnet data dynamically downloaded from updater server** check box in the Configuration > Firewall > Botnet Traffic Filter > Botnet Database > Dynamic Database Configuration area.

Note To use the database, be sure to configure a domain name server for the ASA so that it can access the URL.

To use the domain names in the dynamic database, you need to enable DNS packet inspection with Botnet Traffic Filter snooping; the ASA looks inside the DNS packets for the domain name and associated IP address.

Database Traffic Types

The dynamic database includes the following types of addresses:

- Ads—These are advertising networks that deliver banner ads, interstitials, rich media ads, pop-ups, and pop-unders for websites, spyware and adware. Some of these networks send ad-oriented HTML emails and email verification services.
- Data Tracking—These are sources associated with companies and websites that offer data tracking and metrics services to websites and other online entities. Some of these also run small advertising networks.
- Spyware—These are sources that distribute spyware, adware, greyware, and other potentially unwanted advertising software. Some of these also run exploits to install such software.
- Malware—These are sources that use various exploits to deliver adware, spyware and other malware to victim computers. Some of these are associated with rogue online vendors and distributors of dialers which deceptively call premium-rate phone numbers.
- Adult—These are sources associated with adult networks/services offering web hosting for adult content, advertising, content aggregation, registration & billing, and age verification. These may be tied to distribution of adware, spyware, and dialers.
- Bot and Threat Networks—These are rogue systems that control infected computers. They are either systems hosted on threat networks or systems that are part of the botnet itself.

Information About the Static Database

You can manually enter domain names or IP addresses (host or subnet) that you want to tag as bad names in a blacklist. Static blacklist entries are always designated with a Very High threat level. You can also enter names or IP addresses in a whitelist, so that names or addresses that appear on both the *dynamic* blacklist and the whitelist are identified only as whitelist addresses in syslog messages and reports. Note that you see syslog messages for whitelisted addresses even if the address is not also in the dynamic blacklist.

When you add a domain name to the static database, the ASA waits 1 minute, and then sends a DNS request for that domain name and adds the domain name/IP address pairing to the *DNS host cache*. (This action is a background process, and does not affect your ability to continue configuring the ASA). We

recommend also enabling DNS packet inspection with Botnet Traffic Filter snooping. The ASA uses Botnet Traffic Filter snooping instead of the regular DNS lookup to resolve static blacklist domain names in the following circumstances:

- The ASA DNS server is unavailable.
- A connection is initiated during the 1 minute waiting period before the ASA sends the regular DNS request.

If DNS snooping is used, when an infected host sends a DNS request for a name on the static database, the ASA looks inside the DNS packets for the domain name and associated IP address and adds the name and IP address to the DNS reverse lookup cache.

If you do not enable Botnet Traffic Filter snooping, and one of the above circumstances occurs, then that traffic will not be monitored by the Botnet Traffic Filter.

Information About the DNS Reverse Lookup Cache and DNS Host Cache

When you use the dynamic database with DNS snooping, entries are added to the DNS reverse lookup cache. If you use the static database, entries are added to the DNS host cache (see the "Information About the Static Database" section on page 76-3 about using the static database with DNS snooping and the DNS reverse lookup cache).

Entries in the DNS reverse lookup cache and the DNS host cache have a time to live (TTL) value provided by the DNS server. The largest TTL value allowed is 1 day (24 hours); if the DNS server provides a larger TTL, it is truncated to 1 day maximum.

For the DNS reverse lookup cache, after an entry times out, the ASA renews the entry when an infected host initiates a connection to a known address, and DNS snooping occurs.

For the DNS host cache, after an entry times out, the ASA periodically requests a refresh for the entry.

For the DNS host cache, the maximum number of blacklist entries and whitelist entries is 1000 each.

Table 76-1 lists the maximum number of entries in the DNS reverse lookup cache per model.

Table 76-1 DNS Reverse Lookup Cache Entries per Model

ASA Model	Maximum Entries
ASA 5505	5000
ASA 5510	10,000
ASA 5520	20,000
ASA 5540	40,000
ASA 5550	40,000
ASA 5580	100,000

How the Botnet Traffic Filter Works

Figure 76-1 shows how the Botnet Traffic Filter works with the dynamic database plus DNS inspection with Botnet Traffic Filter snooping.

Figure 76-1 How the Botnet Traffic Filter Works with the Dynamic Database

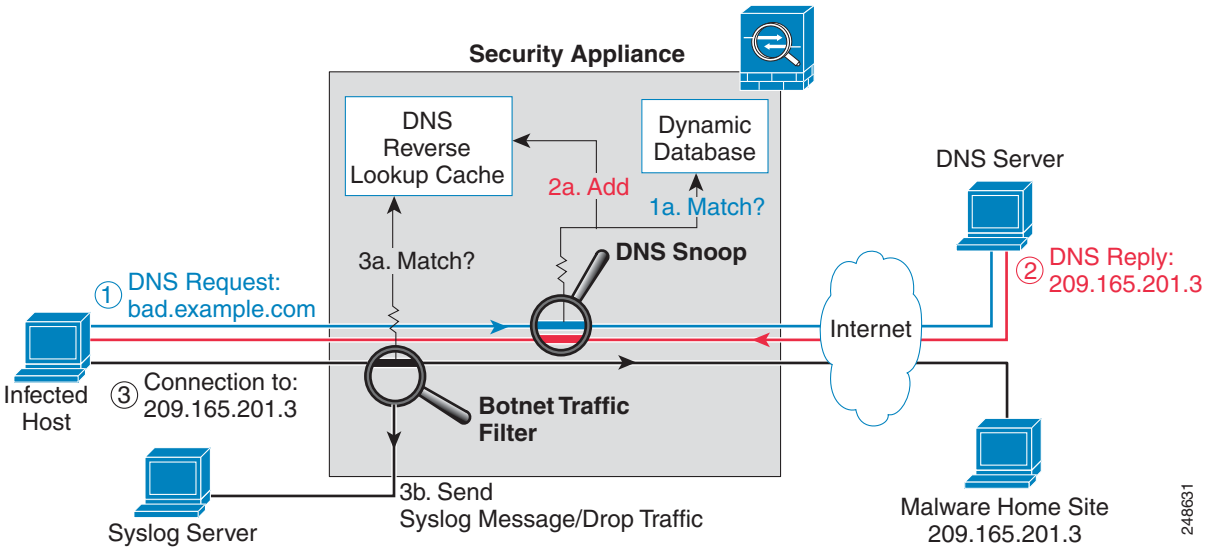

Figure 76-2 shows how the Botnet Traffic Filter works with the static database.

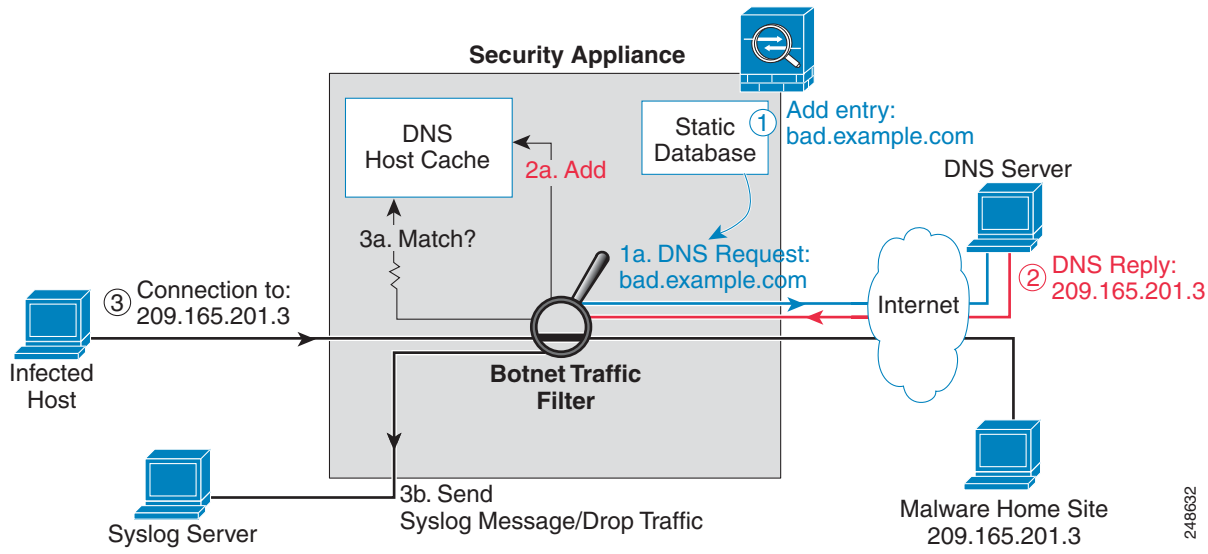
Figure 76-2 How the Botnet Traffic Filter Works with the Static Database



Licensing Requirements for the Botnet Traffic Filter

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	You need the following licenses: • Botnet Traffic Filter License. • Strong Encryption (3DES/AES) License to download the dynamic database.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Failover Guidelines

Does not support replication of the DNS reverse lookup cache, DNS host cache, or the dynamic database in Stateful Failover.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines and Limitations

- TCP DNS traffic is not supported.
- You can add up to 1000 blacklist entries and 1000 whitelist entries in the static database.
- The packet tracer is not supported.

Default Settings

By default, the Botnet Traffic Filter is disabled, as is use of the dynamic database.

For DNS inspection, which is enabled by default, Botnet Traffic Filter snooping is disabled by default.

Configuring the Botnet Traffic Filter

This section includes the following topics:

- Task Flow for Configuring the Botnet Traffic Filter, page 76-7

- Configuring the Dynamic Database, page 76-7
- Enabling DNS Snooping, page 76-9
- Adding Entries to the Static Database, page 76-9
- Enabling Traffic Classification and Actions for the Botnet Traffic Filter, page 76-10
- Blocking Botnet Traffic Manually, page 76-12
- Searching the Dynamic Database, page 76-13

Task Flow for Configuring the Botnet Traffic Filter

To configure the Botnet Traffic Filter, perform the following steps:

Step 1 Enable use of the dynamic database. See the "Configuring the Dynamic Database" section on page 76-7.

This procedure enables database updates from the Cisco update server, and also enables use of the downloaded dynamic database by the ASA. Disallowing use of the downloaded database is useful in multiple context mode so you can configure use of the database on a per-context basis.

Step 2 (Optional) Add static entries to the database. See the "Adding Entries to the Static Database" section on page 76-9.

This procedure lets you augment the dynamic database with domain names or IP addresses that you want to blacklist or whitelist. You might want to use the static database instead of the dynamic database if you do not want to download the dynamic database over the Internet.

Step 3 Enable DNS snooping. See the "Enabling DNS Snooping" section on page 76-9.

This procedure enables inspection of DNS packets, compares the domain name with those in the dynamic database or the static database (when a DNS server for the ASA is unavailable), and adds the name and IP address to the DNS reverse lookup cache. This cache is then used by the Botnet Traffic Filter when connections are made to the suspicious address.

Step 4 Enable traffic classification and actions for the Botnet Traffic Filter. See the "Enabling Traffic Classification and Actions for the Botnet Traffic Filter" section on page 76-10.

This procedure enables the Botnet Traffic Filter, which compares the source and destination IP address in each initial connection packet to the IP addresses in the dynamic database, static database, DNS reverse lookup cache, and DNS host cache, and sends a syslog message or drops any matching traffic.

Step 5 (Optional) Block traffic manually based on syslog message information. See the "Blocking Botnet Traffic Manually" section on page 76-12.

If you choose not to block malware traffic automatically, you can block traffic manually by configuring an access rule to deny traffic, or by using the **shun** command in the Command Line Interface tool to block all traffic to and from a host.

Configuring the Dynamic Database

This procedure enables database updates, and also enables use of the downloaded dynamic database by the ASA. Disabling use of the downloaded database is useful in multiple context mode so you can configure use of the database on a per-context basis.

By default, downloading and using the dynamic database is disabled.

Prerequisites

Enable ASA use of a DNS server in the Device Management > DNS > DNS Client > DNS Lookup area. In multiple context mode, enable DNS per context.

Detailed Steps

Step 1 Enable downloading of the dynamic database.

- In Single mode, choose the **Configuration > Firewall > Botnet Traffic Filter > Botnet Database** pane, then check the **Enable Botnet Updater Client** check box.
- In multiple context mode in the System execution space, choose the **Configuration > Device Management > Botnet Database** pane, then check the **Enable Botnet Updater Client** check box.

This setting enables downloading of the dynamic database from the Cisco update server. In multiple context mode, enter this command in the system execution space. If you do not have a database already installed on the ASA, it downloads the database after approximately 2 minutes. The update server determines how often the ASA polls the server for future updates, typically every hour.

Step 2 (Multiple context mode only) In multiple context mode, click **Apply**. Then change to the context where you want to configure the Botnet Traffic Filter by double-clicking the context name in the Device List.

Step 3 In the Configuration > Firewall > Botnet Traffic Filter > Botnet Database > Dynamic Database Configuration area, check the **Use Botnet data dynamically downloaded from updater server** check box.

Step 4 Click **Apply**.

Step 5 (Optional) If you want to later remove the database from running memory, perform the following steps:

a. Disable use of the database by unchecking the **Use Botnet data dynamically downloaded from updater server** check box.

b. Click **Apply**.

c. Click **Purge Botnet Database**.

d. To redownload the database, re-check the **Use Botnet data dynamically downloaded from updater server** check box.

e. Click **Apply**.

Note The Fetch Botnet Database button is for testing purposes only; it downloads and verifies the dynamic database, but does not store it in running memory.

For information about the Search Dynamic Database area, see the "Searching the Dynamic Database" section on page 76-13.

What to Do Next

See the "Adding Entries to the Static Database" section on page 76-9.

Adding Entries to the Static Database

The static database lets you augment the dynamic database with domain names or IP addresses that you want to blacklist or whitelist. Static blacklist entries are always designated with a Very High threat level. See the "Information About the Static Database" section on page 76-3 for more information.

Prerequisites

- In multiple context mode, perform this procedure in the context execution space.
- Enable ASA use of a DNS server in the Device Management > DNS > DNS Client > DNS Lookup area. In multiple context mode, enable DNS per context.

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Botnet Traffic Filter > Black** or White List pane, click **Add** for the Whitelist or Blacklist.

The Enter hostname or IP Address dialog box appears.

Step 2 In the Addresses field, enter one or more domain names, IP addresses, and IP address/netmasks.

Enter multiple entries separated by commas, spaces, lines, or semi-colons. You can enter up to 1000 entries for each type.

Step 3 Click **OK**.

Step 4 Click **Apply**.

What to Do Next

See the "Enabling DNS Snooping" section on page 76-9.

Enabling DNS Snooping

This procedure enables inspection of DNS packets and enables Botnet Traffic Filter snooping, which compares the domain name with those on the dynamic database or static database, and adds the name and IP address to the Botnet Traffic Filter DNS reverse lookup cache. This cache is then used by the Botnet Traffic Filter when connections are made to the suspicious address.

Prerequisites

- In multiple context mode, perform this procedure in the context execution space.
- You must first configure DNS inspection for traffic that you want to snoop using the Botnet Traffic Filter. See the "DNS Inspection" section on page 58-1 and Chapter 44, "Configuring a Service Policy," for detailed information about configuring advanced DNS inspection options using the Modular Policy Framework.

Note You can also configure DNS snooping directly in the Configuration > Firewall > Service Policy Rules > Rule Actions > Protocol Inspection > Select DNS Inspect Map dialog box by checking the **Enable Botnet traffic filter DNS snooping** check box.

Restrictions

TCP DNS traffic is not supported.

Default DNS Inspection Configuration and Recommended Configuration

The default configuration for DNS inspection inspects all UDP DNS traffic on all interfaces, and does not have DNS snooping enabled.

We suggest that you enable DNS snooping only on interfaces where external DNS requests are going. Enabling DNS snooping on all UDP DNS traffic, including that going to an internal DNS server, creates unnecessary load on the ASA.

For example, if the DNS server is on the outside interface, you should enable DNS inspection with snooping for all UDP DNS traffic on the outside interface.

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Botnet Traffic Filter > DNS Snooping** pane.

All existing service rules that include DNS inspection are listed in the table.

Step 2 For each rule for which you want to enable DNS snooping, in the DNS Snooping Enabled column, check the check box.

Step 3 Click **Apply**.

What to Do Next

See the "Enabling Traffic Classification and Actions for the Botnet Traffic Filter" section on page 76-10.

Enabling Traffic Classification and Actions for the Botnet Traffic Filter

This procedure enables the Botnet Traffic Filter. The Botnet Traffic Filter compares the source and destination IP address in each initial connection packet to the following:

- Dynamic database IP addresses
- Static database IP addresses
- DNS reverse lookup cache (for dynamic database domain names)
- DNS host cache (for static database domain names)

When an address matches, the ASA sends a syslog message. The only additional action currently available is to drop the connection.

Prerequisites

In multiple context mode, perform this procedure in the context execution space.

Recommended Configuration

Although DNS snooping is not required, we recommend configuring DNS snooping for maximum use of the Botnet Traffic Filter (see the "Enabling DNS Snooping" section on page 76-9). Without DNS snooping for the dynamic database, the Botnet Traffic Filter uses only the static database entries, plus any IP addresses in the dynamic database; domain names in the dynamic database are not used.

We recommend enabling the Botnet Traffic Filter on all traffic on the Internet-facing interface, and enabling dropping of traffic with a severity of moderate and higher.

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Botnet Traffic Filter > Traffic Settings** pane.

Step 2 To enable the Botnet Traffic Filter on specified traffic, perform the following steps:

a. In the Traffic Classification area, check the **Traffic Classified** check box for each interface on which you want to enable the Botnet Traffic Filter.

You can configure a global classification that applies to all interfaces by checking the Traffic Classified check box for Global (All Interfaces). If you configure an interface-specific classification, the settings for that interface overrides the global setting.

b. For each interface, from the **ACL Used** drop-down list choose either --ALL TRAFFIC-- (the default), or any access list configured on the ASA.

For example, you might want to monitor all port 80 traffic on the outside interface.

To add or edit access lists, click **Manage ACL** to bring up the ACL Manager. See the "Adding ACLs and ACEs" section on page 26-2 for more information.

Step 3 (Optional) To treat greylisted traffic as blacklisted traffic for action purposes, in the Ambiguous Traffic Handling area, check the **Treat ambiguous (greylisted) traffic as malicious (blacklisted) traffic** check box.

If you do not enable this option, greylisted traffic will not be dropped if you configure a rule in the Blacklisted Traffic Actions area. See the "Botnet Traffic Filter Address Types" section on page 76-2 for more information about the greylist.

Step 4 (Optional) To automatically drop malware traffic, perform the following steps.

To manually drop traffic, see the "Blocking Botnet Traffic Manually" section on page 76-12.

a. In the Blacklisted Traffic Actions area, click **Add**.

The Add Blacklisted Traffic Action dialog box appears.

b. From the Interface drop-down list, choose the interface on which you want to drop traffic. Only interfaces on which you enabled Botnet Traffic Filter traffic classification are available.

c. In the Threat Level area, choose one of the following options to drop traffic specific threat levels. The default level is a range between Moderate and Very High.

Note We highly recommend using the default setting unless you have strong reasons for changing the setting.

- Value—Specify the threat level you want to drop:
  - **Very Low**
  - **Low**
  - **Moderate**
  - **High**
  - **Very High**

Note Static blacklist entries are always designated with a Very High threat level.

- Range—Specify a range of threat levels.

d. In the ACL Used area, from the **ACL Used** drop-down list choose either --ALL TRAFFIC-- (the default), or any access list configured on the ASA.

Note Be sure the access list is a subset of the traffic you specified in the Traffic Classification area.

To add or edit access lists, click **Manage** to bring up the ACL Manager. See the "Adding ACLs and ACEs" section on page 26-2 for more information.

e. Click **OK**.

You return to the Traffic Settings pane.

f. If you want to apply additional rules to a given interface, repeat steps a through e.

Make sure you do not specify overlapping traffic in multiple rules for a given interface. Because you cannot control the exact order that rules are matched, overlapping traffic means you do not know which command will be matched. For example, do not specify both a rule that matches --ALL TRAFFIC-- as well as a command with and access list for a given interface. In this case, the traffic might never match the command with the access list. Similarly, if you specify multiple commands with access lists, make sure each access list is unique, and that the networks do not overlap.

Step 5 Click **Apply**.

Blocking Botnet Traffic Manually

If you choose not to block malware traffic automatically (see the "Enabling Traffic Classification and Actions for the Botnet Traffic Filter" section on page 76-10), you can block traffic manually by configuring an access rule to deny traffic, or by using the **shun** command in the Command Line Interface tool to block all traffic to and from a host. For some messages, you can automatically configure access rules in ASDM.

For example, you receive the following syslog message:

```
ASA-4-338002: Dynamic Filter permitted black listed TCP traffic from inside:10.1.1.45/6798
(209.165.201.1/7890) to outside:209.165.202.129/80 (209.165.202.129/80), destination
209.165.202.129 resolved from dynamic list: bad.example.com
```

You can then perform one of the following actions:

- Create an access rule to deny traffic.

For example, using the syslog message above, you might want to deny traffic from the infected host at 10.1.1.45 to the malware site at 209.165.202.129. Or, if there are many connections to different blacklisted addresses, you can create an access list to deny all traffic from 10.1.1.45 until you resolve the infection on the host computer.

For the following syslog messages, a reverse access rule can be automatically created from the Real Time Log Viewer:

- 338001, 338002, 338003, 338004 (blacklist)
- 338201, 338202 (greylist)

See Chapter 96, "Configuring Logging," and Chapter 51, "Configuring Access Rules," for more information about creating an access rule.

Note If you create a reverse access rule form a Botnet Traffic Filter syslog message, and you do not have any other access rules applied to the interface, then you might inadvertently block all traffic. Normally, without an access rule, all traffic from a high security to a low security interface is allowed. But when you apply an access rule, all traffic is denied except traffic that you explicitly permit. Because the reverse access rule is a deny rule, be sure to edit the resulting access policy for the interface to permit other traffic.

Access lists block all future connections. To block the current connection, if it is still active, enter the **clear conn** command. For example, to clear only the connection listed in the syslog message, enter the **clear conn address 10.1.1.45 address 209.165.202.129** command. See the command reference for more information.

- Shun the infected host.

  Shunning blocks all connections from the host, so you should use an access list if you want to block connections to certain destination addresses and ports. To shun a host, enter the following command in Tools > Command Line Interface. To drop the current connection as well as blocking all future connections, enter the destination address, source port, destination port, and optional protocol.

  shun *src_ip* [*dst_ip src_port dest_port* [*protocol*]]

  For example, to block future connections from 10.1.1.45, and also drop the current connection to the malware site in the syslog message, enter:

  ```
  shun 10.1.1.45 209.165.202.129 6798 80
  ```

After you resolve the infection, be sure to remove the access list or the shun. To remove the shun, enter **no shun** *src_ip*.

Searching the Dynamic Database

If you want to check if a domain name or IP address is included in the dynamic database, you can search the database for a string.

Detailed Steps

Step 1 Go to the Search Dynamic Database area:

- In Single mode or within a context, choose the **Configuration > Firewall > Botnet Traffic Filter > Botnet Database Update** pane.

- In multiple context mode in the System execution space, choose the **Configuration > Device Management > Botnet Database Update** pane.

Step 2 In the Search string field, enter a string at least 3 characters in length, and click **Find Now**.

The first two matches are shown. To refine your search for a more specific match, enter a longer string.

Step 3 To clear the displayed matches and the search string, click **Clear**, or you can just enter a new string and click **Find Now** to get a new display.

Monitoring the Botnet Traffic Filter

Whenever a known address is classified by the Botnet Traffic Filter, then a syslog message is generated. You can also monitor Botnet Traffic Filter statistics and other parameters by entering commands on the ASA. This section includes the following topics:

- Botnet Traffic Filter Syslog Messaging, page 76-14
- Botnet Traffic Filter Monitor Panes, page 76-15

Botnet Traffic Filter Syslog Messaging

The Botnet Traffic Filter generates detailed syslog messages numbered 338*nnn*. Messages differentiate between incoming and outgoing connections, blacklist, whitelist, or greylist addresses, and many other variables. (The greylist includes addresses that are associated with multiple domain names, but not all of these domain names are on the blacklist.)

See the syslog messages guide for detailed information about syslog messages.

For the following syslog messages, a reverse access rule can be automatically created from the Real Time Log Viewer:

- 338001, 338002, 338003, 338004 (blacklist)
- 338201, 338202 (greylist)

See Chapter 96, “Configuring Logging.”

Botnet Traffic Filter Monitor Panes

To monitor the Botnet Traffic Filter, see the following panes:

Command	Purpose
Home > Firewall Dashboard	Shows the Top Botnet Traffic Filter Hits, which shows reports of the top 10 malware sites, ports, and infected hosts. This report is a snapshot of the data, and may not match the top 10 items since the statistics started to be collected. If you right-click an IP address, you can invoke the whois tool to learn more about the botnet site. • Top Malware Sites—Shows top malware sites. • Top Malware Ports—Shows top malware ports. • Top Infected Hosts—Shows the top infected hosts.
Monitoring > Botnet Traffic Filter > Statistics	Shows how many connections were classified as whitelist, blacklist, and greylist connections, and how many connections were dropped. (The greylist includes addresses that are associated with multiple domain names, but not all of these domain names are on the blacklist.) The Details button shows how many packets at each threat level were classified or dropped.
Monitoring > Botnet Traffic Filter > Real-time Reports	Generates reports of the top 10 malware sites, ports, and infected hosts monitored. The top 10 malware-sites report includes the number of connections dropped, and the threat level and category of each site. This report is a snapshot of the data, and may not match the top 10 items since the statistics started to be collected. If you right-click a site IP address, you can invoke the whois tool to learn more about the malware site. Reports can be saved as a PDF file.
Monitoring > Botnet Traffic Filter > Infected Hosts	Generates reports about infected hosts. These reports contain detailed history about infected hosts, showing the correlation between infected hosts, visited malware sites, and malware ports. The Maximum Connections option shows the 20 infected hosts with the most number of connections. The Latest Activity option shows the 20 hosts with the most recent activity. The Highest Threat Level option shows the 20 hosts that connected to the malware sites with the highest threat level. The Subnet option shows up to 20 hosts within the specified subnet. Reports can be saved as a PDF file, as either the Current View or the Whole Buffer. The Whole Buffer option shows all buffered infected-hosts information.
Monitoring > Botnet Traffic Filter > Updater Client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
Monitoring > Botnet Traffic Filter > DNS Snooping	Shows the Botnet Traffic Filter DNS snooping actual IP addresses and names. All inspected DNS data is included in this output, and not just matching names in the blacklist. DNS data from static entries are not included.

Command	Purpose
Monitoring > Botnet Traffic Filter > Dynamic Database	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.
Monitoring > Botnet Traffic Filter > ASP Table Hits	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.

Where to Go Next

- To configure the syslog server, see Chapter 96, "Configuring Logging."
- To block connections with an access rule, see Chapter 51, "Configuring Access Rules."

Feature History for the Botnet Traffic Filter

Table 76-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 76-2 Feature History for the Botnet Traffic Filter

Feature Name	Platform Releases	Feature Information
Botnet Traffic Filter	8.2(1)	This feature was introduced.
Automatic blocking, and blacklist category and threat level reporting.	8.2(2)	The Botnet Traffic Filter now supports automatic blocking of blacklisted traffic based on the threat level. You can also view the category and threat level of malware sites in statistics and reports. The 1 hour timeout for reports for top hosts was removed; there is now no timeout. The following screens were introduced or modified: Configuration > Firewall > Botnet Traffic Filter > Traffic Settings, and Monitoring > Botnet Traffic Filter > Infected Hosts.

Configuring Threat Detection

This chapter describes how to configure threat detection statistics and scanning threat detection and includes the following sections:

- Information About Threat Detection, page 77-1
- Licensing Requirements for Threat Detection, page 77-1
- Configuring Basic Threat Detection Statistics, page 77-2
- Configuring Advanced Threat Detection Statistics, page 77-5
- Configuring Scanning Threat Detection, page 77-8

Information About Threat Detection

The threat detection feature consists of the following elements:

- Different levels of statistics gathering for various threats.

  Threat detection statistics can help you manage threats to your ASA; for example, if you enable scanning threat detection, then viewing statistics can help you analyze the threat. You can configure two types of threat detection statistics:

  - Basic threat detection statistics—Includes information about attack activity for the system as a whole. Basic threat detection statistics are enabled by default and have no performance impact.
  - Advanced threat detection statistics—Tracks activity at an object level, so the ASA can report activity for individual hosts, ports, protocols, or access lists. Advanced threat detection statistics can have a major performance impact, depending on the statistics gathered, so only the access list statistics are enabled by default.

- Scanning threat detection, which determines when a host is performing a scan.

  You can optionally shun any hosts determined to be a scanning threat.

Licensing Requirements for Threat Detection

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Configuring Basic Threat Detection Statistics

Basic threat detection statistics include activity that might be related to an attack, such as a DoS attack.

This section includes the following topics:

- Information About Basic Threat Detection Statistics, page 77-2
- Guidelines and Limitations, page 77-3
- Default Settings, page 77-3
- Configuring Basic Threat Detection Statistics, page 77-4
- Monitoring Basic Threat Detection Statistics, page 77-4
- Feature History for Basic Threat Detection Statistics, page 77-5

Information About Basic Threat Detection Statistics

Using basic threat detection statistics, the ASA monitors the rate of dropped packets and security events due to the following reasons:

- Denial by access lists
- Bad packet format (such as invalid-ip-header or invalid-tcp-hdr-length)
- Connection limits exceeded (both system-wide resource limits, and limits set in the configuration)
- DoS attack detected (such as an invalid SPI, Stateful Firewall check failure)
- Basic firewall checks failed (This option is a combined rate that includes all firewall-related packet drops in this bulleted list. It does not include non-firewall-related drops such as interface overload, packets failed at application inspection, and scanning attack detected.)
- Suspicious ICMP packets detected
- Packets failed application inspection
- Interface overload
- Scanning attack detected (This option monitors scanning attacks; for example, the first TCP packet is not a SYN packet, or the TCP connection failed the 3-way handshake. Full scanning threat detection (see the "Configuring Scanning Threat Detection" section on page 77-8) takes this scanning attack rate information and acts on it by classifying hosts as attackers and automatically shunning them, for example.)
- Incomplete session detection such as TCP SYN attack detected or no data UDP session attack detected

When the ASA detects a threat, it immediately sends a system log message (733100). The ASA tracks two types of rates: the average event rate over an interval, and the burst event rate over a shorter burst interval. The burst rate interval is 1/30th of the average rate interval or 10 seconds, whichever is higher. For each received event, the ASA checks the average and burst rate limits; if both rates are exceeded, then the ASA sends two separate system messages, with a maximum of one message for each rate type per burst period.

Basic threat detection affects performance only when there are drops or potential threats; even in this scenario, the performance impact is insignificant.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

Security Context Guidelines

Supported in single mode only. Multiple mode is not supported.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Types of Traffic Monitored

Only through-the-box traffic is monitored; to-the-box traffic is not included in threat detection.

Default Settings

Basic threat detection statistics are enabled by default.

Table 77-1 lists the default settings. You can view all these default settings using the **show running-config all threat-detection** command in Tools > Command Line Interface.

Table 77-1 Basic Threat Detection Default Settings

	Trigger Settings	
Packet Drop Reason	**Average Rate**	**Burst Rate**
• DoS attack detected • Bad packet format • Connection limits exceeded • Suspicious ICMP packets detected	100 drops/sec over the last 600 seconds.	400 drops/sec over the last 20 second period.
	80 drops/sec over the last 3600 seconds.	320 drops/sec over the last 120 second period.
Scanning attack detected	5 drops/sec over the last 600 seconds.	10 drops/sec over the last 20 second period.
	4 drops/sec over the last 3600 seconds.	8 drops/sec over the last 120 second period.
Incomplete session detected such as TCP SYN attack detected or no data UDP session attack detected (combined)	100 drops/sec over the last 600 seconds.	200 drops/sec over the last 20 second period.
	80 drops/sec over the last 3600 seconds.	160 drops/sec over the last 120 second period.
Denial by access lists	400 drops/sec over the last 600 seconds.	800 drops/sec over the last 20 second period.
	320 drops/sec over the last 3600 seconds.	640 drops/sec over the last 120 second period.
• Basic firewall checks failed • Packets failed application inspection	400 drops/sec over the last 600 seconds.	1600 drops/sec over the last 20 second period.
	320 drops/sec over the last 3600 seconds.	1280 drops/sec over the last 120 second period.

Table 77-1 Basic Threat Detection Default Settings (continued)

	Trigger Settings	
Packet Drop Reason	**Average Rate**	**Burst Rate**
Interface overload	2000 drops/sec over the last 600 seconds.	8000 drops/sec over the last 20 second period.
	1600 drops/sec over the last 3600 seconds.	6400 drops/sec over the last 120 second period.

Configuring Basic Threat Detection Statistics

This section describes how to configure basic threat detection statistics, including enabling or disabling it and changing the default limits.

Detailed Steps

Step 1 To enable or disable basic threat detection, choose the **Configuration > Firewall > Threat Detection** pane, and check the **Enable Basic Threat Detection** check box.

Step 2 Click **Apply**.

Monitoring Basic Threat Detection Statistics

To monitor basic threat detection statistics, perform the following task:

Path	Purpose
Home > Firewall Dashboard > Traffic Overview	Displays basic threat detection statistics. For a description of each event type, see the "Information About Basic Threat Detection Statistics" section on page 77-2.

Feature History for Basic Threat Detection Statistics

Table 77-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 77-2 Feature History for Basic Threat Detection Statistics

Feature Name	Platform Releases	Feature Information
Basic threat detection statistics	8.0(2)	Basic threat detection statistics was introduced. The following screen was introduced: Configuration > Firewall > Threat Detection, Home > Firewall Dashboard > Traffic Overview.
Burst rate interval changed to 1/30th of the average rate.	8.2(1)	In earlier releases, the burst rate interval was 1/60th of the average rate. To maximize memory usage, the sampling interval was reduced to 30 times during the average rate.
Improved memory usage	8.3(1)	The memory usage for threat detection was improved.

Configuring Advanced Threat Detection Statistics

You can configure the ASA to collect extensive statistics. This section includes the following topics:

- Information About Advanced Threat Detection Statistics, page 77-5
- Guidelines and Limitations, page 77-5
- Default Settings, page 77-6
- Configuring Advanced Threat Detection Statistics, page 77-6
- Monitoring Advanced Threat Detection Statistics, page 77-7
- Feature History for Advanced Threat Detection Statistics, page 77-8

Information About Advanced Threat Detection Statistics

Advanced threat detection statistics show both allowed and dropped traffic rates for individual objects such as hosts, ports, protocols, or access lists.

Caution Enabling advanced statistics can affect the ASA performance, depending on the type of statistics enabled. Enabling host statistics affects performance in a significant way; if you have a high traffic load, you might consider enabling this type of statistics temporarily. Port statistics, however, has modest impact.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

Security Context Guidelines

Only TCP Intercept statistics are available in multiple mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Types of Traffic Monitored

Only through-the-box traffic is monitored; to-the-box traffic is not included in threat detection.

Default Settings

By default, statistics for access lists are enabled.

Configuring Advanced Threat Detection Statistics

By default, statistics for access lists are enabled. To enable other statistics, perform the following steps.

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Threat Detection** pane.

Step 2 In the Scanning Threat Statistics area, choose one of the following options:

- Enable *all* statistics—Click the **Enable All Statistics** radio button.
- Disable *all* statistics—Click the **Disable All Statistics** radio button.
- Enable only certain statistics—Click the **Enable Only Following Statistics** radio button.

Step 3 If you chose to **Enable Only Following Statistics**, then check one or more of the following check boxes:

- **Hosts**—Enables host statistics. The host statistics accumulate for as long as the host is active and in the scanning threat host database. The host is deleted from the database (and the statistics cleared) after 10 minutes of inactivity.
- **Access Rules** (enabled by default)—Enables statistics for access rules.
- **Port**—Enables statistics for TCP and UDP ports.
- **Protocol**—Enables statistics for non-TCP/UDP IP protocols.
- **TCP-Intercept**—Enables statistics for attacks intercepted by TCP Intercept (see the "Configuring Connection Settings" section on page 71-8 to enable TCP Intercept).

Step 4 For host, port, and protocol statistics, you can change the number of rate intervals collected. In the Rate Intervals area, choose **1 hour**, **1 and 8 hours**, or **1, 8 and 24 hours** for each statistics type. The default interval is **1 hour**, which keeps the memory usage low.

Step 5 For TCP Intercept statistics, you can set the following options in the TCP Intercept Threat Detection area:

- **Monitoring Window Size**—Sets the size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. The ASA samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

- **Burst Threshold Rate**—Sets the threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, syslog message 733104 is generated.
- **Average Threshold Rate**—Sets the average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, syslog message 733105 is generated.

Click **Set Default** to restore the default values.

Step 6 Click **Apply**.

Monitoring Advanced Threat Detection Statistics

To monitor advanced threat detection statistics, perform one of the following tasks:

Path	Purpose
Home > Firewall Dashboard > Top 10 Access Rules Home > Firewall Dashboard > Top Usage Statistics	Displays the top 10 statistics. For the Top 10 Access Rules, permitted and denied traffic are not differentiated in this display. In the Traffic Overview > Dropped Packets Rate graph, you can track access list denies. The Top 10 Sources and Top 10 Destinations tabs show statistics for hosts. **Note**: Due to the threat detction algorithm, an interface used as a combination failover and state link could appear in the top 10 hosts; this is expected behavior, and you can ignore this IP address in the display. The Top 10 Services tab shows statistics for both ports and protocols (both must be enabled for the display), and shows the combined statistics of TCP/UDP port and IP protocol types. TCP (protocol 6) and UDP (protocol 17) are not included in the display for IP protocols; TCP and UDP ports are, however, included in the display for ports. If you only enable statistics for one of these types, port or protocol, then you will only view the enabled statistics. The Top Ten Protected Servers under SYN Attack area shows the TCP Intercept statistics. The display includes the top 10 protected servers under attack. The **detail** button shows history sampling data. The ASA samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds. From the Interval drop-down list, choose **Last 1 hour**, **Last 8 hour**, or **Last 24 hour**.

Feature History for Advanced Threat Detection Statistics

Table 77-3 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 77-3 Feature History for Advanced Threat Detection Statistics

Feature Name	Platform Releases	Feature Information
Advanced threat detection statistics	8.0(2)	Advanced threat detection statistics was introduced. The following screens were introduced: Configuration > Firewall > Threat Detection, Home > Firewall Dashboard > Top 10 Access Rules, Home > Firewall Dashboard > Top Usage Status, Home > Firewall Dashboard > Top 10 Protected Servers Under SYN Attack.
TCP Intercept statistics	8.0(4)/8.1(2)	TCP Intercept statistics were introduced. The following screens were introduced or modified: Configuration > Firewall > Threat Detection, Home > Firewall Dashboard > Top 10 Protected Servers Under SYN Attack.
Customize host statistics rate intervals	8.1(2)	You can now customize the number of rate intervals for which statistics are collected. The default number of rates was changed from 3 to 1. The following screen was modified: Configuration > Firewall > Threat Detection.
Burst rate interval changed to 1/30th of the average rate.	8.2(1)	In earlier releases, the burst rate interval was 1/60th of the average rate. To maximize memory usage, the sampling interval was reduced to 30 times during the average rate.
Customize port and protocol statistics rate intervals	8.3(1)	You can now customize the number of rate intervals for which statistics are collected. The default number of rates was changed from 3 to 1. The following screen was modified: Configuration > Firewall > Threat Detection.
Improved memory usage	8.3(1)	The memory usage for threat detection was improved.

Configuring Scanning Threat Detection

This section includes the following topics:

- Information About Scanning Threat Detection, page 77-9
- Guidelines and Limitations, page 77-9
- Default Settings, page 77-10
- Configuring Scanning Threat Detection, page 77-10

- Feature History for Scanning Threat Detection, page 77-11

Information About Scanning Threat Detection

A typical scanning attack consists of a host that tests the accessibility of every IP address in a subnet (by scanning through many hosts in the subnet or sweeping through many ports in a host or subnet). The scanning threat detection feature determines when a host is performing a scan. Unlike IPS scan detection that is based on traffic signatures, the ASA scanning threat detection feature maintains an extensive database that contains host statistics that can be analyzed for scanning activity.

The host database tracks suspicious activity such as connections with no return activity, access of closed service ports, vulnerable TCP behaviors such as non-random IPID, and many more behaviors.

If the scanning threat rate is exceeded, then the ASA sends a syslog message (733101), and optionally shuns the attacker. The ASA tracks two types of rates: the average event rate over an interval, and the burst event rate over a shorter burst interval. The burst event rate is 1/30th of the average rate interval or 10 seconds, whichever is higher. For each event detected that is considered to be part of a scanning attack, the ASA checks the average and burst rate limits. If either rate is exceeded for traffic sent from a host, then that host is considered to be an attacker. If either rate is exceeded for traffic received by a host, then that host is considered to be a target.

Caution The scanning threat detection feature can affect the ASA performance and memory significantly while it creates and gathers host- and subnet-based data structure and information.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

Security Context Guidelines

Supported in single mode only. Multiple mode is not supported.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Types of Traffic Monitored

- Only through-the-box traffic is monitored; to-the-box traffic is not included in threat detection.
- Traffic that is denied by an access list does not trigger scanning threat detection; only traffic that is allowed through the ASA and that creates a flow is affected by scanning threat detection.

Default Settings

Table 77-4 lists the default rate limits for scanning threat detection.

Table 77-4 Default Rate Limits for Scanning Threat Detection

Average Rate	Burst Rate
5 drops/sec over the last 600 seconds.	10 drops/sec over the last 20 second period.
5 drops/sec over the last 3600 seconds.	10 drops/sec over the last 120 second period.

The burst rate is calculated as the average rate every *N* seconds, where *N* is the burst rate interval. The burst rate interval is 1/30th of the rate interval or 10 seconds, whichever is larger.

Configuring Scanning Threat Detection

Detailed Steps

Step 1 Choose the **Configuration > Firewall > Threat Detection** pane, and check the **Enable Scanning Threat Detection** check box.

Step 2 (Optional) To automatically terminate a host connection when the ASA identifies the host as an attacker, check the **Shun Hosts detected by scanning threat** check box.

Step 3 (Optional) To except host IP addresses from being shunned, enter an address in the Networks excluded from shun field.

You can enter multiple addresses or subnets separated by commas. To choose a network from the list of IP address objects, click the **...** button.

Step 4 (Optional) To set the duration of a shun for an attacking host, check the **Set Shun Duration** check box and enter a value between 10 and 2592000 seconds. The default length is 3600 seconds (1 hour). To restore the default value, click **Set Default**.

Feature History for Scanning Threat Detection

Table 77-5 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 77-5 Feature History for Scanning Threat Detection

Feature Name	Platform Releases	Feature Information
Scanning threat detection	8.0(2)	Scanning threat detection was introduced. The following screen was introduced: Configuration > Firewall > Threat Detection.
Shun duration	8.0(4)/8.1(2)	You can now set the shun duration, The following screen was modified: Configuration > Firewall > Threat Detection.
Burst rate interval changed to 1/30th of the average rate.	8.2(1)	In earlier releases, the burst rate interval was 1/60th of the average rate. To maximize memory usage, the sampling interval was reduced to 30 times during the average rate.
Improved memory usage	8.3(1)	The memory usage for threat detection was improved.

Using Protection Tools

This chapter describes some of the many tools available to protect your network and includes the following sections:

- Preventing IP Spoofing, page 78-1
- Configuring the Fragment Size, page 78-2
- Configuring TCP Options, page 78-3
- Configuring IP Audit for Basic IPS Support, page 78-5

Preventing IP Spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the ASA only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the ASA to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the ASA, the ASA routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the ASA can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the ASA uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the ASA drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the ASA drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Configuration > Firewall > Advanced > Anti-Spoofing Fields

- Interface—Lists the interface names.

- Anti-Spoofing Enabled—Shows whether an interface has Unicast RPF enabled, Yes or No.
- Enable—Enables Unicast RPF for the selected interface.
- Disable—Disables Unicast RPF for the selected interface.

Configuring the Fragment Size

By default, the ASA allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the ASA. Fragmented packets are often used as DoS attacks.

To modify the IP fragment database parameters of an interface, perform the following steps:

Step 1 Choose the **Configuration > Firewall > Advanced > Fragment** pane, choose the interface to change in the Fragment table, and click **Edit**.

The Edit Fragment dialog box appears.

Step 2 In the Size field, set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200.

Step 3 In the Chain field, set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.

Step 4 In the Timeout field, set the maximum number of seconds to wait for an entire fragmented packet to arrive.

The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Step 5 Click **OK**.

Step 6 Click **Apply**.

Step 7 To view the fragment statistics, click **Show Fragment**. See the "Show Fragment" section on page 78-2 for more information.

Show Fragment

The Configuration > Properties > Fragment > Show Fragment pane displays the current IP fragment database statistics for each interface.

Fields

- Size—*Display only.* Displays the number of packets in the IP reassembly database waiting for reassembly. The default is 200.
- Chain—*Display only.* Displays the number of packets into which a full IP packet can be fragmented. The default is 24 packets.

- Timeout—*Display only.* Displays the number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds displayed, all fragments of the packet that were already received will be discarded. The default is 5 seconds.
- Threshold—*Display only.* Displays the IP packet threshold, or the limit after which no new chains can be created in the reassembly module.
- Queue—*Display only.* Displays the number of IP packets waiting in the queue for reassembly.
- Assembled—*Display only.* Displays the number of IP packets successfully reassembled.
- Fail—*Display only.* Displays the number of failed reassembly attempts.
- Overflow—*Display only.* Displays the number of IP packets in the overflow queue.

Configuring TCP Options

The Configuration > Properties > TCP Options pane lets you set parameters for TCP connections.

Fields

- Inbound and Outbound Reset—Sets whether to reset denied TCP connections for inbound and outbound traffic.
  - Interface—Shows the interface name.
  - Inbound Reset—Shows the interface reset setting for inbound TCP traffic, Yes or No. Enabling this setting causes the ASA to send TCP resets for all inbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets.
  - Outbound Reset—Shows the interface reset setting for outbound TCP traffic, Yes or No. Enabling this setting causes the ASA to send TCP resets for all outbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets.
  - Edit—Sets the inbound and outbound reset settings for the interface.
- Other Options—Sets additional TCP options.
  - Send Reset Reply for Denied Outside TCP Packets—Enables resets for TCP packets that terminate at the least secure interface and are denied by the ASA based on access lists or AAA settings. When this option is not enabled, the ASA silently discards denied packets. If you enable Inbound Resets for the least secure interface (see TCP Reset Settings), then you do not also have to enable this setting; Inbound Resets handle to-the-ASA traffic as well as through the ASA traffic.
  - Force Maximum Segment Size for TCP—Sets the maximum TCP segment size in bytes, between 48 and any maximum number. The default value is 1380 bytes. You can disable this feature by setting the bytes to 0. Both the host and the server can set the maximum segment size when they first establish a connection. If either maximum exceeds the value you set here, then the ASA overrides the maximum and inserts the value you set. For example, if you set a maximum size of 1200 bytes, when a host requests a maximum size of 1300 bytes, then the ASA alters the packet to request 1200 bytes.

- Force Minimum Segment Size for TCP—Overrides the maximum segment size to be no less than the number of bytes you set, between 48 and any maximum number. This feature is disabled by default (set to 0). Both the host and the server can set the maximum segment size when they first establish a connection. If either maximum is less than the value you set for the Force Minimum Segment Size for TCP Proxy field, then the ASA overrides the maximum and inserts the "minimum" value you set (the minimum value is actually the smallest maximum allowed). For example, if you set a minimum size of 400 bytes, if a host requests a maximum value of 300 bytes, then the ASA alters the packet to request 400 bytes.
- Force TCP Connection to Linger in TIME_WAIT State for at Least 15 Seconds—Forces each TCP connection to linger in a shortened TIME_WAIT state of at least 15 seconds after the final normal TCP close-down sequence. You might want to use this feature if an end host application default TCP terminating sequence is a simultaneous close. The default behavior of the ASA is to track the shutdown sequence and release the connection after two FINs and the ACK of the last FIN segment. This quick release heuristic enables the ASA to sustain a high connection rate, based on the most common closing sequence, known as the normal close sequence. However, in a simultaneous close, both ends of the transaction initiate the closing sequence, as opposed to the normal close sequence where one end closes and the other end acknowledges prior to initiating its own closing sequence (see RFC 793). Thus, in a simultaneous close, the quick release forces one side of the connection to linger in the CLOSING state. Having many sockets in the CLOSING state can degrade the performance of an end host. For example, some WinSock mainframe clients are known to exhibit this behavior and degrade the performance of the mainframe server. Using this feature creates a window for the simultaneous close down sequence to complete.

TCP Reset Settings

The Configuration > Properties > TCP Options > TCP Reset Settings dialog box sets the inbound and outbound reset settings for an interface.

Fields

- Send Reset Reply for Denied Inbound TCP Packets—Sends TCP resets for all inbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets.

  You might want to explicitly send resets for inbound traffic if you need to reset identity request (IDENT) connections. When you send a TCP RST (reset flag in the TCP header) to the denied host, the RST stops the incoming IDENT process so that you do not have to wait for IDENT to time out. Waiting for IDENT to time out can cause traffic to slow because outside hosts keep retransmitting the SYN until the IDENT times out, so the **service resetinbound** command might improve performance.
- Send Reset Reply for Denied Outbound TCP Packets—Sends TCP resets for all outbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets. This option is enabled by default. You might want to disable outbound resets to reduce the CPU load during traffic storms, for example.

Configuring IP Audit for Basic IPS Support

The IP audit feature provides basic IPS support for the ASA that does not have an AIP SSM. It supports a basic list of signatures, and you can configure the ASA to perform one or more actions on traffic that matches a signature.

This section includes the following topics:

- IP Audit Policy, page 78-5
- Add/Edit IP Audit Policy Configuration, page 78-5
- IP Audit Signatures, page 78-6
- IP Audit Signature List, page 78-6

IP Audit Policy

The Configuration > Firewall > Advanced > IP Audit > IP Audit Policy pane lets you add audit policies and assign them to interfaces. You can assign an attack policy and an informational policy to each interface. The attack policy determines the action to take with packets that match an attack signature; the packet might be part of an attack on your network, such as a DoS attack. The informational policy determines the action to take with packets that match an informational signature; the packet is not currently attacking your network, but could be part of an information-gathering activity, such as a port sweep. For a complete list of signatures, see the IP Audit Signature List.

Fields

- Name—Shows the names of the defined IP audit policies. Although the default actions for a named policy are listed in this table ("--Default Action--"), they are not named policies that you can assign to an interface. Default actions are used by named policies if you do not set an action for the policy. You can modify the default actions by selecting them and clicking the Edit button.
- Type—Shows the policy type, either Attack or Info.
- Action—Shows the actions taken against packets that match the policy, Alarm, Drop, and/or Reset. Multiple actions can be listed.
- Add—Adds a new IP audit policy.
- Edit—Edits an IP audit policy or the default actions.
- Delete—Deletes an IP audit policy. You cannot delete a default action.
- Policy-to-Interface Mappings—Assigns an attack and informational policy to each interface.
  - Interface—Shows the interface name.
  - Attack Policy—Lists the attack audit policy names available. Assign a policy to an interface by clicking the name in the list.
  - Info Policy—Lists the informational audit policy names available. Assign a policy to an interface by clicking the name in the list.

Add/Edit IP Audit Policy Configuration

The Configuration > Firewall > Advanced > IP Audit > IP Audit Policy > Add/Edit IP Audit Policy Configuration dialog box lets you add or edit a named IP audit policy that you can assign to interfaces, and lets you modify the default actions for each signature type.

Fields

- Policy Name—Sets the IP audit policy name. You cannot edit the name after you add it.
- Policy Type—Sets the policy type. You cannot edit the policy type after you add it.
  - Attack—Sets the policy type as attack.
  - Information—Sets the policy type as informational.
- Action—Sets one or more actions to take when a packet matches a signature. If you do not choose an action, then the default policy is used.
  - Alarm—Generates a system message showing that a packet matched a signature. For a complete list of signatures, see IP Audit Signature List.
  - Drop—Drops the packet.
  - Reset—Drops the packet and closes the connection.

IP Audit Signatures

The Configuration > Firewall > Advanced > IP Audit > IP Audit Signatures pane lets you disable audit signatures. You might want to disable a signature if legitimate traffic continually matches a signature, and you are willing to risk disabling the signature to avoid large numbers of alarms.

For a complete list of signatures, see the "IP Audit Signature List" section on page 78-6.

Fields

- Enabled—Lists the enabled signatures.
- Disabled—Lists the disabled signatures.
- Disable—Moves the selected signature to the Disabled pane.
- Enable—Moves the selected signature to the Enabled pane.

IP Audit Signature List

Table 78-1 lists supported signatures and system message numbers.

Table 78-1 Signature IDs and System Message Numbers

Signature ID	Message Number	Signature Title	Signature Type	Description
1000	400000	IP options-Bad Option List	Informational	Triggers on receipt of an IP datagram where the list of IP options in the IP datagram header is incomplete or malformed. The IP options list contains one or more options that perform various network management or debugging tasks.
1001	400001	IP options-Record Packet Route	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 7 (Record Packet Route).

Table 78-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
1002	400002	IP options-Timestamp	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 4 (Timestamp).
1003	400003	IP options-Security	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 2 (Security options).
1004	400004	IP options-Loose Source Route	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 3 (Loose Source Route).
1005	400005	IP options-SATNET ID	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 8 (SATNET stream identifier).
1006	400006	IP options-Strict Source Route	Informational	Triggers on receipt of an IP datagram in which the IP option list for the datagram includes option 2 (Strict Source Routing).
1100	400007	IP Fragment Attack	Attack	Triggers when any IP datagram is received with an offset value less than 5 but greater than 0 indicated in the offset field.
1102	400008	IP Impossible Packet	Attack	Triggers when an IP packet arrives with source equal to destination address. This signature will catch the so-called Land Attack.
1103	400009	IP Overlapping Fragments (Teardrop)	Attack	Triggers when two fragments contained within the same IP datagram have offsets that indicate that they share positioning within the datagram. This could mean that fragment A is being completely overwritten by fragment B, or that fragment A is partially being overwritten by fragment B. Some operating systems do not properly handle fragments that overlap in this manner and may throw exceptions or behave in other undesirable ways upon receipt of overlapping fragments, which is how the Teardrop attack works to create a DoS.
2000	400010	ICMP Echo Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 0 (Echo Reply).
2001	400011	ICMP Host Unreachable	Informational	Triggers when an IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 3 (Host Unreachable).

Table 78-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
2002	400012	ICMP Source Quench	Informational	Triggers when an IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 4 (Source Quench).
2003	400013	ICMP Redirect	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 5 (Redirect).
2004	400014	ICMP Echo Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 8 (Echo Request).
2005	400015	ICMP Time Exceeded for a Datagram	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 11(Time Exceeded for a Datagram).
2006	400016	ICMP Parameter Problem on Datagram	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 12 (Parameter Problem on Datagram).
2007	400017	ICMP Timestamp Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 13 (Timestamp Request).
2008	400018	ICMP Timestamp Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 14 (Timestamp Reply).
2009	400019	ICMP Information Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 15 (Information Request).
2010	400020	ICMP Information Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 16 (ICMP Information Reply).
2011	400021	ICMP Address Mask Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 17 (Address Mask Request).
2012	400022	ICMP Address Mask Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 18 (Address Mask Reply).

Table 78-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
2150	400023	Fragmented ICMP Traffic	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and either the more fragments flag is set to 1 (ICMP) or there is an offset indicated in the offset field.
2151	400024	Large ICMP Traffic	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1(ICMP) and the IP length > 1024.
2154	400025	Ping of Death Attack	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1(ICMP), the Last Fragment bit is set, and (IP offset * 8) + (IP data length) > 65535 that is to say, the IP offset (which represents the starting position of this fragment in the original packet, and which is in 8 byte units) plus the rest of the packet is greater than the maximum size for an IP packet.
3040	400026	TCP NULL flags	Attack	Triggers when a single TCP packet with none of the SYN, FIN, ACK, or RST flags set has been sent to a specific host.
3041	400027	TCP SYN+FIN flags	Attack	Triggers when a single TCP packet with the SYN and FIN flags are set and is sent to a specific host.
3042	400028	TCP FIN only flags	Attack	Triggers when a single orphaned TCP FIN packet is sent to a privileged port (having port number less than 1024) on a specific host.
3153	400029	FTP Improper Address Specified	Informational	Triggers if a port command is issued with an address that is not the same as the requesting host.
3154	400030	FTP Improper Port Specified	Informational	Triggers if a port command is issued with a data port specified that is <1024 or >65535.
4050	400031	UDP Bomb attack	Attack	Triggers when the UDP length specified is less than the IP length specified. This malformed packet type is associated with a denial of service attempt.
4051	400032	UDP Snork attack	Attack	Triggers when a UDP packet with a source port of either 135, 7, or 19 and a destination port of 135 is detected.
4052	400033	UDP Chargen DoS attack	Attack	This signature triggers when a UDP packet is detected with a source port of 7 and a destination port of 19.
6050	400034	DNS HINFO Request	Informational	Triggers on an attempt to access HINFO records from a DNS server.

Table 78-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
6051	400035	DNS Zone Transfer	Informational	Triggers on normal DNS zone transfers, in which the source port is 53.
6052	400036	DNS Zone Transfer from High Port	Informational	Triggers on an illegitimate DNS zone transfer, in which the source port is not equal to 53.
6053	400037	DNS Request for All Records	Informational	Triggers on a DNS request for all records.
6100	400038	RPC Port Registration	Informational	Triggers when attempts are made to register new RPC services on a target host.
6101	400039	RPC Port Unregistration	Informational	Triggers when attempts are made to unregister existing RPC services on a target host.
6102	400040	RPC Dump	Informational	Triggers when an RPC dump request is issued to a target host.
6103	400041	Proxied RPC Request	Attack	Triggers when a proxied RPC request is sent to the portmapper of a target host.
6150	400042	ypserv (YP server daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP server daemon (ypserv) port.
6151	400043	ypbind (YP bind daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP bind daemon (ypbind) port.
6152	400044	yppasswdd (YP password daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP password daemon (yppasswdd) port.
6153	400045	ypupdated (YP update daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP update daemon (ypupdated) port.
6154	400046	ypxfrd (YP transfer daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP transfer daemon (ypxfrd) port.
6155	400047	mountd (mount daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the mount daemon (mountd) port.
6175	400048	rexd (remote execution daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the remote execution daemon (rexd) port.

Table 78-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
6180	400049	rexd (remote execution daemon) Attempt	Informational	Triggers when a call to the rexd program is made. The remote execution daemon is the server responsible for remote program execution. This may be indicative of an attempt to gain unauthorized access to system resources.
6190	400050	statd Buffer Overflow	Attack	Triggers when a large statd request is sent. This could be an attempt to overflow a buffer and gain access to system resources.

Configuring Filtering Services

This chapter describes how to use filtering services to provide greater control over traffic passing through the ASA and includes the following sections:

- Information About Web Traffic Filtering, page 79-1
- Configuring Filtering Rules, page 79-6
- Filtering the Rule Table, page 79-11
- Defining Queries, page 79-12
- Filtering URLs and FTP Requests with an External Server, page 79-2

Information About Web Traffic Filtering

You can use web traffic filtering in two distinct ways:

- Filtering ActiveX objects or Java applets
- Filtering with an external filtering server

Instead of blocking access altogether, you can remove specific undesirable objects from web traffic, such as ActiveX objects or Java applets, that may pose a security threat in certain situations.

You can use web traffic filtering to direct specific traffic to an external filtering server, such an Secure Computing SmartFilter (formerly N2H2) or the Websense filtering server. You can enable long URL, HTTPS, and FTP filtering using either Websense or Secure Computing SmartFilter for web traffic filtering. Filtering servers can block traffic to specific sites or types of sites, as specified by the security policy.

Note URL caching will only work if the version of the URL server software from the URL server vendor supports it.

Because web traffic filtering is CPU-intensive, using an external filtering server ensures that the throughput of other traffic is not affected. However, depending on the speed of your network and the capacity of your web traffic filtering server, the time required for the initial connection may be noticeably slower when filtering traffic with an external filtering server.

Model	License Requirement
All models	Base License.

Filtering URLs and FTP Requests with an External Server

This section describes how to filter URLs and FTP requests with an external server and includes the following topics:

- Information About URL Filtering, page 79-2
- Licensing Requirements for URL Filtering, page 79-3
- Guidelines and Limitations for URL Filtering, page 79-3
- Identifying the Filtering Server, page 79-3
- Configuring Additional URL Filtering Settings, page 79-4
- Feature History for URL Filtering, page 79-12

Information About URL Filtering

You can apply filtering to connection requests originating from a more secure network to a less secure network. Although you can use ACLs to prevent outbound access to specific content servers, managing usage this way is difficult because of the size and dynamic nature of the Internet. You can simplify configuration and improve ASA performance by using a separate server running one of the following Internet filtering products:

- Websense Enterprise for filtering HTTP, HTTPS, and FTP.
- McAfee SmartFilter (formerly N2H2) for filtering HTTP, HTTPS, FTP, and long URL filtering.

  In long URLs, the URL in the Referer field might contain a “host:” text string, which could cause the HTTP GET header to be incorrectly parsed as containing the HTTP Host parameter. The ASA, however, correctly parses the Referer field even when it contains a “host:” text string and forwards the header to the McAfee SmartFilter server with the correct Referer URL.

Note URL caching will only work if the version of the URL server software from the URL server vendor supports it.

Although ASA performance is less affected when using an external server, you might notice longer access times to websites or FTP servers when the filtering server is remote from the ASA.

When filtering is enabled and a request for content is directed through the ASA, the request is sent to the content server and to the filtering server at the same time. If the filtering server allows the connection, the ASA forwards the response from the content server to the originating client. If the filtering server denies the connection, the ASA drops the response and sends a message or return code indicating that the connection was not successful.

If user authentication is enabled on the ASA, then the ASA also sends the username to the filtering server. The filtering server can use user-specific filtering settings or provide enhanced reporting about usage.

Licensing Requirements for URL Filtering

The following table shows the licensing requirements for URL filtering:

Table 79-1 Licensing Requirements

Model	License Requirement
All models	Base License.

Guidelines and Limitations for URL Filtering

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Does not support IPv6.

Identifying the Filtering Server

You can identify up to four filtering servers per context. The ASA uses the servers in order until a server responds. In single mode, a maximum of 16 of the same type of filtering servers are allowed. You can only configure a single type of server (Websense or Secure Computing SmartFilter) in your configuration.

Note You must add the filtering server before you can configure filtering for HTTP or HTTPS.

To specify the external filtering server, perform the following steps:

Step 1 In the ASDM main window, choose **Configuration > Firewall > URL Filtering Servers**.

Step 2 In the URL Filtering Server Type area, click one of the following options:

- **Websense**
- **Secure Computing SmartFilter**

Step 3 If you chose the second option, enter the Secure Computing SmartFilter port number if it is different than the default port number, which is 4005.

Step 4 In the URL Filtering Servers area, click **Add**.

If you chose the Websense option, the Add Parameters for Websense URL Filtering dialog box appears.

- Choose the interface on which the URL filtering server is connected from the drop-down list.
- Enter the IP address of the URL filtering server.

- Enter the number of seconds after which the request to the URL filtering server times out. The default is 30 seconds.
- In the Protocol area, to specify which TCP version to use to communicate with the URL filtering server, click one of the following radio buttons:
  - TCP 1
  - TCP 4
  - UDP 4
- Enter the maximum number of TCP connections allowed for communicating with the URL filtering server, and click **OK**.

The new Websense URL filtering server properties appear in the URL Filtering Servers pane. To change these properties, click **Edit**. To add more Websense URL filtering servers after you have added the first Websense URL filtering server, click **Add** or **Insert**. To remove a Websense URL filtering server, click **Delete**.

If you chose the Secure Computing SmartFilter URL Filtering option, the Add Parameters for Secure Computing SmartFilter URL Filtering dialog box appears.

- Choose the interface on which the URL filtering server is connected from the drop-down list.
- Enter the IP address of the URL filtering server.
- Enter the number of seconds after which the request to the URL filtering server times out. The default is 30 seconds.
- In the Protocol area, to specify which protocol type to use to communicate with the URL filtering server, click one of the following radio buttons:
  - TCP
  - UDP
- Enter the maximum number of TCP connections allowed for communicating with the URL filtering server, and click **OK**.

The new Secure Computing SmartFilter URL filtering server properties appear in the URL Filtering Servers pane. To change these properties, click **Edit**. To add more Secure Computing SmartFilter URL filtering servers after you have defined the first Secure Computing SmartFilter URL filtering server, click **Add** or **Insert**. To remove a Secure Computing SmartFilter URL filtering server, click **Delete**.

Configuring Additional URL Filtering Settings

After you have accessed a website, the filtering server can allow the ASA to cache the server address for a certain period of time, as long as each website hosted at the address is in a category that is permitted at all times. When you access the server again, or if another user accesses the server, the ASA does not need to consult the filtering server again to obtain the server address.

Note Requests for cached IP addresses are not passed to the filtering server and are not logged. As a result, this activity does not appear in any reports.

This section describes how to configure additional URL filtering settings and includes the following topics:

- Buffering the Content Server Response, page 79-5
- Caching Server Addresses, page 79-5
- Filtering HTTP URLs, page 79-6

Buffering the Content Server Response

When you issue a request to connect to a content server, the ASA sends the request to the content server and to the filtering server at the same time. If the filtering server does not respond before the content server, the server response is dropped. This behavior delays the web server response for the web client, because the web client must reissue the request.

By enabling the HTTP response buffer, replies from web content servers are buffered, and the responses are forwarded to the requesting client if the filtering server allows the connection. This behavior prevents the delay that might otherwise occur.

To configure buffering for responses to HTTP or FTP requests, perform the following steps:

Step 1 In the URL Filtering Servers pane, click **Advanced** to display the Advanced URL Filtering dialog box.

Step 2 In the URL Buffer Size area, check the **Enable buffering** check box.

Step 3 Enter the number of 1550-byte buffers. Valid values range from 1 to 128.

Step 4 Click **OK** to close this dialog box.

Caching Server Addresses

After you access a website, the filtering server can allow the ASA to cache the server address for a certain period of time, as long as each website hosted at the address is in a category that is permitted at all times. When you access the server again, or if another user accesses the server, the ASA does not need to consult the filtering server again.

Note Requests for cached IP addresses are not passed to the filtering server and are not logged. As a result, this activity does not appear in any reports. You can accumulate Websense run logs before using the **url-cache** command.

To improve throughput, perform the following steps:

Step 1 In the URL Filtering Servers pane, click **Advanced** to display the Advanced URL Filtering dialog box.

Step 2 In the URL Cache Size area, check the **Enable caching based on** check box to enable caching according to the specified criteria.

Step 3 Click one of the following radio buttons:

- Destination Address—This option caches entries according to the URL destination address. Choose this setting if all users share the same URL filtering policy on the Websense server.
- Source/Destination Address—This option caches entries according to both the source address that initiates the URL request and the URL destination address. Choose this setting if users do not share the same URL filtering policy on the server.

Step 4 Enter the cache size within the range from 1 to 128 (KB).

Step 5 Click **OK** to close this dialog box.

Filtering HTTP URLs

This section describes how to configure HTTP filtering with an external filtering server and includes the following topics:

- Enabling Filtering of Long HTTP URLs, page 79-6

Enabling Filtering of Long HTTP URLs

By default, the ASA considers an HTTP URL to be a long URL if it is greater than 1159 characters. You can increase the maximum length allowed.

To configure the maximum size of a single URL, perform the following steps:

Step 1 In the URL Filtering Servers pane, click **Advanced** to display the Advanced URL Filtering dialog box.

Step 2 In the Long URL Support area, check the **Use Long URL** check box to enable long URLs for filtering servers.

Step 3 Enter the maximum URL length allowed, up to a maximum of 4 KB.

Step 4 Enter the memory allocated for long URLs in KB.

Step 5 Click **OK** to close this dialog box.

Configuring Filtering Rules

Before you can add an HTTP, HTTPS, or FTP filter rule, you must enable a URL filtering server. To enable a URL filtering server, choose **Configuration > Firewall > URL Filtering Servers**.

To configure filtering rules, perform the following steps:

Step 1 From the ASDM main window, choose **Configuration > Firewall > Filter Rules**.

Step 2 In the toolbar, click **Add** to display the types of filter rules that are available to add from the following list:

- Add Filter ActiveX Rule
- Add Filter Java Rule
- Add Filter HTTP Rule
- Add Filter HTTPS Rule
- Add Filter FTP Rule

Step 3 If you chose Add Filter ActiveX Rule, specify the following settings:

- Click one of the following radio buttons: **Filter ActiveX** or **Do not filter ActiveX**.
- Enter the source of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any source address.

  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Source dialog box. Choose a host or address from the drop-down list.
- Enter the destination of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any destination address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Destination dialog box. Choose a host or address from the drop-down list.
- Identify the service of the traffic to which the filtering action applies. To identify the service, enter one of the following:
  - tcp/*port*—The port number can range from 1 to 65535. Additionally, you can use the following modifiers with the TCP service:

    !=—Not equal to. For example, !=tcp/443.

    <—Less than. For example, <tcp/2000.

    >—Greater than. For example, >tcp/2000.

    - —Range. For example, tcp/2000-3000.
  - Enter a well-known service name, such as HTTP or FTP.
  - Click the ellipses to display the Browse Service dialog box. Choose a service from the drop-down list.
- Click **OK** to close this dialog box.
- Click **Apply** to save your changes.

Step 4 If you chose Add Filter Java Rule, specify the following settings:

- Click one of the following radio buttons: **Filter Java** or **Do not filter Java**.
- Enter the source of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any source address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Source dialog box. Choose a host or address from the drop-down list.
- Enter the destination of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any destination address.
  - Enter a hostname.

  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Destination dialog box. Choose a host or address from the drop-down list.
- Identify the service of the traffic to which the filtering action applies. To identify the service, enter one of the following:
  - tcp/*port*—The port number can be from 1 to 65535. Additionally, you can use the following modifiers with the TCP service:

    !=—Not equal to. For example, !=tcp/443.

    <—Less than. For example, <tcp/2000.

    >—Greater than. For example, >tcp/2000.

    - —Range. For example, tcp/2000-3000.
  - Enter a well-known service name, such as HTTP or FTP.
  - Click the ellipses to display the Browse Service dialog box. Choose a service from the drop-down list.
- Click **OK** to close this dialog box.
- Click **Apply** to save your changes.

Step 5 If you chose Add Filter HTTP Rule, specify the following settings:

- Click one of the following radio buttons: **Filter HTTP** or **Do not filter HTTP**.
- Enter the source of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any source address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Source dialog box. Choose a host or address from the drop-down list.
- Enter the destination of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any destination address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Destination dialog box. Choose a host or address from the drop-down list.
- Identify the service of the traffic to which the filtering action applies. To identify the service, enter one of the following:
  - tcp/*port*—The port number can range from 1 to 65535. Additionally, you can use the following modifiers with the TCP service:

    !=—Not equal to. For example, !=tcp/443.

    <—Less than. For example, <tcp/2000.

>—Greater than. For example, >tcp/2000.

- —Range. For example, tcp/2000-3000.

– Enter a well-known service name, such as HTTP or FTP.

– Click the ellipses to display the Browse Service dialog box. Choose a service from the drop-down list.

- Choose the action to take when the URL exceeds the specified size from the drop-down list.
- Check the **Allow outbound traffic if URL server is not available check box** to connect without URL filtering being performed. When this check box is unchecked, you cannot connect to Internet websites if the URL server is unavailable.
- Check the **Block users from connecting to an HTTP proxy server check box to** prevent HTTP requests made through a proxy server.
- Check the **Truncate CGI parameters from URL sent to URL server** check box to have the ASA forward only the CGI script location and the script name, without any parameters, to the filtering server.
- Click **OK** to close this dialog box.
- Click **Apply** to save your changes.

Step 6 If you chose Add Filter HTTPS Rule, specify the following settings:

- Click one of the following radio buttons: **Filter HTTPS** or **Do not filter HTTPS**.
- Enter the source of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  – Enter **any** to indicate any source address.
  – Enter a hostname.
  – Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  – Click the ellipses to display the Browse Source dialog box. Choose a host or address from the drop-down list.
- Enter the destination of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  – Enter **any** to indicate any destination address.
  – Enter a hostname.
  – Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  – Click the ellipses to display the Browse Destination dialog box. Choose a host or address from the drop-down list.
- Identify the service of the traffic to which the filtering action applies. To identify the service, enter one of the following:
  – tcp/*port*—The port number can range from 1 to 65535. Additionally, you can use the following modifiers with the TCP service:

    !=—Not equal to. For example, !=tcp/443

    <—Less than. For example, <tcp/2000.

    >—Greater than. For example, >tcp/2000.

    - —Range. For example, tcp/2000-3000.

  - Enter a well-known service name, such as HTTP or FTP.
  - Click the ellipses to display the Browse Service dialog box. Choose a service from the drop-down list.
- Check the **Allow outbound traffic if URL server is not available check box** to connect without URL filtering being performed. When this check box is unchecked, you cannot connect to Internet websites if the URL server is unavailable.
- Click **OK** to close this dialog box.
- Click **Apply** to save your changes.

Step 7 If you chose Add Filter FTP Rule, specify the following settings:

- Click one of the following radio buttons: **Filter FTP** or **Do not filter FTP**.
- Enter the source of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any source address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Source dialog box. Choose a host or address from the drop-down list.
- Enter the destination of the traffic to which the filtering action applies. To enter the source, choose from the following options:
  - Enter **any** to indicate any destination address.
  - Enter a hostname.
  - Enter an IP address and optional network mask. You can express the netmask in CIDR or dotted decimal notation. For example, you can enter **10.1.1.0/24** or **10.1.1.0/255.255.255.0**.
  - Click the ellipses to display the Browse Destination dialog box. Choose a host or address from the drop-down list.
- Identify the service of the traffic to which the filtering action applies. To identify the service, enter one of the following:
  - tcp/*port*—The port number can range from 1 to 65535. Additionally, you can use the following modifiers with the TCP service:

    !=—Not equal to. For example, !=tcp/443

    <—Less than. For example, <tcp/2000.

    >—Greater than. For example, >tcp/2000.

    - —Range. For example, tcp/2000-3000.
  - Enter a well-known service name, such as http or ftp.
  - Click the ellipses to display the Browse Service dialog box. Choose a service from the drop-down list.
- Check the **Allow outbound traffic if URL server is not available check box** to connect without URL filtering being performed. When this check box is unchecked, you cannot connect to Internet websites if the URL server is unavailable.
- Check the **Block interactive FTP sessions (block if absolute FTP path is not provided)** check box to drop FTP requests if they use a relative path name to the FTP directory.

- Click **OK** to close this dialog box.
- Click **Apply** to save your changes.

Step 8 To modify a filtering rule, select it and click **Edit** to display the Edit Filter Rule dialog box for the specified filtering rule.

Step 9 Make the required changes, then click **OK** to close this dialog box.

Step 10 Click **Apply** to save your changes.

Filtering the Rule Table

To find a specific rule if your rule table includes a lot of entries, you can apply a filter to the rule table to show only the rules specified by the filter. To filter the rule table, perform the following steps:

Step 1 Click **Find** on the toolbar to display the Filter toolbar.

Step 2 Choose the type of filter from the Filter drop-down list:

- Source—Displays rules based on the specified source address or hostname.
- Destination—Displays rules based on the specified destination address or hostname.
- Source or Destination—Displays rules based on the specified source or destination address or hostname.
- Service—Displays rules based on the specified service.
- Rule Type—Displays rules based on the specified rule type.
- Query—Displays rules based on a complex query composed of source, destination, service, and rule type information.

Step 3 For Source, Destination, Source or Destination, and Service filters, perform the following steps:

a. Enter the string to match using one of the following methods:

  – Type the source, destination, or service name in the adjacent field.

  – Click the ellipses to open a Browse dialog box from which you can choose existing services, IP addresses, or host names.

b. Choose the match criteria from the drop-down list. Choose **is** for exact string matches or **contains** for partial string matches.

Step 4 For Rule Type filters, choose the rule type from the list.

Step 5 For Query filters, click **Define Query**. To define queries, see the "Defining Queries" section on page 79-12.

Step 6 To apply the filter to the rule table, click **Filter**.

Step 7 To remove the filter from the rule table and display all rule entries, click **Clear**.

Step 8 To show the packet trace for the selected rule, click **Packet Trace**.

Step 9 To show and hide the selected rule diagram, click **Diagram**.

Step 10 To remove a filter rule and place it elsewhere, click **Cut**.

Step 11 To copy a filter rule, click **Copy**. Then to move the copied filter rule elsewhere, click **Paste**.

Step 12 To delete a selected filter rule, click **Delete**.

Defining Queries

To define queries, perform the following steps:

Step 1 Enter the IP address or hostname of the source. Choose **is** for an exact match or choose **contains** for a partial match. Click the ellipses to display the Browse Source dialog box. You can specify a network mask using CIDR notation (address/bit-count). You can specify multiple addresses by separating them with commas.

Step 2 Enter the IP address or hostname of the destination. Choose **is** for an exact match or choose **contains** for a partial match. Click the ellipses to display the Browse Destination dialog box. You can specify a network mask using CIDR notation (address/bit-count). You can specify multiple addresses by separating them with commas.

Step 3 Enter the IP address or hostname of the source or destination. Choose **is** for an exact match or choose **contains** for a partial match. Click the ellipses to display the Browse Source dialog box. You can specify a network mask using CIDR notation (address/bit-count). You can specify multiple addresses by separating them with commas.

Step 4 Enter the protocol, port, or name of a service. Choose **is** for an exact match or choose **contains** for a partial match. Click the ellipses to display the Browse Service dialog box. You can specify a network mask using CIDR notation (address/bit-count). You can specify multiple addresses by separating them with commas.

Step 5 Choose the rule type from the drop-down list.

Step 6 Click **OK** to close this dialog box.

After you click **OK**, the filter is immediately applied to the rule table. To remove the filter, click **Clear**.

Feature History for URL Filtering

Table 79-2 lists the release history for URL filtering. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 79-2 Feature History for URL Filtering

Feature Name	Platform Releases	Feature Information
URL filtering	7.0(1)	Filters URLs based on an established set of filtering criteria.

PART 14

Configuring Modules

Configuring the ASA IPS Module

This chapter describes how to configure the ASA IPS module. The ASA IPS module might be a physical module or a software module, depending on your ASA model. For a list of supported ASA IPS modules per ASA model, see the *Cisco ASA Compatibility Matrix*:

http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html

This chapter includes the following sections:

- Information About the ASA IPS module, page 81-1
- Licensing Requirements for the ASA IPS module, page 81-5
- Guidelines and Limitations, page 81-5
- Default Settings, page 81-6
- Configuring the ASA IPS module, page 81-7
- Managing the ASA IPS module, page 81-19
- Monitoring the ASA IPS module, page 81-24
- Feature History for the ASA IPS module, page 81-24

Information About the ASA IPS module

The ASA IPS module runs advanced IPS software that provides proactive, full-featured intrusion prevention services to stop malicious traffic, including worms and network viruses, before they can affect your network. This section includes the following topics:

- How the ASA IPS module Works with the ASA, page 81-2
- Operating Modes, page 81-3
- Using Virtual Sensors (ASA 5510 and Higher), page 81-3
- Information About Management Access, page 81-4

How the ASA IPS module Works with the ASA

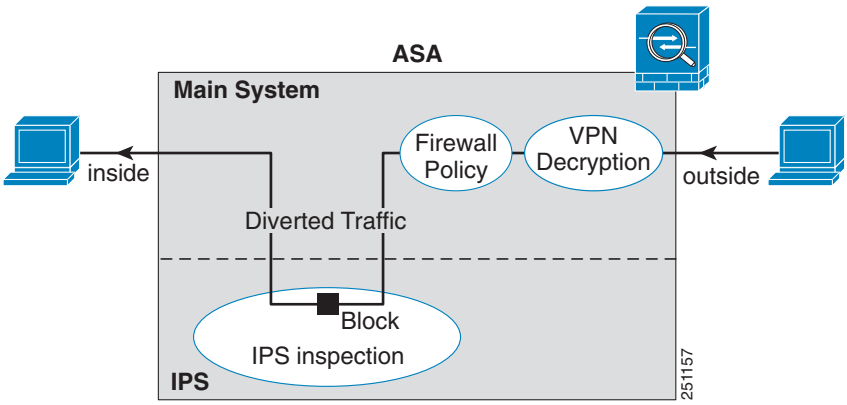
The ASA IPS module runs a separate application from the ASA. The ASA IPS module might include an external management interface so you can connect to the ASA IPS module directly; if it does not have a management interface, you can connect to the ASA IPS module through the ASA interface. The ASA IPS SSP on the ASA 5585-X includes data interfaces; these interfaces provide additional port-density for the ASA. However, the overall through-put of the ASA is not increased.

Traffic goes through the firewall checks before being forwarded to the ASA IPS module. When you identify traffic for IPS inspection on the ASA, traffic flows through the ASA and the ASA IPS module as follows. **Note**: This example is for "inline mode." See the "Operating Modes" section on page 81-3 for information about "promiscuous mode," where the ASA only sends a copy of the traffic to the ASA IPS module.

1. Traffic enters the ASA.
2. Incoming VPN traffic is decrypted.
3. Firewall policies are applied.
4. Traffic is sent to the ASA IPS module.
5. The ASA IPS module applies its security policy to the traffic, and takes appropriate actions.
6. Valid traffic is sent back to the ASA; the ASA IPS module might block some traffic according to its security policy, and that traffic is not passed on.
7. Outgoing VPN traffic is encrypted.
8. Traffic exits the ASA.

Figure 81-1 shows the traffic flow when running the ASA IPS module in inline mode. In this example, the ASA IPS module automatically blocks traffic that it identified as an attack. All other traffic is forwarded through the ASA.

Figure 81-1 ASA IPS module Traffic Flow in the ASA: Inline Mode

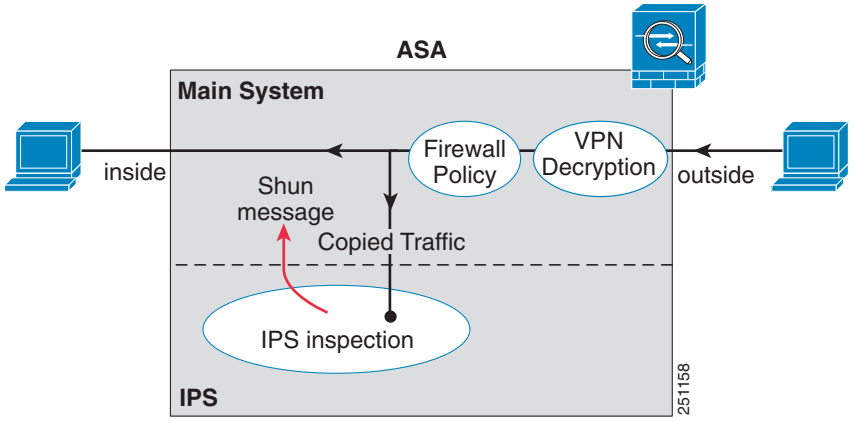


Operating Modes

You can send traffic to the ASA IPS module using one of the following modes:

- Inline mode—This mode places the ASA IPS module directly in the traffic flow (see Figure 81-1). No traffic that you identified for IPS inspection can continue through the ASA without first passing through, and being inspected by, the ASA IPS module. This mode is the most secure because every packet that you identify for inspection is analyzed before being allowed through. Also, the ASA IPS module can implement a blocking policy on a packet-by-packet basis. This mode, however, can affect throughput.
- Promiscuous mode—This mode sends a duplicate stream of traffic to the ASA IPS module. This mode is less secure, but has little impact on traffic throughput. Unlike inline mode, in promiscuous mode the ASA IPS module can only block traffic by instructing the ASA to shun the traffic or by resetting a connection on the ASA. Also, while the ASA IPS module is analyzing the traffic, a small amount of traffic might pass through the ASA before the ASA IPS module can shun it. Figure 81-2 shows the ASA IPS module in promiscuous mode. In this example, the ASA IPS module sends a shun message to the ASA for traffic it identified as a threat.

Figure 81-2 ASA IPS module Traffic Flow in the ASA: Promiscuous Mode



Using Virtual Sensors (ASA 5510 and Higher)

The ASA IPS module running IPS software Version 6.0 and later can run multiple virtual sensors, which means you can configure multiple security policies on the ASA IPS module. You can assign each ASA security context or single mode ASA to one or more virtual sensors, or you can assign multiple security contexts to the same virtual sensor. See the IPS documentation for more information about virtual sensors, including the maximum number of sensors supported.

Figure 81-3 shows one security context paired with one virtual sensor (in inline mode), while two security contexts share the same virtual sensor.

Figure 81-3 Security Contexts and Virtual Sensors

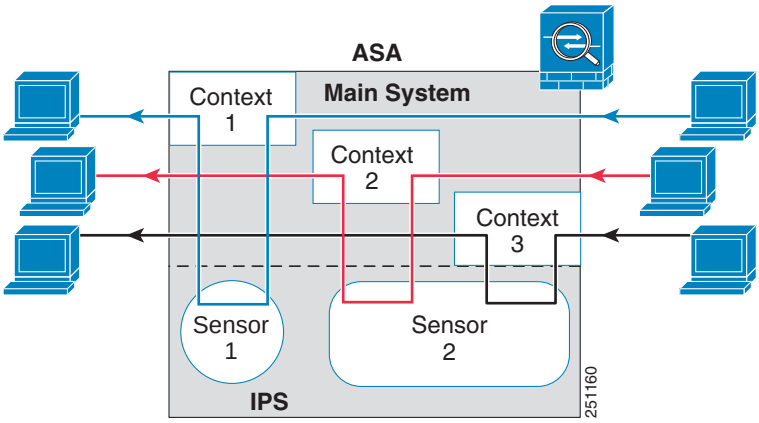


Figure 81-4 shows a single mode ASA paired with multiple virtual sensors (in inline mode); each defined traffic flow goes to a different sensor.

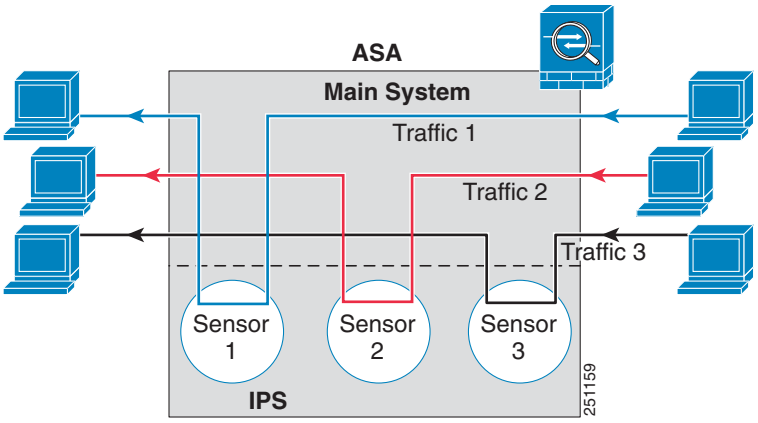
Figure 81-4 Single Mode ASA with Multiple Virtual Sensors



Information About Management Access

You can manage the IPS application using the following methods:

- Sessioning to the module from the ASA—If you have CLI access to the ASA, then you can session to the module and access the module CLI. See the "Sessioning to the Module from the ASA (May Be Required)" section on page 81-11.
- Connecting to the IPS management interface using ASDM or SSH—After you launch ASDM from the ASA, your management station connects to the module management interface to configure the IPS application. For SSH, you can access the module CLI directly on the module management interface. (Telnet access requires additional configuration in the module application). The module management interface can also be used for sending syslog messages or allowing updates for the module application, such as signature database updates.

See the following information about the management interface:

- ASA 5510, ASA 5520, ASA 5540, ASA 5580, ASA 5585-X—The IPS management interface is a separate external Gigabit Ethernet interface.
- ASA 5512-X, ASA 5515-X, ASA 5525-X, ASA 5545-X, ASA 5555-X—These models run the ASA IPS module as a software module. The IPS management interface shares the Management 0/0 interface with the ASA. Separate MAC addresses and IP addresses are supported for the ASA and ASA IPS module. You must perform configuration of the IPS IP address within the IPS operating system (using the CLI or ASDM). However, physical characteristics (such as enabling the interface) are configured on the ASA. You can remove the ASA interface configuration (specifically the interface name) to dedicate this interface as an IPS-only interface. This interface is management-only.
- ASA 5505—You can use an ASA VLAN to allow access to an internal management IP address over the backplane.

Licensing Requirements for the ASA IPS module

The following table shows the licensing requirements for this feature:

Model	License Requirement
ASA 5512-X, ASA 5515-X, ASA 5525-X, ASA 5545-X, ASA 5555-X	IPS Module License. **Note** The IPS module license lets you run the IPS software module on the ASA. You must also purchase a separate IPS signature subscription; for failover, purchase a subscription for each unit. To obtain IPS signature support, you must purchase the ASA with IPS pre-installed (the part number must include "IPS"). The combined failover cluster license does not let you pair non-IPS and IPS units. For example, if you buy the IPS version of the ASA 5515-X (part number ASA5515-IPS-K9) and try to make a failover pair with a non-IPS version (part number ASA5515-K9), then you will not be able to obtain IPS signature updates for the ASA5515-K9 unit, even though it has an IPS module license inherited from the other unit.
All other models	Base License.

The ASA IPS module requires a separate Cisco Services for IPS license in order to support signature updates. All other updates are available without a license.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

The ASA 5505 does not support multiple context mode, so multiple context features, such as virtual sensors, are not supported on the AIP SSC.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Model Guidelines

- See the *Cisco ASA Compatibility Matrix* for information about which models support which modules:

  http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html

- The ASA 5505 does not support multiple context mode, so multiple context features, such as virtual sensors, are not supported on the AIP SSC.
- The ASA IPS module for the ASA 5510 and higher supports higher performance requirements, while the ASA IPS module for the ASA 5505 is designed for a small office installation. The following features are not supported for the ASA 5505:
  - Virtual sensors
  - Anomaly detection
  - Unretirement of default retired signatures

Additional Guidelines

- The total throughput for the ASA plus the IPS module is lower than ASA throughput alone.
  - ASA 5512-X through ASA 5555-X—See http://www.cisco.com/en/US/prod/collateral/vpndevc/ps6032/ps6094/ps6120/qa_c67-700608.html
  - ASA 5585-X—See http://www.cisco.com/en/US/prod/collateral/vpndevc/ps6032/ps6094/ps6120/qa_c67-617018.html
  - ASA 5505 through ASA 5540—See http://www.cisco.com/en/US/prod/collateral/vpndevc/ps6032/ps6094/ps6120/product_data_sheet0900aecd802930c5.html
- You cannot change the software type installed on the module; if you purchase an ASA IPS module, you cannot later install other software on it.

Default Settings

Table 81-1 lists the default settings for the ASA IPS module.

Table 81-1 Default Network Parameters

Parameters	Default
Management VLAN (ASA 5505 only)	VLAN 1
Management IP address	192.168.1.2/24
Gateway	192.168.1.1/24 (the default ASA management IP address)
Username	cisco
Password	cisco

Note The default management IP address on the ASA is 192.168.1.1/24.

Configuring the ASA IPS module

This section describes how to configure the ASA IPS module and includes the following topics:

- Task Flow for the ASA IPS Module, page 81-7
- Connecting the ASA IPS Management Interface, page 81-8
- Configuring Basic IPS Module Network Settings, page 81-12
- (ASA 5512-X through ASA 5555-X) Booting the Software Module, page 81-12
- Configuring the Security Policy on the ASA IPS Module, page 81-15
- Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher), page 81-17
- Diverting Traffic to the ASA IPS module, page 81-18

Task Flow for the ASA IPS Module

Configuring the ASA IPS module is a process that includes configuration of the IPS security policy on the ASA IPS module and then configuration of the ASA to send traffic to the ASA IPS module. To configure the ASA IPS module, perform the following steps:

Step 1 Cable the ASA IPS management interface. See the "Connecting the ASA IPS Management Interface" section on page 81-8.

Step 2 Session to the module. Access the IPS CLI over the backplane. For ASDM users, you may need to session to the module to boot the IPS software if it is not running. See the "Sessioning to the Module from the ASA (May Be Required)" section on page 81-11.

Step 3 (ASA 5512-X through ASA 5555-X; may be required) Install the software module. See the "(ASA 5512-X through ASA 5555-X) Booting the Software Module" section on page 81-12.

Step 4 Depending on your ASA model:

- (ASA 5510 and higher) Configure basic network settings for the IPS module. See the "(ASA 5510 and Higher) Configuring Basic Network Settings" section on page 81-13.
- (ASA 5505) Configure the management VLAN and IP address for the IPS module. See the "(ASA 5505) Configuring Basic Network Settings" section on page 81-14.

Step 5 On the module, configure the inspection and protection policy, which determines how to inspect traffic and what to do when an intrusion is detected. See the "Configuring the Security Policy on the ASA IPS Module" section on page 81-15.

Step 6 (ASA 5510 and higher, optional) On the ASA in multiple context mode, specify which IPS virtual sensors are available for each context (if you configured virtual sensors). See the "Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)" section on page 81-17.

Step 7 On the ASA, identify traffic to divert to the ASA IPS module. See the "Diverting Traffic to the ASA IPS module" section on page 81-18.

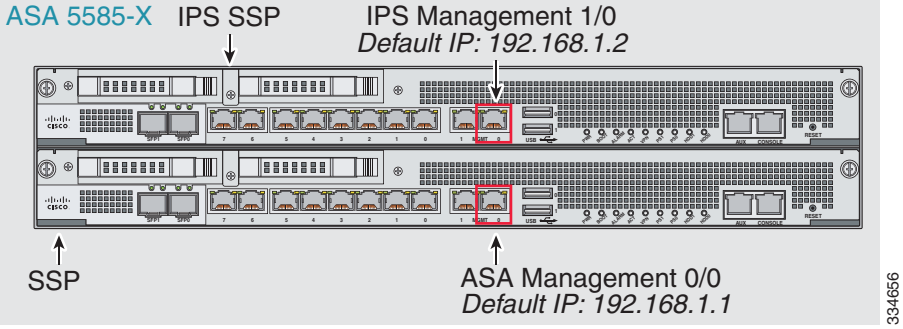
Connecting the ASA IPS Management Interface

In addition to providing management access to the IPS module, the IPS management interface needs access to an HTTP proxy server or a DNS server and the Internet so it can download global correlation, signature updates, and license requests. This section describes recommended network configurations. Your network may differ.

- ASA 5510, ASA 5520, ASA 5540, ASA 5580, ASA 5585-X (Physical Module), page 81-8
- ASA 5512-X through ASA 5555-X (Software Module), page 81-9
- ASA 5505, page 81-10

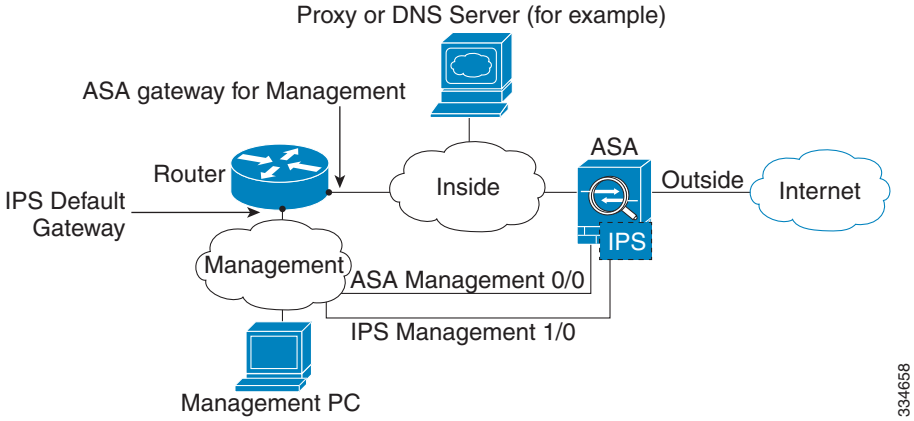
ASA 5510, ASA 5520, ASA 5540, ASA 5580, ASA 5585-X (Physical Module)

The IPS module includes a separate management interface from the ASA.



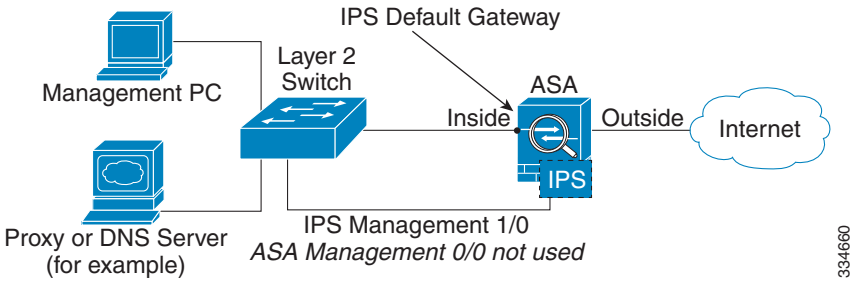
If you have an inside router

If you have an inside router, you can route between the management network, which can include both the ASA Management 0/0 and IPS Management 1/0 interfaces, and the ASA inside network. Be sure to also add a route on the ASA to reach the Management network through the inside router.



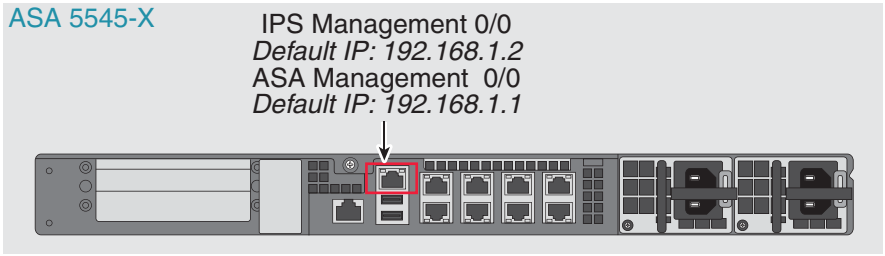
If you do not have an inside router

If you have only one inside network, then you cannot also have a separate management network, which would require an inside router to route between the networks. In this case, you can manage the ASA from the inside interface instead of the Management 0/0 interface. Because the IPS module is a separate device from the ASA, you can configure the IPS Management 1/0 address to be on the same network as the inside interface.



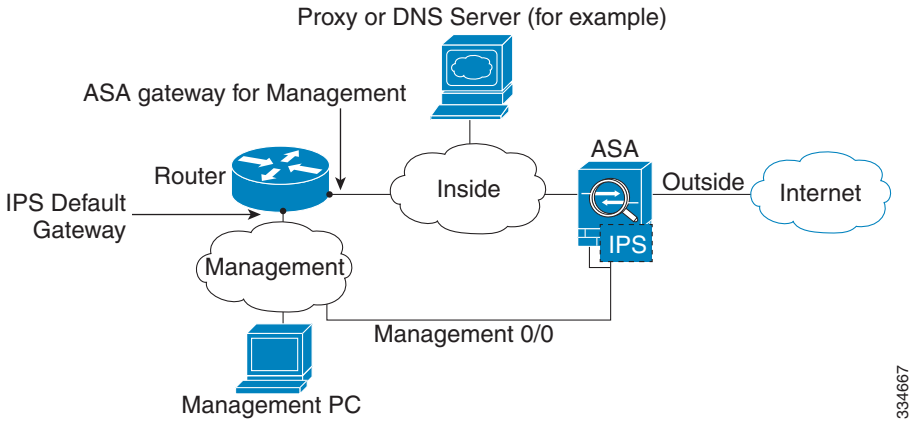
ASA 5512-X through ASA 5555-X (Software Module)

These models run the IPS module as a software module, and the IPS management interface shares the Management 0/0 interface with the ASA.



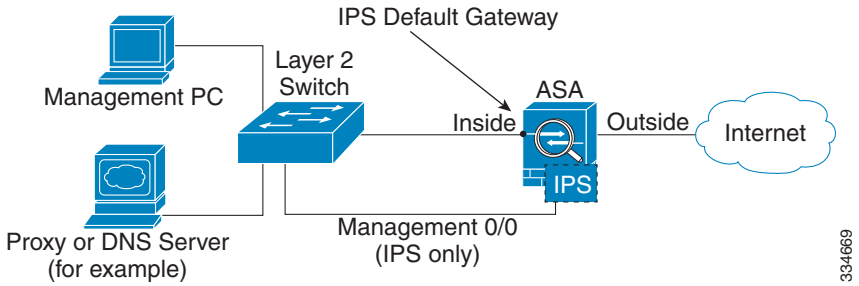
If you have an inside router

If you have an inside router, you can route between the Management 0/0 network, which includes both the ASA and IPS management IP addresses, and the inside network. Be sure to also add a route on the ASA to reach the Management network through the inside router.



If you do not have an inside router

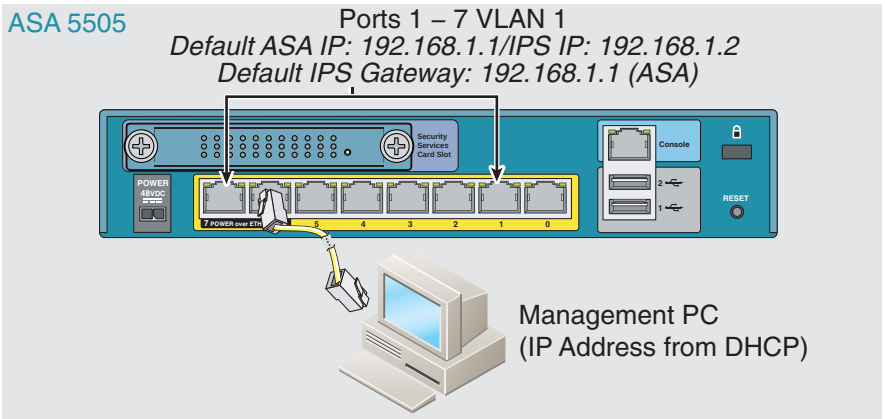
If you have only one inside network, then you cannot also have a separate management network. In this case, you can manage the ASA from the inside interface instead of the Management 0/0 interface. If you remove the ASA-configured name from the Management 0/0 interface, you can still configure the IPS IP address for that interface. Because the IPS module is essentially a separate device from the ASA, you *can* configure the IPS management address to be on the same network as the inside interface.



Note You must remove the ASA-configured name for Management 0/0; if it is configured on the ASA, then the IPS address must be on the same network as the ASA, and that excludes any networks already configured on other ASA interfaces. If the name is not configured, then the IPS address can be on any network, for example, the ASA inside network.

ASA 5505

The ASA 5505 does not have a dedicated management interface. You must use an ASA VLAN to access an internal management IP address over the backplane. Connect the management PC to one of the following ports: Ethernet 0/1 through 0/7, which are assigned to VLAN 1.



What to Do Next

- (ASA 5510 and higher) Configure basic network settings. See the "(ASA 5510 and Higher) Configuring Basic Network Settings" section on page 81-13.
- (ASA 5505) Configure management interface settings. See the "(ASA 5505) Configuring Basic Network Settings" section on page 81-14.

Sessioning to the Module from the ASA (May Be Required)

To access the IPS module CLI from the ASA, you can session from the ASA. For software modules, you can either session to the module (using Telnet) or create a virtual console session. A console session might be useful if the control plane is down and you cannot establish a Telnet session.

You may need to access the CLI if you are using multiple context mode and you need to set basic network settings using the CLI, or for troubleshooting.

Detailed Steps

Command	Purpose

Telnet session.
 	
For a physical module (for example, the ASA 5585-X):
session 1
 	
For a software module (for example, the ASA 5545-X):
session ips
 	
Example:
`hostname# session 1`
 	
`Opening command session with slot 1.`
`Connected to slot 1. Escape character sequence is 'CTRL-^X'.`
 	
`sensor login: cisco`
`Password: cisco`
	Accesses the module using Telnet. You are prompted for the username and password. The default username is **cisco**, and the default password is **cisco**.
	
	Note The first time you log in to the module, you are prompted to change the default password. Passwords must be at least eight characters long and cannot be a word in the dictionary.

Console session (software module only).
 	
session ips console
 	
Example:
`hostname# session ips console`
 	
`Establishing console session with slot 1`
`Opening console session with module ips.`
`Connected to module ips. Escape character sequence is 'CTRL-SHIFT-6 then x'.`
 	
`sensor login: cisco`
`Password: cisco`
	Accesses the module console. You are prompted for the username and password. The default username is **cisco**, and the default password is **cisco**.
	
	Note Do not use this command in conjunction with a terminal server where **Ctrl-Shift-6, x** is the escape sequence to return to the terminal server prompt. **Ctrl-Shift-6, x** is also the sequence to escape the IPS console and return to the ASA prompt. Therefore, if you try to exit the IPS console in this situation, you instead exit all the way to the terminal server prompt. If you reconnect the terminal server to the ASA, the IPS console session is still active; you can never exit to the ASA prompt. You must use a direct serial connection to return the console to the ASA prompt.
	
	Use the **session ips** command instead.

(ASA 5512-X through ASA 5555-X) Booting the Software Module

Your ASA typically ships with IPS module software present on Disk0. If the module is not running, or if you are adding the IPS module to an existing ASA, you must boot the module software. If you are unsure if the module is running, you will not see the IPS Basic COnfiguration screen when you run the Startup Wizard (see the "Configuring Basic IPS Module Network Settings" section on page 81-12).

Detailed Steps

Step 1 Do one of the following:

- New ASA with IPS pre-installed—To view the IPS module software filename in flash memory, choose **Tools > File Management**.

  For example, look for a filename like IPS-SSP_5512-K9-sys-1.1-a-7.1-4-E4.aip. Note the filename; you will need this filename later in the procedure.

- Existing ASA with new IPS installation—Download the IPS software from Cisco.com to your computer. If you have a Cisco.com login, you can obtain the software from the following website:

  http://www.cisco.com/cisco/software/navigator.html?mdfid=282164240

  Choose **Tools > File Management**, then choose **File Transfer > Between Local PC and Flash** to upload the new image to disk0. Note the filename; you will need this filename later in the procedure.

Step 2 Choose **Tools > Command Line Interface**.

Step 3 To set the IPS module software location in disk0, enter the following command and then click **Send**:

```
sw-module module ips recover configure image disk0:file_path
```

For example, using the filename in the example in Step 1, enter:

```
sw-module module ips recover configure image disk0:IPS-SSP_5512-K9-sys-1.1-a-7.1-4-E4.aip
```

Step 4 To install and load the IPS module software, enter the following command and then click **Send**:

```
sw-module module ips recover boot
```

Step 5 To check the progress of the image transfer and module restart process, enter the following command and then click **Send**:

```
show module ips details
```

The Status field in the output indicates the operational status of the module. A module operating normally shows a status of "Up." While the ASA transfers an application image to the module, the Status field in the output reads "Recover." When the ASA completes the image transfer and restarts the module, the newly transferred image is running.

Configuring Basic IPS Module Network Settings

- (ASA 5510 and Higher) Configuring Basic Network Settings, page 81-13
- (ASA 5505) Configuring Basic Network Settings, page 81-14

(ASA 5510 and Higher) Configuring Basic Network Settings

In single context mode, you can use the Startup Wizard in ASDM to configure basic IPS network configuration. These settings are saved to the IPS configuration, not the ASA configuration.

In multiple context mode, session to the module from the ASA and configure basic settings using the **setup** command.

Note (ASA 5512-X through ASA 5555-X) If you do not see the IPS Basic Configuration screen in your wizard, then the IPS module is not running. See the "(ASA 5512-X through ASA 5555-X) Booting the Software Module" section on page 81-12, and then repeat this procedure after you install the module.

Detailed Steps—Single Mode

Step 1 Choose **Wizards > Startup Wizard**.

Step 2 Click **Next** to advance through the initial screens until you reach the IPS Basic Configuration screen.

Step 3 In the Network Settings area, configure the following:

- IP Address—The management IP address. By default, the address is 192.168.1.2.
- Subnet Mask—The subnet mask for the management IP address.
- Gateway—The IP address of the upstream router. The IP address of the next hop router. See the "Connecting the ASA IPS Management Interface" section on page 81-8 to understand the requirements for your network. The default setting of the ASA management IP address will not work.
- HTTP Proxy Server—(Optional) The HTTP proxy server address. You can use a proxy server to download global correlation updates and other information instead of downloading over the Internet.
- HTTP Proxy Port—(Optional) The HTTP proxy server port.
- DNS Primary—(Optional) The primary DNS server address. If you are using a DNS server, you must configure at least one DNS server and it must be reachable for global correlation updates to be successful.

  For global correlation to function, you must have either a DNS server or an HTTP proxy server configured at all times. DNS resolution is supported only for accessing the global correlation update server.

Step 4 In the Management Access List area, enter an IP address and subnet mask for any hosts that are allowed to access the IPS management interface, and click **Add**. You can add multiple IP addresses.

Step 5 In the Cisco Account Password area, set the password for the username **cisco** and confirm it. The username **cisco** and this password are used for Telnet sessions from hosts specified by the management access list and when accessing the IPS module from ASDM (Configuration > IPS). By default, the password is **cisco**.

Step 6 In the Network Participation area, which you use to have the IPS module participate in SensorBase data sharing, click **Full**, **Partial**, or **Off**.

Detailed Steps—Multiple Mode Using the CLI

	Command	Purpose
Step 1	Session to the IPS module according to the "Sessioning to the Module from the ASA (May Be Required)" section on page 81-11.	

Step 2	`setup`
	
	Example:
	`sensor# setup`
		Runs the setup utility for initial configuration of the ASA IPS module. You are prompted for basic settings. For the default gateway, specify the IP address of the upstream router. See the "Connecting the ASA IPS Management Interface" section on page 81-8 to understand the requirements for your network. The default setting of the ASA management IP address will not work.

(ASA 5505) Configuring Basic Network Settings

An ASA IPS module on the ASA 5505 does not have any external interfaces. You can configure a VLAN to allow access to an internal IPS management IP address over the backplane. By default, VLAN 1 is enabled for IPS management. You can only assign one VLAN as the management VLAN. This section describes how to change the management VLAN and IP address if you do not want to use the default, and how to set other required network parameters.

Note Perform this configuration on the ASA 5505, not on the ASA IPS module.

Prerequisites

When you change the IPS VLAN and management address from the default, be sure to also configure the matching ASA VLAN and switch port(s) according to the procedures listed in Chapter 16, "Starting Interface Configuration (ASA 5505)." You must define and configure the VLAN for the ASA so the IPS management interface is accessible on the network.

Restrictions

Do not configure NAT for the management address if you intend to access it using ASDM. For initial setup with ASDM, you need to access the real address. After initial setup (where you set the password on the ASA IPS module), you can configure NAT and supply ASDM with the translated address for accessing the ASA IPS module.

Detailed Steps

Step 1 In ASDM, choose **Configuration > Device Setup > SSC Setup**.

Note The following settings are written to the ASA IPS module application configuration, not the ASA configuration.

Step 2 In the Management Interface area, set the following:

a. Choose the Interface VLAN from the drop-down list.

This setting allows you to manage the ASA IPS module using this VLAN.

b. Enter the IPS management IP address. Make sure this address is on the same subnet as the ASA VLAN IP address. For example, if you assigned 10.1.1.1 to the VLAN for the ASA, then assign another address on that network, such as 10.1.1.2, for the IPS management address. By default, the address is 192.168.1.2

c. Choose the subnet mask from the drop-down list.

d. Enter the default gateway IP address.

Set the gateway to be the ASA IP address for the management VLAN. By default, this IP address is 192.168.1.1.

Step 3 In the Management Access List area, enter the following:

a. Enter the IP address for the management host network.

b. Choose the subnet mask from the drop-down list.

c. Click **Add** to add these settings to the Allowed Hosts/Networks list.

Step 4 In the IPS Password area, do the following:

a. Enter the current password. The default password is **cisco**.

b. Enter the new password, and confirm the change.

Step 5 Click **Apply** to save the settings to the running configuration.

Step 6 To launch the IPS Startup Wizard, click the **Configure the IPS SSC module** link.

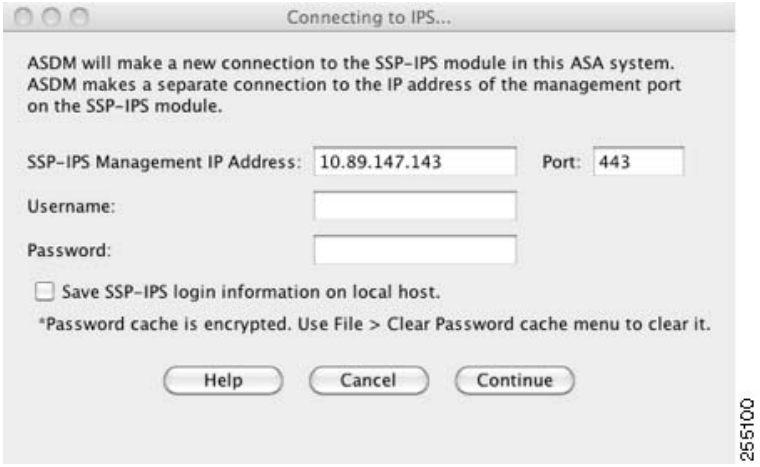
Configuring the Security Policy on the ASA IPS Module

This section describes how to configure the ASA IPS module application.

Detailed Steps

Step 1 Connect to ASDM using the *ASA* management IP address. See the "Starting ASDM" section on page 3-13.

Step 2 To access the IPS Device Manager (IDM) from ASDM, click **Configuration > IPS**.



Step 3 Enter the IP address, username and password that you set in the "Configuring Basic IPS Module Network Settings" section on page 81-12, as well as the port. The default IP address and port is 192.168.1.2:443. The default username and password is **cisco** and **cisco**.

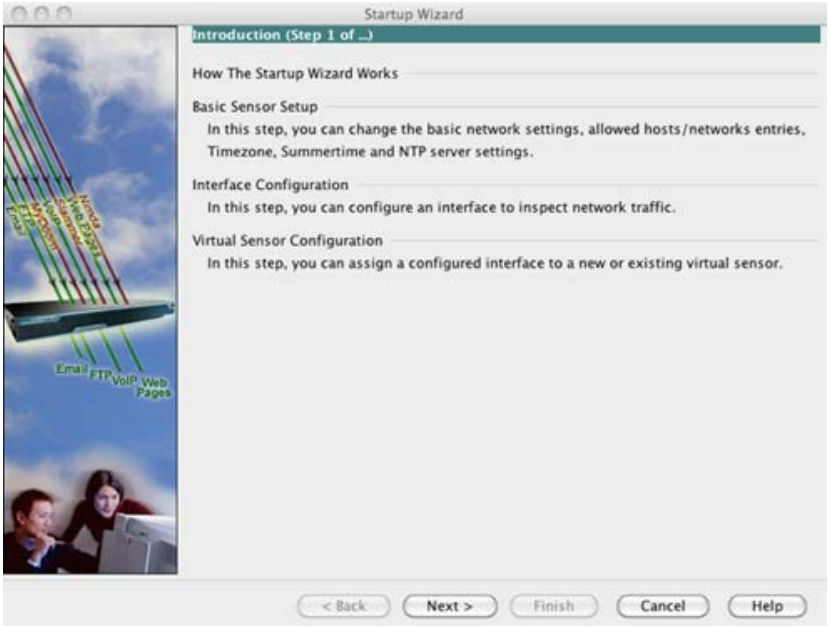
If the password to access IDM is lost, you can reset the password using ASDM. See the "Resetting the Password" section on page 81-22, for more information.

Step 4 To save the login information on your local PC, check the **Save IPS login information on local host** check box.

Step 5 Click **Continue**.

The Startup Wizard pane appears.

Step 6 Click **Launch Startup Wizard**. Complete the screens as prompted. For more information, see the IDM online help.



(ASA 5510 and higher) If you configure virtual sensors, you identify one of the sensors as the default. If the ASA series does not specify a virtual sensor name in its configuration, the default sensor is used.

What to Do Next

- For the ASA in multiple context mode, see the "Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)" section on page 81-17.
- For the ASA in single context mode, see the "Diverting Traffic to the ASA IPS module" section on page 81-18.

Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)

If the ASA is in multiple context mode, then you can assign one or more IPS virtual sensors to each context. Then, when you configure the context to send traffic to the ASA IPS module, you can specify a sensor that is assigned to the context; you cannot specify a sensor that you did not assign to the context. If you do not assign any sensors to a context, then the default sensor configured on the ASA IPS module is used. You can assign the same sensor to multiple contexts.

Note You do not need to be in multiple context mode to use virtual sensors; you can be in single mode and use different sensors for different traffic flows.

Prerequisites

For more information about configuring contexts, see the "Configuring Multiple Contexts" section on page 9-15.

Detailed Steps

Step 1 In the ASDM Device List pane, double-click **System** under the active device IP address.

Step 2 On the Context Management > Security Contexts pane, choose a context that you want to configure, and click **Edit**.

The Edit Context dialog box appears. For more information about configuring contexts, see the "Configuring Multiple Contexts" section on page 9-15.

Step 3 In the IPS Sensor Allocation area, click **Add**.

The IPS Sensor Selection dialog box appears.

Step 4 From the Sensor Name drop-down list, choose a sensor name from those configured on the ASA IPS module.

Step 5 (Optional) To assign a mapped name to the sensor, enter a value in the Mapped Sensor Name field.

This sensor name can be used within the context instead of the actual sensor name. If you do not specify a mapped name, the sensor name is used within the context. For security purposes, you might not want the context administrator to know which sensors are being used by the context. Or you might want to genericize the context configuration. For example, if you want all contexts to use sensors called "sensor1" and "sensor2," then you can map the "highsec" and "lowsec" sensors to sensor1 and sensor2 in context A, but map the "medsec" and "lowsec" sensors to sensor1 and sensor2 in context B.

Step 6 Click **OK** to return to the Edit Context dialog box.

Step 7 (Optional) To set one sensor as the default sensor for this context, from the Default Sensor drop-down list, choose a sensor name.

If you do not specify a sensor name when you configure IPS within the context configuration, the context uses this default sensor. You can only configure one default sensor per context. If you do not specify a sensor as the default, and the context configuration does not include a sensor name, then traffic uses the default sensor on the ASA IPS module.

Step 8 Repeat this procedure for each security context.

Step 9 Change to each context to configure the IPS security policy as described in "Diverting Traffic to the ASA IPS module" section on page 81-18.

What to Do Next

Change to each context to configure the IPS security policy as described in "Diverting Traffic to the ASA IPS module" section on page 81-18.

Diverting Traffic to the ASA IPS module

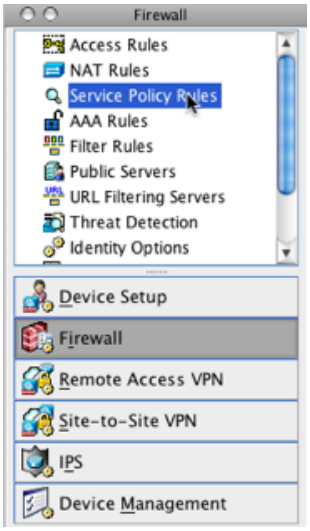
This section identifies traffic to divert from the ASA to the ASA IPS module.

Prerequisites

In multiple context mode, perform these steps in each context execution space. To change to a context, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Service Policy Rules**.



Step 2 Choose **Add > Add Service Policy Rule**. The Add Service Policy Rule Wizard - Service Policy dialog box appears.

Step 3 Complete the Service Policy dialog box, and then the Traffic Classification Criteria dialog box as desired. See the ASDM online help for more information about these screens.

Step 4 Click **Next** to show the Add Service Policy Rule Wizard - Rule Actions dialog box.

Step 5 Click the **Intrusion Prevention** tab.

Step 6 Check the **Enable IPS for this traffic flow** check box.

Step 7 In the Mode area, click **Inline Mode** or **Promiscuous Mode**. See the "Operating Modes" section on page 81-3 for more information.

Step 8 In the If IPS Card Fails area, click **Permit traffic** or **Close traffic**. The Close traffic option sets the ASA to block all traffic if the ASA IPS module is unavailable. The Permit traffic option sets the ASA to allow all traffic through, uninspected, if the ASA IPS module is unavailable. For information about the IPS Sensor Selection area, see the ASDM online help.

Step 9 (ASA 5510 and higher) From the IPS Sensor to use drop-down list, choose a virtual sensor name.

If you use virtual sensors, you can specify a sensor name using this option. If you use multiple context mode on the ASA, you can only specify sensors that you assigned to the context (see the "Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher)" section on page 81-17). If you do not specify a sensor name, then the traffic uses the default sensor. In multiple context mode, you can specify a default sensor for the context. In single mode or if you do not specify a default sensor in multiple mode, the traffic uses the default sensor that is set on the ASA IPS module.

Step 10 Click **OK** and then **Apply**.

Step 11 Repeat this procedure to configure additional traffic flows as desired.

Managing the ASA IPS module

This section includes procedures that help you recover or troubleshoot the module and includes the following topics:

- Installing and Booting an Image on the Module, page 81-20
- Shutting Down the Module, page 81-22

- Uninstalling a Software Module Image, page 81-22
- Resetting the Password, page 81-22
- Reloading or Resetting the Module, page 81-23

Installing and Booting an Image on the Module

If the module suffers a failure, and the module application image cannot run, you can reinstall a new image on the module from a TFTP server (for a physical module), or from the local disk (software module).

Note Do not use the **upgrade** command within the module software to install the image.

Prerequisites

- Physical module—Be sure the TFTP server that you specify can transfer files up to 60 MB in size.

  Note This process can take approximately 15 minutes to complete, depending on your network and the size of the image.

- Software module—Copy the image to the ASA internal flash (disk0) before completing this procedure.

  Note Before you download the IPS software to disk0, make sure at least 50% of the flash memory is free. When you install IPS, IPS reserves 50% of the internal flash memory for its file system.

Detailed Steps

	Command	Purpose

Step 1	For a physical module (for example, the ASA 5585-X):
	hw-module module 1 recover configure
	For a software module (for example, the ASA 5545-X):
	sw-module module ips recover configure image disk0:*file_path*
	Example:
	`hostname# hw-module module 1 recover configure`
	`Image URL [tftp://127.0.0.1/myimage]: tftp://10.1.1.1/ids-newimg`
	`Port IP Address [127.0.0.2]: 10.1.2.10`
	`Port Mask [255.255.255.254]: 255.255.255.0`
	`Gateway IP Address [1.1.2.10]: 10.1.2.254`
	`VLAN ID [0]: 100`
		Specifies the location of the new image.
		For a physical module—This command prompts you for the URL for the TFTP server, the management interface IP address and netmask, gateway address, and VLAN ID (ASA 5505 only). These network parameters are configured in ROMMON; the network parameters you configured in the module application configuration are not available to ROMMON, so you must set them separately here.
		For a software module—Specify the location of the image on the local disk.
		You can view the recovery configuration using the **show module** {**1** | **ips**} **recover** command.
		In multiple context mode, enter this command in the system execution space.

Step 2	For a physical module: **hw-module module 1 recover boot** For a software module: **sw-module module ips recover boot** **Example:** `hostname# hw-module module 1 recover boot`	Installs and boots the IPS module software.
Step 3	For a physical module: **show module 1 details** For a software module: **show module ips details** **Example:** `hostname# show module 1 details`	Checks the progress of the image transfer and module restart process. The Status field in the output indicates the operational status of the module. A module operating normally shows a status of "Up." While the ASA transfers an application image to the module, the Status field in the output reads "Recover." When the ASA completes the image transfer and restarts the module, the newly transferred image is running.

Shutting Down the Module

Shutting down the module software prepares the module to be safely powered off without losing configuration data. **Note**: If you reload the ASA, the module is not automatically shut down, so we recommend shutting down the module before reloading the ASA. To gracefully shut down the module, perform the following steps at the ASA CLI.

Detailed Steps

Command	Purpose
For a physical module (for example, the ASA 5585-X): **hw-module module 1 shutdown** For a software module (for example, the ASA 5545-X): **sw-module module ips shutdown** **Example:** `hostname# hw-module module 1 shutdown`	Shuts down the module.

Uninstalling a Software Module Image

To uninstall a software module image and associated configuration, perform the following steps.

Detailed Steps

Command	Purpose

sw-module module ips uninstall
Example:
`hostname# sw-module module ips uninstall`
`Module ips will be uninstalled. This will completely remove the`
`disk image associated with the sw-module including any configuration`
`that existed within it.`
`Uninstall module <id>? [confirm]`
	Permanently uninstalls the software module image and associated configuration.

Resetting the Password

You can reset the module password to the default. The default password is **cisco**. After resetting the password, you should change it to a unique value using the module application.

Resetting the module password causes the module to reboot. Services are not available while the module is rebooting.

If you cannot connect to ASDM with the new password, restart ASDM and try to log in again. If you defined a new password and still have an existing password in ASDM that is different from the new password, clear the password cache by choosing **File > Clear ASDM Password Cache**, then restart ASDM and try to log in again.

To reset the module password to the default of cisco, perform the following steps.

Detailed Steps

Step 1 From the ASDM menu bar, choose **Tools >** *module* **Password Reset**.

The Password Reset confirmation dialog box appears.

Step 2 Click **OK** to reset the password to the default.

A dialog box displays the success or failure of the password reset.

Step 3 Click **Close** to close the dialog box.

Reloading or Resetting the Module

To reload or reset the module, enter one of the following commands at the ASA CLI.

Detailed Steps

Command	Purpose
For a physical module (for example, the ASA 5585-X): **hw-module module 1 reload** For a software module (for example, the ASA 5545-X): **sw-module module ips reload** **Example:** `hostname# hw-module module 1 reload`	Reloads the module software.
For a physical module: **hw-module module 1 reset** For a software module: **sw-module module ips reset** **Example:** `hostname# hw-module module 1 reset`	Performs a reset, and then reloads the module.

Monitoring the ASA IPS module

See the "Intrusion Prevention Tab" section on page 4-28.

Feature History for the ASA IPS module

Table 81-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 81-2 Feature History for the ASA IPS module

Feature Name	Platform Releases	Feature Information
AIP SSM	7.0(1)	We introduced support for the AIP SSM for the ASA 5510, 5520, and 5540. The following screen was introduced: Configuration > Firewall > Service Policy Rules > Add/Edit Service Policy Rule > Intrusion Prevention.
Virtual sensors (ASA 5510 and higher)	8.0(2)	Virtual sensor support was introduced. Virtual sensors let you configure multiple security policies on the ASA IPS module. The following screen was modified: Context Management > Security Contexts > Edit Context.
AIP SSC for the ASA 5505	8.2(1)	We introduced support for the AIP SSC for the ASA 5505. The following screen was introduced: Configuration > Device Setup > SSC Setup.
Support for the ASA IPS SSP-10, -20, -40, and -60 for the ASA 5585-X	8.2(5)/ 8.4(2)	We introduced support for the ASA IPS SSP-10, -20, -40, and -60 for the ASA 5585-X. You can only install the ASA IPS SSP with a matching-level SSP; for example, SSP-10 and ASA IPS SSP-10. **Note** The ASA 5585-X is not supported in Version 8.3.

Table 81-2 Feature History for the ASA IPS module (continued)

Feature Name	Platform Releases	Feature Information
Support for Dual SSPs for SSP-40 and SSP-60	8.4(2)	For SSP-40 and SSP-60, you can use two SSPs of the same level in the same chassis. Mixed-level SSPs are not supported (for example, an SSP-40 with an SSP-60 is not supported). Each SSP acts as an independent device, with separate configurations and management. You can use the two SSPs as a failover pair if desired. **Note** When using two SSPs in the chassis, VPN is not supported; note, however, that VPN has not been disabled. We did not modify any screens.
Support for the ASA IPS SSP for the ASA 5512-X through ASA 5555-X	8.6(1)	We introduced support for the ASA IPS SSP software module for the ASA 5512-X, ASA 5515-X, ASA 5525-X, ASA 5545-X, and ASA 5555-X. We did not modify any screens.

Configuring the ASA CX Module

This chapter describes how to configure the ASA CX module that runs on the ASA. This chapter includes the following sections:

- Information About the ASA CX Module, page 82-1
- Licensing Requirements for the ASA CX Module, page 82-4
- Guidelines and Limitations, page 82-4
- Default Settings, page 82-5
- Configuring the ASA CX Module, page 82-5
- Managing the ASA CX Module, page 82-14
- Monitoring the ASA CX Module, page 82-15
- Troubleshooting the ASA CX Module, page 82-20
- Feature History for the ASA CX Module, page 82-21

Information About the ASA CX Module

The ASA CX module lets you enforce security based on the complete context of a situation. This context includes the identity of the user (who), the application or website that the user is trying to access (what), the origin of the access attempt (where), the time of the attempted access (when), and the properties of the device used for the access (how). With the ASA CX module, you can extract the full context of a flow and enforce granular policies such as permitting access to Facebook but denying access to games on Facebook or permitting finance employees access to a sensitive enterprise database but denying the same to other employees.

This section includes the following topics:

- How the ASA CX Module Works with the ASA, page 82-2
- Information About ASA CX Management, page 82-2
- Information About Authentication Proxy, page 82-3
- Information About VPN and the ASA CX Module, page 82-4
- Compatibility with ASA Features, page 82-4

How the ASA CX Module Works with the ASA

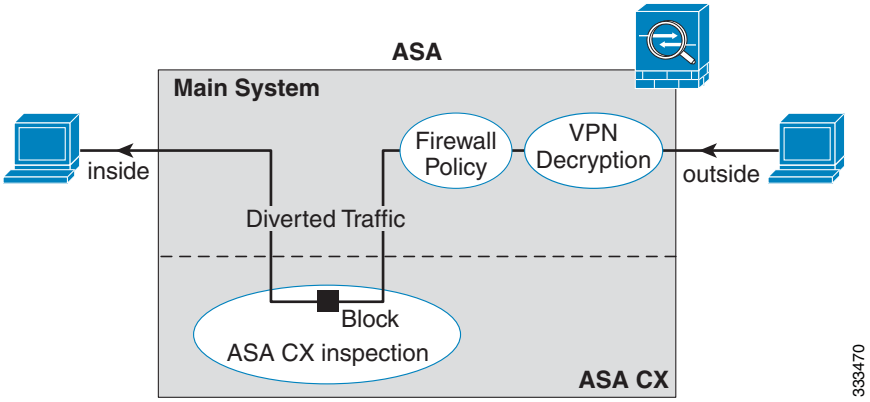
The ASA CX module runs a separate application from the ASA. The ASA CX module includes external management interface(s) so you can connect to the ASA CX module directly. Any data interfaces on the ASA CX module are used for ASA traffic only.

Traffic goes through the firewall checks before being forwarded to the ASA CX module. When you identify traffic for ASA CX inspection on the ASA, traffic flows through the ASA and the ASA CX module as follows:

1. Traffic enters the ASA.
2. Incoming VPN traffic is decrypted.
3. Firewall policies are applied.
4. Traffic is sent to the ASA CX module.
5. The ASA CX module applies its security policy to the traffic, and takes appropriate actions.
6. Valid traffic is sent back to the ASA; the ASA CX module might block some traffic according to its security policy, and that traffic is not passed on.
7. Outgoing VPN traffic is encrypted.
8. Traffic exits the ASA.

Figure 82-1 shows the traffic flow when using the ASA CX module. In this example, the ASA CX module automatically blocks traffic that is not allowed for a certain application. All other traffic is forwarded through the ASA.

Figure 82-1 ASA CX Module Traffic Flow in the ASA



Note If you have a connection between hosts on two ASA interfaces, and the ASA CX service policy is only configured for one of the interfaces, then all traffic between these hosts is sent to the ASA CX module, including traffic orginiating on the non-ASA CX interface (the feature is bidirectional). However, the ASA only performs the authentication proxy on the interface to which the service policy is applied, because this feature is ingress-only.

Information About ASA CX Management

- Initial Configuration, page 82-3

- Policy Configuration and Management, page 82-3

Initial Configuration

For initial configuration, you must use the CLI on the ASA CX module to run the **setup** command and configure other optional settings.

To access the CLI, you can use the following methods:

- ASA CX console port—The ASA CX console port is a separate external console port.
- ASA CX Management 1/0 interface using SSH—You can connect to the default IP address (192.168.8.8), or you can use ASDM to change the management IP address and then connect using SSH. The ASA CX management interface is a separate external Gigabit Ethernet interface.

Note You cannot access the ASA CX module CLI over the ASA backplane using the **session** command.

Policy Configuration and Management

After you perform initial configuration, configure the ASA CX policy using Cisco Prime Security Manager (PRSM). Then configure the ASA policy for sending traffic to the ASA CX module using ASDM or the ASA CLI.

Note When using PRSM in multiple device mode, you can configure the ASA policy for sending traffic to the ASA CX module within PRSM, instead of using ASDM or the ASA CLI. Using PRSM lets you consolodate management to a single management system. However, PRSM has some limitations when configuring the ASA service policy; see the ASA CX user guide for more information.

Information About Authentication Proxy

When the ASA CX needs to authenticate an HTTP user (to take advantage of identity policies), you must configure the ASA to act as an authentication proxy: the ASA CX module redirects authentication requests to the ASA interface IP address/proxy port. By default, the port is 885 (user configurable). Configure this feature as part of the service policy to divert traffic from the ASA to the ASA CX module. If you do not enable the authentication proxy, only passive authentication is available.

Note If you have a connection between hosts on two ASA interfaces, and the ASA CX service policy is only configured for one of the interfaces, then all traffic between these hosts is sent to the ASA CX module, including traffic orginiating on the non-ASA CX interface (the feature is bidirectional). However, the ASA only performs the authentication proxy on the interface to which the service policy is applied, because this feature is ingress-only.

Information About VPN and the ASA CX Module

The ASA includes VPN client and user authentication metadata when forwarding traffic to the ASA CX module, which allows the ASA CX module to include this information as part of its policy lookup criteria. The VPN metadata is sent only at VPN tunnel establishment time along with a type-length-value (TLV) containing the session ID. The ASA CX module caches the VPN metadata for each session. Each tunneled connection sends the session ID so the ASA CX module can look up that session's metadata.

Compatibility with ASA Features

The ASA includes many advanced application inspection features, including HTTP inspection. However, the ASA CX module provides more advanced HTTP inspection than the ASA provides, as well as additional features for other applications, including monitoring and controlling application usage.

To take full advantage of the ASA CX module features, see the following guidelines for traffic that you send to the ASA CX module:

- Do not configure ASA inspection on HTTP traffic.
- Do not configure Cloud Web Security (ScanSafe) inspection. If you configure both the ASA CX action and Cloud Web Security inspection for the same traffic, the ASA only performs the ASA CX action.
- Other application inspections on the ASA are compatible with the ASA CX module, including the default inspections.
- Do not enable the Mobile User Security (MUS) server; it is not compatible with the ASA CX module.
- Do not enable ASA clustering; they are not compatible; it is not compatible with the ASA CX module.
- If you enable failover, when the ASA fails over, any existing ASA CX flows are transferred to the new ASA, but the traffic is allowed through the ASA without being acted upon by the ASA CX module. Only new flows recieved by the new ASA are acted upon by the ASA CX module.

Licensing Requirements for the ASA CX Module

Model	License Requirement
All models	Base License.

The ASA CX module and PRSM require additional licenses. See the ASA CX documentation for more information.

Guidelines and Limitations

Context Mode Guidelines

Supported in single context mode only. Does not support multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Failover Guidelines

Does not support failover directly; when the ASA fails over, any existing ASA CX flows are transferred to the new ASA, but the traffic is allowed through the ASA without being inspected by the ASA CX.

ASA Clustering Guidelines

Does not support clustering.

IPv6 Guidelines

Supports IPv6.

Model Guidelines

Supported only on the ASA 5585-X. See the *Cisco ASA Compatibility Matrix* for more information:

http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html

Additional Guidelines and Limitations

- See the "Compatibility with ASA Features" section on page 82-4.
- You cannot change the software type installed on the module; if you purchase an ASA CX module, you cannot later install other software on it.

Default Settings

Table 82-1 lists the default settings for the ASA CX module.

Table 82-1 Default Network Parameters

Parameters	Default
Management IP address	Management 1/0 192.168.8.8/24
Gateway	192.168.8.1/24
SSH Username	admin
Password	Admin123

Configuring the ASA CX Module

This section describes how to configure the ASA CX module and includes the following topics:

- Task Flow for the ASA CX Module, page 82-6
- Connecting the ASA CX Management Interface, page 82-7
- Configuring the ASA CX Management IP Address, page 82-8
- Configuring Basic ASA CX Settings at the ASA CX CLI, page 82-9

- Configuring the Security Policy on the ASA CX Module Using PRSM, page 82-11
- Redirecting Traffic to the ASA CX Module, page 82-12

Task Flow for the ASA CX Module

Configuring the ASA CX module is a process that includes configuration of the ASA CX security policy on the ASA CX module and then configuration of the ASA to send traffic to the ASA CX module. To configure the ASA CX module, perform the following steps:

Step 1 Cable the ASA CX management interfaces interface. See the "Connecting the ASA CX Management Interface" section on page 82-7.

Step 2 On the ASA, configure the ASA CX module management IP address for initial SSH access. See the "Configuring the ASA CX Management IP Address" section on page 82-8.

Step 3 On the ASA CX module, configure basic settings. You must use the CLI to configure these settings. See the "Configuring Basic ASA CX Settings at the ASA CX CLI" section on page 82-9.

Step 4 On the ASA CX module, configure the security policy using PRSM. See the "Configuring the Security Policy on the ASA CX Module Using PRSM" section on page 82-11.

Step 5 (Optional) On the ASA, configure the authentication proxy port. See the "(Optional) Configuring the Authentication Proxy Port" section on page 82-12.

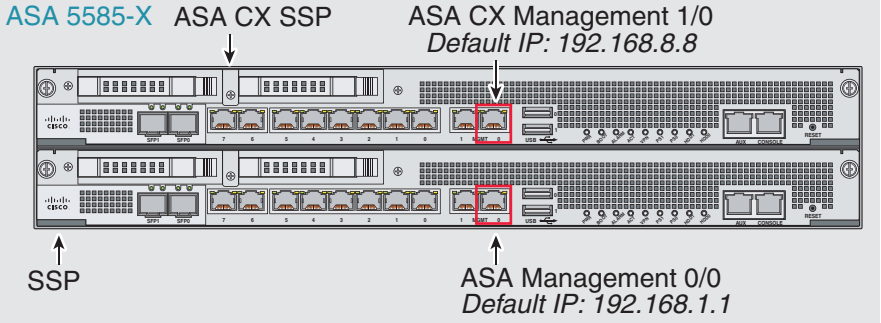
Step 6 On the ASA, identify traffic to divert to the ASA CX module. See the "Redirecting Traffic to the ASA CX Module" section on page 82-12.

Note When using PRSM in multiple device mode, you can configure the ASA policy for sending traffic to the ASA CX module within PRSM, instead of using ASDM or the ASA CLI. However, PRSM has some limitations when configuring the ASA service policy; see the ASA CX user guide for more information.

Connecting the ASA CX Management Interface

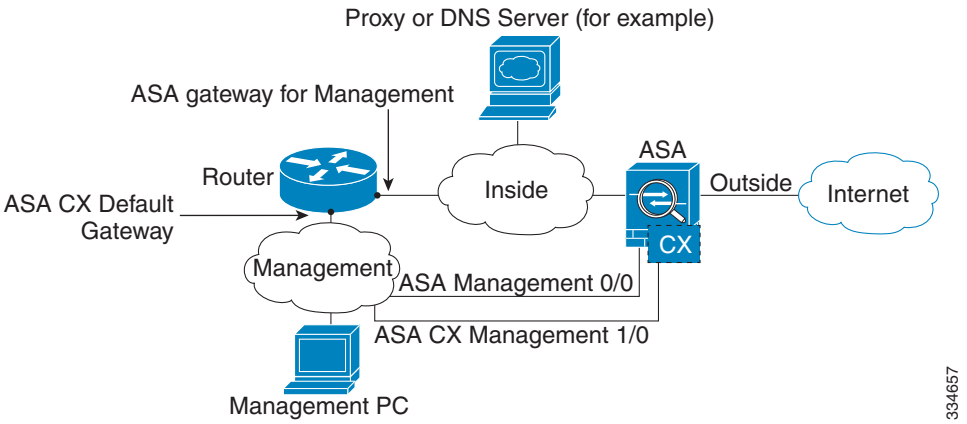
In addition to providing management access to the ASA CX module, the ASA CX management interface needs access to an HTTP proxy server or a DNS server and the Internet for signature updates and more. This section describes recommended network configurations. Your network may differ.

The ASA CX module includes a separate management interface from the ASA. For initial setup, you can connect with SSH to the ASA CX Management 1/0 interface using the default IP address (192.168.8.8/24). If you cannot use the default IP address, you can either use the console port or use ASDM to change the management IP address so you can use SSH.



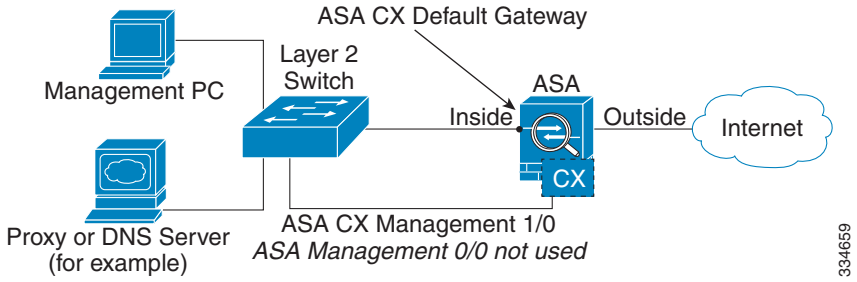
If you have an inside router

If you have an inside router, you can route between the management network, which can include both the ASA Management 0/0 and ASA CX Management 1/0 interfaces, and the ASA inside network for Internet access. Be sure to also add a route on the ASA to reach the Management network through the inside router.



If you do not have an inside router

If you have only one inside network, then you cannot also have a separate management network, which would require an inside router to route between the networks. In this case, you can manage the ASA from the inside interface instead of the Management 0/0 interface. Because the ASA CX module is a separate device from the ASA, you can configure the ASA CX Management 1/0 address to be on the same network as the inside interface.



What to Do Next

- Configure the ASA CX management IP address. See the "Configuring the ASA CX Management IP Address" section on page 82-8.

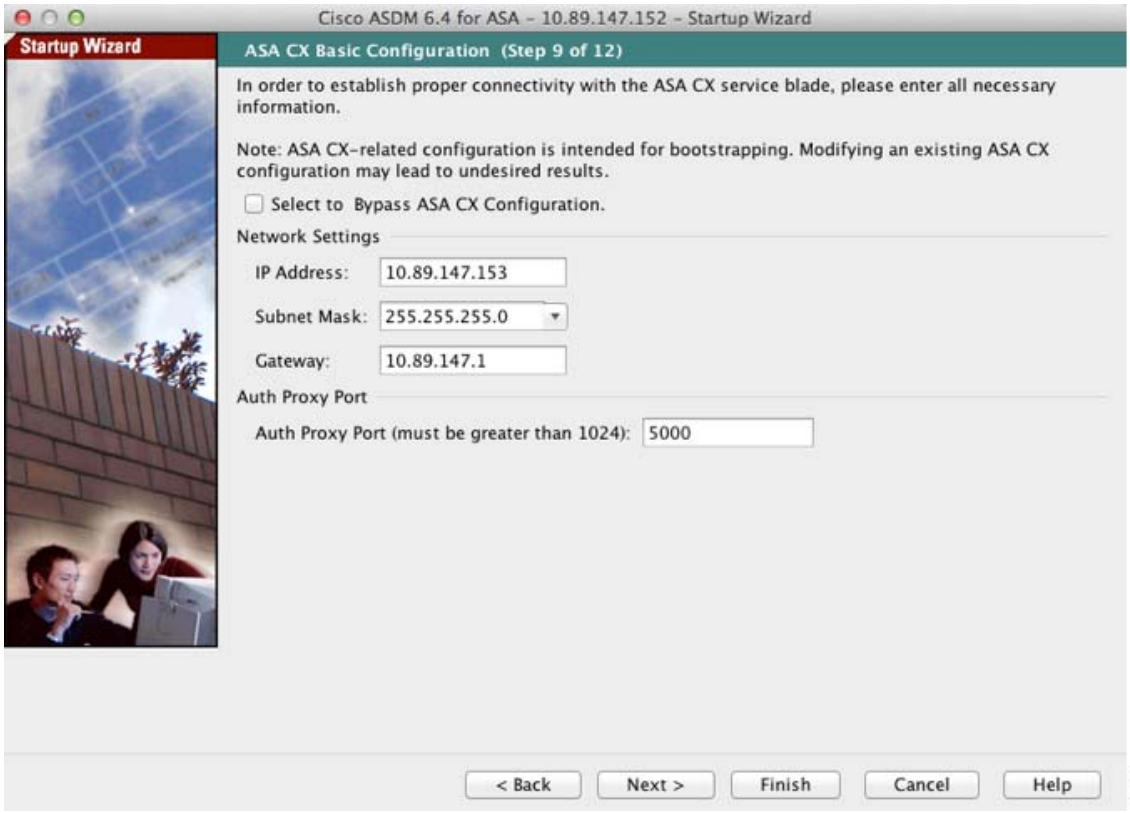
Configuring the ASA CX Management IP Address

If you cannot use the default management IP address (192.168.8.8), then you can set the management IP address from the ASA. After you set the management IP address, you can access the ASA CX module using SSH to perform initial setup.

Detailed Steps

Step 1 In ASDM, choose **Wizards > Startup Wizard**.

Step 2 Click **Next** to advance through the initial screens until you reach the ASA CX Basic Configuration screen.



Step 3 Enter the new management IP address, subnet mask, and default gateway.

Step 4 (Optional) Change the Auth Proxy Port. You can set this later if desired. See the "(Optional) Configuring the Authentication Proxy Port" section on page 82-12 for more information.

Step 5 Click **Finish** to skip the remaining screens, or click **Next** to advance through the remaining screens and complete the wizard.

Configuring Basic ASA CX Settings at the ASA CX CLI

You must configure basic network settings and other parameters on the ASA CX module before you can configure your security policy.

Detailed Steps

Step 1 Connect to the ASA CX CLI:

- Using SSH to the ASA CX Management 1/0 interface—Log in with the username **admin** and the password **Admin123**. You will change the password as part of this procedure.
- Using the ASA CX console port.

Step 2 Enter the following command:

```
asacx> setup
```

Example:

```
asacx> setup
    Welcome to Cisco Prime Security Manager Setup
    [hit Ctrl-C to abort]
    Default values are inside [ ]
```

You are prompted through the setup wizard. The following example shows a typical path through the wizard; if you enter **Y** instead of **N** at a prompt, you will be able to configure some additional settings. This example shows how to configure both IPv4 and IPv6 static addresses. You can configure IPv6 stateless auto configuration by answering **N** when asked if you want to configure a static IPv6 address.

```
Enter a hostname [asacx]: asa-cx-host
Do you want to configure IPv4 address on management interface?(y/n) [Y]: Y
Do you want to enable DHCP for IPv4 address assignment on management interface?(y/n)[N]: N
Enter an IPv4 address [192.168.8.8]: 10.89.31.65
Enter the netmask [255.255.255.0]: 255.255.255.0
Enter the gateway [192.168.8.1]: 10.89.31.1
Do you want to configure static IPv6 address on management interface?(y/n) [N]: Y
Enter an IPv6 address: 2001:DB8:0:CD30::1234/64
Enter the gateway: 2001:DB8:0:CD30::1
Enter the primary DNS server IP address [ ]: 10.89.47.11
Do you want to configure Secondary DNS Server? (y/n) [N]: N
Do you want to configure Local Domain Name? (y/n) [N] Y
Enter the local domain name: example.com
Do you want to configure Search domains? (y/n) [N] Y
Enter the comma separated list for search domains: example.com
Do you want to enable the NTP service?(y/n) [N]: Y
Enter the NTP servers separated by commas: 1.ntp.example.com, 2.ntp.example.com
```

Step 3 After you complete the final prompt, you are presented with a summary of the settings. Look over the summary to verify that the values are correct, and enter **Y** to apply your changed configuration. Enter **N** to cancel your changes.

Example:

```
Apply the changes?(y,n) [Y]: Y
Configuration saved successfully!
Applying...
Done.
Generating self-signed certificate, the web server will be restarted after that
...
Done.
Press ENTER to continue...
asacx>
```

Note If you change the host name, the prompt does not show the new name until you log out and log back in.

Step 4 If you do not use NTP, configure the time settings. The default time zone is the UTC time zone. Use the **show time** command to see the current settings. You can use the following commands to change time settings:

```
asacx> config timezone
asacx> config time
```

Step 5 Change the admin password by entering the following command:

```
asacx> config passwd
```

Example:

```
asacx> config passwd
The password must be at least 8 characters long and must contain
at least one uppercase letter (A-Z), at least one lowercase letter
(a-z) and at least one digit (0-9).
Enter password: Farscape1
Confirm password: Farscape1
SUCCESS: Password changed for user admin
```

Step 6 Enter the **exit** command to log out.

Configuring the Security Policy on the ASA CX Module Using PRSM

This section describes how to launch PRSM to configure the ASA CX module application. For details on using PRSM to configure your ASA CX security policy, see the ASA CX user guide.

Detailed Steps

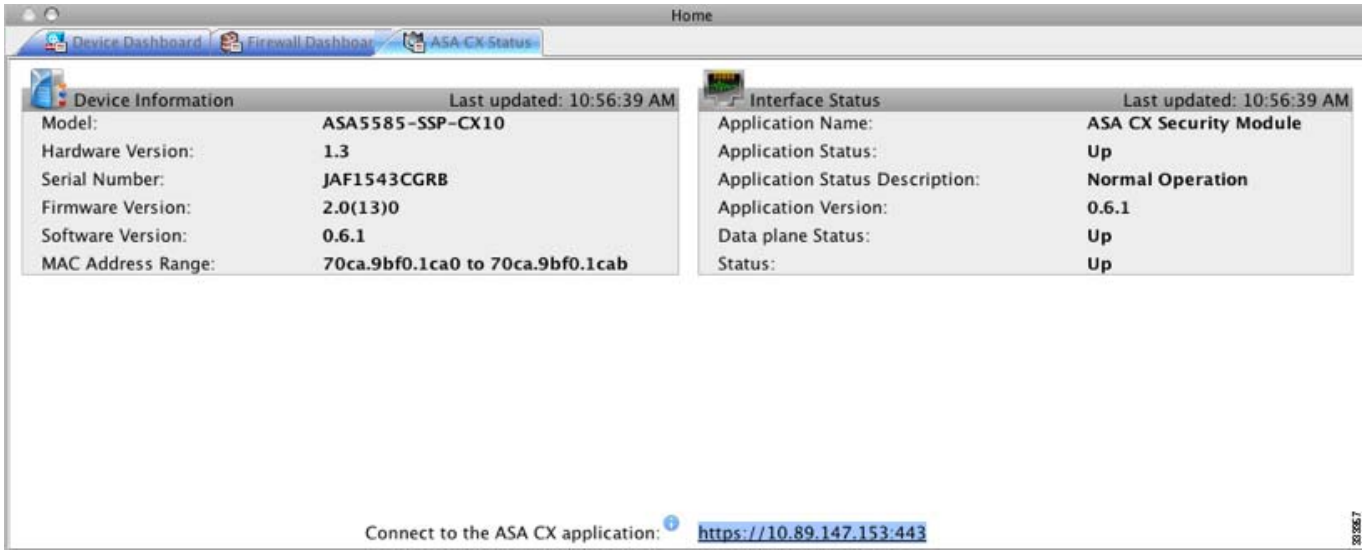
You can launch PRSM from your web browser, or you can launch it from ASDM.

- Launch PRSM from a web browser by enter the following URL:

  `https://`*`ASA_CX_management_IP`*

  Where the ASA CX management IP address is the one you set in the "Configuring Basic ASA CX Settings at the ASA CX CLI" section on page 82-9.

- Launch PRSM from ASDM by choosing **Home > ASA CX Status**, and clicking the **Connect to the ASA CX application** link.



What to Do Next

- (Optional) Configure the authentication proxy port. See the "(Optional) Configuring the Authentication Proxy Port" section on page 82-12.

- Divert traffic to the ASA CX module. See the "Redirecting Traffic to the ASA CX Module" section on page 82-12.

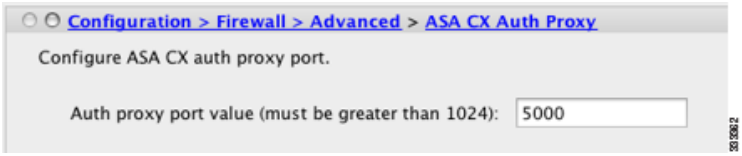
(Optional) Configuring the Authentication Proxy Port

The default authentication port is 885. To change the authentication proxy port, perform the following steps. For more information about the authentication proxy, see the "Information About Authentication Proxy" section on page 82-3.

Note You can also set the port as part of the ASDM startup wizard. See the "Configuring Basic ASA CX Settings at the ASA CX CLI" section on page 82-9.

Detailed Steps

Step 1 In ASDM, choose **Configuration > Firewall > Advanced > ASA CX Auth Proxy**.



Step 2 Enter a port greater than 1024. The default is 885.

Step 3 Click **Apply**.

Redirecting Traffic to the ASA CX Module

This section identifies traffic to redirect from the ASA to the ASA CX module. Configure this policy on the ASA.

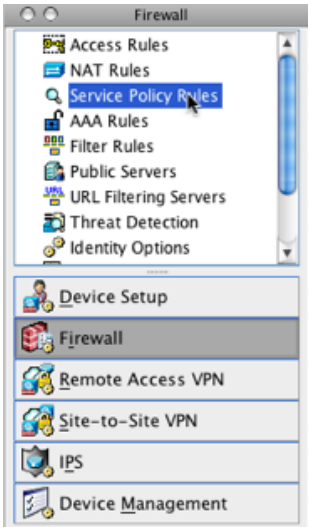
Note When using PRSM in multiple device mode, you can configure the ASA policy for sending traffic to the ASA CX module within PRSM, instead of using ASDM or the ASA CLI. However, PRSM has some limitations when configuring the ASA service policy; see the ASA CX user guide for more information.

Prerequisites

If you enable the authentication proxy on the ASA using this procedure, be sure to also configure a directory realm for authentication on the ASA CX module. See the ASA CX user guide for more information.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Service Policy Rules**.

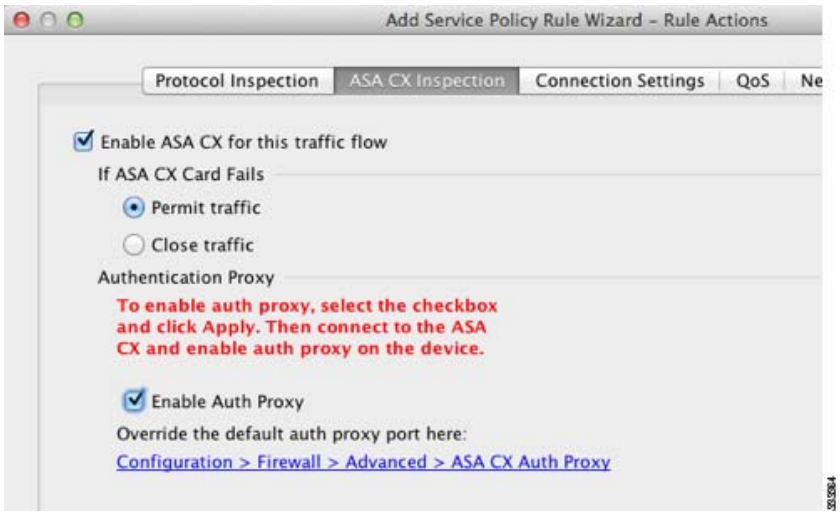


Step 2 Choose **Add > Add Service Policy Rule**. The Add Service Policy Rule Wizard - Service Policy dialog box appears.

Step 3 Complete the Service Policy dialog box, and then the Traffic Classification Criteria dialog box as desired. See the ASDM online help for more information about these screens.

Step 4 Click **Next** to show the Add Service Policy Rule Wizard - Rule Actions dialog box.

Step 5 Click the **ASA CX Inspection** tab.



Step 6 Check the **Enable ASA CX for this traffic flow** check box.

Step 7 In the If ASA CX Card Fails area, click **Permit traffic** or **Close traffic**. The Close traffic option sets the ASA to block all traffic if the ASA CX module is unavailable. The Permit traffic option sets the ASA to allow all traffic through, uninspected, if the ASA CX module is unavailable.

Step 8 To enable the authentication proxy, which is required for active authentication, check the **Enable Auth Proxy** check box.

Step 9 Click **OK** and then **Apply**.

Step 10 Repeat this procedure to configure additional traffic flows as desired.

Managing the ASA CX Module

This section includes procedures that help you manage the module and includes the following topics:

- Resetting the Password, page 82-14
- Reloading or Resetting the Module, page 82-15
- Shutting Down the Module, page 82-15

Note You can install or upgrade your image from within the ASA CX module. See the ASA CX module documentaiton for more information.

Resetting the Password

You can reset the module password to the default. For the user **admin**, the default password is **Admin123**. After resetting the password, you should change it to a unique value using the module application.

Resetting the module password causes the module to reboot. Services are not available while the module is rebooting.

If you cannot connect to ASDM with the new password, restart ASDM and try to log in again. If you defined a new password and still have an existing password in ASDM that is different from the new password, clear the password cache by choosing **File > Clear ASDM Password Cache**, then restart ASDM and try to log in again.

To reset the module password to the default of Admin123, perform the following steps.

Detailed Steps

Step 1 From the ASDM menu bar, choose **Tools > ASA CX Password Reset**.

The Password Reset confirmation dialog box appears.

Step 2 Click **OK** to reset the password to the default **Admin123**.

A dialog box displays the success or failure of the password reset.

Step 3 Click **Close** to close the dialog box.

Reloading or Resetting the Module

To reload or reset the module, enter one of the following commands at the ASA CLI.

Detailed Steps

Command	Purpose
hw-module module 1 reload **Example:** `hostname# hw-module module 1 reload`	Reloads the module software.
hw-module module 1 reset **Example:** `hostname# hw-module module 1 reset`	Performs a reset, and then reloads the module.

Shutting Down the Module

If you restart the ASA, the module is not automatically restarted. To shut down the module, perform the following steps at the ASA CLI.

Detailed Steps

Command	Purpose
hw-module module 1 shutdown **Example:** `hostname# hw-module module 1 shutdown`	Shuts down the module.

Monitoring the ASA CX Module

Use Tools > Command Line Interface to use monitoring commands.

- Showing Module Status, page 82-16
- Showing Module Statistics, page 82-16
- Monitoring Module Connections, page 82-17
- Capturing Module Traffic, page 82-20

- Problems with the Authentication Proxy, page 82-20

Note For ASA CX-related syslog messages, see the syslog messages guide. ASA CX syslog messages start with message number 429001.

Showing Module Status

See the "ASA CX Status Tab" section on page 4-30.

Showing Module Statistics

To show module statistics, enter the following command:

Command	Purpose
`show service-policy cxsc`	Displays the ASA CX statistics and status per service policy.

Examples

The following is sample output from the **show service-policy** command showing the ASA CX policy and the current statistics as well as the module status when the authentication proxy is disabled:

```
hostname# show service-policy cxsc
Global policy:
  Service-policy: global_policy
    Class-map: bypass
      CXSC: card status Up, mode fail-open, auth-proxy disabled
        packet input 2626422041, packet output 2626877967, drop 0, reset-drop 0, proxied 0
```

The following is sample output from the **show service-policy** command showing the ASA CX policy and the current statistics as well as the module status when the authentication proxy is enabled; in this case, the proxied counters also increment:

```
hostname# show service-policy cxsc
Global policy:
  Service-policy: pmap
    Class-map: class-default
      Default Queueing      Set connection policy: random-sequence-number disable
        drop 0
      CXSC: card status Up, mode fail-open, auth-proxy enabled
        packet input 7724, packet output 7701, drop 0, reset-drop 0, proxied 10
```

Monitoring Module Connections

To show connections through the ASA CX module, enter the one of the following commands:

Command	Purpose
show asp table classify domain cxsc	Shows the NP rules created to send traffic to the ASA CX module.
show asp table classify domain cxsc-auth-proxy	Shows the NP rules created for the authentication proxy for the ASA CX module.
show asp drop	Shows dropped packets. The following drop types are used: Frame Drops: • cxsc-bad-tlv-received—This occurs when ASA receives a packet from CXSC without a Policy ID TLV. This TLV must be present in non-control packets if it does not have the Standy Active bit set in the actions field. • cxsc-request—The frame was requested to be dropped by CXSC due a policy on CXSC whereby CXSC would set the actions to Deny Source, Deny Destination, or Deny Pkt. • cxsc-fail-close—The packet is dropped because the card is not up and the policy configured was 'fail-close' (rather than 'fail-open' which allows packets through even if the card was down). • cxsc-fail—The CXSC configuration was removed for an existing flow and we are not able to process it through CXSC it will be dropped. This should be very unlikely. • cxsc-malformed-packet—The packet from CXSC contains an invalid header. For instance, the header length may not be correct. Flow Drops: • cxsc-request—The CXSC requested to terminate the flow. The actions bit 0 is set. • reset-by-cxsc—The CXSC requested to terminate and reset the flow. The actions bit 1 is set. • cxsc-fail-close—The flow was terminated because the card is down and the configured policy was 'fail-close'.
show asp event dp-cp cxsc-msg	This output shows how many ASA CX module messages are on the dp-cp queue. Currently, only VPN queries from the ASA CX module are sent to dp-cp.
show conn	This command already shows if a connection is being forwarded to an module by displaying the ‘X - inspected by service module’ flag. Connections being forwarded to the ASA CX module will also display the ‘X’ flag.

Examples

The following is sample output from the **show asp table classify domain cxsc** command:

```
hostname# show asp table classify domain cxsc
Input Table
```

```
in  id=0x7ffedb4acf40, priority=50, domain=cxsc, deny=false

Capturing Module Traffic

To configure and view packet captures for the ASA CX module, enter one of the following commands:

Command	Purpose
capture *name* **interface asa_dataplane**	Captures packets between ASA CX module and the ASA on the backplane.
copy capture	Copies the capture file to a server.
show capture	Shows the capture at the ASA console.

Note Captured packets contain an additional AFBP header that your PCAP viewer might not understand; be sure to use the appropriate plugin to view these packets.

Troubleshooting the ASA CX Module

- Problems with the Authentication Proxy, page 82-20

Problems with the Authentication Proxy

If you are having a problem using the authentication proxy feature, follow these steps to troubleshoot your configuration and connections:

1. Check your configurations.
   - On the ASA, check the output of the **show asp table classify domain cxsc-auth-proxy** command and make sure there are rules installed and that they are correct.
   - In PRSM, ensure the directory realm is created with the correct credentials and test the connection to make sure you can reach the authentication server; also ensure that a policy object or objects are configured for authentication.
2. Check the output of the **show service-policy cxsc** command to see if any packets were proxied.
3. Perform a packet capture on the backplane, and check to see if traffic is being redirected on the correct configured port. See the "Capturing Module Traffic" section on page 82-20. You can check the configured port using the **show running-config cxsc** command or the **show asp table classify domain cxsc-auth-proxy** command.

Note If you have a connection between hosts on two ASA interfaces, and the ASA CX service policy is only configured for one of the interfaces, then all traffic between these hosts is sent to the ASA CX module, including traffic orginiating on the non-ASA CX interface (the feature is bidirectional). However, the ASA only performs the authentication proxy on the interface to which the service policy is applied, because this feature is ingress-only.

Example 82-1 Make sure port 2000 is used consistently:

1. Check the authentication proxy port:

```
hostname# show running-config cxsc
cxsc auth-proxy port 2000
```

2. Check the authentication proxy rules:

```
hostname# show asp table classify domain cxsc-auth-proxy

Input Table
in  id=0x7ffed86cc470, priority=121, domain=cxsc-auth-proxy, deny=false
    hits=0, user_data=0x7ffed86ca220, cs_id=0x0, flags=0x0, protocol=6
    src ip/id=0.0.0.0, mask=0.0.0.0, port=0
    dst ip/id=192.168.0.100, mask=255.255.255.255, port=2000, dscp=0x0
    input_ifc=inside, output_ifc=identity
```

3. In the packet captures, the redirect request should be going to destination port 2000.

Feature History for the ASA CX Module

Table 82-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 82-2 Feature History for the ASA CX Module

Feature Name	Platform Releases	Feature Information
ASA 5585-X support for the ASA CX SSP	8.4(4.1)	ASA CX module lets you enforce security based on the complete context of a situation. This context includes the identity of the user (who), the application or website that the user is trying to access (what), the origin of the access attempt (where), the time of the attempted access (when), and the properties of the device used for the access (how). With the ASA CX module, you can extract the full context of a flow and enforce granular policies such as permitting access to Facebook but denying access to games on Facebook or permitting finance employees access to a sensitive enterprise database but denying the same to other employees. We introduced the following screens: Home > ASA CX Status Wizards > Startup Wizard > ASA CX Basic Configuration Configuration > Firewall > Service Policy Rules > Add Service Policy Rule > Rule Actions > ASA CX Inspection *This feature is not available in Version 8.6(1).*

Configuring the ASA CSC Module

This chapter describes how to configure the Content Security and Control (CSC) application that is installed in a CSC SSM in the ASA.

This chapter includes the following sections:

- Information About the CSC SSM, page 83-1
- Licensing Requirements for the CSC SSM, page 83-5
- Prerequisites for the CSC SSM, page 83-5
- Guidelines and Limitations, page 83-6
- Default Settings, page 83-6
- Configuring the CSC SSM, page 83-7
- CSC SSM Setup Wizard, page 83-10
- Using the CSC SSM GUI, page 83-20
- Monitoring the CSC SSM, page 83-24
- Troubleshooting the CSC Module, page 83-27
- Additional References, page 83-31
- Feature History for the CSC SSM, page 83-31

Information About the CSC SSM

Some ASA models support the CSC SSM, which runs Content Security and Control software. The CSC SSM provides protection against viruses, spyware, spam, and other unwanted traffic by scanning the FTP, HTTP/HTTPS, POP3, and SMTP packets that you configure the ASA to send to it.

For more information about the CSC SSM, see the following URL:

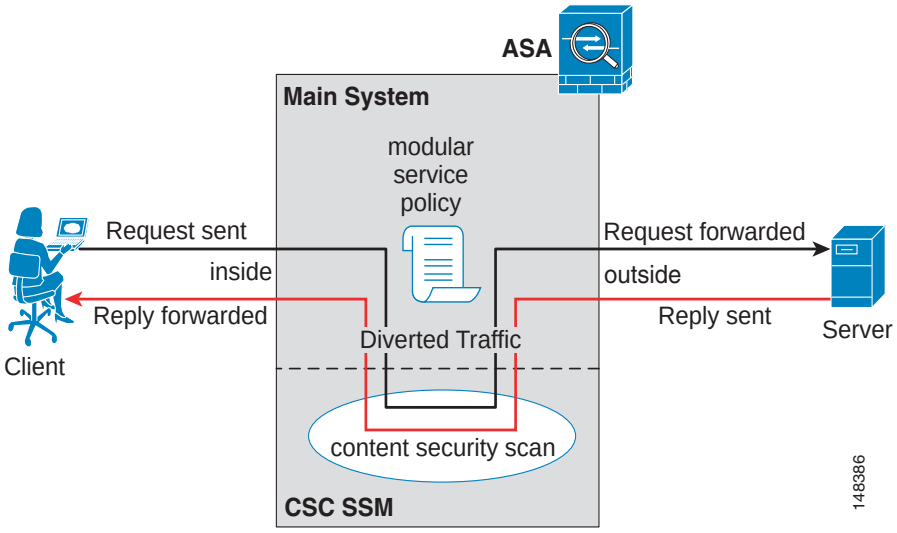
http://www.cisco.com/en/US/products/ps6823/index.html

Figure 83-1 shows the flow of traffic through an ASA that has the following:

- A CSC SSM installed and configured.
- A service policy that determines what traffic is diverted to the CSC SSM for scanning.

In this example, the client could be a network user who is accessing a website, downloading files from an FTP server, or retrieving mail from a POP3 server. SMTP scans differ in that you should configure the ASA to scan traffic sent from the outside to SMTP servers protected by the ASA.

Figure 83-1 Flow of Scanned Traffic with the CSC SSM



You use ASDM for system setup and monitoring of the CSC SSM. For advanced configuration of content security policies in the CSC SSM software, you access the web-based GUI for the CSC SSM by clicking links within ASDM. The CSC SSM GUI appears in a separate web browser window. To access the CSC SSM, you must enter the CSC SSM password. To use the CSC SSM GUI, see the *Cisco Content Security and Control SSM Administrator Guide*.

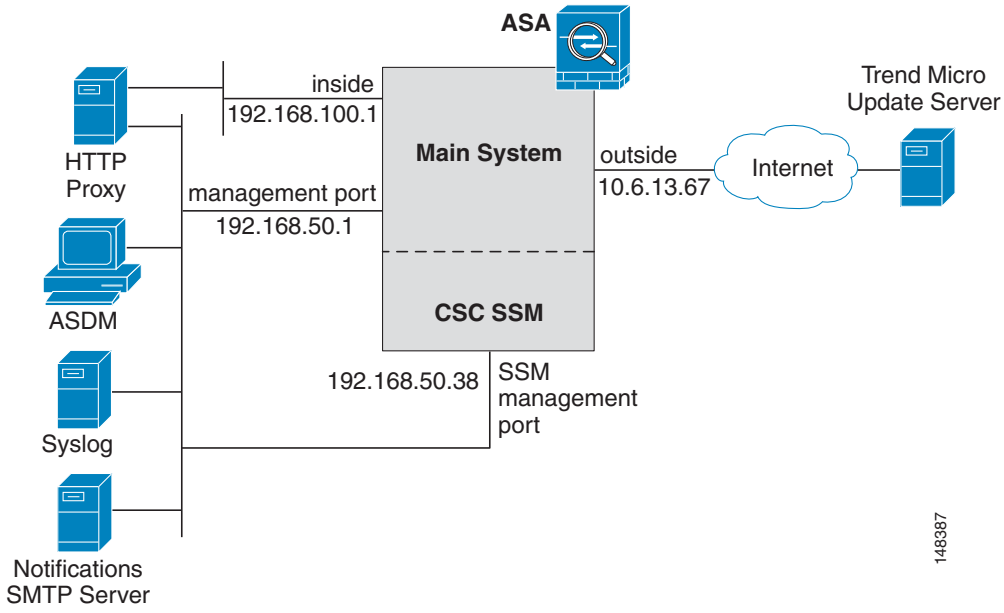
Note ASDM and the CSC SSM maintain separate passwords. You can configure their passwords to be identical; however, changing one of these two passwords does not affect the other password.

The connection between the host running ASDM and the ASA is made through a management port on the ASA. The connection to the CSC SSM GUI is made through the SSM management port. Because these two connections are required to manage the CSC SSM, any host running ASDM must be able to reach the IP address of both the ASA management port and the SSM management port.

Figure 83-2 shows an ASA with a CSC SSM that is connected to a dedicated management network. While use of a dedicated management network is not required, we recommend it. In this configuration, the following items are of particular interest:

- An HTTP proxy server is connected to the inside network and to the management network. This HTTP proxy server enables the CSC SSM to contact the Trend Micro Systems update server.
- The management port of the ASA is connected to the management network. To allow management of the ASA and the CSC SSM, hosts running ASDM must be connected to the management network.
- The management network includes an SMTP server for e-mail notifications for the CSC SSM and a syslog server to which the CSC SSM can send syslog messages.

Figure 83-2 CSC SSM Deployment with a Management Network



Determining What Traffic to Scan

The CSC SSM can scan FTP, HTTP/HTTPS, POP3, and SMTP traffic only when the destination port of the packet requesting the connection is the well-known port for the specified protocol. The CSC SSM can scan only the following connections:

- FTP connections opened to TCP port 21.
- HTTP connections opened to TCP port 80.
- HTTPS connections opened to TCP port 443.
- POP3 connections opened to TCP port 110.
- SMTP connections opened to TCP port 25.

You can choose to scan traffic for all of these protocols or any combination of them. For example, if you do not allow network users to receive POP3 e-mail, do not configure the ASA to divert POP3 traffic to the CSC SSM. Instead, block this traffic.

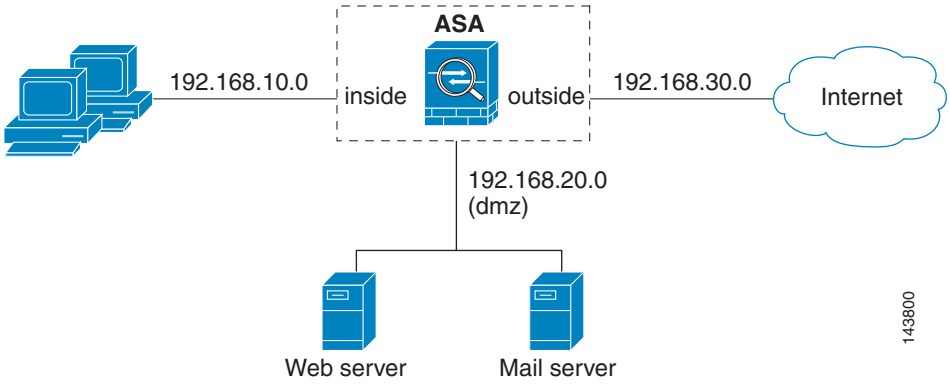
To maximize performance of the ASA and the CSC SSM, divert only the traffic to the CSC SSM that you want the CSC SSM to scan. Diverting traffic that you do not want scanned, such as traffic between a trusted source and destination, can adversely affect network performance.

Note When traffic is first classified for CSC inspection, it is flow-based. If traffic is part of a pre-existing connection, the traffic goes directly to the service policy set for that connection.

You can apply service policies that include CSC scanning globally or to specific interfaces; therefore, you can choose to enable CSC scans globally or for specific interfaces. For more information, see the "Determining Service Policy Rule Actions for CSC Scanning" section on page 83-9.

Based on the configuration shown in Figure 83-3, configure the ASA to divert to the CSC SSM only requests from clients on the inside network for HTTP, FTP, and POP3 connections to the outside network, and incoming SMTP connections from outside hosts to the mail server on the DMZ network. Exclude from scanning HTTP requests from the inside network to the web server on the DMZ network.

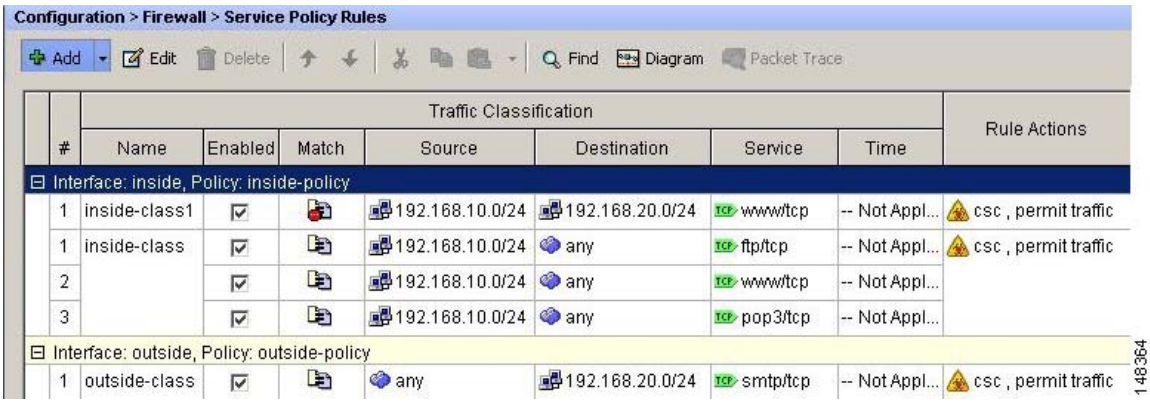
Figure 83-3 Common Network Configuration for CSC SSM Scanning



There are many ways you could configure the ASA to identify the traffic that you want to scan. One approach is to define two service policies: one on the inside interface and the other on the outside interface, each with access lists that match traffic to be scanned.

Figure 83-4 shows service policy rules that select only the traffic that the ASA should scan.

Figure 83-4 Optimized Traffic Selection for CSC Scans



In the inside-policy, the first class, inside-class1, ensures that the ASA does not scan HTTP traffic between the inside network and the DMZ network. The Match column indicates this setting by displaying the “Do not match” icon. This setting does not mean the ASA blocks traffic sent from the 192.168.10.0 network to TCP port 80 on the 192.168.20.0 network. Instead, this setting exempts the traffic from being matched by the service policy applied to the inside interface, which prevents the ASA from sending the traffic to the CSC SSM.

The second class of the inside-policy, inside-class matches FTP, HTTP, and POP3 traffic between the inside network and any destination. HTTP connections to the DMZ network are exempted because of the inside-class1 setting. As previously mentioned, policies that apply CSC scanning to a specific interface affect both incoming and outgoing traffic, but by specifying 192.168.10.0 as the source network, inside-class1 matches only connections initiated by the hosts on the inside network.

In the outside-policy, outside-class matches SMTP traffic from any outside source to the DMZ network. This setting protects the SMTP server and inside users who download e-mail from the SMTP server on the DMZ network, without having to scan connections from SMTP clients to the server.

If the web server on the DMZ network receives files uploaded by HTTP from external hosts, you can add a rule to the outside policy that matches HTTP traffic from any source to the DMZ network. Because the policy is applied to the outside interface, the rule would only match connections from HTTP clients outside the ASA.

Licensing Requirements for the CSC SSM

Model	License Requirement
ASA 5510	• Base License—Supports SMTP virus scanning, POP3 virus scanning and content filtering, web mail virus scanning, HTTP file blocking, FTP virus scanning and file blocking, logging, and automatic updates. Supports two contexts. *Optional licenses: 5 contexts.* • Security Plus License—Supports the Base license features, plus SMTP anti-spam, SMTP content filtering, POP3 anti-spam, URL blocking, and URL filtering. Supports two contexts. *Optional license: 5 contexts.*
ASA 5520	Base License—Supports all features. Supports two contexts. *Optional licenses: 5, 10, or 20 contexts.*
ASA 5540	Base License—Supports all features. Supports two contexts. *Optional licenses: 5, 10, 20, or 50 contexts.*
All other models	No support.

Prerequisites for the CSC SSM

The CSC SSM has the following prerequisites:

- A CSC SSM card must be installed in the ASA.
- A Product Authorization Key (PAK) for use in registering the CSC SSM.
- Activation keys that you receive by e-mail after you register the CSC SSM.
- The management port of the CSC SSM must be connected to your network to allow management and automatic updates of the CSC SSM software.
- The CSC SSM management port IP address must be accessible by the hosts used to run ASDM.
- You must obtain the following information to use in configuring the CSC SSM:
  - The CSC SSM management port IP address, netmask, and gateway IP address.
  - DNS server IP address.
  - HTTP proxy server IP address (needed only if your security policies require the use of a proxy server for HTTP access to the Internet).

- Domain name and hostname for the CSC SSM.
- An e-mail address and an SMTP server IP address and port number for e-mail notifications.
- E-mail address(es) for product license renewal notifications.
- IP addresses of hosts or networks that are allowed to manage the CSC SSM. The IP addresses for the CSC SSM management port and the ASA management interface can be in different subnets.
- Password for the CSC SSM.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context modes.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

Failover Guidelines

Does not support sessions in Stateful Failover. The CSC SSM does not maintain connection information, and therefore cannot provide the failover unit with the required information. The connections that a CSC SSM is scanning are dropped when the ASA in which the CSC SSM is installed fails. When the standby ASA becomes active, it forwards the scanned traffic to the CSC SSM and the connections are reset.

IPv6 Guidelines

Does not support IPv6.

Model Guidelines

Supported on the ASA 5510, ASA 5520, and ASA 5540 only. Not supported on the ASA 5580 and the ASA 5585-X.

Additional Guidelines

You cannot change the software type installed on the module; if you purchase a CSC module, you cannot later install IPS software on it.

Default Settings

Table 83-1 lists the default settings for the CSC SSM.

Table 83-1 Default CSC SSM Parameters

Parameter	Default
FTP inspection on the ASA	Enabled
All features included in the license(s) that you have purchased	Enabled

Configuring the CSC SSM

This section describes how to configure the CSC SSM and includes the following topics:

- Before Configuring the CSC SSM, page 83-7
- Connecting to the CSC SSM, page 83-8
- Determining Service Policy Rule Actions for CSC Scanning, page 83-9

Before Configuring the CSC SSM

Before configuring the ASA and the CSC SSM, perform the following steps:

Step 1 If the CSC SSM did not come preinstalled in a Cisco ASA, install it and connect a network cable to the management port of the SSM. For assistance with installation and connecting the SSM, see the *Cisco ASA 5500 Series Quick Start Guide*.

The management port of the CSC SSM must be connected to your network to allow management of and automatic updates to the CSC SSM software. Additionally, the CSC SSM uses the management port for e-mail notifications and syslog messages.

Step 2 You should have received a Product Authorization Key (PAK) with the CSC SSM. Use the PAK to register the CSC SSM at the following URL.

http://www.cisco.com/go/license

After you register, you receive activation keys by e-mail. The activation keys are required before you can complete Step 6.

Step 3 Obtain the following information for use in Step 6:

- Activation keys
- CSC SSM management port IP address, netmask, and gateway IP address
- DNS server IP address
- HTTP proxy server IP address (needed only if your security policies require the use of a proxy server for HTTP access to the Internet)
- Domain name and hostname for the CSC SSM
- An e-mail address, and SMTP server IP address and port number for e-mail notifications
- E-mail address(es) for product license renewal notifications
- IP addresses of hosts or networks that are allowed to manage the CSC SSM
- Password for the CSC SSM

Step 4 In a web browser, access ASDM for the ASA in which the CSC SSM is installed.

Note If you are accessing ASDM for the first time, see the "Additional References" section on page 83-31.

For more information about enabling ASDM access, see the "Configuring ASA Access for ASDM, Telnet, or SSH" section on page 52-1.

Step 5 Verify time settings on the ASA. Time setting accuracy is important for logging of security events and for automatic updates of CSC SSM software. Do one of the following:

- If you manually control time settings, verify the clock settings, including time zone. Choose **Configuration > Properties > Device Administration > Clock**.
- If you are using NTP, verify the NTP configuration. Choose **Configuration > Properties > Device Administration > NTP**.

Step 6 Open ASDM.

Step 7 Connect to and log in to the CSC SSM. For instructions, see the "Connecting to the CSC SSM" section on page 83-8.

Step 8 Run the CSC Setup Wizard.

- To access the CSC Setup Wizard, choose **Configuration > Trend Micro Content Security > CSC Setup > Wizard Setup > Launch Setup Wizard**.
- If you are rerunning the CSC Setup Wizard, perform the same step listed in the previous bullet.

The CSC Setup Wizard appears.

Step 9 Complete the CSC Setup Wizard, which includes configuration of service policies to divert traffic that you want scanned to the CSC SSM.

Note If you create a global service policy to divert traffic for CSC scans, all traffic (inbound and outbound) for the supported protocols is scanned. To maximize performance of the ASA and the CSC SSM, scan traffic only from untrusted sources.

Step 10 To reduce the load on the CSC SSM, configure the service policy rules that send packets to the CSC SSM to support only HTTP/HTTPS, SMTP, POP3, or FTP traffic. For instructions, see the "Determining Service Policy Rule Actions for CSC Scanning" section on page 83-9.

Step 11 (Optional) Review the default content security policies in the CSC SSM GUI, which are suitable for most implementations. You review the content security policies by viewing the enabled features in the CSC SSM GUI. For the availability of features, see the "Licensing Requirements for the CSC SSM" section on page 83-5. For the default settings, see the "Default Settings" section on page 83-6.

What to Do Next

See the "Connecting to the CSC SSM" section on page 83-8.

Connecting to the CSC SSM

With each session you start in ASDM, the first time you access features related to the CSC SSM, you must specify the management IP address and provide the password for the CSC SSM. After you successfully connect to the CSC SSM, you are not prompted again for the management IP address and password. If you start a new ASDM session, the connection to the CSC SSM is reset and you must specify the IP address and the CSC SSM password again. The connection to the CSC SSM is also reset if you change the time zone on the ASA.

Note The CSC SSM has a password that is maintained separately from the ASDM password. You can configure the two passwords to be identical, but changing the CSC SSM password does not affect the ASDM password.

To connect to the CSC SSM, perform the following steps:

Step 1 In the ASDM main application window, click the **Content Security** tab.

Step 2 In the Connecting to CSC dialog box, click one of the following radio buttons:

- To connect to the IP address of the management port on the SSM, click **Management IP Address**. ASDM automatically detects the IP address for the SSM in the ASA. If this detection fails, you can specify the management IP address manually.
- To connect to an alternate IP address or hostname on the SSM, click **Other IP Address or Hostname**.

Step 3 Enter the port number in the Port field, and then click **Continue**.

Step 4 In the CSC Password field, type your CSC password, and then click **OK**.

Note If you have not completed the CSC Setup Wizard (choose **Configuration > Trend Micro Content Security > CSC Setup > Wizard Setup**), complete the configuration in the CSC Setup Wizard, which includes changing the default password, "cisco."

For ten minutes after you have entered the password, you do not need to reenter the CSC SSM password to access other parts of the CSC SSM GUI.

Step 5 To access the CSC SSM GUI, choose **Configuration > Trend Micro Content Security**, and then click one of the following tabs: **Web**, **Mail**, **File Transfer**, or **Updates**.

What to Do Next

See the "Determining Service Policy Rule Actions for CSC Scanning" section on page 83-9.

Determining Service Policy Rule Actions for CSC Scanning

The CSC SSM scans only HTTP/HTTPS, SMTP, POP3, and FTP traffic. If your service policy includes traffic that supports other protocols in addition to these four, packets for other protocols are passed through the CSC SSM without being scanned. You should configure the service policy rules that send packets to the CSC SSM to support only HTTP/HTTPS, SMTP, POP3, or FTP traffic.

The CSC Scan tab in the Add Service Policy Rule Wizard lets you determine whether or not the CSC SSM scans traffic identified by the current traffic class. This tab appears only if a CSC SSM is installed in the ASA.

To configure service policy rules for CSC scanning, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Firewall > Service Policy Rules**.

Step 2 On the toolbar, click **Add**.

The Add Service Policy Rule Wizard screen appears.

Step 3 Click the **Global - applies to all interfaces** option, and then click **Next**.

The Traffic Classification Criteria screen appears.

Step 4 Click the **Create a new traffic class** option, type a name for the traffic class in the adjacent field, check the **Any traffic** check box, and then click **Next**.

The Rule Actions screen appears.

Step 5 Click the **CSC Scan** tab, and then check the **Enable CSC scan for this traffic flow** check box.

Step 6 Choose whether the ASA should permit or deny selected traffic to pass if the CSC SSM is unavailable by making the applicable selection in the area labeled: If CSC card fails, then. When this check box is checked, the other parameters on this tab become active.

Step 7 In the If CSC card fails area, if the CSC SSM becomes inoperable, choose one of the following actions:

- To allow traffic, check the **Permit traffic** check box.
- To block traffic, check the **Close traffic** check box.

Step 8 Click **Finish**.

The new service policy rule appears in the Service Policy Rules pane.

Step 9 Click **Apply**.

The ASA begins diverting traffic to the CSC SSM, which performs the content security scans that have been enabled according to the license that you purchased.

CSC SSM Setup Wizard

The CSC Setup Wizard lets you configure basic operational parameters for the CSC SSM. You must complete this wizard at least once before you can configure options in each screen separately. After you complete the CSC Setup Wizard, you can modify each screen individually without using this wizard again.

Additionally, you cannot access the panes under Configuration > Trend Micro Content Security > CSC Setup or under Monitoring > Trend Micro Content Security > Content Security until you complete the CSC Setup Wizard. If you try to access these panes before completing this wizard, a dialog box appears and lets you access the wizard directly to complete the configuration.

To start the CSC Setup Wizard, click **Launch Setup Wizard**.

This section includes the following topics:

- Activation/License, page 83-11
- IP Configuration, page 83-11
- Host/Notification Settings, page 83-12
- Management Access Host/Networks, page 83-13
- Password, page 83-13
- Restoring the Default Password, page 83-14
- Wizard Setup, page 83-15

Activation/License

The Activation/License pane lets you review or renew activation codes for the CSC SSM Basic License and the Plus License.

You can use ASDM to configure CSC licenses only once each for the two licenses. Renewed license activation codes are downloaded automatically with scheduled software updates. Links to the licensing status pane and the CSC UI home pane appear at the bottom of this window. The serial number for the assigned license is filled in automatically.

To review license status or renew a license, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Activation/License.**

Step 2 The Activation/License pane shows the following display-only information for the Basic License and the Plus License:

- The name of the component.
- The activation code for the corresponding Product field.
- The status of the license. If the license is valid, the expiration date appears. If the expiration date has passed, this field indicates that the license has expired.
- The maximum number of network devices that the Basic License supports. The Plus License does not affect the number of network devices supported; therefore, the Nodes field does not appear in the Plus License area. The Basic License includes anti-virus, anti-spyware, and file blocking. The Plus License includes anti-spam, anti-phishing, content filtering, URL blocking and filtering, and web reputation.

Step 3 To review license status or renew your license, click the link provided.

Step 4 To go to the CSC home pane in ASDM, click the link provided.

What to Do Next

See the "IP Configuration" section on page 83-11.

IP Configuration

The IP Configuration pane lets you configure management access for the CSC SSM, the DNS servers it should use, and a proxy server for retrieving CSC SSM software updates.

To configure management access and other related details for the CSC SSM, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > IP Configuration**.

Step 2 Set the following parameters for management access to the CSC SSM:

- Enter the IP address for management access to the CSC SSM.
- Enters the netmask for the network containing the management IP address of the CSC SSM.
- Enter the IP address of the gateway device for the network that includes the management IP address of the CSC SSM.

Step 3 Set parameters of the DNS servers for the network that includes the management IP address of the CSC SSM.

- Enter the IP address of the primary DNS server.
- (Optional) Enter the IP address of the secondary DNS server, if configured.

Step 4 (Optional) Enter parameters for an HTTP proxy server, used by the CSC SSM to contact a CSC SSM software update server. If your network configuration does not require the CSC SSM to use a proxy server, leave the fields in this group blank.

- Enter the IP address of the proxy server, if configured.
- Enter the listening port of the proxy server, if configured.

What to Do Next

See the "Host/Notification Settings" section on page 83-12.

Host/Notification Settings

The Host/Notification Settings pane lets you configure details about hostname, domain name, e-mail notifications, and a domain name for e-mail to be excluded from detailed scanning.

To configure host and notification settings, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Host/Notification Settings**.

Step 2 In the Host and Domain Names area, set the hostname and domain name of the CSC SSM.

Step 3 In the Incoming E-mail Domain Name area, set the trusted incoming e-mail domain name for SMTP-based e-mail. The CSC SSM scans SMTP e-mail sent to this domain. The types of threats that the CSC SSM scans for depend on the license that you purchased for the CSC SSM and the configuration of the CSC SSM software.

Note CSC SSM lets you configure a list of many incoming e-mail domains. ASDM displays only the first domain in the list. To configure additional incoming e-mail domains, access the CSC SSM interface. To do so, choose **Configuration > Trend Micro Content Security > CSC Setup > Mail,** and then click one of the links. After logging in to the CSC SSM, choose **Mail (SMTP) > Configuration**, and then click the **Incoming Mail** tab.

Step 4 Configure the following settings for e-mail notification of events:

- The administrator e-mail address for the account to which notification e-mails should be sent.
- The IP address of the SMTP server.
- The port to which the SMTP server listens.
- The e-mail address(es) for the product license renewal to which notification e-mails should be sent. Separate multiple e-mail addresses with semicolons. The maximum number of characters allowed for e-mail addresses is 1024. Make sure that the specified e-mail addresses are valid.

What to Do Next

See the "Management Access Host/Networks" section on page 83-13.

Management Access Host/Networks

The Management Access Host/Networks pane lets you specify the hosts and networks for which management access to the CSC SSM is permitted. You must specify at least one permitted host or network, up to a maximum of eight permitted hosts or networks.

To specify hosts and networks for which management access to the CSC SSM is allowed, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Management Access Host/Networks**.

Step 2 Enter the IP address of a host or network that you want to add to the Selected Hosts/Network list.

Step 3 Enter the netmask for the host or network that you specified in the IP Address field.

Note To allow all hosts and networks, enter **0.0.0.0** in the IP Address field, and choose 0.0.0.0 from the Mask list.

The Selected Hosts/Networks list displays the hosts or networks trusted for management access to the CSC SSM.

Step 4 To add the host or network that you specified in the IP Address field in the Selected Hosts/Networks list, click **Add**.

The Selected Hosts/Networks table lists the IP addresses of networks and hosts whose connection to the CSC SSM you have added.

Step 5 To remove a host or network from the Selected Hosts/Networks list, choose an entry from the list and click **Delete**.

What to Do Next

See the "Password" section on page 83-13.

Password

The Password pane lets you change the password required for management access to the CSC SSM. The CSC SSM has a password that is maintained separately from the ASDM password. You can configure them to be identical; however, changing the CSC SSM password does not affect the ASDM password.

If ASDM is connected to the CSC SSM and you change the CSC SSM password, the connection to the CSC SSM is dropped. As a result, ASDM displays a confirmation dialog box that you must respond to before the password is changed.

Tip Whenever the connection to the CSC SSM is dropped, you can reestablish it. To do so, click the **Connection to Device** icon on the status bar to display the Connection to Device dialog box, and then click **Reconnect**. ASDM prompts you for the CSC SSM password, which is the new password that you have defined.

Passwords must be 5 - 32 characters long.

Passwords appears as asterisks when you type them.

Note The default password is "cisco."

To change the password required for management access to the CSC SSM, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Password**.

Step 2 In the Old Password field, enter the current password for management access to the CSC SSM.

Step 3 In the New Password field, enter the new password for management access to the CSC SSM.

Step 4 In the Confirm New Password field, reenter the new password for management access to the CSC SSM.

What to Do Next

If required, see the "Restoring the Default Password" section on page 83-14.

See the "Wizard Setup" section on page 83-15.

Restoring the Default Password

You can use ASDM to reset the CSC SSM password. You can reset this password to the default value, which is "cisco" (excluding quotation marks). If the CSC password-reset policy has been set to "Denied," then you cannot reset the password through the ASDM CLI. To change this policy, you must access the CSC SSM through the ASA CLI by entering the **session** command. For more information, see the *Cisco Content Security and Control SSM Administrator Guide*.

Note This option does not appear in the menu if an SSM is not installed.

To reset the CSC SSM password to the default value, perform the following steps:

Step 1 Choose **Tools > CSC Password Reset**.

The CSC Password Reset confirmation dialog box appears.

Step 2 Click **OK** to reset the CSC SSM password to the default value.

A dialog box appears, indicating the success or failure of the password reset. If the password was not reset, make sure you are using Version 8.0(2) software on the ASA and the most recent Version 6.1.x software on the CSC SSM.

Step 3 Click **Close** to close the dialog box.

Step 4 After you have reset the password, you should change it to a unique value.

What to Do Next

See the "Password" section on page 83-13.

Wizard Setup

The Wizard Setup screen lets you start the CSC Setup Wizard. To start the CSC Setup Wizard, click **Launch Setup Wizard**. To access the Wizard Setup screen, choose **Configuration > Trend Micro Content Security > CSC Setup > Wizard Setup**.

Before you can directly access any of the other screens under CSC Setup, you must complete the CSC Setup Wizard. This wizard includes the following screens:

- CSC Setup Wizard Activation Codes Configuration, page 83-15
- CSC Setup Wizard IP Configuration, page 83-16
- CSC Setup Wizard Host Configuration, page 83-16
- CSC Setup Wizard Management Access Configuration, page 83-17
- CSC Setup Wizard Password Configuration, page 83-17
- CSC Setup Wizard Traffic Selection for CSC Scan, page 83-17
- CSC Setup Wizard Summary, page 83-19

After you complete the CSC Setup Wizard once, you can change any settings in screens related to the CSC SSM without using the CSC Setup Wizard again.

CSC Setup Wizard Activation Codes Configuration

To display the activation codes that you have entered to enable features on the CSC SSM, perform the following steps:

Choose **Configuration > Trend Micro Content Security > CSC Setup > Activation/License**.

The activation code settings that you have made appear on this screen, according to the type of license you have, as follows:

- The activation code for the Basic License appears. The Basic License includes anti-virus, anti-spyware, and file blocking.
- The activation code for the Plus License appears, if you have entered one. If not, this field is blank. The Plus License includes anti-spam, anti-phishing, content filtering, URL blocking and filtering, and web reputation.

What to Do Next

See the "CSC Setup Wizard IP Configuration" section on page 83-16.

CSC Setup Wizard IP Configuration

To display the IP configuration settings that you have entered for the CSC SSM, perform the following steps:

Choose **Configuration > Trend Micro Content Security > CSC Setup > IP Configuration**.

The IP configuration settings that you have entered for the CSC SSM appear, including the following:

- The IP address for the management interface of the CSC SSM.
- The network mask for the management interface of the CSC SSM that you have selected from the drop-down list.
- The IP address of the gateway device for the network that contains the CSC SSM management interface.
- The primary DNS server IP address.
- The secondary DNS server IP address (if configured).
- The proxy server (if configured).
- The proxy port (if configured).

What to Do Next

See the "CSC Setup Wizard Host Configuration" section on page 83-16.

CSC Setup Wizard Host Configuration

To display the host configuration settings that you have entered for the CSC SSM, perform the following steps:

Choose **Configuration > Trend Micro Content Security > CSC Setup > Host Configuration**.

The host configuration settings that you have entered for the CSC SSM appear, including the following:

- The hostname of the CSC SSM.
- The name of the domain in which the CSC SSM resides.
- The domain name for incoming e-mail.
- The e-mail address of the domain administrator.
- The IP address of the SMTP server.
- The port to which the SMTP server listens.
- The e-mail address(es) for the product license renewal notification.

What to Do Next

See the "CSC Setup Wizard Management Access Configuration" section on page 83-17.

CSC Setup Wizard Management Access Configuration

To display the subnet and host settings that you have entered to grant access to the CSC SSM, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Management Access Configuration**.

The management access configuration settings that you have entered for the CSC SSM appear, including the following:

- The IP address for networks and hosts that are allowed to connect to the CSC SSM.
- The network mask for networks and hosts that are allowed to connect to the CSC SSM that you have selected from the drop-down list.

Step 2 To add the IP address of the networks and hosts that you want to allow to connect to the CSC SSM, click **Add**.

Step 3 To remove the IP address of a network or host whose ability to connect to the CSC SSM you no longer want, click **Delete**.

The Selected Hosts/Networks table lists the IP addresses of networks and hosts whose connection to the CSC SSM you have added.

What to Do Next

See the "CSC Setup Wizard Password Configuration" section on page 83-17.

CSC Setup Wizard Password Configuration

To change the password required for management access to the CSC SSM, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Password**.

Step 2 In the Old Password field, enter the current password for management access to the CSC SSM.

Step 3 In the New Password field, enter the new password for management access to the CSC SSM.

Step 4 In the Confirm New Password field, reenter the new password for management access to the CSC SSM.

What to Do Next

See the "CSC Setup Wizard Traffic Selection for CSC Scan" section on page 83-17.

CSC Setup Wizard Traffic Selection for CSC Scan

To display the settings that you have made to select traffic for CSC scanning, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Traffic Selection for CSC Scan**.

The traffic selection for CSC scanning configuration settings that you have entered for the CSC SSM appear, including the following:

- The interface to the CSC SSM that you have chosen from the drop-down list.
- The source of network traffic for the CSC SSM to scan.
- The destination of network traffic for the CSC SSM to scan.
- The source or destination service for the CSC SSM to scan.

Step 2 Do one of the following:

- To specify additional traffic details for CSC scanning, click **Add**. For more information, see "Specifying Traffic for CSC Scanning" section on page 83-18.
- To modify additional traffic details for CSC scanning, click **Edit**. For more information, see "Specifying Traffic for CSC Scanning" section on page 83-18.
- To remove additional traffic details for CSC scanning, click **Delete**.

Specifying Traffic for CSC Scanning

To define, modify, or remove additional settings for selecting traffic for CSC scanning, perform the following steps:

Step 1 In the Traffic Selection for CSC Scan screen, click **Specify traffic for CSC Scan**.

The Specify traffic for CSC Scan dialog box appears.

Step 2 Choose the type of interface to the CSC SSM from the drop-down list. Available settings are global (all interfaces), inside, management, and outside.

Step 3 Choose the source of network traffic for the CSC SSM to scan from the drop-down list.

Step 4 Choose the destination of network traffic for the CSC SSM to scan from the drop-down list.

Step 5 Choose the type of service for the CSC SSM to scan from the drop-down list.

Step 6 Enter a description for the network traffic that you define for the CSC SSM to scan.

Step 7 Specify whether or not to allow the CSC SSM to scan network traffic if the CSC card fails. Choose one of the following options:

- To allow traffic through without being scanned, click **Permit**.
- To prevent traffic from going through without being scanned, click **Close**.

Step 8 Click **OK** to save your settings.

The added traffic details appear on the CSC Setup Wizard Traffic selection for CSC Scan screen.

Step 9 Click **Cancel** to discard these settings and return to the CSC Setup Wizard Traffic selection for CSC Scan screen. If you click **Cancel**, ASDM displays a dialog box to confirm your decision.

What to Do Next

See the "CSC Setup Wizard Summary" section on page 83-19.

CSC Setup Wizard Summary

To review the settings that you have made with the CSC Setup Wizard, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > CSC Setup > Summary**.

The CSC Setup Wizard Summary screen shows the following display-only settings:

- The settings that you made in the Activation Codes Configuration screen, including the Base License activation code and the Plus License activation code, if you entered one. If not, this field is blank.
- The settings that you made in the IP Configuration screen, including the following information:
  - IP address and netmask for the management interface of the CSC SSM.
  - IP address of the gateway device for the network that includes the CSC SSM management interface.
  - Primary DNS server IP address.
  - Secondary DNS server IP address (if configured).
  - Proxy server and port (if configured).
- The settings that you made in the Host Configuration screen, including the following information:
  - Hostname of the CSC SSM.
  - Domain name for the domain that includes the CSC SSM.
  - Domain name for incoming e-mail.
  - Administrator e-mail address.
  - E-mail server IP address and port number.
  - E-mail address(es) for product licensing renewal notifications.
- The settings that you made in the Management Access Configuration screen. The drop-down list includes the hosts and networks from which the CSC SSM allows management connections.
- Indicates whether or not you have changed the password in the Password Configuration screen.

Step 2 (Optional) Click **Back** to return to the previous screens of the CSC Setup Wizard to change any settings.

Note The Next button is dimmed; however, if you click **Back** to access any of the preceding screens in this wizard, click **Next** to return to the Summary screen.

Step 3 Click **Finish** to complete the CSC Setup Wizard and save all settings that you have specified. After you click **Finish**, you can change any settings related to the CSC SSM without using the CSC Setup Wizard again.

A summary of the status of commands that were sent to the device appears.

Step 4 Click **Close** to close this screen, and then click **Next**.

A message appears indicating that the CSC SSM has been activated and is ready for use.

Step 5 (Optional) Click **Cancel** to exit the CSC Setup Wizard without saving any of the selected settings. If you click **Cancel**, a dialog box appears to confirm your decision.

What to Do Next

See the "Using the CSC SSM GUI" section on page 83-20.

Using the CSC SSM GUI

This section describes how to configure features using the CSC SSM GUI, and includes the following topics:

- Web, page 83-20
- Mail, page 83-21
- SMTP Tab, page 83-21
- POP3 Tab, page 83-22
- File Transfer, page 83-22
- Updates, page 83-23

Web

Note To access the CSC SSM, you must reenter the CSC SSM password. Sessions in the CSC SSM browser time out after ten minutes of inactivity. If you close the CSC SSM browser and click another link in ASDM, you are not prompted for the CSC SSM password again, because one session is already open.

To view whether or not web-related features are enabled and access the CSC SSM GUI for configuring these features, perform the following steps:

Step 1 Choose **Configuration > Trend Micro Content Security > Web**.

The URL Blocking and Filtering area is display-only and shows whether or not URL blocking is enabled on the CSC SSM.

Step 2 Click **Configure URL Blocking** to open a screen for configuring URL blocking on the CSC SSM.

The URL Filtering area is display-only and shows whether or not URL filtering is enabled on the CSC SSM.

Step 3 Click **Configure URL Filtering** to open a screen for configuring URL filtering rules on the CSC SSM.

The File Blocking area is display-only and shows whether or not URL file blocking is enabled on the CSC SSM.

Step 4 Click **Configure File Blocking** to open a screen for configuring file blocking settings on the CSC SSM.

The HTTP Scanning area is display-only and shows whether or not HTTP scanning is enabled on the CSC SSM.

Step 5 Click **Configure Web Scanning** to open a screen for configuring HTTP scanning settings on the CSC SSM.

The Web Reputation area is display-only and shows whether or not the Web Reputation service is enabled on the CSC SSM.

Step 6 Click **Configure Web Reputation** to open a screen for configuring the Web Reputation service on the CSC SSM.

What to Do Next

See the "Mail" section on page 83-21.

Mail

The Mail pane lets you see whether or not e-mail-related features are enabled and lets you access the CSC SSM GUI to configure these features. To configure e-mail related features, choose **Configuration > Trend Micro Content Security > Mail**.

This section includes the following topics:

- SMTP Tab, page 83-21
- POP3 Tab, page 83-22

SMTP Tab

Note To access the CSC SSM, you must reenter the CSC SSM password. Sessions in the CSC SSM browser time out after ten minutes of inactivity. If you close the CSC SSM browser and click another link in ASDM, you are not prompted for the CSC SSM password again, because one session is already open.

To configure SMTP scanning, perform the following steps:

Step 1 Click the **SMTP** Tab.

Step 2 The Incoming Scan area is display-only and shows whether or not the incoming SMTP scanning feature is enabled on the CSC SSM. Click **Configure Incoming Scan** to open a screen for configuring incoming SMTP scan settings on the CSC SSM.

Step 3 The Outgoing Scan area is display-only and shows whether or not the outgoing SMTP scanning feature is enabled on the CSC SSM. Click **Configure Outgoing Scan** to open a screen for configuring outgoing SMTP scan settings on the CSC SSM.

Step 4 The Incoming Filtering area is display-only and shows whether or not content filtering for incoming SMTP e-mail is enabled on the CSC SSM. Click **Configure Incoming Filtering** to open a screen for configuring incoming SMTP e-mail content filtering settings on the CSC SSM.

Step 5 The Outgoing Filtering area is display-only and shows whether or not content filtering for outgoing SMTP e-mail is enabled on the CSC SSM. Click **Configure Outgoing Filtering** to open a screen for configuring outgoing SMTP e-mail content filtering settings on the CSC SSM.

Step 6 The Anti-spam area is display-only and shows whether or not the SMTP anti-spam feature is enabled on the CSC SSM. Click **Configure Anti-spam** to open a screen for configuring SMTP anti-spam settings, including E-mail Reputation, on the CSC SSM.

Step 7 The Global Approved List area is display-only and shows whether or not the SMTP global approved list feature is enabled on the CSC SSM. Click **Configure Global Approved List** to open a screen for configuring SMTP global approved list settings on the CSC SSM.

POP3 Tab

Note To access the CSC SSM, you must reenter the CSC SSM password. Sessions in the CSC SSM browser time out after ten minutes of inactivity. If you close the CSC SSM browser and click another link in ASDM, you are not prompted for the CSC SSM password again, because one session is already open.

To configure POP3 scanning, perform the following steps:

Step 1 Click the **POP3** Tab.

Step 2 The Scanning area is display-only and shows whether or not POP3 e-mail scanning is enabled on the CSC SSM. Click **Configure Scanning** to open a window for configuring POP3 e-mail scanning on the CSC SSM.

Step 3 The Anti-spam area is display-only and shows whether or not the POP3 anti-spam feature is enabled on the CSC SSM. Click **Configure Anti-spam** to open a window for configuring the POP3 anti-spam feature on the CSC SSM.

Step 4 The Content Filtering area is display-only and shows whether or not POP3 e-mail content filtering is enabled on the CSC SSM. Click **Configure Content Filtering** to open a window for configuring POP3 e-mail content filtering on the CSC SSM.

Step 5 The Global Approved List area is display-only and shows whether or not the POP3 global approved list feature is enabled on the CSC SSM. Click **Configure Global Approved List** to open a screen for configuring POP3 global approved list settings on the CSC SSM.

What to Do Next

See the "File Transfer" section on page 83-22.

File Transfer

The File Transfer pane lets you view whether or not FTP-related features are enabled and lets you access the CSC SSM for configuring FTP-related features.

Note To access the CSC SSM, you must reenter the CSC SSM password. Sessions in the CSC SSM browser time out after ten minutes of inactivity. If you close the CSC SSM browser and click another link in ASDM, you are not prompted for the CSC SSM password again, because one session is already open.

To view the status or configure FTP-related features, perform the following steps:

Step 1 Click the **File Transfer** tab.

The File Scanning area is display-only and shows whether or not FTP file scanning is enabled on the CSC SSM.

Step 2 Click **Configure File Scanning** to open a window for configuring FTP file scanning settings on the CSC SSM.

The File Blocking area is display-only and shows whether or not FTP blocking is enabled on the CSC SSM.

Step 3 Click **Configure File Blocking** to open a window for configuring FTP file blocking settings on the CSC SSM.

What to Do Next

See the "Updates" section on page 83-23.

Updates

The Updates pane lets you view whether or not scheduled updates are enabled and lets you access the CSC SSM for configuring scheduled updates.

Note To access the CSC SSM, you must reenter the CSC SSM password. Sessions in the CSC SSM browser time out after ten minutes of inactivity. If you close the CSC SSM browser and click another link in ASDM, you are not prompted for the CSC SSM password again, because one session is already open.

To view the status or configure scheduled update settings, perform the following steps:

Step 1 Click the **Updates** tab.

The Scheduled Updates area is display-only and shows whether or not scheduled updates are enabled on the CSC SSM.

The Scheduled Update Frequency area displays information about when updates are scheduled to occur, such as "Hourly at 10 minutes past the hour."

The Component area displays names of parts of the CSC SSM software that can be updated.

In the Components area, the Scheduled Updates area is display-only and shows whether or not scheduled updates are enabled for the corresponding components.

Step 2 Click **Configure Updates** to open a window for configuring scheduled update settings on the CSC SSM.

Note If you restart the ASA, the SSM is not automatically restarted. For more information, see the "Managing SSMs and SSCs" section in the CLI configuration guide.

What to Do Next

See the "Monitoring the CSC SSM" section on page 83-24.

Monitoring the CSC SSM

ASDM lets you monitor the CSC SSM statistics as well as CSC SSM-related features.

Note If you have not completed the CSC Setup Wizard in Configuration > Trend Micro Content Security > CSC Setup, you cannot access the panes under Monitoring > Trend Micro Content Security. Instead, a dialog box appears and lets you access the CSC Setup Wizard directly from Monitoring > Trend Micro Content Security.

This section includes the following topics:

- Threats, page 83-24
- Live Security Events, page 83-25
- Live Security Events Log, page 83-25
- Software Updates, page 83-26
- Resource Graphs, page 83-27

Threats

To view information about various types of threats detected by the CSC SSM in a graph, perform the following steps:

Step 1 Choose **Monitoring > Trend Micro Content Security > Threats**.

The Available Graphs area lists the components whose statistics you can view in a graph. You can include a maximum of four graphs in one frame. The graphs display real-time data in 12-second intervals for the following:

- Viruses detected
- URLs filtered, URLs blocked
- Spam detected
- Files blocked
- Spyware blocked
- Damage Cleanup Services

Step 2 The Graph Window Title lists the types of statistics available for monitoring. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time. The statistics already included in the graph window appear in the Selected Graphs list.

Step 3 To move the selected statistics type in the Available Graphs For list to the Selected Graphs list, click **Add**.

Step 4 To remove the selected statistics type from the Selected Graphs list, click **Remove**. The button name changes to **Delete** if the item you are removing was added from another pane, and is not being returned to the Available Graphs pane.

Step 5 To display a new window that shows a Graph tab and an updated graph with the selected statistics, click **Show Graphs**. Click the **Table** tab to display the same information in tabular form.

Step 6 From the Graph or Table tab, click **Export** in the menu bar or choose **File > Export** to save the graph or tabular information as a file on your local PC.

Step 7 From the Graph or Table tab, click **Print** in the menu bar or choose **File > Print** to print the information displayed in the window.

What to Do Next

See the "Live Security Events" section on page 83-25.

Live Security Events

To view live, real-time security events in a separate window, perform the following steps:

Step 1 Choose **Monitoring > Trend Micro Content Security > Live Security Events**.

The Buffer Limit field shows the maximum number of log messages that you may view. The default is 1000.

Step 2 Click **View** to display the Live Security Events Log dialog box. You can pause incoming messages, clear the message window, and save event messages. You can also search messages for specific text.

What to Do Next

See the "Live Security Events Log" section on page 83-25.

Live Security Events Log

To view live security events messages that are received from the CSC SSM, perform the following steps:

Step 1 To filter security event messages from the Filter By drop-down list, choose one of the following:

- Filter by Text, type the text, then click **Filter**.
- Show All, to display all messages or remove the filter.

Step 2 To use the Latest CSC Security Events pane, in which all columns are *display-only*, choose one of the following options:

- The time an event occurred.
- The IP address or hostname from which the threat came.
- The type of threat, or the security policy that determines event handling, or in the case of a URL filtering event, the filter that triggered the event.

- The subject of e-mails that include a threat, or the names of FTP files that include a threat, or blocked or filtered URLs.
- The recipient of e-mails that include a threat, or the IP address or hostname of a threatened node, or the IP address of a threatened client.
- The type of event (such as Web, Mail, or FTP), or the name of a user or group for HTTP or FTP events, which include a threat.
- The action taken upon the content of a message, such as cleaning attachments or deleting attachments.
- The action taken on a message, such as delivering it unchanged, delivering it after deleting the attachments, or delivering it after cleaning the attachments.

Step 3 To search security event messages based on the text that you enter, choose one of the following:

- In the Text field, enter the text to search for in the security event messages log, then click **Find Messages**.
- To find the next entry that matches the text you typed in this field, click **Find**.

Step 4 To pause scrolling of the Latest CSC Security Events pane, click **Pause**. To resume scrolling of the Latest CSC Security Events pane, click **Resume**.

Step 5 To save the log to a file on your PC, click **Save**.

Step 6 To clear the list of messages shown, click **Clear Display**.

Step 7 To close the pane and return to the previous one, click **Close**.

What to Do Next

See the "Software Updates" section on page 83-26.

Software Updates

To view information about CSC SSM software updates, choose **Monitoring > Trend Micro Content Security > Software Updates**.

The Software Updates pane displays the following information, which is refreshed automatically about every 12 seconds:

- The names of parts of the CSC SSM software that can be updated.
- The current version of the corresponding component.
- The date and time that the corresponding component was last updated. If the component has not been updated since the CSC SSM software was installed, None appears in this column.
- The date and time that ASDM last received information about CSC SSM software updates.

What to Do Next

See the "CSC CPU" section on page 83-27.

Resource Graphs

The ASA lets you monitor CSC SSM status, including CPU resources and memory usage. This section includes the following topics:

- CSC CPU, page 83-27
- CSC Memory, page 83-27

CSC CPU

To view CPU usage by the CSC SSM in a graph, perform the following steps:

Step 1 Choose **Monitoring > Trend Micro Content Security > Resource Graphs > CSC CPU**.

The CSC CPU pane displays the components whose statistics you can view in a graph, including statistics for CPU usage on the CSC SSM.

Step 2 To continue, go to Step 2 of the "Threats" section on page 83-24.

What to Do Next

See the "CSC Memory" section on page 83-27.

CSC Memory

To view information about memory usage on the CSC SSM in a graph, perform the following steps:

Step 1 Choose **Monitoring > Trend Micro Content Security > Resource Graphs > CSC Memory**.

The Available Graphs area lists the components whose statistics you can view in a graph, including the following:

- The amount of memory not in use.
- The amount of memory in use.

Step 2 To continue, go to Step 2 of the "Threats" section on page 83-24.

Troubleshooting the CSC Module

This section includes procedures that help you recover or troubleshoot the module and includes the following topics:

- Installing an Image on the Module, page 83-28

- Resetting the Password, page 83-29
- Reloading or Resetting the Module, page 83-30
- Shutting Down the Module, page 83-30

Note This section covers all ASA module types; follow the steps appropriate for your module.

Installing an Image on the Module

If the module suffers a failure, and the module application image cannot run, you can reinstall a new image on the module from a TFTP server.

Note Do not use the **upgrade** command within the module software to install the image.

Prerequisites

Be sure the TFTP server that you specify can transfer files up to 60 MB in size.

Note This process can take approximately 15 minutes to complete, depending on your network and the size of the image.

Detailed Steps

	Command	Purpose

Step 1	**hw-module module 1 recover configure**
	
	Example:
	`hostname# hw-module module 1 recover configure`
	`Image URL [tftp://127.0.0.1/myimage]: tftp://10.1.1.1/ids-newimg`
	`Port IP Address [127.0.0.2]: 10.1.2.10`
	`Port Mask [255.255.255.254]: 255.255.255.0`
	`Gateway IP Address [1.1.2.10]: 10.1.2.254`
	`VLAN ID [0]: 100`
		Specifies the location of the new image. This command prompts you for the URL for the TFTP server, the management interface IP address and netmask, gateway address, and VLAN ID (ASA 5505 only). These network parameters are configured in ROMMON; the network parameters you configured in the module application configuration are not available to ROMMON, so you must set them separately here.
		
		You can view the recovery configuration using the **show module 1 recover** command.
		
		In multiple context mode, enter this command in the system execution space.

	Command	Purpose
Step 2	**hw-module module 1 recover boot** **Example:** `hostname# hw-module module 1 recover boot`	Transfers the image from the TFTP server to the module and restarts the module.
Step 3	**show module 1 details** **Example:** `hostname# show module 1 details`	Checks the progress of the image transfer and module restart process. The Status field in the output indicates the operational status of the module. A module operating normally shows a status of "Up." While the ASA transfers an application image to the module, the Status field in the output reads "Recover." When the ASA completes the image transfer and restarts the module, the newly transferred image is running.

Resetting the Password

You can reset the module password to the default. The default password is cisco. After resetting the password, you should change it to a unique value using the module application.

Resetting the module password causes the module to reboot. Services are not available while the module is rebooting.

If you cannot connect to ASDM with the new password, restart ASDM and try to log in again. If you defined a new password and still have an existing password in ASDM that is different from the new password, clear the password cache by choosing **File > Clear ASDM Password Cache**, then restart ASDM and try to log in again.

To reset the module password to the default of cisco, perform the following steps.

Detailed Steps

Step 1 From the ASDM menu bar, choose **Tools > CSC Password Reset**.

The Password Reset confirmation dialog box appears.

Step 2 Click **OK** to reset the password to the default.

A dialog box displays the success or failure of the password reset.

Step 3 Click **Close** to close the dialog box.

Reloading or Resetting the Module

To reload or reset the module, enter one of the following commands at the ASA CLI.

Detailed Steps

Command	Purpose
hw-module module 1 reload **Example:** `hostname# hw-module module 1 reload`	Reloads the module software.
hw-module module 1 reset **Example:** `hostname# hw-module module 1 reset`	Performs a reset, then reloads the module.

Shutting Down the Module

If you restart the ASA, the module is not automatically restarted. To shut down the module, perform the following steps at the ASA CLI.

Detailed Steps

Command	Purpose
hw-module module 1 shutdown **Example:** `hostname# hw-module module 1 shutdown`	Shuts down the module.

Feature History for the CSC SSM

Table 83-2 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 83-2 Feature History for the CSC SSM

Feature Name	Platform Releases	Feature Information
CSC SSM	7.0(1)	The CSC SSM runs Content Security and Control software, which provides protection against viruses, spyware, spam, and other unwanted traffic. The CSC Setup Wizard enables you to configure the CSC SSM in ASDM. We introduced the following screen: Configuration > Trend Micro Content Security > CSC Setup.
CSC SSM	8.1(1) and 8.1(2)	This feature is not supported on the ASA 5580.

Table 83-2 Feature History for the CSC SSM (continued)

Feature Name	Platform Releases	Feature Information
CSC syslog format	8.3(1)	CSC syslog format is consistent with the ASA syslog format. Syslog message explanations have been added to the *Cisco Content Security and Control SSM Administrator Guide*. The source and destination IP information has been added to the ASDM Log Viewer GUI. All syslog messages include predefined syslog priorities and cannot be configured through the CSC SSM GUI.
Clearing CSC events	8.4(1)	Support for clearing CSC events in the Latest CSC Security Events pane has been added. We modified the following screen: Home > Content Security.
CSC SSM	8.4(2)	Support for the following features has been added: • HTTPS traffic redirection: URL filtering and WRS queries for incoming HTTPS connections. • Configuring global approved whitelists for incoming and outgoing SMTP and POP3 e-mail. • E-mail notification for product license renewals. We modified the following screens: Configuration > Trend Micro Content Security > Mail > SMTP. Configuration > Trend Micro Content Security > Mail > POP3. Configuration > Trend Micro Content Security > Host/Notification Settings. Configuration > Trend Micro Content Security > CSC Setup > Host Configuration.

PART 15

Configuring VPN

VPN Wizards

The ASA provides Secure Socket Layer (SSL) remote access connectivity from almost any Internet-enabled location using only a Web browser and its native SSL encryption. Clientless, browser-based VPN lets users establish a secure, remote-access VPN tunnel to the adaptive security appliance using a web browser. After authentication, users access a portal page and can access specific, supported internal resources. The network administrator provides access to resources by users on a group basis. Users have no direct access to resources on the internal network.

The Cisco AnyConnect VPN client provides secure SSL connections to the ASA for remote users with full VPN tunneling to corporate resources. Without a previously-installed client, remote users enter the IP address in their browser of an interface configured to accept clientless VPN connections. The ASA downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection and either remains or uninstalls itself (depending on the ASA configuration) when the connection terminates. In the case of a previously installed client, when the user authenticates, the ASA examines the revision of the client and upgrades the client as necessary.

With the addition of IKEv2 support in release 8.4, the end user can have the same experience independent of the tunneling protocol used by the AnyConnect client session. This addition allows other vendors' VPN clients to connect to the ASAs. This support enhances security and complies with the IPsec remote access requirements defined in federal and public sector mandates.

The VPN wizard lets you configure basic LAN-to-LAN and remote access VPN connections and assign either preshared keys or digital certificates for authentication. Use ASDM to edit and configure advanced features.

VPN Overview

The ASA creates a Virtual Private Network by creating a secure connection across a TCP/IP network (such as the Internet) that users see as a private connection. It can create single-user-to-LAN connections and LAN-to-LAN connections.

For LAN-to-LAN connections using both IPv4 and IPv6 addressing, the security appliance supports VPN tunnels if both peers are Cisco ASA 5500 series security appliances, and if both inside networks have matching addressing schemes (both IPv4 or both IPv6). This is also true if both peer inside networks are IPv6 and the outside network is IPv6.

The secure connection is called a tunnel, and the ASA uses tunneling protocols to negotiate security parameters, create and manage tunnels, encapsulate packets, transmit or receive them through the tunnel, and unencapsulate them. The ASA functions as a bidirectional tunnel endpoint: it can receive plain

packets, encapsulate them, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets, unencapsulate them, and send them to their final destination.

The four VPN wizards described in this section are as follows:

- IPsec IKEv1 Remote Access Wizard
- IPsec Site-to-Site VPN Wizard
- AnyConnect VPN Wizard
- Clientless SSL VPN Wizard

IPsec IKEv1 Remote Access Wizard

Use the IKEv1 Remote Access Wizard to configuresecure remote access for VPN clients, such as mobile users, and to identify the interface that connects to the remote IPsec peer.

Fields

- VPN Tunnel Interface—Choose the interface that establishes a secure tunnel with the remote IPsec peer. If the ASA has multiple interfaces, you need to plan the VPN configuration before running this wizard, identifying the interface to use for each remote IPsec peer with which you plan to establish a secure connection.
- Enable inbound IPsec sessions to bypass interface access lists—Enable IPsec authenticated inbound sessions to always be permitted through the security appliance (that is, without a check of the interface access-list statements). Be aware that the inbound sessions bypass only the interface ACLs. Configured group-policy, user, and downloaded ACLs still apply.

Remote Access Client

Remote access users of various types can open VPN tunnels to this ASA. Choose the type of VPN client for this tunnel.

Fields

- VPN Client Type
  - Cisco VPN Client, Release 3.x or higher, or an Easy VPN Remote product.
  - Microsoft Windows client using L2TP over IPsec—Specify the PPP authentication protocol. The choices are PAP, CHAP, MS-CHAP-V1, MS-CHAP-V2, and EAP-PROXY:

    PAP—Passes cleartext username and password during authentication and is not secure.

    CHAP—In response to the server challenge, the client returns the encrypted [challenge plus password] with a cleartext username. This protocol is more secure than the PAP, but it does not encrypt data.

    MS-CHAP, Version 1—Similar to CHAP but more secure in that the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP.

    MS-CHAP, Version 2—Contains security enhancements over MS-CHAP, Version 1.

    EAP-Proxy—Enables EAP which permits the ASA to proxy the PPP authentication process to an external RADIUS authentication server.

    If a protocol is not specified on the remote client, do no specify it.

– Specify if the client will send tunnel group name as username@tunnelgroup.

VPN Client Authentication Method and Tunnel Group Name

Use the VPN Client Authentication Method and Name pane to configure an authentication method and create a connection policy (tunnel group).

Fields

- Authentication Method—The remote site peer authenticates either with a preshared key or a certificate.
  - Pre-shared Key—Click to use a preshared key for authentication between the local ASA and the remote IPsec peer.

    Using a preshared key is a quick and easy way to set up communication with a limited number of remote peers and a stable network. It may cause scalability problems in a large network because each IPsec peer requires configuration information for each peer with which it establishes secure connections.

    Each pair of IPsec peers must exchange preshared keys to establish secure tunnels. Use a secure method to exchange the preshared key with the administrator of the remote site.
  - Pre-shared Key—Type an alphanumeric string between 1 and 128 characters.
  - Certificate—Click to use certificates for authentication between the local ASA and the remote IPsec peer. To complete this section, you must have previously enrolled with a CA and downloaded one or more certificates to the ASA.

    You can efficiently manage the security keys used to establish an IPsec tunnel with digital certificates. A digital certificate contains information that identifies a user or device, such as a name, serial number, company, department or IP address. A digital certificate also contains a copy of the public key.

    To use digital certificates, each peer enrolls with a certification authority (CA), which is responsible for issuing digital certificates. A CA can be a trusted vendor or a private CA that you establish within an organization.

    When two peers want to communicate, they exchange certificates and digitally sign data to authenticate each other. When you add a new peer to the network, it enrolls with a CA, and none of the other peers require additional configuration.

    Certificate Signing Algorithm—Displays the algorithm for signing digital certificates, rsa-sig for RSA.
  - Challenge/response authentication (CRACK)—Provides strong mutual authentication when the client authenticates using a popular method such as RADIUS and the server uses public key authentication. The security appliance supports CRACK as an IKE option in order to authenticate the Nokia VPN Client on Nokia 92xx Communicator Series devices.
- Tunnel Group Name—Type a name to create the record that contains tunnel connection policies for this IPsec connection. A connection policy can specify authentication, authorization, and accounting servers, a default group policy, and IKE attributes. A connection policy that you configure with this VPN wizard specifies an authentication method and uses the ASA Default Group Policy.

Client Authentication

Use the Client Authentication pane to select the method by which the ASA authenticates remote users.

Fields

Select one of the following options:

- Authenticate using the local user database—Click to use authentication internal to the ASA. Use this method for environments with a small, stable number of users. The next pane lets you create accounts on the ASA for individual users.
- Authenticate using an AAA server group—Click to use an external server group for remote user authentication.
  - AAA Server Group Name—Choose a AAA server group configured previously.
  - New...—Click to configure a new AAA server group.

User Accounts

Use the User Accounts pane to add new users to the ASA internal user database for authentication purposes.

Fields

- Use the fields in this section to add a user.
  - Username—Enter the username.
  - Password—(Optional) Enter a password.
  - Confirm Password—(Optional) Reenter the password.
- Add—Click to add a user to the database after you have entered the username and optional password.
- Delete—To remove a user from the database, highlight the appropriate username and click **Delete**.

Address Pool

Use the Address Pool pane to configure a pool of local IP addresses that the ASA assigns to remote VPN clients.

Fields

- Tunnel Group Name—Displays the name of the connection profile (tunnel group) to which this address pool applies. You set this name in the VPN Client and Authentication Method pane (step 3).
- Pool Name—Select a descriptive identifier for the address pool.
- New...—Click to configure a new address pool.
- Range Start Address—Type the starting IP address in the address pool.
- Range End Address—Type the ending IP address in the address pool.
- Subnet Mask—(Optional) Choose the subnet mask for these IP addresses.

Attributes Pushed to Client (Optional)

Use the Attributes Pushed to Client (Optional) pane to have the ASA pass information about DNS and WINS servers and the default domain name to remote access clients.

Fields

- Tunnel Group—Displays the name of the connection policy to which the address pool applies. You set this name in the VPN Client Name and Authentication Method pane.
- Primary DNS Server—Type the IP address of the primary DNS server.
- Secondary DNS Server—Type the IP address of the secondary DNS server.
- Primary WINS Server—Type the IP address of the primary WINS server.
- Secondary WINS Server— Type the IP address of the secondary WINS server.
- Default Domain Name—Type the default domain name.

IKE Policy

IKE, also called Internet Security Association and Key Management Protocol (ISAKMP), is the negotiation protocol that lets two hosts agree on how to build an IPsec Security Association. Each IKE negotiation is divided into two sections called Phase1 and Phase 2.

- Phase 1 creates the first tunnel, which protects later IKE negotiation messages.
- Phase 2 creates the tunnel that protects data.

Use the IKE Policy pane to set the terms of the Phase 1 IKE negotiations, which include the following:

- An encryption method to protect the data and ensure privacy.
- An authentication method to ensure the identity of the peers.
- A Diffie-Hellman group to establish the strength of the of the encryption-key-determination algorithm. The ASA uses this algorithm to derive the encryption and hash keys.

Fields

- Encryption—Select the symmetric encryption algorithm the ASA uses to establish the Phase 1 SA that protects Phase 2 negotiations. The ASA supports the following encryption algorithms:

Algorithm	Explanation
DES	Data Encryption Standard. Uses a 56-bit key.
3DES	Triple DES. Performs encryption three times using a 56-bit key.
AES-128	Advanced Encryption Standard. Uses a 128-bit key.
AES-192	AES using a 192-bit key.
AES-256	AES using a 256-bit key.

  The default, 3DES, is more secure than DES but requires more processing for encryption and decryption. Similarly, the AES options provide increased security but also require increased processing.

- Authentication—Choose the hash algorithm used for authentication and ensuring data integrity. The default is SHA. MD5 has a smaller digest and is considered to be slightly faster than SHA. There has been a demonstrated successful (but extremely difficult) attack against MD5. However, the Keyed-Hash Message Authentication Code (HMAC) version used by the ASA prevents this attack.
- Diffie-Hellman Group—Choose the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other. The default, Group 2 (1024-bit Diffie-Hellman), requires less CPU time to execute but is less secure than Group 5 (1536-bit).

Note The default value for the VPN 3000 Series Concentrator is MD5. A connection between the ASA and the VPN Concentrator requires that the authentication method for Phase I and II IKE negotiations be the same on both sides of the connection.

IPsec Settings (Optional)

Use the IPsec Settings (Optional) pane to identify local hosts/networks which do not require address translation. By default, the ASA hides the real IP addresses of internal hosts and networks from outside hosts by using dynamic or static Network Address Translation (NAT). NAT minimizes risks of attack by untrusted outside hosts but may be improper for those who have been authenticated and protected by VPN.

For example, an inside host using dynamic NAT has its IP address translated by matching it to a randomly selected address from a pool. Only the translated address is visible to the outside. Remote VPN clients that attempt to reach these hosts by sending data to their real IP addresses cannot connect to these hosts, unless you configure a NAT exemption rule.

Note If you want all hosts and networks to be exempt from NAT, configure nothing on this pane. If you have even one entry, all other hosts and networks are subject to NAT.

Fields

- Interface—Choose the name of the interface that connects to the hosts or networks you have selected.
- Exempt Networks—Select the IP address of the host or network that you want to exempt from the chosen interface network.
- Enable split tunneling—Select to have traffic from remote access clients destined for the public Internet sent unencrypted. Split tunneling causes traffic for protected networks to be encrypted, while traffic to unprotected networks is unencrypted. When you enable split tunneling, the ASA pushes a list of IP addresses to the remote VPN client after authentication. The remote VPN client encrypts traffic to the IP addresses that are behind the ASA. All other traffic travels unencrypted directly to the Internet without involving the ASA.
- Enable Perfect Forwarding Secrecy (PFS)—Specify whether to use Perfect Forward Secrecy, and the size of the numbers to use, in generating Phase 2 IPsec keys. PFS is a cryptographic concept where each new key is unrelated to any previous key. In IPsec negotiations, Phase 2 keys are based on Phase 1 keys unless PFS is enabled. PFS uses Diffie-Hellman techniques to generate the keys.

  PFS ensures that a session key derived from a set of long-term public and private keys is not compromised if one of the private keys is compromised in the future.

  PFS must be enabled on both sides of the connection.

  - Diffie-Hellman Group—Select the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other. The default, Group 2 (1024-bit Diffie-Hellman), requires less CPU time to execute but is less secure than Group 5 (1536-bit).

Summary

The Summary pane displays all of the attributes of this VPN LAN-to-LAN connection as configured.

Fields

Back—To make changes, click **Back** until you reach the appropriate pane.

Finish—When you are satisfied with the configuration, click **Finish**. ASDM saves the LAN-to-LAN configuration. After you click **Finish**, you can no longer use the VPN wizard to make changes to this configuration. Use ASDM to edit and configure advanced features.

Cancel—To remove the configuration, click **Cancel**.

IPsec Site-to-Site VPN Wizard

Use this wizard to set up new site-to-site VPN tunnels. A tunnel between two devices is called a site-to-site tunnel and is bidirectional. A site-to-site VPN tunnel protects the data using the IPsec protocol.

Peer Device Identification

Identify the peer VPN device by its IP address and the interface used to access the peer.

Fields

- Peer IP Address—Configure the IP address of the peer device.
- VPN Access Interface—Use the drop-down to specify the interface for the site-to-site tunnel.

IKE Version

ASA supports both version 1 and version 2 of the IKE (Internet Key Exchange) protocol. This step lets you decide which version or versions to support in this connection profile.

Fields

- IKEv1
- IKEv2

Traffic to Protects

This step lets you identify the local network and remote network These networks protect the traffic using IPsec encryption.

Fields

- Network Type—Choose IPv4 or IPv6.
- Local Networks—Identify the host used in the IPsec tunnel.
- Remote Networks—Identify the networks used in the IPsec tunnel.

Authentication Methods

This step lets you configure the methods to authenticate with the peer device.

Fields

IKE version 1

- Pre-shared Key—Using a preshared key is a quick and easy way to set up communication with a limited number of remote peers and a stable network. It may cause scalability problems in a large network because each IPsec peer requires configuration information for each peer with which it establishes secure connections.

  Each pair of IPsec peers must exchange preshared keys to establish secure tunnels. Use a secure method to exchange the preshared key with the administrator of the remote site.

- Device Certificate—Click to use certificates for authentication between the local ASA and the remote IPsec peer.

  You can efficiently manage the security keys used to establish an IPsec tunnel with digital certificates. A digital certificate contains information that identifies a user or device, such as a name, serial number, company, department or IP address. A digital certificate also contains a copy of the public key.

  When two peers want to communicate, they exchange certificates and digitally sign data to authenticate each other. When you add a new peer to the network, it enrolls with a CA, and none of the other peers require additional configuration.

IKE version 2

- Local Pre-shared Key—Specify IPsec IKEv2 authentication methods and encryption algorithms.
- Local Device Certificate—Authenticates VPN access through the security appliance.
- Remote Peer Pre-shared Key—Click to use a preshared key for authentication between the local ASA and the remote IPsec peer.
- Remote Peer Certificate Authentication—When checked, the peer device is allowed to use the certificate to authenticate itself to this device.

Encryption Algorithm

This step lets you select the types of encryption algorithms used to protect the data.

Fields

IKE version 1

- IKE Policy—Specify IKEv1 authentication methods.
- IPsec Proposal—Specify IPsec encryption algorithms.

IKE version 2

- IKE Policy—Specify IKEv2 authentication methods.
- IPsec Proposal—Specify IPsec encryption algorithms.

Miscellaneous

You can enable or disable Perfect Forward Secrecy (PFS). PFS ensures that the key for a given IPsec SA was not derived from any other secret. PFS makes it difficult to break a key by deriving from other keys.

Fields

- Enable inbound IPsec sessions to bypass interface access lists—Enable IPsec authenticated inbound sessions to always be permitted through the security appliance (that is, without a check of the interface access-list statements). Be aware that the inbound sessions bypass only the interface ACLs. Configured group-policy, user, and downloaded ACLs still apply.
- Enable Perfect Forward Secrecy (PFS)—Ensures the key for a given IPsec SA was not derived from any other secret.
- Diffie-Hellman Group—Choose the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other. The default, Group 2 (1024-bit Diffie-Hellman), requires less CPU time to execute but is less secure than Group 5 (1536-bit).
- Exempt ASA side host/network from address translation—Use the drop-down to choose a host or network to be excluded from address translation.

Summary

Provides a summary of your selections from the previous wizard windows. The supported VPN protocols are included in the summary as well as the IKE version chosen on the VPN Connection Type window.

AnyConnect VPN Wizard

Use this wizard to configure ASA to accept VPN connections from the AnyConnect VPN client. This wizard configures either IPsec (IKEv2) or SSL VPN protocols for full network access. The ASA automatically uploads the AnyConnect VPN client to the end user's device when a VPN connection is established.

Warn the user that running the wizard does not mean the IKEv2 profile automatically applies in predeployment scenarios. Either provide a pointer or the steps necessary to successfully predeploy IKEv2.

Connection Profile Identification

The connection profile identification is used to identify the ASA to the remote acess users.

Fields

- Connection Profile Name—Provide a name that the remote access users will access for VPN connections.
- VPN Access Interface—Choose an interface that the remote access users will access for VPN connections.

VPN Protocols

Specify the VPN protocol allowed for this connection profile.

The AnyConnect client defaults to SSL. If you enable IPsec as a VPN tunnel protocol for the connection profile, you must also create and deploy a client profile with IPsec enabled using the profile editor from ASDM, and deploy the profile.

If you predeploy instead of weblaunch the AnyConnect client, the first client connection uses SSL, and receives the client profile from the ASA during the session. For subsequent connections, the client uses the protocol specified in the profile, either SSL or IPsec. If you predeploy the profile with IPsec specified with the client, the first client connection uses IPsec. For more information about predeploying a client profile with IPsec enabled, see the AnyConnect Secure Mobility Client Administrator Guide.

Fields

- SSL
- IPsec (IKE v2)
- Device Certificate—Identifies the ASA to the remote access clients.

Note Some AnyConnect features (such as always on, IPsec/IKEv2) require a valid device certificate on the ASA.

- Manage—Choosing **Manage** opens the Manage Identity Certificates window.
  - Add—Choose **Add** to add an identity certificate and its details.
  - Show Details—If you choose a particular certificate and click **Show Details**, the Certificate Details window appears and provides who the certificate was issued to and issued by, as well as specifics about its serial number, usage, associated trustpoints, valid timeframe, and so on.
  - Delete—Highlight the certificate you want to remove and click **Delete**.
  - Export—Highlight the certificate and click **Export** to export the certificate to a file with or without an encryption passphrase.
  - Enroll ASA SSL VPN with Entrust—Gets your Cisco ASA SSL VPN appliance up and running quickly with an SSL Advantage digitial certificate from Entrust.

Client Images

ASA can automatically upload the latest AnyConnect package to the client device when it accesses the enterprise network. You can use a regular expression to match the user agent of a browser to an image. You can also minimize connection setup time by moving the most commonly encountered operation system to the top of the list.

Fields

- Add
- Replace
- Delete

Authentication Methods

Specify authentication information on this screen.

Fields

- AAA server group—Enable to let the ASA contact a remote AAA server group to authenticate the user. Select a AAA server group from the list of pre-configured groups or click **New** to create a new group.
- Local User Database Details—Add new users to the local database stored on the ASA.
  - Username—Create a username for the user.
  - Password—Create a password for the user.
  - Confirm Password—Re-type the same password to confirm.
  - Add/Delete—Add or delete the user from the local database.

Client Address Assignment

Provide a range of IP addresses to remote SSL VPN users.

Fields

- IPv4 Address Pools—SSL VPN clients receive new IP addresses when they connect to the ASA. Clientless connections do not require new IP addresses. Address Pools define a range of addresses that remote clients can receive. Select an existing IP Address Pool or click **New** to create a new pool.

  If you select **New**, you will have to provide a starting and ending IP address and subnet mask.
- IPv6 Address Pool—Select an existing IP Address Pool or click **New** to create a new pool.

Note IPv6 address pools can not be created for IKEv2 connection profiles.

Network Name Resolution Servers

This step lets you specify which domain names are resolved for the remote user when accessing the internal network.

Fields

- DNS Servers—Enter the IP address of the DNS server.
- WINS Servers—Enter the IP address of the WINS server.
- Domain Name—Type the default domain name.

NAT Exempt

If network translation is enabled on the ASA, the VPN traffic must be exempt from this translation.

Fields

- Exempt VPN traffic from network address translation

AnyConnect Client Deployment

You can install the AnyConnect client program to a client device with one of the following two methods:

- Web launch—Installs automatically when accessing the ASA using a web browser.
- Pre-deployment—Manually installs the AnyConnect client package.

Fields

- Allow Web Launch—A global setting that affects all connections. If it is unchecked (disallowed), AnyConnect SSL connections and clientless SSL connections do not work.

For pre-deployment, the disk0:/test2_client_profile.xml profile bundle contains an .msi file, and you must include this client profile from the ASA in your AnyConnect package to ensure IPsec connection functions as expected.

Summary

Provides a summary of your selections from the previous wizard windows. The supported VPN protocols are part of the summary as well as the IKE version chosen.

Clientless SSL VPN Wizard

This wizard enables clientless, browser-based connections for specific, supported internal resources through a portal page.

SSL VPN Interface

Provide a connection profile and the interface that SSL VPN users connect to.

Fields

- Connection Profile Name
- SSL VPN Interface—The interface users access for SSL VPN connections.
- Digital Certificate—Specifies what the security appliance sends to the remote web browser to authenticate the ASA.
  - Certificate—Choose from the drop-down menu.
- Accessing the Connection Profile
  - Connection Group Alias/URL—The group alias is chosen during login from the Group drop-down list. This URL is entered into the web browser.
  - Display Group Alias list at the login page

User Authentication

Specify authentication information on this screen.

Fields

- Authenticate using a AAA server group—Enable to let the ASA contact a remote AAA server group to authenticate the user.

  - AAA Server Group Name—Select a AAA server group from the list of pre-configured groups or click **New** to create a new group.
- Authenticate using the local user database—Add new users to the local database stored on the ASA.
  - Username—Create a username for the user.
  - Password—Create a password for the user.
  - Confirm Password—Re-type the same password to confirm.
  - Add/Delete—Add or delete the user from the local database.

Group Policy

Group policies configure common attributes for groups of users. Create a new group policy or select an existing one to modify.

Fields

- Create new group policy—Enables you to create a new group policy. Provide a name for the new policy.
- Modify existing group policy—Select an existing group policy to modify.

Bookmark List

Configure a list of group intranet websites that appear in the portal page as links. Some examples include https://intranet.acme.com, rdp://10.120.1.2, vnc://100.1.1.1 and so on.

Fields

- Bookmark List
- Manage

Summary

Provides a summary of your selections from the previous wizard windows.

Configuring IKE, Load Balancing, and NAC

IKE, also called ISAKMP, is the negotiation protocol that lets two hosts agree on how to build an IPsec security association. To configure the ASA for virtual private networks, you set global IKE parameters that apply system wide, and you also create IKE policies that the peers negotiate to establish a VPN connection.

Load balancing distributes VPN traffic among two or more ASAs in a VPN cluster.

Network Access Control (NAC) protects the enterprise network from intrusion and infection from worms, viruses, and rogue applications by performing endpoint compliance and vulnerability checks as a condition for production access to the network. We refer to these checks as *posture validation.*

This chapter describes how to configure IKE, load balancing, and NAC. It includes the following sections:

- Setting IKE Parameters, page 86-1
- Creating IKE Policies, page 86-5
- Configuring IPsec, page 86-10
- Configuring Load Balancing, page 86-20
- Setting Global NAC Parameters, page 86-29
- Configuring Network Admission Control Policies, page 86-30

Setting IKE Parameters

Configuration > VPN > IKE > Global Parameters

This pane lets you set system wide values for VPN connections. The following sections describe each of the options.

Enabling IKE on Interfaces

You must enable IKE for each interface that you want to use for VPN connections.

Enabling IPsec over NAT-T

NAT-T lets IPsec peers establish both remote access and LAN-to-LAN connections through a NAT device. It does this by encapsulating IPsec traffic in UDP datagrams, using port 4500, thereby providing NAT devices with port information. NAT-T auto-detects any NAT devices, and only encapsulates IPsec traffic when necessary. This feature is disabled by default.

- The ASA can simultaneously support standard IPsec, IPsec over TCP, NAT-T, and IPsec over UDP, depending on the client with which it is exchanging data.
- When both NAT-T and IPsec over UDP are enabled, NAT-T takes precedence.
- When enabled, IPsec over TCP takes precedence over all other connection methods.

The ASA implementation of NAT-T supports IPsec peers behind a single NAT/PAT device as follows:

- One LAN-to-LAN connection.
- Either a LAN-to-LAN connection or multiple remote access clients, but not a mixture of both.

To use NAT-T you must:

- Open port 4500 on the ASA.
- Enable IPsec over NAT-T globally in this pane.
- Choose the second or third option for the Fragmentation Policy parameter in the Configuration > VPN > IPsec > Pre-Fragmentation pane. These options let traffic travel across NAT devices that do not support IP fragmentation; they do not impede the operation of NAT devices that do support IP fragmentation.

Enabling IPsec over TCP

IPsec over TCP enables a VPN client to operate in an environment in which standard ESP or IKE cannot function, or can function only with modification to existing firewall rules. IPsec over TCP encapsulates both the IKE and IPsec protocols within a TCP packet, and enables secure tunneling through both NAT and PAT devices and firewalls. This feature is disabled by default.

Note This feature does not work with proxy-based firewalls.

IPsec over TCP works with remote access clients. It works on all physical and VLAN interfaces. It is a client to ASA feature only. It does not work for LAN-to-LAN connections.

- The ASA can simultaneously support standard IPsec, IPsec over TCP, NAT-Traversal, and IPsec over UDP, depending on the client with which it is exchanging data.
- The VPN 3002 hardware client, which supports one tunnel at a time, can connect using standard IPsec, IPsec over TCP, NAT-Traversal, or IPsec over UDP.
- When enabled, IPsec over TCP takes precedence over all other connection methods.

You enable IPsec over TCP on both the ASA and the client to which it connects.

You can enable IPsec over TCP for up to 10 ports that you specify. If you enter a well-known port, for example port 80 (HTTP) or port 443 (HTTPS), the system displays a warning that the protocol associated with that port will no longer work. The consequence is that you can no longer use a browser to manage the ASA through the IKE-enabled interface. To solve this problem, reconfigure the HTTP/HTTPS management to different ports.

You must configure TCP port(s) on the client as well as on the ASA. The client configuration must include at least one of the ports you set for the ASA.

Determining ID Method

During IKE negotiations the peers must identify themselves to each other. You can choose the identification methods from the following options:

Address	Uses the IP addresses of the hosts exchanging ISAKMP identity information.
Hostname	Uses the fully-qualified domain name of the hosts exchanging ISAKMP identity information (default). This name comprises the hostname and the domain name.
Key ID	Uses the string the remote peer uses to look up the preshared key.
Automatic	Determines IKE negotiation by connection type: • IP address for preshared key • Cert DN for certificate authentication.

Disabling Inbound Aggressive Mode Connections

Phase 1 IKE negotiations can use either Main mode or Aggressive mode. Both provide the same services, but Aggressive mode requires only two exchanges between the peers, rather than three. Aggressive mode is faster, but does not provide identity protection for the communicating parties. It is therefore necessary that they exchange identification information prior to establishing a secure SA in which to encrypt in formation. This feature is disabled by default.

Alerting Peers Before Disconnecting

Client or LAN-to-LAN sessions may be dropped for several reasons, such as: a ASA shutdown or reboot, session idle timeout, maximum connection time exceeded, or administrator cut-off.

The ASA can notify qualified peers (in LAN-to-LAN configurations), VPN Clients and VPN 3002 hardware clients of sessions that are about to be disconnected, and it conveys to them the reason. The peer or client receiving the alert decodes the reason and displays it in the event log or in a pop-up pane. This feature is disabled by default.

This pane lets you enable the feature so that the ASA sends these alerts, and conveys the reason for the disconnect.

Qualified clients and peers include the following:

- Security appliances with Alerts enabled.
- VPN clients running 4.0 or later software (no configuration required).
- VPN 3002 hardware clients running 4.0 or later software, and with Alerts enabled.
- VPN 3000 concentrators running 4.0 or later software, with Alerts enabled.

Waiting for Active Sessions to Terminate Prior to Reboot

You can schedule a ASA reboot to occur only when all active sessions have terminated voluntarily. This feature is disabled by default.

Preventing DoS Attacks by Limiting IKEv2 Open SAs

You can prevent denial-of-service (DoS) attacks for IPsec IKEv2 connections by always cookie challenging incoming SAs or by limiting the number of open SAs and cookie challenge any additional connections, or by By default, the ASA does not limit the number of open SAs and never cookie challenges SAs. You can also limit the number of SAs allowed, which stops further connections from negotiating to protect against memory and/or CPU attacks that the cookie-challenge feature may be unable to thwart and protects the current connections.

With a DoS attack, an attacker initiates the attack when the peer device sends an SA initiate packet and the ASA sends its response, but the peer device does not respond further. If the peer device does this continually, all the allowed SA requests on the ASA can be used up until it stops responding.

Enabling a threshold percentage for cookie challenging limits the number of open SA negotiations. For example, with the default setting of 50%, when 50% of the allowed SAs are in-negotiation (open), the ASA cookie challenges any additional SA initiate packets that arrive. For the Cisco ASA 5580 with 10000 allowed IKEv2 SAs, after 5000 SAs become open, any more incoming SAs are cookie-challenged.

If used in conjunction with the ***Number of SAs in Negotiation***, or the *Maximum Number of SAs Allowed*, configure the cookie-challenge threshold lower than these settings for an effective cross-check.

Fields

- Enable IKE—Shows IKE status for all configured interfaces.
  - Interface—Displays names of all configured ASA interfaces.
  - IKE Enabled—Shows whether IKE is enabled for each configured interface.
  - Enable/Disables—Click to enable or disable IKE for the highlighted interface.
- NAT Transparency—Lets you enable or disable IPsec over NAT-T and IPsec over TCP.
  - Enable IPsec over NAT-T—Choose to enable IPsec over NAT-T.
  - NAT Keepalive—Type the number of seconds that can elapse with no traffic before the ASA terminates the NAT-T session. The default is 20 seconds. The range is 10 to 3600 seconds (one hour).
  - Enable IPsec over TCP—Choose to enable IPsec over TCP.
  - Enter up to 10 comma-separated TCP port values—Type up to 10 ports on which to enable IPsec over TCP. Use a comma to separate the ports. You do not need to use spaces. The default port is 10,000. The range is 1 to 65,635.
- Identity to Be Sent to Peer—Lets you set the way that IPsec peers identify themselves to each other.
  - Identity—Choose one of the following methods by which IPsec peers identify themselves:

Address	Uses the IP addresses of the hosts.
Hostname	Uses the fully-qualified domain names of the hosts. This name comprises the hostname and the domain name.
Key ID	Uses the string the remote peer uses to look up the preshared key.
Automatic	Determines IKE negotiation by connection type: IP address for preshared key or cert DN for certificate authentication.

  - Key Id String—Type the alpha-numeric string the peers use to look up the preshared key.
- Disable inbound aggressive mode connections—Choose to disable aggressive mode connections.
- Alert peers before disconnecting—Choose to have the ASA notify qualified LAN-to-LAN peers and remote access clients before disconnecting sessions.
- Wait for all active sessions to voluntarily terminate before rebooting—Choose to have the ASA postpone a scheduled reboot until all active sessions terminate.
- IKEv2 Specific Settings—These settings apply only to IPsec IKEv2 connections and limit the number of open SAs. By default, the ASA does not limit the number of open SAs:
  - Cookie Challenge—Enables the ASA to send cookie challenges to peer devices in response to SA initiate packets.

  - % threshold before incoming SAs are cookie challenged—The percentage of the total allowed SAs for the ASA that are in-negotiation, which triggers cookie challenges for any future SA negotiations. The range is zero to 100%. The default is 50%.
  - Number of Allowed SAs in Negotiation—Limits the maximum number of SAs that can be in negotiation at any time. If used in conjunction with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.
  - Maximum Number of SAs Allowed—Limits the number of allowed IKEv2 connections on the ASA. By default, the limit is the maximum number of connections specified by the license.

Creating IKE Policies

Configuration > VPN > IKE > Policies

Each IKE negotiation is divided into two sections called Phase1 and Phase 2.

Phase 1 creates the first tunnel, which protects later IKE negotiation messages. Phase 2 creates the tunnel that protects data.

To set the terms of the IKE negotiations, you create one or more IKE policies, which include the following:

- A unique priority (1 through 65,543, with 1 the highest priority).
- An authentication method, to ensure the identity of the peers.
- An encryption method, to protect the data and ensure privacy.
- An HMAC method to ensure the identity of the sender, and to ensure that the message has not been modified in transit.
- A Diffie-Hellman group to establish the strength of the of the encryption-key-determination algorithm. The ASA uses this algorithm to derive the encryption and hash keys.
- A limit for how long the ASA uses an encryption key before replacing it.

For IKEv1, you can only enable one setting for each parameter. For IKEv2, each proposal can have multiples settings for Encryption, D-H Group, Integrity Hash, and PRF Hash.

If you do not configure any IKE policies, the ASA uses the default policy, which is always set to the lowest priority, and which contains the default value for each parameter. If you do not specify a value for a specific parameter, the default value takes effect.

When IKE negotiation begins, the peer that initiates the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order.

A match between IKE policies exists if they have the same encryption, hash, authentication, and Diffie-Hellman values, and an SA lifetime less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter lifetime—from the remote peer policy—applies. If no match exists, IKE refuses negotiation and the IKE SA is not established.

Fields

- IKEv1 Policies—Displays parameter settings for each configured IKE policy.
  - Priority #—Shows the priority of the policy.
  - Encryption—Shows the encryption method.
  - Hash—Shows the hash algorithm.
  - D-H Group—Shows the Diffie-Hellman group.

  - Authentication—Shows the authentication method.
  - Lifetime (secs)—Shows the SA lifetime in seconds.
- Add/Edit/Delete—Click to add, edit, or delete an IKEv1 policy.
- IKEv2 Policies—Displays parameter settings for each configured IKEv2 policy.
  - Priority #—Shows the priority of the policy.
  - Encryption—Shows the encryption method.
  - Integrity Hash—Shows the hash algorithm.
  - PRF Hash—Shows the pseudo random function (PRF) hash algorithm.
  - D-H Group—Shows the Diffie-Hellman group.
  - Lifetime (secs)—Shows the SA lifetime in seconds.
- Add/Edit/Delete—Click to add, edit, or delete an IKEv2 policy.

Add/Edit IKEv1 Policy

Configuration > VPN > IKE > Policies > Add/Edit IKEv1 Policy

Fields

Priority #—Type a number to set a priority for the IKE policy. The range is 1 to 65535, with 1 the highest priority.

Encryption—Choose an encryption method. This is a symmetric encryption method that protects data transmitted between two IPsec peers.The choices follow:

des	56-bit DES-CBC. Less secure but faster than the alternatives. The default.
3des	168-bit Triple DES.
aes	128-bit AES.
aes-192	192-bit AES.
aes-256	256-bit AES.

Hash—Choose the hash algorithm that ensures data integrity. It ensures that a packet comes from whom you think it comes from, and that it has not been modified in transit.

sha	SHA-1	The default is SHA-1. MD5 has a smaller digest and is considered to be slightly faster than SHA-1. A successful (but extremely difficult) attack against MD5 has occurred; however, the HMAC variant IKE uses prevents this attack.
md5	MD5	

Authentication—Choose the authentication method the ASA uses to establish the identity of each IPsec peer. Preshared keys do not scale well with a growing network but are easier to set up in a small network. The choices follow:

pre-share	Preshared keys.
rsa-sig	A digital certificate with keys generated by the RSA signatures algorithm.
crack	IKE Challenge/Response for Authenticated Cryptographic Keys protocol for mobile IPsec-enabled clients which use authentication techniques other than certificates.

D-H Group—Choose the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other.

1	Group 1 (768-bit)	The default, Group 2 (1024-bit Diffie-Hellman) requires less CPU time to execute but is less secure than Group 1or 5.
2	Group 2 (1024-bit)	
5	Group 5 (1536-bit)	

Lifetime (secs)—Either check *Unlimited* or enter an integer for the SA lifetime. The default is 86,400 seconds or 24 hours. With longer lifetimes, the ASA sets up future IPsec security associations less quickly. Encryption strength is great enough to ensure security without using very fast rekey times, on the order of every few minutes. We recommend that you accept the default.

Time Measure—Choose a time measure. The ASA accepts the following values:.

120 - 86,400 seconds

2 - 1440 minutes

1 - 24 hours

1 day

Add/Edit IKEv2 Policy (Proposal)

Configuration > VPN > IKE > Policies > Add/Edit IKEv2 Policy

Fields

Priority #—Type a number to set a priority for the IKEv2 policy. The range is 1 to 65535, with 1 the highest priority.

Encryption—Choose an encryption method. This is a symmetric encryption method that protects data transmitted between two IPsec peers.The choices follow:

des	Specifies 56-bit DES-CBC encryption for ESP.
3des	(Default) Specifies the triple DES encryption algorithm for ESP.
aes	Specifies AES with a 128-bit key encryption for ESP.
aes-192	Specifies AES with a 192-bit key encryption for ESP.
aes-256	Specifies AES with a 256-bit key encryption for ESP.
aes-gcm	Specifies AES-GCM/GMAC 128-bit support for symmetric encryption and integrity.
aes-gcm-192	Specifies AES-GCM/GMAC 192-bit support for symmetric encryption and integrity.
aes-gcm-256	Specifies AES-GCM/GMAC 256-bit support for symmetric encryption and integrity.
NULL	Indicates no encryption.

D-H Group—Choose the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other.

1	Group 1 (768-bit)	The default, Group 2 (1024-bit Diffie-Hellman) requires less CPU time to execute but is less secure than Group 2 or 5.
2	Group 2 (1024-bit)	
5	Group 5 (1536-bit)	
14	Group 14	
19	Group 19	
20	Group 20	
21	Group 21	
24	Group 24	

Integrity Hash—Choose the hash algorithm that ensures data integrity for the ESP protocol. It ensures that a packet comes from whom you think it comes from, and that it has not been modified in transit.

sha md5	SHA 1 MD5	The default is SHA 1. MD5 has a smaller digest and is considered to be slightly faster than SHA 1. A successful (but extremely difficult) attack against MD5 has occurred; however, the HMAC variant IKE uses prevents this attack.
sha256	SHA 2, 256-bit digest	Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
sha384	**SHA 2, 384-bit digest**	Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
sha512	**SHA 2, 512-bit digest**	Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.
null		Indicates that AES-GCM or AES-GMAC is configured as the encryption algorithm. You must choose the null integrity algorithm if AES-GCM has been configured as the encryption algorithm.

Pseudo-Random Function (PRF)—Specify the PRF used for the construction of keying material for all of the cryptographic algorithms used in the SA..

sha md5	SHA-1 MD5	The default is SHA-1. MD5 has a smaller digest and is considered to be slightly faster than SHA-1. A successful (but extremely difficult) attack against MD5 has occurred; however, the HMAC variant IKE uses prevents this attack.
sha256	SHA 2, 256-bit digest	Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
sha384	**SHA 2, 384-bit digest**	Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
sha512	**SHA 2, 512-bit digest**	Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

Lifetime (secs)—Either check *Unlimited* or enter an integer for the SA lifetime. The default is 86,400 seconds or 24 hours. With longer lifetimes, the ASA sets up future IPsec security associations more quickly. Encryption strength is great enough to ensure security without using very fast rekey times, on the order of every few minutes. We recommend that you accept the default.

Time Measure—Choose a time measure. The ASA accepts the following values:.

120 - 86,400 seconds

2 - 1440 minutes

1 - 24 hours

1 day

Assignment Policy

IP addresses make internetwork connections possible. They are like telephone numbers: both the sender and receiver must have an assigned number to connect. But with VPNs, there are actually two sets of addresses: the first set connects client and server on the public network; and once that connection is made, the second set connects client and server through the VPN tunnel.

In ASA address management, we are dealing with the second set of IP addresses: those private IP addresses that connect a client with a resource on the private network, through the tunnel, and let the client function as if it were directly connected to the private network. Furthermore, we are dealing only with the private IP addresses that get assigned to- clients. The IP addresses assigned to other resources on your private network are part of your network administration responsibilities, not part of ASA management.

Therefore, when we discuss IP addresses here, we mean those IP addresses available in your private network addressing scheme, that let the client function as a tunnel endpoint.

The Assignment Policy pane lets you choose a way to assign IP addresses to remote access clients.

Fields

- Use authentication server—Choose to assign IP addresses retrieved from an authentication server on a per-user basis. If you are using an authentication server (external or internal) that has IP addresses configured, we recommend using this method. Configure AAA servers in the Configuration > AAA Setup pane.
- Use DHCP— Choose to obtain IP addresses from a DHCP server. If you use DHCP, configure the server in the Configuration > DHCP Server pane.
- Use internal address pools—Choose to have the ASA assign IP addresses from an internally configured pool. Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, configure the IP address pools in Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Address Pools pane.
  - Allow the reuse of an IP address __ minutes after it is released—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, this is unchecked, meaning the ASA does not impose a delay. If you want one, check the box and enter the number of minutes in the range 1 - 480 to delay IP address reassignment.

Configuring IPsec

The ASA uses IPsec for LAN-to-LAN VPN connections, and provides the option of using IPsec for client-to-LAN VPN connections. In IPsec terminology, a “peer” is a remote-access client or another secure gateway.

Note The ASA supports LAN-to-LAN IPsec connections with Cisco peers (IPv4 or IPv6), and with third-party peers that comply with all relevant standards.

During tunnel establishment, the two peers negotiate security associations that govern authentication, encryption, encapsulation, and key management. These negotiations involve two phases: first, to establish the tunnel (the IKE SA); and second, to govern traffic within the tunnel (the IPsec SA).

A LAN-to-LAN VPN connects networks in different geographic locations. In IPsec LAN-to-LAN connections, the ASA can function as initiator or responder. In IPsec client-to-LAN connections, the ASA functions only as responder. Initiators propose SAs; responders accept, reject, or make counter-proposals—all in accordance with configured SA parameters. To establish a connection, both entities must agree on the SAs.

The ASA supports these IPsec attributes:

- Main mode for negotiating phase one ISAKMP security associations when using digital certificates for authentication
- Aggressive mode for negotiating phase one ISAKMP Security Associations (SAs) when using preshared keys for authentication
- Authentication Algorithms:
  - ESP-MD5-HMAC-128
  - ESP-SHA1-HMAC-160
- Authentication Modes:
  - Preshared Keys
  - X.509 Digital Certificates
- Diffie-Hellman Groups 1, 2, and 5.
- Encryption Algorithms:
  - AES-128, -192, and -256
  - 3DES-168
  - DES-56
  - ESP-NULL
- Extended Authentication (XAuth)
- Mode Configuration (also known as ISAKMP Configuration Method)
- Tunnel Encapsulation Mode
- IP compression (IPCOMP) using LZS

Adding Crypto Maps

Configuration > VPN > IPSec > IPSec Rules

This pane shows the currently configured crypto maps, including the IPsec rules. Use it to add, edit, delete and move up, move down, cut, copy, and paste an IPsec rule.

Fields

Note You cannot edit, delete, or copy an implicit rule. The ASA implicitly accepts the traffic selection proposal from remote clients when configured with a dynamic tunnel policy. You can override it by giving a specific traffic selection.

- Add—Click to launch the Create IPsec Rule dialog box, where you can configure basic, advanced, and traffic selection parameters for a rule.
- Edit—Click to edit an existing rule.
- Delete—Click to delete a rule highlighted in the table.
- Cut—Deletes a highlighted rule in the table and keeps it in the clipboard for copying.
- Copy—Copies a highlighted rule in the table.
- Find—Click to enable the Find toolbar where you can specify the parameters of existing rules that you want to find:
  - Filter—Filter the find results by selecting Interface, Source, Destination, Destination Service, or Rule Query, selecting is or contains, and entering the filter parameter. Click ... to launch a browse dialog box that displays all existing entries that you can choose.
- Diagram—Displays a diagram that illustrates the highlighted IPsec rule.
- Type: Priority—Displays the type of rule (static or dynamic) and its priority.
- Traffic Selection
  - #—Indicates the rule number.
  - Source—Indicates the IP addresses that are subject to this rule when traffic is sent to the IP addresses listed in the Remote Side Host/Network column. In detail mode (see the Show Detail button), an address column might contain an interface name with the word any, such as inside:any. any means that any host on the inside interface is affected by the rule.
  - Destination—Lists the IP addresses that are subject to this rule when traffic is sent from the IP addresses listed in the Security Appliance Side Host/Network column. In detail mode (see the Show Detail button), an address column might contain an interface name with the word any, such as outside:any. any means that any host on the outside interface is affected by the rule. Also in detail mode, an address column might contain IP addresses in square brackets, for example, [209.165.201.1-209.165.201.30]. These addresses are translated addresses. When an inside host makes a connection to an outside host, the ASA maps the inside host's address to an address from the pool. After a host creates an outbound connection, the ASA maintains this address mapping. This address mapping structure is called an xlate, and remains in memory for a period of time.
  - Service—Specifies the service and protocol specified by the rule (TCP, UDP, ICMP, or IP).
  - Action—Specifies the type of IPsec rule (protect or do not protect).
- Transform Set—Displays the transform set for the rule.
- Peer—Identifies the IPsec peer.
- PFS—Displays perfect forward secrecy settings for the rule.
- NAT-T Enabled—Indicates whether NAT Traversal is enabled for the policy.

- Reverse Route Enabled—Indicates whether Reverse Route Injection is enabled for the policy.
- Connection Type—(Meaningful only for static tunnel policies.) Identifies the connection type for this policy as bidirectional, originate-only, or answer-only).
- SA Lifetime—Displays the SA lifetime for the rule.
- CA Certificate—Displays the CA certificate for the policy. This applies to static connections only.
- IKE Negotiation Mode—Displays whether IKE negotiations use main or aggressive mode.
- Description—(Optional) Specifies a brief description for this rule. For an existing rule, this is the description you typed when you added the rule. An implicit rule includes the following description: "Implicit rule." To edit the description of any but an implicit rule, right-click this column, and choose Edit Description or double-click the column.
- Enable Anti-replay window size—Sets the anti-replay window size, between 64 and 1028 in multiples of 64. One side-effect of priority queueing in a hierarchical QoS policy with traffic shaping (see the "Rule Actions > QoS Tab") is packet re-ordering. For IPsec packets, out-of-order packets that are not within the anti-replay window generate warning syslog messages. These warnings becomes false alarms in the case of priority queueing. Configuring the anti-replay pane size helps you avoid possible false alarms.

Creating an IPsec Rule/Tunnel Policy (Crypto Map) - Basic Tab

Configuration > VPN > IPSec > IPSec Rules > Add/Edit Rule > Tunnel Policy (Crypto Map) - Basic Tab

Use this pane to define a new Tunnel Policy for an IPsec rule. The values you define here appear in the IPsec Rules table after you click OK. All rules are enabled by default as soon as they appear in the IPsec Rules table.

The Tunnel Policy pane lets you define a tunnel policy that is used to negotiate an IPsec (Phase 2) security association (SA). ASDM captures your configuration edits, but does not save them to the running configuration until you click Apply.

Every tunnel policy must specify a transform set and identify the security appliance interface to which it applies. The transform set identifies the encryption and hash algorithms that perform IPsec encryption and decryption operations. Because not every IPsec peer supports the same algorithms, you might want to specify a number of policies and assign a priority to each. The security appliance then negotiates with the remote IPsec peer to agree on a transform set that both peers support.

Tunnel policies can be *static* or *dynamic*. A static tunnel policy identifies one or more remote IPsec peers or subnetworks to which your security appliance permits IPsec connections. A static policy can be used whether your security appliance initiates the connection or receives a connection request from a remote host. A static policy requires you to enter the information necessary to identify permitted hosts or networks.

A dynamic tunnel policy is used when you cannot or do not want to provide information about remote hosts that are permitted to initiate a connection with the security appliance. If you are only using your security appliance as a VPN client in relation to a remote VPN central-site device, you do not need to configure any dynamic tunnel policies. Dynamic tunnel policies are most useful for allowing remote access clients to initiate a connection to your network through a security appliance acting as the VPN central-site device. A dynamic tunnel policy is useful when the remote access clients have dynamically assigned IP addresses or when you do not want to configure separate policies for a large number of remote access clients.

Fields

- Interface—Choose the interface name to which this policy applies.

- Policy Type—Choose the type, static or dynamic, of this tunnel policy.
- Priority—Enter the priority of the policy.
- IKE Proposals (Transform Sets)--Specifies IKEv1 and IKEv2 IPsec proposals:
  - IKEv1 IPsec Proposal—Choose the proposal (transform set) for the policy and click Add to move it to the list of active transform sets. Click Move Up or Move Down to rearrange the order of the proposals in the list box. You can add a maximum of 11 proposals to a crypto map entry or a dynamic crypto map entry.
  - IKEv2 IPsec Proposal—Choose the proposal (transform set) for the policy and click Add to move it to the list of active transform sets. Click Move Up or Move Down to rearrange the order of the proposals in the list box. You can add a maximum of 11 proposals to a crypto map entry or a dynamic crypto map entry.
- Peer Settings - Optional for Dynamic Crypto Map Entries—Configure the peer settings for the policy.
  - Connection Type—(Meaningful only for static tunnel policies.) Choose bidirectional, originate-only, or answer-only to specify the connection type of this policy. For LAN-to-LAN connections, choose bidirectional or answer-only (not originate-only). Choose answer-only for LAN-to-LAN redundancy. If you choose Originate Only, you can specify up to 10 redundant peers. For uni-directional, you can specify originate only or answer only, and neither are enabled by default.
  - IP Address of Peer to Be Added—Enter the IP address of the IPsec peer you are adding.
- Enable Perfect Forwarding Secrecy—Check to enable perfect forward secrecy for the policy. PFS is a cryptographic concept where each new key is unrelated to any previous key. In IPsec negotiations, Phase 2 keys are based on Phase 1 keys unless you specify Perfect Forward Secrecy.
- Diffie-Hellman Group—When you enable PFS you must also choose a Diffie-Hellman group which the ASA uses to generate session keys. The choices are as follows:
  - Group 1 (768-bits) = Use perfect forward secrecy, and use Diffie-Hellman Group 1 to generate IPsec session keys, where the prime and generator numbers are 768 bits. This option is more secure but requires more processing overhead.
  - Group 2 (1024-bits) = Use perfect forward secrecy, and use Diffie-Hellman Group 2 to generate IPsec session keys, where the prime and generator numbers are 1024 bits. This option is more secure than Group 1 but requires more processing overhead.
  - Group 5 (1536-bits) = Use perfect forward secrecy, and use Diffie-Hellman Group 5 to generate IPsec session keys, where the prime and generator numbers are 1536 bits. This option is more secure than Group 2 but requires more processing overhead.
  - Group 14= Use perfect forward secrecy and use Diffie-Hellman Group 14 for IKEv2.
  - Group 19= Use perfect forward secrecy and use Diffie-Hellman Group 19 for IKEv2 to support ECDH.
  - Group 20= Use perfect forward secrecy and use Diffie-Hellman Group 20 for IKEv2 to support ECDH.
  - Group 21= Use perfect forward secrecy and use Diffie-Hellman Group 21 for IKEv2 to support ECDH.
  - Group 24= Use perfect forward secrecy and use Diffie-Hellman Group 24 for IKEv2.

Creating IPsec Rule/Tunnel Policy (Crypto Map) - Advanced Tab

Configuration > VPN > IPSec > IPSec Rules > Add/Edit Rule > Tunnel Policy (Crypto Map) - Advanced Tab

Fields

- Enable NAT-T— Enables NAT Traversal (NAT-T) for this policy.
- Enable Reverse Route Injection—Enables Reverse Route Injection for this policy.
  Reverse Route Injection (RRI) is used to populate the routing table of an internal router that runs dynamic routing protocols such as Open Shortest Path First (OSPF), or Enhanced Interior Gateway Routing Protocol (EIGRP), if you run ASA, or Routing Information Protocol (RIP) for remote VPN Clients or LAN to LAN sessions.
- Security Association Lifetime Settings—Configures the duration of a Security Association (SA). This parameter specifies how to measure the lifetime of the IPsec SA keys, which is how long the IPsec SA lasts until it expires and must be renegotiated with new keys.
  - Time—Specifies the SA lifetime in terms of hours (hh), minutes (mm) and seconds (ss).
  - Traffic Volume—Defines the SA lifetime in terms of kilobytes of traffic. Enter the number of kilobytes of payload data after which the IPsec SA expires. Minimum is 100 KB, default is 10000 KB, maximum is 2147483647 KB.
- Static Type Only Settings—Specifies parameters for static tunnel policies.
  - Device Certificate—Choose the certificate to use. If you choose something other than None (Use Preshared Keys), which is the default. The Send CA certificate chain check box becomes active when you select something other than None.
  - Send CA certificate chain—Enables transmission of the entire trust point chain.
  - IKE Negotiation Mode—Chooses the IKE negotiation mode, Main or Aggressive. This parameter sets the mode for exchanging key information and setting up the SAs. It sets the mode that the initiator of the negotiation uses; the responder auto-negotiates. Aggressive Mode is faster, using fewer packets and fewer exchanges, but it does not protect the identity of the communicating parties. Main Mode is slower, using more packets and more exchanges, but it protects the identities of the communicating parties. This mode is more secure and it is the default selection. If you choose Aggressive, the Diffie-Hellman Group list becomes active.
  - Diffie-Hellman Group—Choose the Diffie-Hellman group to apply. The choices are as follows: Group 1 (768-bits), Group 2 (1024-bits), or Group 5 (1536-bits).
- ESP v3—Specify whether incoming ICMP error messages are validated for cryptography and dynamic cryptography maps, set the per-security association policy, or enable traffic flow packets:
  - Validate incoming ICMP error messages—Choose whether to validate those ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.
  - Enable Do Not Fragment (DF) policy—Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header. Choose one of the following:

    Clear DF bit—Ignores the DF bit.

    Copy DF bit—Maintains the DF bit.

    Set DF bit—Sets and uses the DF bit.
  - Enable Traffic Flow Confidentiality (TFC) packets—Enable dummy TFC packets that mask the traffic profile which traverses the tunnel.

Note You must have an IKE v2 IPsec proposal set on the Tunnel Policy (Crypto Map) Basic tab before enabling TFC.

Use the Burst, Payload Size, and Timeout parameters to generate random length packets at random intervals across the specified SA.

Creating IPsec Rule/Traffic Selection Tab

Configuration > VPN > IPSec > IPSec Rules > Add/Edit Rule > Tunnel Policy (Crypto Map) - Traffic Selection Tab

This pane lets you define what traffic to protect (permit) or not protect (deny).

Fields

- Action—Specify the action for this rule to take. The selections are protect and do not protect.
- Source—Specify the IP address, network object group or interface IP address for the source host or network. A rule cannot use the same address as both the source and destination. Click ... to launch the Browse Source dialog box that contains the following fields:
  - Add/Edit—Choose IP Address or Network Object Group to add more source addresses or groups.
  - Delete—Click to delete an entry.
  - Filter—Enter an IP Address to filter the results displayed.
  - Name—Indicates that the parameters that follow specify the name of the source host or network.
  - IP Address—Indicates that the parameters that follow specify the interface, IP address, and subnet mask of the source host or network.
  - Netmask—Chooses a standard subnet mask to apply to the IP address. This parameter appears when you choose the IP Address option button.
  - Description—Enter a description.
  - Selected Source—Click **Source** to include the selected entry as a source.
- Destination—Specify the IP address, network object group or interface IP address for the destination host or network. A rule cannot use the same address as both the source and destination. Click ... to launch the Browse Destination dialog box that contains the following fields:
  - Add/Edit—Choose IP Address or Network Object Group to add more destination addresses or groups.
  - Delete—Click to delete an entry.
  - Filter—Enter an IP Address to filter the results displayed.
  - Name—Indicates that the parameters that follow specify the name of the destination host or network.
  - IP Address—Indicates that the parameters that follow specify the interface, IP address, and subnet mask of the destination host or network.
  - Netmask—Chooses a standard subnet mask to apply to the IP address. This parameter appears when you choose the IP Address option button.
  - Description—Enter a description.
  - Selected Destination—Click **Destination** to include the selected entry as a destination.

- Service—Enter a service or click ... to launch the browse service dialog box where you can choose from a list of services.
- Description—Enter a description for the Traffic Selection entry.
- More Options
  - Enable Rule—Click to enable this rule.
  - Source Service—Enter a service or click **...** to launch the browse service dialog box where you can choose from a list of services.
  - Time Range—Define a time range for which this rule applies.
  - Group—Indicates that the parameters that follow specify the interface and group name of the source host or network.
  - Interface—Choose the interface name for the IP address. This parameter appears when you choose the IP Address option button.
  - IP address—Specifies the IP address of the interface to which this policy applies. This parameter appears when you choose the IP Address option button.
  - Destination—Specify the IP address, network object group or interface IP address for the source or destination host or network. A rule cannot use the same address as both the source and destination. Click ... for either of these fields to launch the Browse dialog box that contain the following fields:
  - Name—Choose the interface name to use as the source or destination host or network. This parameter appears when you choose the Name option button. This is the only parameter associated with this option.
  - Interface—Choose the interface name for the IP address. This parameter appears when you choose the Group option button.
  - Group—Choose the name of the group on the specified interface for the source or destination host or network. If the list contains no entries, you can enter the name of an existing group. This parameter appears when you choose the Group option button.
- **Protocol and Service**—Specifies protocol and service parameters relevant to this rule.

Note "Any - any" IPsec rules are not allowed. This type of rule would prevent the device and its peer from supporting multiple LAN -to-LAN tunnels.

  - **TCP**—Specifies that this rule applies to TCP connections. This selection also displays the **Source Port** and **Destination Port** group boxes.
  - **UDP**—Specifies that this rule applies to UDP connections. This selection also displays the **Source Port** and **Destination Port** group boxes.
  - **ICMP**—Specifies that this rule applies to ICMP connections. This selection also displays the **ICMP Type** group box.
  - **IP**—Specifies that this rule applies to IP connections. This selection also displays the **IP Protocol** group box.
  - **Manage Service Groups**—Displays the Manage Service Groups pane, on which you can add, edit, or delete a group of TCP/UDP services/ports.
  - **Source Port** and **Destination Port** —Contains TCP or UDP port parameters, depending on which option button you chose in the Protocol and Service group box.

  - **Service**—Indicates that you are specifying parameters for an individual service. Specifies the name of the service and a boolean operator to use when applying the filter.
  - **Boolean operator** (unlabeled)—Lists the boolean conditions (equal, not equal, greater than, less than, or range) to use in matching the service specified in the service box.
  - **Service** (unlabeled)—Identifies the service (such as https, kerberos, or any) to be matched. If you specified the range service operator this parameter becomes two boxes, into which you enter the start and the end of the range.
  - **...** —Displays a list of services from which you can choose the service to display in the Service box.
  - **Service Group**—Indicates that you are specifying the name of a service group for the source port.
  - **Service** (unlabeled)—Choose the service group to use.
  - **ICMP Type**—Specifies the ICMP type to use. The default is any. Click the **...** button to display a list of available types.
- **Options**
  - **Time Range**—Specify the name of an existing time range or create a new range.
  - **...** —Displays the Add Time Range pane, on which you can define a new time range.
  - **Please enter the description below (optional)**—Provides space for you to enter a brief description of the rule.

Pre-Fragmentation

Configuration > VPN > IPSec > Pre-Fragmentation

Use this pane to set the IPsec pre-fragmentation policy and do-not-fragment (DF) bit policy for any interface.

The IPsec pre-fragmentation policy specifies how to treat packets that exceed the maximum transmission unit (MTU) setting when tunneling traffic through the public interface. This feature provides a way to handle cases where a router or NAT device between the ASA and the client rejects or drops IP fragments. For example, suppose a client wants to FTP get from an FTP server behind a ASA. The FTP server transmits packets that when encapsulated would exceed the ASA's MTU size on the public interface. The selected options determine how the ASA processes these packets. The pre-fragmentation policy applies to all traffic travelling out the ASA public interface.

The ASA encapsulates all tunneled packets. After encapsulation, the ASA fragments packets that exceed the MTU setting before transmitting them through the public interface. This is the default policy. This option works for situations where fragmented packets are allowed through the tunnel without hindrance. For the FTP example, large packets are encapsulated and then fragmented at the IP layer. Intermediate devices may drop fragments or just out-of-order fragments. Load-balancing devices can introduce out-of-order fragments.

When you enable pre-fragmentation, the ASA fragments tunneled packets that exceed the MTU setting before encapsulating them. If the DF bit on these packets is set, the ASA clears the DF bit, fragments the packets, and then encapsulates them. This action creates two independent non-fragmented IP packets leaving the public interface and successfully transmits these packets to the peer site by turning the fragments into complete packets to be reassembled at the peer site. In our example, the ASA overrides the MTU and allows fragmentation by clearing the DF bit.

Note Changing the MTU or the pre-fragmentation option on *any* interface tears down *all* existing connections. For example, if 100 active tunnels terminate on the public interface, and you change the MTU or the pre-fragmentation option on the external interface, all of the active tunnels on the public interface are dropped.

Fields

- **Pre-Fragmentation**—Shows the current pre-fragmentation configuration for every configured interface.
  - **Interface**—Shows the name of each configured interface.
  - **Pre-Fragmentation Enabled**—Shows, for each interface, whether pre-fragmentation is enabled.
  - **DF Bit Policy**—Shows the DF Bit Policy for each interface.
- **Edit**—Displays the Edit IPsec Pre-Fragmentation Policy dialog box.

Edit IPsec Pre-Fragmentation Policy

Configuration > VPN > IPSec > Pre-Fragmentation > Edit IPSec Pre-Fragmentation Policy

Use this pane to modify an existing IPsec pre-fragmentation policy and do-not-fragment (DF) bit policy for an interface selected on the parent pane, **Configuration > VPN > IPsec > Pre-Fragmentation**

Fields

- **Interface**—Identifies the chosen interface. You cannot change this parameter using this dialog box.
- **Enable IPsec pre-fragmentation**—Enables or disables IPsec pre-fragmentation. The ASA fragments tunneled packets that exceed the MTU setting before encapsulating them. If the DF bit on these packets is set, the ASA clears the DF bit, fragments the packets, and then encapsulates them. This action creates two independent, non-fragmented IP packets leaving the public interface and successfully transmits these packets to the peer site by turning the fragments into complete packets to be reassembled at the peer site.
- **DF Bit Setting Policy**—Choose the do-not-fragment bit policy: Copy, Clear, or Set.

IPsec Transform Sets

Configuration > VPN > IPSec > Transform Sets

Use this pane to view and add or edit transform sets. A transform is a set of operations done on a data flow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with 3DES encryption and the HMAC-MD5 authentication algorithm (ESP-3DES-MD5).

Fields

- **IKEv1 IPsec Proposals (Transform Sets)**—Shows the configured transform sets.
  - **Name**—Shows the name of the transform sets.

  - **Mode**—Shows the mode, Tunnel, of the transform set. This parameter specifies the mode for applying ESP encryption and authentication; in other words, what part of the original IP packet has ESP applied. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), thus hiding the ultimate source and destination addresses.
  - **ESP Encryption**—Shows the Encapsulating Security Protocol (ESP) encryption algorithms for the transform sets. ESP provides data privacy services, optional data authentication, and anti-replay services. ESP *encapsulates* the data being protected.
  - **ESP Authentication**—Shows the ESP authentication algorithms for the transform sets.
- **Add**—Opens the Add Transform Set dialog box, in which you can add a new transform set.
- **Edit**—Opens the Edit Transform Set dialog box, in which you can modify an existing transform set.
- **Delete**—Removes the selected transform set. There is no confirmation or undo.
- **IKEv2 IPsec Proposals**—Shows the configured transform sets.
  - **Name**—Shows the name of the **IKEv2 IPsec Proposal**.
  - **Encryption**—Shows the Encapsulating Security Protocol (ESP) encryption algorithms for the **IKEv2 IPsec Proposal**. ESP provides data privacy services, optional data authentication, and anti-replay services. ESP *encapsulates* the data being protected.
  - **Integrity Hash**—Shows the hash algorithm that ensures data integrity for the ESP protocol. It ensures that a packet comes from whom you would expect and that no modifications were made in transit. It ensures that a packet comes from who you would expect and that no modifications were made in transit. You must choose the null integrity algorithm if AES-GCM/GMAC has been configured as the encryption algorithm.
- **Add**—Opens the Add IPsec Proposal dialog box, in which you can add a new proposal.
- **Edit**—Opens the Edit IPsec Proposal dialog box, in which you can modify an existing proposal.
- **Delete**—Removes the selected proposal. There is no confirmation or undo.

Add/Edit IPsec Proposal (Transform Set)

(Configuration > VPN > IPSec > Transform Sets > Add/Edit IPsec_Proposal_(Transform Set)

Use this pane to add or modify an IPsec IKEv1 transform set. A transform is a set of operations done on a data flow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with 3DES encryption and the HMAC-MD5 authentication algorithm (ESP-3DES-MD5).

Fields

- **Set Name**—Specifies a name for this transform set.
- **Properties**—Configures properties for this transform set. These properties appear in the Transform Sets table.
  - **Mode**—Shows the mode, Tunnel, of the transform set. This field shows the mode for applying ESP encryption and authentication; in other words, what part of the original IP packet has ESP applied. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), thus hiding the ultimate source and destination addresses.
  - **ESP Encryption**—Choose the Encapsulating Security Protocol (ESP) encryption algorithms for the transform sets. ESP provides data privacy services, optional data authentication, and anti-replay services. ESP *encapsulates* the data being protected.
  - **ESP Authentication**—Choose the ESP authentication algorithms for the transform sets.

Note The IPsec ESP (Encapsulating Security Payload) protocol provides both encryption and authentication. Packet authentication proves that data comes from whom you think it comes from; it is often referred to as "data integrity."

Add/Edit IPsec Proposal

Configuration > VPN > IPSec > Transform Sets > Add/Edit IPsec_Proposal

Use this pane to add or modify an IPsec IKEv2 proposal. A proposal is a set of operations done on a data flow to provide data authentication, data confidentiality, and data compression. For example, one proposal is the ESP protocol with 3DES encryption and the HMAC-MD5 authentication algorithm (ESP-3DES-MD5).

Fields

- **Name**—Specifies a name for this proposal.
- **Encryption**—Choose the Encapsulating Security Protocol (ESP) encryption algorithms for the proposal. ESP provides data privacy services, optional data authentication, and anti-replay services. ESP *encapsulates* the data being protected.
- **Integrity Hash**—Choose the ESP authentication algorithms for the proposal. The hash algorithm ensures data integrity for the ESP protocol. It ensures that a packet comes from whom you think it comes from, and that it has not been modified in transit.

Note The IPsec ESP (Encapsulating Security Payload) protocol provides both encryption and authentication. Packet authentication proves that data comes from whom you think it comes from; it is often referred to as "data integrity."

Configuring Load Balancing

If you have a remote-client configuration in which you are using two or more ASAs connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature is called *load balancing*. Load balancing directs session traffic to the least loaded device, thus distributing the load among all devices. It makes efficient use of system resources and provides increased performance anodize availability.

The following sections explain load balancing:

- Creating Virtual Clusters
- Geographical Load Balancing
- Mixed Cluster Scenarios
- Comparing Load Balancing to Failover
- Load Balancing Licensing Requirements
- Load Balancing Prerequisites
- Eligible Clients

- Configuring VPN Cluster Load Balancing with the High Availability and Scalability Wizard
- Configuring Load Balancing (Without the Wizard)

Creating Virtual Clusters

To implement load balancing, you group together logically two or more devices on the same private LAN-to-LAN network into a *virtual cluster*.

All devices in the virtual cluster carry session loads. One device in the virtual cluster, the *virtual cluster master*, directs incoming connection requests to the other devices, called *backup devices*. The virtual cluster master monitors all devices in the cluster, keeps track of how busy each is, and distributes the session load accordingly. The role of virtual cluster master is not tied to a physical device; it can shift among devices. For example, if the current virtual cluster master fails, one of the backup devices in the cluster takes over that role and immediately becomes the new virtual cluster master.

The virtual cluster appears to outside clients as a single *virtual cluster IP address*. This IP address is not tied to a specific physical device. It belongs to the current virtual cluster master; hence, it is virtual. A VPN client attempting to establish a connection connects first to this virtual cluster IP address. The virtual cluster master then sends back to the client the public IP address of the least-loaded available host in the cluster. In a second transaction (transparent to the user) the client connects directly to that host. In this way, the virtual cluster master directs traffic evenly and efficiently across resources.

Note All clients other than the Cisco VPN client, the Cisco VPN 3002 Hardware Client, or the ASA 5505 operating as an Easy VPN Client connect directly to the ASA as usual; they do not use the virtual cluster IP address.

If a machine in the cluster fails, the terminated sessions can immediately reconnect to the virtual cluster IP address. The virtual cluster master then directs these connections to another active device in the cluster. Should the virtual cluster master itself fail, a backup device in the cluster immediately and automatically takes over as the new virtual session master. Even if several devices in the cluster fail, users can continue to connect to the cluster as long as any one device in the cluster is up and available

A load-balancing cluster can consist of ASAs of the same release, of mixed releases, as well as VPN 3000 concentrators, or a mixture of these, subject to the following restrictions:

- Load-balancing clusters that consist of both same release ASAs and VPN 3000 concentrators can run load balancing for a mixture of IPsec, AnyConnect, and clientless SSL VPN client and clientless sessions.
- Load-balancing clusters that include mixed release ASAs or same release ASAs and VPN 3000 concentrators or both can support only IPsec sessions. In such a configuration, however, the ASAs might not reach their full IPsec capacity. "Scenario 1: Mixed Cluster with No SSL VPN Connections" on page 22, illustrates this situation.

Since Release 7.1(1), IPsec and SSL VPN sessions count or weigh equally in determining the load that each device in the cluster carries. This represents a departure from the load balancing calculation for the ASA Release 7.0(x) software and the VPN 3000 concentrator, in that these platforms both use a weighting algorithm that, on some hardware platforms, calculates SSL VPN session load differently from IPsec session load.

The virtual master of the cluster assigns session requests to the members of the cluster. The ASA regards all sessions, SSL VPN or IPsec, as equal and assigns them accordingly. You can configure the number of IPsec and SSL VPN sessions to allow, up to the maximum allowed by your configuration and license.

We have tested up to ten nodes in a load-balancing cluster. Larger clusters might work, but we do not officially support such topologies.

Geographical Load Balancing

In a load balancing environment where the DNS resolutions are being changed at regular intervals, you must carefully consider how to set the time to live (TTL) value. For the DNS load balance configuration to work successfully with AnyConnect, the ASA name to address mapping must remain the same from the time the ASA is selected until the tunnel is fully established. If too much time passes before the credentials are entered, the lookup restarts and a different IP address may become the resolved address. If the DNS mapping changes to a different ASA before the credentials are entered, the VPN tunnel fails.

Geographical load balancing for VPN often uses a Cisco Global Site Selector (GSS). The GSS uses DNS for the load balancing, and the time to live (TTL) value for DNS resolution is defaulted to 20 seconds. You can significantly decrease the likelihood of connection failures if you increase the TTL value on the GSS. Increasing to a much higher value allows ample time for the authentication phase when the user is entering credentials and establishing the tunnel.

To increase the time for entering credentials, you may also consider disabling Connect on Start Up.

Note Using a Cisco System VPN client, the geographical load balancing is not impacted, and the 20 second default setting is acceptable.

Mixed Cluster Scenarios

If you have a mixed configuration—that is, if your load-balancing cluster includes devices running a mixture of ASA software releases or at least one ASA running ASA Release 7.1(1) or later and a VPN 3000 concentrator—the difference in weighting algorithms becomes an issue if the initial cluster master fails and another device takes over as master.

The following scenarios illustrate the use of VPN load balancing in clusters consisting of a mixture of ASAs running ASA Release 7.1(1) and ASA Release 7.0(x) software, as well as VPN 3000 Series Concentrators.

Scenario 1: Mixed Cluster with No SSL VPN Connections

In this scenario, the cluster consists of a mixture of ASAs and VPN 3000 Concentrators. Some of the ASA cluster peers are running ASA Release 7.0(x), and some are running Release 7.1(1). The pre-7.1(1) and VPN 3000 peers do not have any SSL VPN connections, and the 7.1(1) cluster peers have only the base SSL VPN license, which allows two SSL VPN sessions, but there are no SSL VPN connections. In this case, all the connections are IPsec, and load balancing works fine.

The two SSL VPN licenses have a very small effect on the user's taking advantage of the maximum IPsec session limit, and then only when a VPN 3000 Concentrator is the cluster master. In general, the smaller the number of SSL VPN licenses is on a ASA in a mixed cluster, the smaller the effect on the ASA 7.1(1) device being able to reach its IPsec session limit in a scenario where there are only IPsec sessions.

Scenario 2: Mixed Cluster Handling SSL VPN Connections

Suppose, for example, a ASA running ASA Release 7.1(1) software is the initial cluster master; then that device fails. Another device in the cluster takes over automatically as master and applies its own load-balancing algorithm to determine processor loads within the cluster. A cluster master running ASA Release 7.1(1) software cannot weight session loads in any way other than what that software provides.

Therefore, it cannot assign a combination of IPsec and SSL VPN session loads properly to ASA devices running earlier versions nor to VPN 3000 Concentrators. Conversely, a VPN 3000 Concentrator acting as the cluster master cannot assign loads properly to an ASA Release 7.1(1) ASA. The following scenario illustrates this dilemma.

This scenario is similar to the previous one, in that the cluster consists of a mixture of ASAs and VPN 3000 Concentrators. Some of the ASA cluster peers are running ASA Release 7.0,(x) and some are running Release 7.1(1). In this case, however, the cluster is handling SSL VPN connections as well as IPsec connections.

If a device that is running software earlier than ASA Release 7.1(1) is the cluster master, the master applies the protocol and logic in effect prior to Release 7.1(1). That is, sessions might be directed to load-balancing peers that have exceeded their session limit. In that case, the user is denied access.

If the cluster master is a device running ASA Release 7.0(x) software, the old session-weighting algorithm applies only to the pre-7.1(1) peers in the cluster. No one should be denied access in this case. Because the pre-7.1(1) peers use the session-weighting algorithm, they are more lightly loaded.

An issue arises, however, because you cannot guarantee that the 7.1(1) peer is always the cluster master. If the cluster master fails, another peer assumes the role of master. The new master might be any of the eligible peers. Because of the innately unpredictability of the results, we recommend that you avoid configuring this type of cluster.

Comparing Load Balancing to Failover

Both load balancing and failover are high-availability features, but they function differently and have different requirements. In some circumstances you can use both load balancing and failover. The following sections describe the differences between these features.

Load balancing is a mechanism for equitably distributing remote-access VPN traffic among the devices in a virtual cluster. It is based on simple distribution of traffic without taking into account throughput or other factors. A load-balancing cluster consists of two or more devices, one of which is the virtual master, and the others backup. These devices do not need to be of the exact same type, or have identical software versions or configurations. All active devices in a virtual cluster carry session loads. Load balancing directs traffic to the least loaded device in the cluster, distributing the load among all devices. It makes efficient use of system resources and provides increased performance and high availability.

A *failover* configuration requires two identical ASAs connected to each other through a dedicated failover link and, optionally, a stateful failover link. The health of the active interfaces and units is monitored to determine when specific failover conditions are met. If those conditions occur, failover occurs. Failover supports both VPN and firewall configurations.

The ASA supports two failover configurations, Active/Active failover and Active/Standby failover. VPN connections run only in Active/Standby, single routed mode. Active/Active failover requires multi-context mode, so does not support VPN connections.

With Active/Active failover, both units can pass network traffic. This is not true load balancing, although it might appear to have the same effect. When failover occurs, the remaining active unit takes over passing the combined traffic, based on he configured parameters. Therefore, when configuring Active/Active failover, you must make sure that the combined traffic for both units is within the capacity of each unit.

With Active/Standby failover, only one unit passes traffic, while the other unit waits in a standby state and does not pass traffic. Active/Standby failover lets you use a second ASAto take over the functions of a failed unit. When the active unit fails, it changes to the standby state, while the standby unit changes to the active state. The unit that becomes active assumes the IP addresses (or, for transparent firewall,

the management IP address) and MAC addresses of the failed unit and begins passing traffic. The unit that is now in standby state takes over the standby IP addresses of the active unit. If an active unit fails, the standby takes over without any interruption to the client VPN tunnel.

Load Balancing Licensing Requirements

To use VPN load balancing, you must have an ASA Model 5510 with a Plus license or an ASA Model 5520 or higher. VPN load balancing also requires an active 3DES/AES license. The security appliance checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the security appliance prevents the enabling of load balancing and also prevents internal configuration of 3DES by the load balancing system unless the license permits this usage.

Eligible Clients

Load balancing is effective only on remote sessions initiated with the following clients:

- Cisco AnyConnect Secure Mobility Client (Release 2.0 and later)
- Cisco VPN Client (Release 3.0 and later)
- Cisco ASA 5505 Security Appliance (when acting as an Easy VPN client)
- Cisco VPN 3002 Hardware Client (Release 3.5 or later)
- Cisco PIX 501/506E when acting as an Easy VPN client
- IOS EZVPN Client devices supporting IKE-redirect (IOS 831/871)
- Clientless SSL VPN (not a client)

Load balancing works with IPsec clients and SSL VPN client and clientless sessions. All other VPN connection types (L2TP, PPTP, L2TP/IPsec), including LAN-to-LAN, can connect to an ASA on which load balancing is enabled, but they cannot participate in load balancing.

Load Balancing Prerequisites

- You must have first configured the ASA's public and private interfaces before configuring load balancing. To do so select **Configuration > Device Setup > Interfaces**. See Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)" or Chapter 16, "Starting Interface Configuration (ASA 5505)" for more information.
- You must have previously configured the interface to which the virtual cluster IP address refers.
- All devices that participate in a cluster must share the same cluster-specific values: IP address, encryption settings, encryption key, and port. All of the outside and inside network interfaces on the load-balancing devices in a cluster must be on the same IP network.

Configuring VPN Cluster Load Balancing with the High Availability and Scalability Wizard

If you have a remote-client configuration in which you are using two or more ASAs connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature is called load balancing, which directs session traffic to the least loaded device, thereby distributing the load among all devices. Load balancing makes efficient use of system resources and provides increased performance and system availability.

Use the VPN Cluster Load Balancing Configuration screen to set required parameters for a device to participate in a load balancing cluster.

Enabling load balancing involves the following:

- Configuring the load-balancing cluster by establishing a common virtual cluster IP address, UDP port (if necessary), and IPsec shared secret for the cluster. These values are identical for each device in the cluster.
- Configuring the participating device by enabling load balancing on the device and defining device-specific properties. These values vary from device to device.

Note Load balancing is effective only on remote sessions initiated with the Cisco VPN client (Version 3.0 and later), the Cisco VPN 3002 hardware client (Version 3.5 and later), or the ASA 5505 configured as an Easy VPN client. All other clients, including LAN-to-LAN connections, can connect to a ASA on which load balancing is enabled, but these clients cannot participate in load balancing.

To implement load balancing, you logically group together two or more devices on the same private LAN-to-LAN network into a virtual cluster by performing the following steps:

Step 1 Choose **Wizards > High Availability and Scalability**.

Step 2 In the Configuration Type screen, click **Configure VPN Cluster Load Balancing**, and click **Next**.

Step 3 Choose the single IP address that represents the entire virtual cluster. Specify an IP address that is within the public subnet address range shared by all the ASAs in the virtual cluster.

Step 4 Specify the UDP port for the virtual cluster in which this device is participating. The default value is 9023. If another application is using this port, enter the UDP destination port number that you want to use for load balancing.

Step 5 To enable IPsec encryption and ensure that all load-balancing information communicated between the devices is encrypted, check the **Enable IPsec Encryption** check box. You must also specify and verify a shared secret. The ASAs in the virtual cluster communicate via LAN-to-LAN tunnels using IPsec. To disable IPsec encryption, uncheck the **Enable IPsec Encryption** check box.

Note When using encryption, you must have previously configured the load balancing inside interface. If that interface is not enabled on the load balancing inside interface, an error message appears when you try to configure cluster encryption.

If the load balancing inside interface is enabled when you configured cluster encryption, but is disabled before you configure the participation of the device in the virtual cluster, an error message appears when you check the **Participate in Load Balancing Cluster** check box, and encryption is not enabled for the cluster.

Step 6 Specify the shared secret to between IPsec peers when you enable IPsec encryption. The value that you enter appears as consecutive asterisk characters.

Step 7 Specify the priority assigned to this device within the cluster. The range is from 1 to 10. The priority indicates the likelihood of this device becoming the virtual cluster master, either at startup or when an existing master fails. The higher the priority set (for example, 10), the more likely that this device will become the virtual cluster master.

Note If the devices in the virtual cluster are powered up at different times, the first device to be powered up assumes the role of virtual cluster master. Because every virtual cluster requires a master, each device in the virtual cluster checks when it is powered up to ensure that the cluster has a virtual master. If none exists, that device assumes the role. Devices powered up and added to the cluster later become secondary devices. If all the devices in the virtual cluster are powered up simultaneously, the device with the highest priority setting becomes the virtual cluster master. If two or more devices in the virtual cluster are powered up simultaneously, and both have the highest priority setting, the one with the lowest IP address becomes the virtual cluster master.

Step 8 Specify the name or IP address of the public interface for this device.

Step 9 Specify the name or IP address of the private interface for this device.

Step 10 Check the **Send FQDN to client instead of an IP address when redirecting** check box to have the VPN cluster master send a fully qualified domain name using the host and domain name of the cluster device instead of the outside IP address when redirecting VPN client connections to that cluster device.

Step 11 Click **Next**. Review your configuration in the Summary screen.

Step 12 Click **Finish**.

The VPN cluster load balancing configuration is sent to the ASA.

Configuring Load Balancing (Without the Wizard)

The pane Load Balancing pane (Configuration > Remote Access VPN > Load Balancing) lets you enable load balancing on the ASA. Enabling load balancing involves:

- Configuring the load-balancing cluster by establishing a common virtual cluster IP address, UDP port (if necessary), and IPsec shared secret for the cluster. These values are identical for every device in the cluster.
- Configuring the participating device by enabling load balancing on the device and defining device-specific properties. These values vary from device to device.

Step 1 Select **Configuration > Remote Access VPN > Load Balancing.**

Step 2 Check **Participate in Load Balancing** to indicate that this ASA is a participant in the load-balancing cluster

You must enable load balancing in this way on every ASA participating in load balancing.

Step 3 Configure the following fields in the **VPN Cluster Configuration** area. These values must be the same for the entire virtual cluster. All servers in the cluster must have an identical cluster configuration.

- **Cluster IPv4 Address**—Specifies the single IPv4 address that represents the entire IPv4 virtual cluster. Choose an IP address that is within the public subnet address range shared by all the ASAs in the virtual cluster.
  - **UDP Port**—Specifies the UDP port for the virtual cluster in which this device is participating. The default value is 9023. If another application is using this port, enter the UDP destination port number you want to use for load balancing.
- **Cluster IPv6 Address**—Specifies the single IPv6 address that represents the entire IPv6 virtual cluster. Choose an IP address that is within the public subnet address range shared by all the ASAs in the virtual cluster.

Note In the Cluster IPv4 Address and Cluster IPv6 Address fields, you can also specify the fully qualified domain name of the virtual cluster, provided that you have a DNS server group configured with at least one DNS server, and DNS lookup is enabled on one of the ASA's interfaces.

- **Enable IPsec Encryption**—Enables or disables IPsec encryption. If you check this box, you must also specify and verify a shared secret.The ASAs in the virtual cluster communicate via LAN-to-LAN tunnels using IPsec. To ensure that all load-balancing information communicated between the devices is encrypted, check this box.

Note When using encryption, you must have previously configured the load-balancing inside interface. If that interface is not enabled on the load-balancing inside interface, you get an error message when you try to configure cluster encryption.

If the load-balancing inside interface was enabled when you configured cluster encryption, but was disabled before you configured the participation of the device in the virtual cluster, you get an error message when you check the Participate in Load Balancing Cluster check box, and encryption is not enabled for the cluster.

- **IPsec Shared Secret**—Specifies the shared secret between IPsec peers when you have enabled IPsec encryption. The value you enter in the box appears as consecutive asterisk characters.
- **Verify Secret**—Re-enter the shared secret. Confirms the shared secret value entered in the IPsec Shared Secret box.

Step 4 Configure the fields in the **VPN Server Configuration** area for a specific ASA:

- **Public Interface**—Specifies the name or IP address of the public interface for this device.
- **Private Interface**—Specifies the name or IP address of the private interface for this device.
- **Priority**—Specifies the priority assigned to this device within the cluster. The range is from 1 to 10. The priority indicates the likelihood of this device becoming the virtual cluster master, either at start-up or when an existing master fails. The higher you set the priority (for example, 10), the more likely this device becomes the virtual cluster master.

Note If the devices in the virtual cluster are powered up at different times, the first device to be powered up assumes the role of virtual cluster master. Because every virtual cluster requires a master, each device in the virtual cluster checks when it is powered-up to ensure that the cluster has a virtual master. If none exists, that device takes on the role. Devices powered up and added to the cluster later become backup devices. If all the devices in the virtual cluster are powered up simultaneously, the device with the highest priority setting becomes the virtual cluster master. If two or more devices in the virtual cluster are powered up simultaneously, and both have the highest priority setting, the one with the lowest IP address becomes the virtual cluster master.

- **NAT Assigned IPv4 Address**—Specifies the IP address that this device's IP address is translated to by NAT. If NAT is not being used (or if the device is not behind a firewall using NAT), leave the field blank.
- **NAT Assigned IPv6 Address**—Specifies the IP address that this device's IP address is translated to by NAT. If NAT is not being used (or if the device is not behind a firewall using NAT), leave the field blank.
- **Send FQDN to client**—Check this check box to cause the VPN cluster master to send a fully qualified domain name using the host and domain name of the cluster device instead of the outside IP address when redirecting VPN client connections to that cluster device.

  By default, the ASA sends only IP addresses in load-balancing redirection to a client. If certificates are in use that are based on DNS names, the certificates will be invalid when redirected to a backup device.

  As a VPN cluster master, this ASA can send a fully qualified domain name (FQDN), using reverse DNS lookup, of a cluster device (another ASA in the cluster), instead of its outside IP address, when redirecting VPN client connections to that cluster device.

  All of the outside and inside network interfaces on the load-balancing devices in a cluster must be on the same IP network.

  Note When using IPv6 and sending FQDNS down to client, those names must be resolvable by the ASA via DNS.

Enable Clientless SSL VPN Load Balancing Using FQDNs

Step 1 Enable the use of FQDNs for Load Balancing by checking the **Send FQDN to client instead of an IP address when redirecting** checkbox.

Step 2 Add an entry for each of your ASA outside interfaces into your DNS server, if such entries are not already present. Each ASA outside IP address should have a DNS entry associated with it for lookups. These DNS entries must also be enabled for Reverse Lookup.

Step 3 Enable DNS lookups on your ASA on the dialog box **Configuration > Device Management > DNS > DNS Client** for whichever interface has a route to your DNS server.

Step 4 Define your DNS server IP address on the ASA. To do this, click Add on this dialog box. This opens the Add DNS Server Group dialog box. Enter the IPv4 or IPv6 address of the DNS server you want to add; for example, 192.168.1.1 or 2001:DB8:2000::1.

Step 5 Click OK and Apply.

Setting Global NAC Parameters

The ASA uses Extensible Authentication Protocol (EAP) over UDP (EAPoUDP) messaging to validate the posture of remote hosts. Posture validation involves checking a remote host for compliancy with safety requirements before the assignment of a network access policy. An Access Control Server must be configured for Network Admission Control before you configure NAC on the ASA.

Fields

The NAC pane lets you set attributes that apply to all NAC communications. The following global attributes at the top of the pane apply to EAPoUDP messaging between the ASA and remote hosts:

- Port—Port number for EAP over UDP communication with the Cisco Trust Agent (CTA) on the host. This number must match the port number configured on the CTA. Enter a value in the range 1024 to 65535. The default setting is 21862.
- Retry if no response—Number of times the ASA resends an EAP over UDP message. This attribute limits the number of consecutive retries sent in response to Rechallenge Interval expirations. The setting is in seconds. Enter a value in the range 1 to 3. The default setting is 3.
- Rechallenge Interval—The ASA starts this timer when it sends an EAPoUDP message to the host. A response from the host clears the timer. If the timer expires before the ASA receives a response, it resends the message. The setting is in seconds. Enter a value in the range 1 to 60. The default setting is 3.
- Wait before new PV Session—The ASA starts this timer when it places the NAC session for a remote host into a hold state. It places a session in a hold state if it does not receive a response after sending EAPoUDP messages equal to the value of the “Retry if no response” setting. The ASA also starts this timer after it receives an Access Reject message from the ACS server. When the timer expires, the ASA tries to initiate a new EAP over UDP association with the remote host. The setting is in seconds. Enter a value in the range 60 to 86400. The default setting is 180.

The Clientless Authentication area of the NAC pane lets you configure settings for hosts that are not responsive to the EAPoUDP requests. Hosts for which there is no CTA running do not respond to these requests.

- Enable clientless authentication—Click to enable clientless authentication. The ASA sends the configured clientless username and password to the Access Control Server in the form of a user authentication request. The ACS in turn requests the access policy for clientless hosts. If you leave this attribute blank, the ASA applies the default ACL for clientless hosts.
- Clientless Username—Username configured for clientless hosts on the ACS. The default setting is clientless. Enter 1 to 64 ASCII characters, excluding leading and trailing spaces, pound signs (#), question marks (?), single and double quotation marks (“ ” and "), asterisks (*), and angle brackets (< and >).
- Password—Password configured for clientless hosts on the ACS. The default setting is clientless. Enter 4 – 32 ASCII characters.
- Confirm Password—Password configured for clientless hosts on the ACS repeated for validation.
- Enable Audit—Click to pass the IP address of the client to an optional audit server if the client does not respond to a posture validation request. The audit server, such as a Trend server, uses the host IP address to challenge the host directly to assess its health. For example, it may challenge the host

to determine whether its virus checking software is active and up-to-date. After the audit server completes its interaction with the remote host, it passes a token to the posture validation server, indicating the health of the remote host.

- None—Click to disable clientless authentication and audit services.

Configuring Network Admission Control Policies

The NAC Policies table displays the Network Admission Control (NAC) policies configured on the ASA.

To add, change, or remove a NAC policy, do one of the following:

- To add a NAC policy, choose **Add**. The Add NAC Framework Policy dialog box opens.
- To change a NAC policy, double-click it, or select it and click **Edit**. The Edit NAC Framework Policy dialog box opens.
- To remove a NAC policy, select it and click **Delete**.

The following sections describe NAC, its requirements, and how to assign values to the policy attributes:

- About NAC
- Uses, Requirements, and Limitations
- Fields
- What to Do Next

About NAC

NAC protects the enterprise network from intrusion and infection from worms, viruses, and rogue applications by performing endpoint compliance and vulnerability checks as a condition for production access to the network. We refer to these checks as *posture validation.* You can configure posture validation to ensure that the anti-virus files, personal firewall rules, or intrusion protection software on a host with an AnyConnect or Clientless SSL VPN session are up-to-date before providing access to vulnerable hosts on the intranet. Posture validation can include the verification that the applications running on the remote hosts are updated with the latest patches. NAC occurs only after user authentication and the setup of the tunnel. NAC is especially useful for protecting the enterprise network from hosts that are not subject to automatic network policy enforcement, such as home PCs.

The establishment of a tunnel between the endpoint and the ASA triggers posture validation.

You can configure the ASA to pass the IP address of the client to an optional audit server if the client does not respond to a posture validation request. The audit server, such as a Trend server, uses the host IP address to challenge the host directly to assess its health. For example, it may challenge the host to determine whether its virus checking software is active and up-to-date. After the audit server completes its interaction with the remote host, it passes a token to the posture validation server, indicating the health of the remote host.

Following successful posture validation or the reception of a token indicating the remote host is healthy, the posture validation server sends a network access policy to the ASA for application to the traffic on the tunnel.

In a *NAC Framework* configuration involving the ASA, only a Cisco Trust Agent running on the client can fulfill the role of posture agent, and only a Cisco Access Control Server (ACS) can fulfill the role of posture validation server. The ACS uses dynamic ACLs to determine the access policy for each client.

As a RADIUS server, the ACS can authenticate the login credentials required to establish a tunnel, in addition to fulfilling its role as posture validation server.

Note Only a NAC Framework policy configured on the ASA supports the use of an audit server.

In its role as posture validation server, the ACS uses access control lists. If posture validation succeeds and the ACS specifies a redirect URL as part of the access policy it sends to the ASA, the ASA redirects all HTTP and HTTPS requests from the remote host to the redirect URL. Once the posture validation server uploads an access policy to the ASA, all of the associated traffic must pass both the Security Appliance and the ACS (or vice versa) to reach its destination.

The establishment of a tunnel between a remote host and the ASA triggers posture validation if a NAC Framework policy is assigned to the group policy. The NAC Framework policy can, however, identify operating systems that are exempt from posture validation and specify an optional ACL to filter such traffic.

Uses, Requirements, and Limitations

When configured to support NAC, the ASA functions as a client of a Cisco Secure Access Control Server, requiring that you install a minimum of one Access Control Server on the network to provide NAC authentication services.

Following the configuration of one or more Access Control Servers on the network, you must register the Access Control Server group, using the **Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies > Add or Edit External** menu option. Then add the NAC policy.

ASA support for NAC Framework is limited to remote access IPsec and Clientless SSL VPN sessions. The NAC Framework configuration supports only single mode.

NAC on the ASA does not support Layer 3 (non-VPN) and IPv6 traffic.

Fields

- Policy Name—Enter a string of up to 64 characters to name the new NAC policy.

  Following the configuration of the NAC policy, the policy name appears next to the NAC Policy attribute in the Network (Client) Access group policies. Assign a name that will help you to distinguish its attributes or purpose from others that you may configure.

- Status Query Period—The ASA starts this timer after each successful posture validation and status query response. The expiration of this timer triggers a query for changes in the host posture, referred to as a *status query*. Enter the number of seconds in the range 30 to 1800. The default setting is 300.

- Revalidation Period—The ASA starts this timer after each successful posture validation. The expiration of this timer triggers the next unconditional posture validation. The ASA maintains posture validation during revalidation. The default group policy becomes effective if the Access Control Server is unavailable during posture validation or revalidation. Enter the interval in seconds between each successful posture validation. The range is 300 to 86400. The default setting is 36000.

- Default ACL— (Optional) The ASA applies the security policy associated with the selected ACL if posture validation fails. Select None or select an extended ACL in the list. The default setting is None. If the setting is None and posture validation fails, the ASA applies the default group policy.

  Use the Manage button to populate the drop-down list and view the configuration of the ACLs in the list.

- Manage— Opens the ACL Manager dialog box. Click to view, enable, disable, and delete standard ACLs and the ACEs in each ACL. The list next to the Default ACL attribute displays the ACLs.

- Authentication Server Group—Specifies the authentication server group to use for posture validation. The drop-down list next to this attribute displays the names of all server groups of type RADIUS configured on this ASA that are available for remote access tunnels. Select an ACS group consisting of at least one server configured to support NAC.
- Posture Validation Exception List—Displays one or more attributes that exempt remote computers from posture validation. At minimum, each entry lists the operating system and an Enabled setting of Yes or No. An optional filter identifies an ACL used to match additional attributes of the remote computer. An entry that consists of an operating system and a filter requires the remote computer to match both to be exempt from posture validation. The ASA ignores the entry if the Enabled setting is set to No.
- Add—Adds an entry to the Posture Validation Exception list.
- Edit—Modifies an entry in the Posture Validation Exception list.
- Delete—Removes an entry from the Posture Validation Exception list.

What to Do Next

Following the configuration of the NAC policy, you must assign it to a group policy for it to become active. To do so, choose **Configuration > Remote Access VPN> Network (Client) Access > Group Policies > Add** or **Edit > General > More Options** and the NAC policy name from the drop-down list next to the NAC Policy attribute.

Add/Edit Posture Validation Exception

The Add/Edit Posture Validation Exception dialog pane lets you exempt remote computers from posture validation, based on their operating system and other optional attributes that match a filter.

- Operating System—Choose the operating system of the remote computer. If the computer is running this operating system, it is exempt from posture validation. The default setting is blank.
- Enable—The ASA checks the remote computer for the attribute settings displayed in this pane only if you check Enabled. Otherwise, it ignores the attribute settings. The default setting is unchecked.
- Filter— (Optional) Use to apply an ACL to filter the traffic if the operating system of the computer matches the value of the Operating System attribute.
- Manage— Opens the ACL Manager dialog box. Click to view, enable, disable, and delete standard ACLs and the ACEs in each ACL. The list next to the Default ACL attribute displays the ACLs. Use this button to populate the list next to the Filter attribute.

General VPN Setup

A virtual private network is a network of virtual circuits that carry private traffic over a public network such as the Internet. VPNs can connect two or more LANS, or remote users to a LAN. VPNs provide privacy and security by requiring all users to authenticate and by encrypting all data traffic.

Client Software

Configuration > VPN > General > Client Update

The Client Software pane lets administrators at a central location do the following actions:

- Enable client update; specify the types and revision numbers of clients to which the update applies.
- Provide a URL or IP address from which to get the update.

- In the case of Windows clients, optionally notify users that they should update their VPN client version.

Note The Client Update function in Configuration > Remote Access VPN > Network (Client) Access > Advanced > IPsec > Upload Software > Client Software applies only to the IPsec VPN client, (For Windows, MAC OS X, and Linux), and the VPN 3002 hardware client. It does not apply to the Cisco AnyConnect VPN clients, which is updated by the ASA automatically when it connects.

For the IPsec VPN client, you can provide a mechanism for users to accomplish that update. For VPN 3002 hardware client users, the update occurs automatically, with no notification. You can apply client updates only to the IPsec remote-access tunnel-group type.

Note If you try to do a client update to an IPsec Site-to-Site IPsec connection or a Clientless VPN IPsec connection, you do not receive an error message, but no update notification or client update goes to those types of IPsec connections.

To enable client update globally for all clients of a particular client type, use this dialog box. You can also notify all Windows, MAC OS X, and Linux clients that an upgrade is needed and initiate an upgrade on all VPN 3002 hardware clients from this dialog box. To configure the client revisions to which the update applies and the URL or IP address from which to download the update, click **Edit**.

To configure client update revisions and software update sources for a specific tunnel group, choose **Configuration > Remote Access VPN > Network (Client) Access > IPsec > Add/Edit > Advanced > IPsec > Client Software Update**.

Fields

- Enable Client Update—Enables or disables client update, both globally and for specific tunnel groups. You must enable client update before you can send a client update notification to Windows, MAC OS X, and Linux VPN clients, or initiate an automatic update to hardware clients.
- Client Type—Lists the clients to upgrade: software or hardware, and for Windows software clients, all Windows or a subset. If you click All Windows Based, do not specify Windows 95, 98 or ME and Windows NT, 2000 or XP individually. The hardware client gets updated with a release of the ASA 5505 software or of the VPN 3002 hardware client.
- VPN Client Revisions—Contains a comma-separated list of software image revisions appropriate for this client. If the user client revision number matches one of the specified revision numbers, there is no need to update the client, and, for Windows-based clients, the user does not receive an update notification. The following caveats apply:
  - The revision list must include the software version for this update.
  - Your entries must match exactly those on the URL for the VPN client, or the TFTP server for the hardware client.
  - The TFTP server for distributing the hardware client image must be a robust TFTP server.
  - A VPN client user must download an appropriate software version from the listed URL.
  - The VPN 3002 hardware client software is automatically updated via TFTP, with no notification to the user.
- Image URL—Contains the URL or IP address from which to download the software image. This URL must point to a file appropriate for this client. For Windows, MAC OS X, and Linux-based clients, the URL must be in the form: http:// or https://. For hardware clients, the URL must be in the form tftp://.

  - For Windows, MAC OS X, and Linux-based VPN clients: To activate the Launch button on the VPN Client Notification, the URL must include the protocol HTTP or HTTPS and the server address of the site that contains the update. The format of the URL is: http(s)://*server_address:port/directory/filename*. The server address can be either an IP address or a hostname if you have configured a DNS server. For example:

    http://10.10.99.70/vpnclient-win-4.6.Rel-k9.exe

    The directory is optional. You need the port number only if you use ports other than 80 for HTTP or 443 for HTTPS.
  - For the hardware client: The format of the URL is tftp://*server_address/directory/filename*. The server address can be either an IP address or a hostname if you have configured a DNS server. For example:

    tftp://10.1.1.1/vpn3002-4.1.Rel-k9.bin

- Edit—Opens the Edit Client Update Entry dialog box, which lets you configure or change client update parameters. See Edit Client Update Entry.
- Live Client Update—Sends an upgrade notification message to all currently connected VPN clients or selected tunnel group(s).
  - Tunnel Group—Selects all or specific tunnel group(s) for updating.
  - Update Now—Immediately sends an upgrade notification containing a URL specifying where to retrieve the updated software to the currently connected VPN clients in the selected tunnel group or all connected tunnel groups. The message includes the location from which to download the new version of software. The administrator for that VPN client can then retrieve the new software version and update the VPN client software.

    For VPN 3002 hardware clients, the upgrade proceeds automatically, with no notification.

    You must check **Enable Client Update** for the upgrade to work. Clients that are not connected receive the upgrade notification or automatically upgrade the next time they log on.

Edit Client Update Entry

Configuration > VPN > General > Client Update > Edit Client Update Entry

The Edit Client Update dialog box lets you change information about VPN client revisions and URLs for the indicated client types. The clients must be running one of the revisions specified for the indicated client type. If not, the clients are notified that an upgrade is required.

Fields

- Client Type—(*Display-only*) Displays the client type selected for editing.
- VPN Client Revisions—Lets you type a comma-separated list of software or firmware images appropriate for this client. If the user client revision number matches one of the specified revision numbers, there is no need to update the client. If the client is not running a software version on the list, an update is in order. The user of a Windows, MAC OS X, or Linux-based VPN client must download an appropriate software version from the listed URL. The VPN 3002 hardware client software is automatically updated via TFTP.
- Image URL—Lets you type the URL for the software/firmware image. This URL must point to a file appropriate for this client.

– For a Windows, MAC OS X, or Linux-based VPN client, the URL must include the protocol HTTP or HTTPS and the server address of the site that contains the update. The format of the URL is: http(s)://*server_address:port/directory/filename*. The server address can be either an IP address or a hostname if you have configured a DNS server. For example:

  ```
  http://10.10.99.70/vpnclient-win-4.6.Rel-k9.exe
  ```

  The directory is optional. You need the port number only if you use ports other than 80 for HTTP or 443 for HTTPS.

– For the hardware client: The format of the URL is tftp://*server_address/directory/filename*. The server address can be either an IP address or a hostname if you have configured a DNS server. For example:

  tftp://10.1.1.1/vpn3002-4.1.Rel-k9.bin

  The directory is optional.

Default Tunnel Gateway

Configuration > VPN > General > Default Tunnel Gateway

To configure the default tunnel gateway, click the **Static Route** link. The Configuration > Routing > Routing > Static Route dialog box opens.

Group Policies

The Group Policies pane lets you manage VPN group policies. A VPN group policy is a collection of user-oriented attribute/value pairs stored either internally on the device or externally on a RADIUS or LDAP server. Configuring the VPN group policy lets users inherit attributes that you have not configured at the individual group or username level. By default, VPN users have no group policy association. The group policy information is used by VPN tunnel groups and user accounts.

The “child” panes and dialog boxes let you configure the group parameters, including those for the default group. The default group parameters are those that are most likely to be common across all groups and users, and they streamline the configuration task. Groups can “inherit” parameters from this default group, and users can “inherit” parameters from their group or the default group. You can override these parameters as you configure groups and users.

You can configure either an internal or an external group policy. An internal group policy is stored locally, and an external group policy is stored externally on a RADIUS or LDAP server. Clicking Edit opens a similar dialog box on which you can create a new group policy or modify an existing one.

In these dialog boxes, you configure the following kinds of parameters:

- General attributes: Name, banner, address pools, protocols, filtering, and connection settings.
- Servers: DNS and WINS servers, DHCP scope, and default domain name.
- Advanced attributes: Split tunneling, IE browser proxy, AnyConnect client, and IPsec client.

Before configuring these parameters, you should configure:

- Access hours.
- Rules and filters.
- IPsec Security Associations.

- Network lists for filtering and split tunneling
- User authentication servers and, specifically the internal authentication server.

You can configure these types of group policies:

- Configuring External Group Policies—An external group policy points the ASA to the RADIUS or LDAP server to retrieve much of the policy information that would otherwise be configured in an internal group policy. External group policies are configured the same way for Network (Client) Access VPN connections, Clientless SSL VPN connections, and Site-to-Site VPN connections.
- Configuring Network (Client) Access Internal Group Policies—These connections are initiated by a VPN client installed on the endpoint. The AnyConnect Secure Mobility Client and Cisco VPN IPsec client are examples of VPN clients. After the VPN client is authenticated, remote users can access corporate networks or applications as if they were on-site. The data traffic between remote users and the corporate network is secured by being encrypted when going through the Internet.
- Configuring Clientless SSL VPN Internal Group Policies—This is also known as browser-based VPN access. On successful login to the ASA's portal page, remote users can access corporate networks and applications from the links shown in the web pages. The data traffic between remote users and the corporate network is secured by traveling through SSL tunnel.
- Configuring Site-to-Site Internal Group Policies

Group Policy Pane Fields

Lists the currently configured group policies and Add, Edit, and Delete buttons to help you manage VPN group policies.

- Add—Offers a drop-down menu on which you can select whether to add an internal or an external group policy. If you simply click Add, then by default, you create an internal group policy. Clicking Add opens the Add Internal Group Policy dialog box or the Add External Group Policy dialog box, which let you add a new group policy to the list. This dialog box includes three menu sections. Click each menu item to display its parameters. As you move from item to item, ASDM retains your settings. When you have finished setting parameters on all menu sections, click **Apply** or **Cancel**. Offers a drop-down menu from which you can select whether to add an internal or an external group policy. If you simply click Add, then by default, you create an internal group policy.
- Edit—Displays the Edit Group Policy dialog box, which lets you modify an existing group policy.
- Delete—Lets you remove a AAA group policy from the list. There is no confirmation or undo.
- Assign—Lets you assign a group policy to one ore more connection profiles.
- Name—Lists the name of the currently configured group policies.
- Type—Lists the type of each currently configured group policy.
- Tunneling Protocol—Lists the tunneling protocol that each currently configured group policy uses.
- Connection Profiles/Users Assigned to—Lists the connection profiles and users configured directly on the ASA that are associated with this group policy.

Configuring External Group Policies

An external group policy points the ASA to the RADIUS or LDAP server to retrieve much of the policy information that would otherwise be configured in an internal group policy. External group policies are configured the same way for Network (Client) Access VPN connections, Clientless SSL VPN connections, and Site-to-Site VPN connections.

External group policies take their attribute values from the external server that you specify. For an external group policy, you must identify the RADIUS or LDAP server group that the ASA can query for attributes and specify the password to use when retrieving attributes from that external server group. If you are using an external authentication server, and if your external group-policy attributes exist in the same RADIUS server as the users that you plan to authenticate, you have to make sure that there is no name duplication between them.

Note External group names on the ASA refer to user names on the RADIUS server. In other words, if you configure external group X on the ASA, the RADIUS server sees the query as an authentication request for user X. So external groups are really just user accounts on the RADIUS server that have special meaning to the ASA. If your external group attributes exist in the same RADIUS server as the users that you plan to authenticate, there must be no name duplication between them.

The ASA supports user authorization on an external LDAP or RADIUS server. Before you configure the ASA to use an external server, you must configure the server with the correct ASA authorization attributes and, from a subset of these attributes, assign specific permissions to individual users. Follow the instructions in Appendix B, "Configuring an External Server for Authorization and Authentication" to configure your external server.

Fields

- Name—Identifies the group policy to be added or changed. For Edit External Group Policy, this field is display-only.
- Server Group—Lists the available server groups to which to apply this policy.
- New—Opens a dialog box that lets you select whether to create a new RADIUS server group or a new LDAP server group. Either of these options opens the Add AAA Server Group dialog box.
- Password—Specifies the password for this server group policy.

Adding an LDAP or RADIUS Server to a Network (Client) Access External Group Policy

Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > Add or Edit External Group Policy > New > RADIUS Server Group/New LDAP Server Group > Add AAA Server Group

The Add AAA Server Group dialog box lets you configure a new AAA server group. The Accounting Mode attribute applies only to RADIUS and TACACS+ protocols.

Fields

- Server Group—Specifies the name of the server group.
- Protocol—(*Display only*) Indicates whether this is a RADIUS or an LDAP server group.
- Accounting Mode—Indicates whether to use simultaneous or single accounting mode. In single mode, the ASA sends accounting data to only one server. In simultaneous mode, the ASA sends accounting data to all servers in the group. The Accounting Mode attribute applies only to RADIUS and TACACS+ protocols.
- Reactivation Mode—Specifies the method by which failed servers are reactivated: Depletion or Timed reactivation mode. In Depletion mode, failed servers are reactivated only after all of the servers in the group become inactive. In Timed mode, failed servers are reactivated after 30 seconds of down time.

- Dead Time—Specifies, for depletion mode, the number of minutes (0 through 1440) that must elapse between the disabling of the last server in the group and the subsequent re-enabling of all servers. The default value is 10 minutes. This field is not available for timed mode.
- Max Failed Attempts— Specifies the number (an integer in the range 1 through 5) of failed connection attempts allowed before declaring a nonresponsive server inactive. The default value is 3 attempts.

Configuring Network (Client) Access Internal Group Policies

Configure Network (Client) Access internal group policies for VPN connections made from AnyConnect Secure Mobility Clients or legacy Cisco IPsec VPN clients installed on an endpoint.

Configuring General Attributes for an Internal Group Policy

The Add or Edit Group Policy dialog box lets you specify tunneling protocols, filters, connection settings, and servers for the group policy being added or modified. For each of the fields on this dialog box, checking the Inherit check box lets the corresponding setting take its value from the default group policy. Inherit is the default value for all of the attributes in this dialog box.

You can configure the general attributes of an internal group policy by starting ASDM and selecting **Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add or Edit Internal Group Policy > General.**

Fields

The following attributes appear in the Add Internal Group Policy > General dialog box. They apply to SSL VPN and IPsec sessions, or clientless SSL VPN sessions. Thus, several are present for one type of session, but not the other.

- Name—Specifies the name of this group policy up to 64 characters; spaces are allowed. For the Edit function, this field is read-only.
- Banner—Specifies the banner text to present to users at login. The length can be up to 491 characters. There is no default value.

  The IPsec VPN client supports full HTML for the banner. However, the clientless portal and the AnyConnect client support partial HTML. To ensure the banner displays properly to remote users, follow these guidelines:

  - For IPsec client users, use the /n tag.
  - For AnyConnect client users, use the <BR> tag.
  - For clientless users, use the <BR> tag.
- Address Pools—Specifies the name of one or more IPv4 address pools to use for this group policy. If the Inherit check box is checked, the group policy will use the IPv4 address pool specified in the Default Group Policy. See Configuring Local IP Address Pools, page 88-3 for information on adding or editing an IPv4 address pool.

  Select—Uncheck the Inherit checkbox to activate the Select command button. Click Select to open the Address Pools dialog box, which shows the pool name, starting and ending addresses, and subnet mask of address pools available for client address assignment and lets you select, add, edit, delete, and assign entries from that list.
- IPv6 Address Pools—Specifies the name of one or more IPv6 address pools to use for this group policy.

The Select button following this field opens the Select Address Pools dialog box, as previously described. See Configuring Local IP Address Pools, page 88-3 for information on adding or editing an IPv6 address pool.

Note You can specify both an IPv4 and an IPv6 address pool for an internal group policy.

- More Options—Click the down arrows at the right of the field to display additional configurable options for this group policy.
- Tunneling Protocols—Specifies the tunneling protocols that this group can use. Users can use only the selected protocols. The choices are as follows:
  - Clientless SSL VPN—Specifies the use of VPN via SSL/TLS, which uses a web browser to establish a secure remote-access tunnel to an ASA; requires neither a software nor hardware client. Clientless SSL VPN can provide easy access to a broad range of enterprise resources, including corporate websites, web-enabled applications, NT/AD file share (web-enabled), e-mail, and other TCP-based applications from almost any computer that can reach HTTPS Internet sites.
  - SSL VPN Client—Specifies the use of the Cisco AnyConnect VPN client or the legacy SSL VPN client. If you are using the AnyConnect client, you must choose this protocol for Mobile User Security (MUS) to be supported.
  - IPsec IKEv1—IP Security Protocol. Regarded as the most secure protocol, IPsec provides the most complete architecture for VPN tunnels. Both Site-to-Site (peer-to-peer) connections and Cisco VPN client-to-LAN connections can use IPsec IKEv1.
  - IPsec IKEv2—Supported by the AnyConnect Secure Mobility Client. AnyConnect connections using IPsec with IKEv2 provide advanced features such as software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy.
  - L2TP over IPsec—Allows remote users with VPN clients provided with several common PC and mobile PC operating systems to establish secure connections over the public IP network to the security appliance and private corporate networks. L2TP uses PPP over UDP (port 1701) to tunnel the data. The security appliance must be configured for IPsec transport mode.
- Filter—Specifies which unified access control list to use for an IPv4 or an IPv6 connection, or whether to inherit the value from the group policy. Filters consist of rules that determine whether to allow or reject tunneled data packets coming through the ASA, based on criteria such as source address, destination address, and protocol. To configure filters and rules, see the ACL Manager dialog box.

  Manage—Displays the ACL Manager dialog box, with which you can add, edit, and delete Access Control Lists (ACLs) and Extended Access Control Lists (ACEs). For more information about the ACL Manager, see the online Help for that dialog box.
- NAC Policy—Selects the name of a Network Admission Control policy to apply to this group policy. You can assign an optional NAC policy to each group policy. The default value is --None--.
- Manage—Opens the Configure NAC Policy dialog box. After configuring one or more NAC policies, the NAC policy names appear as options in the drop-down list next to the NAC Policy attribute.
- Access Hours—Selects the name of an existing access hours policy, if any, applied to this user or create a new access hours policy. The default value is Inherit, or, if the Inherit check box is not checked, the default value is --Unrestricted--.

  Manage—Opens the Browse Time Range dialog box, in which you can add, edit, or delete a time range. See Defining Time Ranges, page 87-29 for more information.

- Simultaneous Logins—Specifies the maximum number of simultaneous logins allowed for this user. The default value is 3. The minimum value is 0, which disables login and prevents user access.

Note While there is no maximum limit, allowing several simultaneous connections might compromise security and affect performance.

- Restrict Access to VLAN—(Optional) Also called "VLAN mapping," this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all traffic from this group to the selected VLAN. Use this attribute to assign a VLAN to the group policy to simplify access control. Assigning a value to this attribute is an alternative to using ACLs to filter traffic on a session. In addition to the default value (Unrestricted), the drop-down list shows only the VLANs that are configured on this ASA.

Note This feature works for HTTP connections, but not for FTP and CIFS.

- Connection Profile (Tunnel Group) Lock—This parameter permits remote VPN access only with the selected connection profile (tunnel group), and prevents access with a different connection profile. The default inherited value is None.
- Maximum Connect Time—If the Inherit check box is not checked, this parameter specifies the maximum user connection time in minutes. At the end of this time, the system terminates the connection. The minimum is 1 minute, and the maximum is 35791394 minutes (over 4000 years, should we be so lucky). To allow unlimited connection time, check Unlimited (the default).
- Idle Timeout—If the Inherit check box is not checked, this parameter specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system terminates the connection. The minimum time is 1 minute, and the maximum time is 10080 minutes. The default is 30 minutes. To allow unlimited connection time, check **Unlimited**. This value does not apply to Clientless SSL VPN users.
- On smart card removal—With the default option, Disconnect, the client tears down the connection if the smart card used for authentication is removed. Click **Keep the connection** if you do not want to require users to keep their smart cards in the computer for the duration of the connection.

Configuring Server Attributes for an Internal Group Policy

Configure DNS servers, WINS servers and DHCP Scope in the Group Policy > Servers window.

Configuring a DNS Server for an Internal Group Policy

Use this procedure to configure a specific DNS server for a group policy.

Note This setting overrides the DNS setting configured on the ASDM in the **Configuration > Remote Access VPN > DNS** window.

Step 1 Select **Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > Servers**.

Step 2 Unless you are editing the DefaultGroupPolicy, uncheck the DNS Servers **Inherit** checkbox.

Step 3 In the DNS Servers field, add the IPv4 or IPv6 addresses of the DNS servers you want this group to use.

You can specify up to four DNS server addresses: Up to two IPv4 addresses and two IPv6 addresses. If you specify more than one DNS server, the remote access client will attempt to use the DNS servers in the order you specify them in the field.

Step 4 Expand the **More Options** area by clicking the double down arrow in the More Options bar.

Step 5 If there is no default domain specified in the **Configuration > Remote Access VPN > DNS** window, you must specify the default domain in the **Default Domain** field. Use the domain name and top level domain for example, **example.com.**

Step 6 Click **OK**.

Step 7 Click **Apply**.

Configuring WINS Servers for an Internal Group Policy

Use this procedure to configure primary and secondary WINS servers. The default value in each case is none.

Step 1 Select **Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > Servers**.

Step 2 Uncheck the WINS Servers **Inherit** checkbox.

Step 3 In the WINS Servers field, enter the IP addresses of the primary and secondary WINS servers. The first IP address you specify is that of the primary WINS server. The second (optional) IP address you specify is that of the secondary WINS server.

Step 4 Click OK.

Configuring Split Tunneling for an Internal Group Policy

Split tunneling enables you to route some network traffic from the endpoint through the VPN tunnel (encrypted) to the ASA and to route other network traffic from the endpoint outside the VPN tunnel (unencrypted or “in the clear”).

You implement split tunneling by creating a unified access control list and then requiring the list to be included in the VPN tunnel or requiring the list to be excluded from the VPN tunnel. You can specify both IPv4 and IPv6 addresses in the unified access control list.

The AnyConnect client and the legacy Cisco VPN client (the IPsec/IKEv1 client) behave differently when passing traffic to sites within the same subnet as the IP address assigned to the client by the ASA. The AnyConnect client passes traffic to all sites specified in the split tunneling policy you configured and to all sites that fall within the same subnet as the IP address assigned by the ASA. For example, if the IP address assigned to the client by the ASA is 10.1.1.1 with a mask of 255.0.0.0, the endpoint device passes all traffic destined to 10.0.0.0/8, regardless of the split tunneling policy. The legacy Cisco VPN client only passes traffic to addresses specified by the split-tunneling policy, regardless of the subnet assigned to the client by the ASA.

Therefore, in the unified access control list defined in the split tunnel IPv4 or IPv6 policy, use a netmask for the assigned IP address that properly references the expected local subnet.

Note In the following procedure, in all cases where there is an Inherit checkbox next to a field, leaving the Inherit check box checked means that the group policy you are configuring will use the same values for that field as the default group policy. Unchecking Inherit lets you specify new values specific to your group policy.

Step 1 Connect to the ASA using ASDM and select **Configuration > Remote Access VPN > Network (Client) Access > Group Policies**.

Step 2 Click **Add** to add a new group policy or select an existing group policy and click **Edit**.

Step 3 Select **Advanced > Split Tunneling**.

Step 4 In the **DNS Names** field, enter the domain names that are to be resolved by AnyConnect via the tunnel. These names correspond to hosts in the private network. If split-include tunneling is configured, the network list must include the specified DNS servers. You can enter a full qualified domain name, IPv4 or IPv6 address in the field.

Step 5 The **Send All DNS Lookups Through Tunnel** field instructs the AnyConnect client to resolve all DNS addresses through the VPN tunnel (SSL or IPsec/IKEv2). Setting this option ensures that DNS traffic is not leaked to the physical adapter and disallows traffic in the clear. If DNS resolution fails, the address remains unresolved and the AnyConnect client does not try to resolve the address through public DNS servers. If you choose No (the default), the client sends DNS queries over the tunnel according to the split tunnel policy.

Step 6 Configure the **Policy** and **IPv6 Policy** fields—The Policy field defines the split tunneling policy for IPv4 network traffic. The IPv6 Policy field selects the split tunneling policy for IPv6 network traffic. Other than that difference, these fields have the same purpose.

You configure split-tunneling by unchecking the Inherit check box and choosing a split-tunneling policy. If you do not uncheck Inherit, your group policy uses the split tunneling settings defined in the default group policy, "DfltGrpPolicy." The default split tunneling policy setting in the default group policy is to Tunnel All Networks.

After unchecking Inherit, you can choose one of these policy options:

- **Exclude Network List Below**—This policy defines a list of networks to which traffic is sent in the clear. This feature is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel. This option applies only to the Cisco VPN client.
- **Tunnel Network List Below**—This policy tunnels all traffic from or to the networks specified in the Network List. This option enables split tunneling. It lets you create a network list of addresses to tunnel. Data to all other addresses travels in the clear and is routed by the remote user's Internet service provider.
- **Tunnel All Networks**—This policy specifies that no traffic goes in the clear or to any other destination than the ASA. This, in effect, disables split tunneling. Remote users reach Internet networks through the corporate network and do not have access to local networks. This is the default option.

Step 7 In the **Network List** field, select the unified access control rule to which you apply the split-tunneling policy. If you do not select Inherit, the group policy uses the network list specified in the default group policy. The default value of the network list in the default group policy is --None--.

Use the **Manage** command button to open the ACL Manager dialog box, in which you can configure access control lists, or select an existing access control list to use as network lists. If you want to create or edit a network list, see Adding ACLs and ACEs, page 26-2.

Note Extended ACL lists can be used for both IPv4 and IPv6 addresses.

Step 8 The **Intercept DHCP Configuration Message from Microsoft Clients** reveals additional parameters specific to DHCP Intercept. DHCP Intercept lets Microsoft XP clients use split-tunneling with the ASA. For Windows clients prior to XP, DHCP Intercept provides the domain name and subnet mask.

- Intercept—Specifies whether to allow the DHCP Intercept to occur. If you do not select, Inherit, the default setting is No.
- Subnet Mask—Selects the subnet mask to use.

Step 9 Click OK.After making this change to the group policy, be sure the group policy is associated with a Connection Profile used by AnyConnect. In ASDM select, **Configuration > Remote Access VPN > Network (Client) Access > AnyConnect Connection Profiles** to configure a Connection Profile.

Configuring a Browser Proxy for an Internal Group Policy

Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > Advanced > Browser Proxy

This dialog box configures attributes for Microsoft Internet Explorer.

Fields

- Proxy Server Policy—Configures the Microsoft Internet Explorer browser proxy actions (“methods”) for a client PC.
  - Do not modify client proxy settings—Leaves the HTTP browser proxy server setting in Internet Explorer unchanged for this client PC.
  - Do not use proxy—Disables the HTTP proxy setting in Internet Explorer for the client PC.
  - Select proxy server settings from the following—Enables the following check boxes for your selections: Auto detect proxy, Use proxy server settings given below, and Use proxy auto configuration (PAC) given below.
  - Auto detect proxy—Enables the use of automatic proxy server detection in Internet Explorer for the client PC.
  - Use proxy server settings specified below—Sets the HTTP proxy server setting in Internet Explorer to use the value configured in the Proxy Server Name or IP Address field.
  - Use proxy auto configuration (PAC) given below—Specifies the use of the file specified in the Proxy Auto Configuration (PAC) field as the source for auto configuration attributes.
- Proxy Server Settings—Configures the proxy server parameters for Microsoft clients using Microsoft Internet Explorer.
  - Server Address and Port—Specifies the IP address or name and the port of an Microsoft Internet Explorer server that is applied for this client PC.
  - Bypass Proxy Server for Local Addresses—Configures Microsoft Internet Explorer browser proxy local-bypass settings for a client PC. Click **Yes** to enable local bypass or **No** to disable local bypass.

  - Exception List—Lists the server names and IP addresses that you want to exclude from proxy server access. Enter the list of addresses that you do not want to have accessed through a proxy server. This list corresponds to the Exceptions list in the Proxy Settings dialog box in Internet Explorer.

- Proxy Auto Configuration Settings—The PAC URL specifies the URL of the auto-configuration file. This file tells the browser where to look for proxy information. To use the proxy auto-configuration (PAC) feature, the remote user must use the Cisco AnyConnect VPN client.

  Many network environments define HTTP proxies that connect a web browser to a particular network resource. The HTTP traffic can reach the network resource only if the proxy is specified in the browser and the client routes the HTTP traffic to the proxy. SSLVPN tunnels complicate the definition of HTTP proxies because the proxy required when tunneled to an enterprise network can differ from that required when connected to the Internet via a broadband connection or when on a third-party network.

  In addition, companies with large networks might need to configure more than one proxy server and let users choose between them, based on transient conditions. By using .pac files, an administrator can author a single script file that determines which of numerous proxies to use for all client computers throughout the enterprise.

  The following are some examples of how you might use a PAC file:

  - Choosing a proxy at random from a list for load balancing.
  - Rotating proxies by time of day or day of the week to accommodate a server maintenance schedule.
  - Specifying a backup proxy server to use in case the primary proxy fails.
  - Specifying the nearest proxy for roaming users, based on the local subnet.

  You can use a text editor to create a proxy auto-configuration (.pac) file for your browser. A .pac file is a JavaScript file that contains logic that specifies one or more proxy servers to be used, depending on the contents of the URL. Use the PAC URL field to specify the URL from which to retrieve the .pac file. Then the browser uses the .pac file to determine the proxy settings.

Configuring General AnyConnect Client Attributes for an Internal Group Policy

Clicking the AnyConnect Client icon in the group policy directory tree shows the list of configurable attributes that follow. Configuring the ASA to distribute and manage AnyConnect client sessions is a larger procedure than just setting these attribute fields in a group policy. See Configuring AnyConnect VPN Client Connections, page 87-42, Configuring AnyConnect VPN Connections, page 87-52, and Configuring AnyConnect Secure Mobility, page 87-64.

Fields

- Keep Installer on Client System—Enable permanent client installation on the remote computer. Enabling disables the automatic uninstalling feature of the client. The client remains installed on the remote computer for subsequent connections, reducing the connection time for the remote user.

Note Keep Installer on Client System is not supported after version 2.5 of the AnyConnect client.

- Datagram Transport Layer Security (DTLS)—Avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

- Ignore Don't Defrag (DF) Bit—This feature allows the force fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel. An example use case is for servers in your network that do not respond correctly to TCP MSS negotiations.
- Client Bypass Protocol—The Client Protocol Bypass feature allows you to configure how the ASA manages IPv4 traffic when it is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic.

  When the AnyConnect client makes a VPN connection to the ASA, the ASA could assign it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the ASA assigns the AnyConnect connection only an IPv4 address or only an IPv6 address, you can now configure the Client Bypass Protocol to drop network traffic for which the ASA did not assign an IP address, or allow that traffic to bypass the ASA and be sent from the client unencrypted or "in the clear".

  For example, assume that the ASA assigns only an IPv4 address to an AnyConnect connection and the endpoint is dual stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.
- FQDN of This Device—This information is used by the client after network roaming in order to resolve the ASA IP address used for re-establishing the VPN session. This setting is critical to support roaming between networks of different IP protocols (such as IPv4 to IPv6).

  Note You cannot use the ASA FQDN present in the AnyConnect profile to derive the ASA IP address after roaming. The addresses may not match the correct device (the one the tunnel was established to) in the load balancing scenario.

  If the device FQDN is not pushed to the client, the client will try to reconnect to whatever IP address the tunnel had previously established. In order to support roaming between networks of different IP protocols (from IPv4 to IPv6), AnyConnect must perform name resolution of the device FQDN after roaming, so that it can determine which ASA address to use for re-establishing the tunnel. The client uses the ASA FQDN present in its profile during the initial connection. During subsequent session reconnects, it always uses the device FQDN pushed by ASA (and configured by the administrator in the group policy), when available. If the FQDN is not configured, the ASA derives the device FQDN (and sends it to the client) from whatever is set under Device Setup > Device Name/Password and Domain Name.

  If the device FQDN is not pushed by the ASA, the client cannot re-establish the VPN session after roaming between networks of different IP protocols.
- MTU—Adjusts the MTU size for SSL connections. Enter a value in bytes, from 256 to 1410 bytes. By default, the MTU size is adjusted automatically based on the MTU of the interface that the connection uses, minus the IP/UDP/DTLS overhead.
- Keepalive Messages—Enter a number, from 15 to 600 seconds, in the Interval field to enable and adjust the interval of keepalive messages to ensure that an connection through a proxy, firewall, or NAT device remains open, even if the device limits the time that the connection can be idle. Adjusting the interval also ensures that the client does not disconnect and reconnect when the remote user is not actively running a socket-based application, such as Microsoft Outlook or Microsoft Internet Explorer.
- **Optional Client Modules to Download**—To minimize download time, the AnyConnect client requests downloads (from the ASA) only of modules that it needs for each feature that it supports. You must specify the names of modules that enable other features. The AnyConnect client, version 3.0, includes the following modules (previous versions have fewer modules):

- AnyConnect DART—The Diagnostic AnyConnect Reporting Tool (DART) captures a snapshot of system logs and other diagnostic information and creates a .zip file on your desktop so you can conveniently send troubleshooting information to Cisco TAC.
- AnyConnect Network Access Manager—Formerly called the Cisco Secure Services Client, this module provides 802.1X (Layer 2) and device authentication for access to both wired and wireless network is integrated into AnyConnect 3.0.
- AnyConnect SBL—Start Before Logon (SBL) forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting AnyConnect before the Windows login dialog box appears.
- AnyConnect Web Security Module—Formerly called ScanSafe Hostscan, this module is integrated into the AnyConnect 3.0.
- AnyConnect Telemetry Module—Sends information about the origin of malicious content to the web filtering infrastructure of the Cisco IronPort Web Security Appliance (WSA), which uses this data to provide better URL filtering rules.
- AnyConnect Posture Module—Formerly called the Cisco Secure Desktop HostScan feature, the posture module is integrated into AnyConnect 3.0 and provides AnyConnect the ability to gather credentials for posture assessment prior to creating a remote access connection to the ASA.

- Always-On VPN—Determine if the always-on VPN flag setting in the AnyConnect service profile is disabled or if the AnyConnect service profile setting should be used. The always-on VPN feature lets AnyConnnect automatically establish a VPN session after the user logs onto a computer. The VPN session remains up until the user logs off the computer. If the physical connection is lost, the session remains up, and AnyConnect continually attempts to reestablish the physical connection with the adaptive security appliance to resume the VPN session.

  Always-on VPN permits the enforcement of corporate policies to protect the device from security threats. You can use it to help ensure AnyConnect establishes a VPN session whenever the endpoint is not in a trusted network. If enabled, a policy is configured to determine how network connectivity is managed in the absence of a connection.

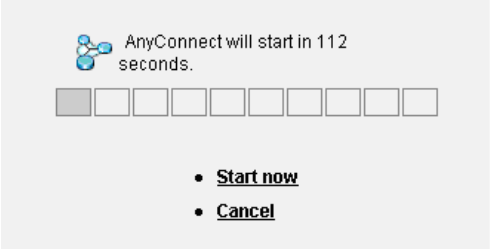
  Note Always-On VPN requires an AnyConnect release that supports AnyConnect Secure Mobility features. Refer to the *Cisco AnyConnect VPN Client Administrator Guide* for additional information.

- Client Profiles to Download—A profile is a group of configuration parameters that the AnyConnect client uses to configure VPN, Network Access Manager, web security, and telemetry settings. Click Add to launch the Select Anyconnect Client Profiles window where you can specify previously-created profiles for this group policy.

Configuring AnyConnect Login Settings for an Internal Group Policy

In this dialog box, you can enable the ASA to prompt remote users to download the AnyConnect client or go to a Clientless SSL VPN portal page. Figure 87-1 shows the prompt displayed:

Figure 87-1 Prompt Displayed to Remote Users for AnyConnect Client Download



Fields

- Post Login Setting—Choose to prompt the user and set the timeout to perform the default post login selection.
- Default Post Login Selection—Choose an action to perform after login.

Configuring AnyConnect Client Client Firewall Attributes for an Internal Group Policy

In ASA 9.0 and later releases, access control lists for client firewalls support both access list entries for both IPv4 and IPv6 addresses.

See Client Firewall with Local Printer and Tethered Device Support, page 87-37 to configure the group policy for these situations.

Configuring AnyConnect Client Key Regeneration for an Internal Group Policy

Rekey Negotiation occurs when the security appliance and the client perform a rekey and they renegotiate the crypto keys and initialization vectors, increasing the security of the connection.

Fields

- Renegotiation Interval—Uncheck the Unlimited check box to specify the number of minutes from the start of the session until the rekey takes place, from 1 to 10080 (1 week).
- Renegotiation Method—Uncheck the Inherit check box to specify a renegotiation method different from the default group policy. Select the **None** radio button to disable rekey, select either the **SSL** or **New Tunnel** radio button to establish a new tunnel during rekey.

Note Configuring the Renegotiation Method as **SSL** or **New Tunnel** specifies that the client establishes a new tunnel during rekey instead of the SSL renegotiation taking place during the rekey. See the Cisco ASA 5500 Series Command Reference, 8.4 for a history of the **anyconnect ssl rekey** command.

Configuring AnyConnect Client Dead Peer Detection for an Internal Group Policy

Dead Peer Detection (DPD) ensures that the security appliance (gateway) or the client can quickly detect a condition where the peer is not responding, and the connection has failed.

Fields

- Gateway Side Detection—Uncheck the **Disable** check box to specify that DPD is performed by the security appliance (gateway). Enter the interval, from 30 to 3600 seconds, with which the security appliance performs DPD.
- Client Side Detection—Uncheck the **Disable** check box to specify that DPD is performed by the client. Enter the interval, from 30 to 3600 seconds, with which the client performs DPD.

Customizing a VPN Access Portal for an Internal Group Policy

To configure customization for a group policy, select a preconfigured portal customization object, or accept the customization provided in the default group policy. You can also configure a URL to display

Fields

- Portal Customization—Selects the customization to apply to the AnyConnect Client/SSL VPN portal page. The default is DfltCustomization.
  - Inherit—To inherit a portal customization from the default group policy, check **Inherit**. To specify a previously configured customization object, uncheck Inherit and choose the customization object from the drop-down list.
  - Manage—Opens the Configure GUI Customization objects dialog box, in which you can specify that you want to add, edit, delete, import, or export a customization object.
- Homepage URL (optional)—To specify a homepage URL for users associated with the group policy, enter it in this field. The string must begin with either http:// or https://. To inherit a home page from the default group policy, click **Inherit**. Clientless users are immediately brought to this page after successful authentication. AnyConnect launches the default web browser to this URL upon successful establishment of the VPN connection. On Linux platforms, AnyConnect does not currently support this field and ignores it.
- Access Deny Message—To create a message to users for whom access is denied, enter it in this field. To accept the message in the default group policy, click **Inherit**.

  The default message, if you deselect Inherit, is: “Login was successful, but because certain criteria have not been met or due to some specific group policy, you do not have permission to use any of the VPN features. Contact your IT administrator for more information.”

Configuring AnyConnect Client Custom Attributes for an Internal Group Policy

This dialog box lists the custom attributes that are assigned to this group policy. Custom attributes can be created in this dialog, or on Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Custom Attributes. In this dialog, you can add custom attributes to this group policy, and define values for those attributes.

For AnyConnect 3.1, custom attributes are available to support AnyConnect Deferred Upgrade and Phone Home.

See the *Cisco AnyConnect Secure Mobility Client Administrator Guide, Release 3.1*, Chapter 2, “User Control Over Upgrade” for more information about the deferred upgrade custom attributes.

IPsec (IKEv1) Client

Configuring IPsec (IKEv1) Client General Attributes for an Internal Group Policy

Configuration > Remote Access > Network (Client) Access > Group Policies > Advanced > IPsec (IKEv1) Client

The Add or Edit Group Policy > IPsec dialog box lets you specify tunneling protocols, filters, connection settings, and servers for the group policy being added or modified.

Fields

- Re-Authentication on IKE Re-key—Enables or disables reauthentication when IKE re-key occurs, unless the Inherit check box is checked. The user has 30 seconds to enter credentials, and up to three attempts before the SA expires at approximately two minutes and the tunnel terminates.
- Allow entry of authentication credentials until SA expires—Allows users the time to reenter authentication credentials until the maximum lifetime of the configured SA.
- IP Compression—Enables or disables IP Compression, unless the Inherit check box is checked.
- Perfect Forward Secrecy—Enables or disables perfect forward secrecy (PFS), unless the Inherit check box is selected. PFS ensures that the key for a given IPsec SA was not derived from any other secret (like some other keys). In other words, if someone were to break a key, PFS ensures that the attacker would not be able to derive any other key. If PFS were not enabled, someone could hypothetically break the IKE SA secret key, copy all the IPsec protected data, and then use knowledge of the IKE SA secret to compromise the IPsec SAs set up by this IKE SA. With PFS, breaking IKE would not give an attacker immediate access to IPsec. The attacker would have to break each IPsec SA individually.
- Store Password on Client System—Enables or disables storing the password on the client system.

Note Storing the password on a client system can constitute a potential security risk.

- IPsec over UDP—Enables or disables using IPsec over UDP.
- IPsec over UDP Port—Specifies the UDP port to use for IPsec over UDP.
- Tunnel Group Lock—Enables locking the tunnel group you select from the list, unless the Inherit check box or the value None is selected.
- IPsec Backup Servers—Activates the Server Configuration and Server IP Addresses fields, so you can specify the UDP backup servers to use if these values are not inherited.
  - Server Configuration—Lists the server configuration options to use as an IPsec backup server. The available options are: Keep Client Configuration (the default), Use the Backup Servers Below, and Clear Client Configuration.
  - Server Addresses (space delimited)—Specifies the IP addresses of the IPsec backup servers. This field is available only when the value of the Server Configuration selection is Use the Backup Servers Below.

Configuring IPsec (IKEv1) Client Client Access Rules for an Internal Group Policy

The Client Access Rules table on this dialog box lets you view up to 25 client access rules. If you uncheck the Inherit check box, the Add, Edit, and Delete buttons become active and the following column headings appear in the table:

- Priority—Shows the priority for this rule.

- Action—Specifies whether this rule permits or denies access.
- VPN Client Type—Specifies the type of VPN client to which this rule applies, software or hardware, and for software clients, all Windows clients or a subset.
- VPN Client Version—Specifies the version or versions of the VPN client to which this rule applies. This column contains a comma-separated list of software or firmware images appropriate for this client.

Configuring IPsec (IKEv1) Client Client Firewall Attributes for an Internal Group Policy

Configuration > Remote Access > Network (Client) Access > Group Policies > Advanced > IPsec (IKEv1) Client > Client Firewall Tab

The Add or Edit Group Policy Client Firewall dialog box lets you configure firewall settings for VPN clients for the group policy being added or modified.

Note Only VPN clients running Microsoft Windows can use these firewall features. They are currently not available to hardware clients or other (non-Windows) software clients.

A *firewall* isolates and protects a computer from the Internet by inspecting each inbound and outbound individual packet of data to determine whether to allow or drop it. Firewalls provide extra security if remote users in a group have split tunneling configured. In this case, the firewall protects the user's PC, and thereby the corporate network, from intrusions by way of the Internet or the user's local LAN. Remote users connecting to the ASA with the VPN client can choose the appropriate firewall option.

In the first scenario, a remote user has a personal firewall installed on the PC. The VPN client enforces firewall policy defined on the local firewall, and it monitors that firewall to make sure it is running. If the firewall stops running, the VPN client drops the connection to the ASA. (This firewall enforcement mechanism is called *Are You There (AYT)*, because the VPN client monitors the firewall by sending it periodic "are you there?" messages; if no reply comes, the VPN client knows the firewall is down and terminates its connection to the ASA.) The network administrator might configure these PC firewalls originally, but with this approach, each user can customize his or her own configuration.

In the second scenario, you might prefer to enforce a centralized firewall policy for personal firewalls on VPN client PCs. A common example would be to block Internet traffic to remote PCs in a group using split tunneling. This approach protects the PCs, and therefore the central site, from intrusions from the Internet while tunnels are established. This firewall scenario is called *push policy* or *Central Protection Policy (CPP)*. On the ASA, you create a set of traffic management rules to enforce on the VPN client, associate those rules with a filter, and designate that filter as the firewall policy. The ASA pushes this policy down to the VPN client. The VPN client then in turn passes the policy to the local firewall, which enforces it.

Fields

- Inherit—Determines whether the group policy obtains its client firewall setting from the default group policy. This option is the default setting. When set, it overrides the remaining attributes in this dialog boxing dims their names.
- Client Firewall Attributes—Specifies the client firewall attributes, including what type of firewall (if any) is implemented and the firewall policy for that firewall.
- Firewall Setting—Lists whether a firewall exists, and if so, whether it is required or optional. If you select No Firewall (the default), none of the remaining fields on this dialog box are active. If you want users in this group to be firewall-protected, select either the Firewall Required or Firewall Optional setting.

If you choose Firewall Required, all users in this group must use the designated firewall. The ASA drops any session that attempts to connect without the designated, supported firewall installed and running. In this case, the ASA notifies the VPN client that its firewall configuration does not match.

Note If you require a firewall for a group, make sure the group does not include any clients other than Windows VPN clients. Any other clients in the group (including ASA 5505 in client mode and VPN 3002 hardware clients) are unable to connect.

If you have remote users in this group who do not yet have firewall capacity, choose Firewall Optional. The Firewall Optional setting allows all the users in the group to connect. Those who have a firewall can use it; users that connect without a firewall receive a warning message. This setting is useful if you are creating a group in which some users have firewall support and others do not—for example, you may have a group that is in gradual transition, in which some members have set up firewall capacity and others have not yet done so.

- Firewall Type—Lists firewalls from several vendors, including Cisco. If you select Custom Firewall, the fields under Custom Firewall become active. The firewall you designate must correlate with the firewall policies available. The specific firewall you configure determines which firewall policy options are supported.
- Custom Firewall—Specifies the vendor ID, Product ID and description for the custom firewall.
  - Vendor ID—Specifies the vendor of the custom firewall for this group policy.
  - Product ID—Specifies the product or model name of the custom firewall being configured for this group policy.
  - Description—(Optional) Describes the custom firewall.
- Firewall Policy—Specifies the type and source for the custom firewall policy.
  - Policy defined by remote firewall (AYT)—Specifies that the firewall policy is defined by the remote firewall (Are You There). Policy defined by remote firewall (AYT) means that remote users in this group have firewalls located on their PCs. The local firewall enforces the firewall policy on the VPN client. The ASA allows VPN clients in this group to connect only if they have the designated firewall installed and running. If the designated firewall is not running, the connection fails. Once the connection is established, the VPN client polls the firewall every 30 seconds to make sure that it is still running. If the firewall stops running, the VPN client ends the session.
  - Policy pushed (CPP)—Specifies that the policy is pushed from the peer. If you choose this option, the Inbound Traffic Policy and Outbound Traffic Policy lists and the Manage button become active. The ASA enforces on the VPN clients in this group the traffic management rules defined by the filter you choose from the Policy Pushed (CPP) drop-down menu. The choices available on the menu are filters defined on this ASA, including the default filters. Keep in mind that the ASA pushes these rules down to the VPN client, so you should create and define these rules relative to the VPN client, not the ASA. For example, “in” and “out” refer to traffic coming into the VPN client or going outbound from the VPN client. If the VPN client also has a local firewall, the policy pushed from the ASA works with the policy of the local firewall. Any packet that is blocked by the rules of either firewall is dropped.
  - Inbound Traffic Policy—Lists the available push policies for inbound traffic.
  - Outbound Traffic Policy—Lists the available push policies for outbound traffic.
  - Manage—Displays the ACL Manager dialog box, in which you can configure Access Control Lists (ACLs).

Configuring IPsec (IKEv1) Client Hardware Client Attributes for an Internal Group Policy

Configuration > Remote Access > Network (Client) Access > Group Policies > Advanced > IPsec (IKEv1) Client > Hardware Client

The Add or Edit Group Policy > Hardware Client dialog box lets you configure settings for the VPN 3002 hardware client for the group policy being added or modified. The Hardware Client dialog box parameters do not pertain to the ASA 5505 in client mode.

Fields

- Inherit—(Multiple instances) Indicates that the corresponding setting takes its value from the default group policy, rather than from the explicit specifications that follow. This is the default setting for all attributes in this dialog box.
- Require Interactive Client Authentication—Enables or disables the requirement for interactive client authentication. This parameter is disabled by default. Interactive hardware client authentication provides additional security by requiring the VPN 3002 to authenticate with a username and password that you enter manually each time the VPN 3002 initiates a tunnel. With this feature enabled, the VPN 3002 does not have a saved username and password. When you enter the username and password, the VPN 3002 sends these credentials to the ASA to which it connects. The ASA facilitates authentication, on either the internal or an external authentication server. If the username and password are valid, the tunnel is established.

  When you enable interactive hardware client authentication for a group, the ASA pushes that policy to the VPN 3002s in the group. If you have previously set a username and password on the VPN 3002, the software deletes them from the configuration file. When you try to connect, the software prompts you for a username and password.

  If, on the ASA, you subsequently disable interactive hardware authentication for the group, it is enabled locally on the VPN 3002s, and the software continues to prompt for a username and password. This lets the VPN 3002 connect, even though it lacks a saved username and password, and the ASA has disabled interactive hardware client authentication. If you subsequently configure a username and password, the feature is disabled, and the prompt no longer appears. The VPN 3002 connects to the ASA using the saved username and password.
- Require Individual User Authentication—Enables or disables the requirement for individual user authentication for users behind ASA 5505 in client mode or the VPN 3002 hardware client in the group. To display a banner to hardware clients in a group, individual user authentication must be enabled. This parameter is disabled by default.

  Individual user authentication protects the central site from access by unauthorized persons on the private network of the hardware client. When you enable individual user authentication, each user that connects through a hardware client must open a web browser and manually enter a valid username and password to access the network behind the ASA, even though the tunnel already exists.

Note You cannot use the command-line interface to log in if user authentication is enabled. You must use a browser.

If you have a default home page on the remote network behind the ASA, or if you direct the browser to a website on the remote network behind the ASA, the hardware client directs the browser to the proper pages for user login. When you successfully log in, the browser displays the page you originally entered.

If you try to access resources on the network behind the ASA that are not web-based, for example, e-mail, the connection fails until you authenticate using a browser.

To authenticate, you must enter the IP address for the private interface of the hardware client in the browser Location or Address field. The browser then displays the login dialog box for the hardware client. To authenticate, click Connect/Login Status.

One user can log in for a maximum of four sessions simultaneously. Individual users authenticate according to the order of authentication servers configured for a group.

- User Authentication Idle Timeout—Configures a user timeout period. The security appliance terminates the connection if it does not receive user traffic during this period. You can specify that the timeout period is a specific number of minutes or unlimited.
  - Unlimited—Specifies that the connection never times out. This option prevents inheriting a value from a default or specified group policy.
  - Minutes—Specifies the timeout period in minutes. Use an integer between 1 and 35791394. The default value is Unlimited.

  Note that the idle timeout indicated in response to the show uauth command is always the idle timeout value of the user who authenticated the tunnel on the Cisco Easy VPN remote device.
- Cisco IP Phone Bypass—Lets Cisco IP Phones bypass the interactive individual user authentication processes. If enabled, interactive hardware client authentication remains in effect. Cisco IP Phone Bypass is disabled by default.

Note You must configure the ASA 5505 in client mode or the VPN 3002 hardware client to use network extension mode for IP phone connections.

- LEAP Bypass—Lets LEAP packets from Cisco wireless devices bypass the individual user authentication processes (if enabled). LEAP Bypass lets LEAP packets from devices behind a hardware client travel across a VPN tunnel *prior* to individual user authentication. This lets workstations using Cisco wireless access point devices establish LEAP authentication. Then they authenticate again per individual user authentication (if enabled). LEAP Bypass is disabled by default.

Note This feature does not work as intended if you enable interactive hardware client authentication.

IEEE 802.1X is a standard for authentication on wired and wireless networks. It provides wireless LANs with strong mutual authentication between clients and authentication servers, which can provide dynamic per-user, per-session wireless encryption privacy (WEP) keys, removing administrative burdens and security issues that are present with static WEP keys.

Cisco Systems has developed an 802.1X wireless authentication type called Cisco LEAP. LEAP implements mutual authentication between a wireless client on one side of a connection and a RADIUS server on the other side. The credentials used for authentication, including a password, are always encrypted before they are transmitted over the wireless medium.

Note Cisco LEAP authenticates wireless clients to RADIUS servers. It does not include RADIUS accounting services.

LEAP users behind a hardware client have a circular dilemma: they cannot negotiate LEAP authentication because they cannot send their credentials to the RADIUS server behind the central site device over the tunnel. The reason they cannot send their credentials over the tunnel is that they have not authenticated on the wireless network. To solve this problem, LEAP Bypass lets LEAP

packets, and only LEAP packets, traverse the tunnel to authenticate the wireless connection to a RADIUS server before individual users authenticate. Then the users proceed with individual user authentication.

LEAP Bypass works as intended under the following conditions:

- The interactive unit authentication feature (intended for wired devices) must be disabled. If interactive unit authentication is enabled, a non-LEAP (wired) device must authenticate the hardware client before LEAP devices can connect using that tunnel.
- Individual user authentication is enabled (if it is not, you do not need LEAP Bypass).
- Access points in the wireless environment must be Cisco Aironet Access Points. The wireless NIC cards for PCs can be other brands.
- The Cisco Aironet Access Point must be running Cisco Discovery Protocol (CDP).
- The ASA 5505 or VPN 3002 can operate in either client mode or network extension mode.
- LEAP packets travel over the tunnel to a RADIUS server via ports 1645 or 1812.

Note Allowing any unauthenticated traffic to traverse the tunnel might pose a security risk.

- Allow C—Restricts the use of Network Extension Mode on the hardware client. Choose the option to let hardware clients use Network Extension Mode. Network Extension Mode is required for the hardware client to support IP phone connections, because the Call Manager can communicate only with actual IP addresses.

Note If you disable network extension mode, the default setting, the hardware client can connect to this ASA in PAT mode only. If you disallow network extension mode here, be careful to configure all hardware clients in a group for PAT mode. If a hardware client is configured to use Network Extension Mode and the ASA to which it connects disables Network Extension Mode, the hardware client attempts to connect every 4 seconds, and every attempt is rejected. In this situation, the hardware client puts an unnecessary processing load on the ASA to which it connects; large numbers of hardware clients that are misconfigured in this way reduces the ability of the security appliance to provide service.

Modes

The following table shows the modes in which this feature is available:

Configuring Clientless SSL VPN Internal Group Policies

Configuring Clientless SSL VPN General Attributes for an Internal Group Policy

Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies > Add/Edit > Add or Edit Internal Group Policy > General

The Add or Edit Group Policy dialog box lets you specify tunneling protocols, filters, connection settings, and servers for the group policy being added or modified. For each of the fields on this dialog box, checking the Inherit check box lets the corresponding setting take its value from the default group policy. Inherit is the default value for all of the attributes in this dialog box.

Fields

The following attributes appear in the Add Internal Group Policy > General dialog box. They apply to SSL VPN and IPsec sessions, or clientless SSL VPN sessions. Thus, several are present for one type of session, but not the other.

- Name—Specifies the name of this group policy up to 64 characters; spaces are allowed. For the Edit function, this field is read-only.
- Banner—Specifies the banner text to present to users at login. The length can be up to 491 characters. There is no default value.

  The IPsec VPN client supports full HTML for the banner. However, the clientless portal and the AnyConnect client support partial HTML. To ensure the banner displays properly to remote users, follow these guidelines:

  - For IPsec client users, use the /n tag.
  - For AnyConnect client users, use the <BR> tag.
  - For clientless users, use the <BR> tag.
- Tunneling Protocols—Specifies the tunneling protocols that this group can use. Users can use only the selected protocols. The choices are as follows:
  - Clientless SSL VPN—Specifies the use of VPN via SSL/TLS, which uses a web browser to establish a secure remote-access tunnel to an ASA; requires neither a software nor hardware client. Clientless SSL VPN can provide easy access to a broad range of enterprise resources, including corporate websites, web-enabled applications, NT/AD file share (web-enabled), e-mail, and other TCP-based applications from almost any computer that can reach HTTPS Internet sites.
  - SSL VPN Client—Specifies the use of the Cisco AnyConnect VPN client or the legacy SSL VPN client. If you are using the AnyConnect client, you must choose this protocol for MUS to be supported.
  - IPsec IKEv1—IP Security Protocol. Regarded as the most secure protocol, IPsec provides the most complete architecture for VPN tunnels. Both Site-to-Site (peer-to-peer) connections and Cisco VPN client-to-LAN connections can use IPsec IKEv1.
  - IPsec IKEv2—Supported by the AnyConnect Secure Mobility Client. AnyConnect connections using IPsec with IKEv2 provide advanced features such as software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy.
  - L2TP over IPsec—Allows remote users with VPN clients provided with several common PC and mobile PC operating systems to establish secure connections over the public IP network to the security appliance and private corporate networks. L2TP uses PPP over UDP (port 1701) to tunnel the data. The security appliance must be configured for IPsec transport mode.

  Note If you do not select a protocol, an error message appears.
- Web ACL—(Clientless SSL VPN only) Choose an access control list (ACL) from the drop-down list if you want to filter traffic. Click Manage next to the list if you want to view, modify, add, or remove ACLs before making a selection.
- Manage—Displays the ACL Manager dialog box, with which you can add, edit, and delete Access Control Lists (ACLs) and Extended Access Control Lists (ACEs). For more information about the ACL Manager, see the online Help for that dialog box.

- Access Hours—Selects the name of an existing access hours policy, if any, applied to this user or create a new access hours policy. The default value is Inherit, or, if the Inherit check box is not checked, the default value is --Unrestricted--.
- Manage—Opens the Browse Time Range dialog box, in which you can add, edit, or delete a time range. See Defining Time Ranges, page 87-29 for more information.
- Simultaneous Logins—Specifies the maximum number of simultaneous logins allowed for this user. The default value is 3. The minimum value is 0, which disables login and prevents user access.

Note While there is no maximum limit, allowing several simultaneous connections might compromise security and affect performance.

- Restrict Access to VLAN—(Optional) Also called "VLAN mapping," this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all traffic on this group to the selected VLAN. Use this attribute to assign a VLAN to the group policy to simplify access control. Assigning a value to this attribute is an alternative to using ACLs to filter traffic on a session. In addition to the default value (Unrestricted), the drop-down list shows only the VLANs that are configured on this ASA.

Note This feature works for HTTP connections, but not for FTP and CIFS.

- Connection Profile (Tunnel Group) Lock—This parameter permits remote VPN access only with the selected connection profile (tunnel group), and prevents access with a different connection profile. The default inherited value is None.
- Maximum Connect Time—If the Inherit check box is not checked, this parameter specifies the maximum user connection time in minutes. At the end of this time, the system terminates the connection. The minimum is 1 minute, and the maximum is 35791394 minutes (over 4000 years). To allow unlimited connection time, check Unlimited (the default).
- Idle Timeout—If the Inherit check box is not checked, this parameter specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system terminates the connection. The minimum time is 1 minute, and the maximum time is 10080 minutes. The default is 30 minutes. To allow unlimited connection time, check **Unlimited**. This value does not apply to Clientless SSL VPN users.
- Session Alert Interval— If you uncheck the Inherit check box, the Default checkbox is checked automatically. This sets the session alert interval to 30 minutes. If you want to specify a new value, uncheck the Default check box and specify a session alert interval from 1 to 30 minutes in the minutes box.
- Idle Alert Interval—If you uncheck the Inherit check box, the Default checkbox is checked automatically. This sets the idle alert interval to 30 minutes. If you want to specify a new value, uncheck the Default check box and specify a session alert interval from 1 to 30 minutes in the minutes box.

Configuring the Clientless SSL VPN Access Portal for an Internal Group Policy

The Portal attributes determine what appears on the portal page for members of this group policy establishing Clientless SSL VPN connections. In this pane, you can enable Bookmark lists and URL Entry, file server access, Port Forwarding and Smart Tunnels, ActiveX Relay, and HTTP settings.

Fields

- Bookmark List—Choose a previously-configured Bookmark list or click **Manage** to create a new one. Bookmarks appear as links, from which users can navigate from the portal page.
- URL Entry—Enable to allow remote users to enter URLs directly into the portal URL field.
- File Access Control—Controls the visibility of "hidden shares" for Common Internet File System (CIFS) files. A hidden share is identified by a dollar sign ($) at the end of the share name. For example, drive C is shared as C$. With hidden shares, a shared folder is not displayed, and users are restricted from browsing or accessing these hidden resources.
  - File Server Entry—Enable to allow remote users to enter the name of a file server.
  - File Server Browsing—Enable to allow remote users to browse for available file servers.
  - Hidden Share Access—Enable to hide shared folders.
- Port Forwarding Control—Provides users access to TCP-based applications over a Clientless SSL VPN connection through a Java Applet.
  - Port Forwarding List—Choose a previously-configured list TCP applications to associate with this group policy. Click **Manage** to create a new list or to edit an existing list.
  - Auto Applet Download—Enables automatic installation and starting of the Applet the first time the user logs in.
  - Applet Name—Changes the name of the title bar that of the Applet dialog box to the name you designate. By default, the name is Application Access.
- Smart Tunnel—Specify your smart tunnel options using a clientless (browser-based) SSL VPN session with the ASA as the pathway and the security appliance as a proxy server:
  - Smart Tunnel Policy—Choose from the network list and specify one of the tunnels options: use smart tunnel for the specified network, do not use smart tunnel for the specified network, or use tunnel for all network traffic. Assigning a smart tunnel network to a group policy or username enables smart tunnel access for all users whose sessions are associated with the group policy or username but restricts smart tunnel access to the applications specified in the list. To view, add, modify, or delete a smart tunnel list, click **Manage**.
  - Smart Tunnel Application—Choose from the drop-down menu to connect a Winsock 2, TCP-based application installed on the end station to a server on the intranet. To view, add, modify, or delete a smart tunnel application, click **Manage**.
  - Smart Tunnel all Applications—Check this check box to tunnel all applications. All applications are tunneled without choosing from the network list or knowing which executables an end user may invoke for external applications.
  - Auto Start—Check this check box to start smart tunnel access automatically upon user login. This option to start smart tunnel access upon user login applies only to Windows. Uncheck the check box to enable smart tunnel access upon user login but require the user to start it manually, using the Application Access > Start Smart Tunnels button on the Clientless SSL VPN Portal Page.
  - Auto Sign-on Server List—Choose the list name from the drop-down menu if you want to reissue the user credentials when the user establishes a smart tunnel connection to a server. Each smart tunnel auto sign-on list entry identifies a server with which to automate the submission of user credentials. To view, add, modify, or delete a smart tunnel auto sign-on list, click **Manage**.

  - Windows Domain Name (Optional)—Specify the Windows domain to add it to the username during auto sign-on, if the universal naming convention (domain\username) is required for authentication. For example, enter CISCO to specify CISCO\qa_team when authenticating for the username qu_team. You must also check the "Use Windows domain name with user name" option when configuring associated entries in the auto sign-on server list.

- ActiveX Relay—Lets Clientless users launch Microsoft Office applications from the browser. The applications use the session to download and upload Microsoft Office documents. The ActiveX relay remains in force until the Clientless SSL VPN session closes.

More Options:

- HTTP Proxy—Enables or disables the forwarding of an HTTP applet proxy to the client. The proxy is useful for technologies that interfere with proper content transformation, such as Java, ActiveX, and Flash. It bypasses mangling while ensuring the continued use of the security appliance. The forwarded proxy automatically modifies the old browser proxy configuration and redirects all HTTP and HTTPS requests to the new proxy configuration. It supports virtually all client side technologies, including HTML, CSS, JavaScript, VBScript, ActiveX, and Java. The only browser it supports is Microsoft Internet Explorer.
- Auto Start (HTTP Proxy)—Check to enable HTTP Proxy automatically upon user login. Uncheck to enable smart tunnel access upon user login, but require the user to start it manually.
- HTTP Compression—Enables compression of HTTP data over the Clientless SSL VPN session.

Configuring Portal Customization for a Clientless SSL VPN Internal Group Policy

To configure customization for a group policy, select a preconfigured portal customization object, or accept the customization provided in the default group policy. You can also configure a URL to display.

The procedure for customizing an access portal for a Clientless SSL VPN Access connection is the same as it is for a Network Client Access connection. See Customizing a VPN Access Portal for an Internal Group Policy, page 87-17.

Configuring Login Settings for a Clientless SSL VPN Internal Group Policy

In this dialog box, you can enable the ASA to prompt remote users to download the AnyConnect client or go to a Clientless SSL VPN portal page. See Configuring AnyConnect Login Settings for an Internal Group Policy, page 87-15.

Configuring Single Signon and Auto Signon Servers for a Clientless SSL VPN Access Internal Group Policy

To configure single sign-on servers and Auto sign-on servers, see "Auto Signon" in Chapter 71, "Clientless SSL VPN" in *Cisco ASA 5500 Series Configuration Guide using ASDM, 6.4 and 6.6* or "Using Single Sign-on with Clientless SSL VPN" in Chapter 73 of *Cisco ASA 5500 Series Configuration Guide using the CLI, 8.4 and 8.6.*

Configuring Session Settings for Clientless SSL VPN Access

The clientless SSL VPN Add/Edit Internal Group Policy > More Options > Session Settings window lets you specify personalized user information between clientless SSL VPN sessions. By default, each group policy inherits the settings from the default group policy. Use this window to specify personalized

clientless SSL VPN user information for the default group policy and any group policies for which you want to differentiate these values. See “Configuring Session Settings” Chapter 71, “Clientless SSL VPN” in *Cisco ASA 5500 Series Configuration Guide using ASDM, 6.4 and 6.6* or in Chapter 73 of *Cisco ASA 5500 Series Configuration Guide using the CLI, 8.4 and 8.6.*

Configuring Site-to-Site Internal Group Policies

Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > Add or Edit Internal Group Policy > General

The Add or Edit Group Policy dialog box lets you specify tunneling protocols, filters, connection settings, and servers for the group policy being added or modified. For each of the fields in this dialog box, checking the Inherit check box lets the corresponding setting take its value from the default group policy. Inherit is the default value for all of the attributes on this dialog box.

Fields

The following attributes appear in the Add Internal Group Policy > General dialog box. They apply to SSL VPN and IPsec sessions, or clientless SSL VPN sessions. Thus, several are present for one type of session, but not the other.

- Name—Specifies the name of this group policy. For the Edit function, this field is read-only.
- Tunneling Protocols—Specifies the tunneling protocols that this group can use. Users can use only the selected protocols. The choices are as follows:
  - Clientless SSL VPN—Specifies the use of VPN via SSL/TLS, which uses a web browser to establish a secure remote-access tunnel to a ASA; requires neither a software nor hardware client. Clientless SSL VPN can provide easy access to a broad range of enterprise resources, including corporate websites, web-enabled applications, NT/AD file share (web-enabled), e-mail, and other TCP-based applications from almost any computer that can reach HTTPS Internet sites.
  - SSL VPN Client—Specifies the use of the Cisco AnyConnect VPN client or the legacy SSL VPN client. If you are using the AnyConnect client, you must choose this protocol for MUS to be supported.
  - IPsec IKEv1—IP Security Protocol. Regarded as the most secure protocol, IPsec provides the most complete architecture for VPN tunnels. Both Site-to-Site (peer-to-peer) connections and Cisco VPN client-to-LAN connections can use IPsec IKEv1.
  - IPsec IKEv2—Supported by the AnyConnect Secure Mobility Client. AnyConnect connections using IPsec with IKEv2 provide advanced features such as software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy.
  - L2TP over IPsec—Allows remote users with VPN clients provided with several common PC and mobile PC operating systems to establish secure connections over the public IP network to the security appliance and private corporate networks. L2TP uses PPP over UDP (port 1701) to tunnel the data. The security appliance must be configured for IPsec transport mode.

  Note If you do not select a protocol, an error message appears.

- Filter—(Network (Client) Access only) Specifies which access control list to use, or whether to inherit the value from the group policy. Filters consist of rules that determine whether to allow or reject tunneled data packets coming through the ASA, based on criteria such as source address, destination address, and protocol. To configure filters and rules, see the Group Policy dialog box.

- Manage—Displays the ACL Manager dialog box, with which you can add, edit, and delete Access Control Lists (ACLs) and Extended Access Control Lists (ACEs). For more information about the ACL Manager, see the online Help for that dialog box.
- Idle Timeout—If the Inherit check box is not checked, this parameter specifies this user's idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system terminates the connection. The minimum time is 1 minute, and the maximum time is 10080 minutes. The default is 30 minutes. To allow unlimited connection time, check **Unlimited**. This value does not apply to Clientless SSL VPN users.
- Maximum Connect Time—If the Inherit check box is not checked, this parameter specifies the maximum user connection time in minutes. At the end of this time, the system terminates the connection. The minimum is 1 minute, and the maximum is 35791394 minutes (over 4000 years). To allow unlimited connection time, check Unlimited (the default).

Defining Time Ranges

You can get to this panel through various paths.

Use the Browse Time Range dialog box to add, edit, or delete a time range. A time range is a reusable component that defines starting and ending times that can be applied to a group policy. After defining a time range, you can select the time range and apply it to different options that require scheduling. For example, you can attach an access list to a time range to restrict access to the ASA. A time range consists of a start time, an end time, and optional recurring (that is, periodic) entries. For more information about time ranges, see the online Help for the Add or Edit Time Range dialog box.

Fields

- Add—Opens the Add Time Range dialog box, in which you can create a new time range.

Note Creating a time range does not restrict access to the device.

- Edit—Opens the Edit Time Range dialog box, in which you can modify an existing time range. This button is active only when you have selected an existing time range from the Browse Time Range table.
- Delete—Removes a selected time range from the Browse Time Range table. There is no confirmation or undo of this action.
- Name—Specifies the name of the time range.
- Start Time—Specifies when the time range begins.
- End Time—Specifies when the time range ends.
- Recurring Entries—Specifies further constraints of active time of the range within the start and stop time specified.

Add/Edit Time Range

You can get to this panel through various paths.

The Add or Edit Time Range dialog box lets you configure a new time range.

Fields

- Time Range Name—Specifies the name that you want to assign to this time range.

- Start Time—Defines the time when you want the time range to start.
  - Start now—Specifies that the time range starts immediately.
  - Start at—Selects the month, day, year, hour, and minute at which you want the time range to start.
- End Time—Defines the time when you want the time range to end.
  - Never end—Specifies that the time range has no defined end point.
  - End at (inclusive)—Selects the month, day, year, hour, and minute at which you want the time range to end.
- Recurring Time Ranges—Constrains the active time of this time range within the start and end times when the time range is active. For example, if the start time is start now and the end time is never end, and you want the time range to be effective every weekday, Monday through Friday, from 8:00 AM to 5:00 PM, you could configure a recurring time range, specifying that it is to be active weekdays from 08:00 through 17:00, inclusive.
- Add—Opens the Add Recurring Time Range dialog box, in which you can configure a recurring time range.
- Edit—Opens the Edit Recurring Time Range dialog box, in which you can modify a selected recurring time range.
- Delete—Removes a selected recurring time range.

Add/Edit Recurring Time Range

You can get to this panel through various paths.

The Add or Edit Recurring Time Range dialog box lets you configure or modify a recurring time range.

Fields

- Specify days of the week and times on which this recurring range will be active—Makes available the options in the Days of the week area. For example, use this option when you want the time range to be active only every Monday through Thursday, from 08:00 through 16:59.
  - Days of the week—Specifies the days that you want to include in this recurring time range. Possible options are: Every day, Weekdays, Weekends, and On these days of the week. For the last of these, you can check a check box for each day that you want included in the range.
  - Daily Start Time—Specifies the hour and minute, in 24-hour format, when you want the recurring time range to be active on each selected day.
  - Daily End Time (inclusive)—Specifies the hour and minute, in 24-hour format, when you want the recurring time range to end on each selected day.
- Specify a weekly interval when this recurring range will be active—Makes available the options in the Weekly Interval area. The range extends inclusively through the end time. All times in this area are in 24-hour format. For example, use this option when you want the time range to be active continuously from Monday at 8:00 AM through Friday at 4:30 PM.
  - From—Selects the day, hour, and minute when you want the weekly time range to start.
  - Through—Selects the day, hour, and minute when you want the weekly time range to end.

Access Control List Manager

You can get to this panel through various paths.

The ACL Manager dialog box lets you define access control lists (ACLs) to control the access of a specific host or network to another host/network, including the protocol or port that can be used.

You can configure ACLs (access control lists) to apply to user sessions. These are filters that permit or deny user access to specific networks, subnets, hosts, and web servers.

- If you do not define any filters, all connections are permitted.
- The ASA supports only an inbound ACL on an interface.
- At the end of each ACL, there is an implicit, unwritten rule that denies all traffic that is not permitted. If traffic is not explicitly permitted by an access control entry (ACE), the ASA denies it. ACEs are referred to as rules in this section.

Standard Access Control List

This pane provides summary information about standard ACLs, and lets you add or edit ACLs and ACEs.

Fields

- Add—Lets you add a new ACL. When you highlight an existing ACL, it lets you add a new ACE for that ACL.
- Edit—Opens the Edit ACE dialog box, in which you can change an existing access control list rule.
- Delete—Removes an ACL or ACE. There is no confirmation or undo.
- Move Up/Move Down—Changes the position of a rule in the ACL Manager table.
- Cut—Removes the selection from the ACL Manager table and places it on the clipboard.
- Copy—Places a copy of the selection on the clipboard.
- Paste—Opens the Paste ACE dialog box, in which you can create a new ACL rule from an existing rule.
- No—Indicates the order of evaluation for the rule. Implicit rules are not numbered, but are represented by a hyphen.
- Address—Displays the IP address or URL of the application or service to which the ACE applies.
- Action—Specifies whether this filter permits or denies traffic flow.
- Description—Shows the description you typed when you added the rule. An implicit rule includes the following description: “Implicit outbound rule.”

Extended Access Control List

This pane provides summary information about extended ACLs, and lets you add or edit ACLs and ACEs.

Fields

- Add—Lets you add a new ACL. When you highlight an existing ACL, it lets you add a new ACE for that ACL.
- Edit—Opens the Edit ACE dialog box, in which you can change an existing access control list rule.

- Delete—Removes an ACL or ACE. There is no confirmation or undo.
- Move Up/Move Down—Changes the position of a rule in the ACL Manager table.
- Cut—Removes the selection from the ACL Manager table and places it on the clipboard.
- Copy—Places a copy of the selection on the clipboard.
- Paste—Opens the Paste ACE dialog box, in which you can create a new ACL rule from an existing rule.
- No—Indicates the order of evaluation for the rule. Implicit rules are not numbered, but are represented by a hyphen.
- Enabled—Enables or disables a rule. Implicit rules cannot be disabled.
- Source—Specifies the IP addresses (Host/Network) that are permitted or denied to send traffic to the IP addresses listed in the Destination column. In detail mode (see the Show Detail radio button), an address column might contain an interface name with the word any, such as inside: any. This means that any host on the inside interface is affected by the rule.
- Destination—Specifies the IP addresses (Host/Network) that are permitted or denied to send traffic to the IP addresses listed in the Source column. An address column might contain an interface name with the word any, such as outside: any. This means that any host on the outside interface is affected by the rule. An address column might also contain IP addresses; for example 209.165.201.1-209.165.201.30. These addresses are translated addresses. When an inside host makes a connection to an outside host, the firewall maps the address of the inside host to an address from the pool. After a host creates an outbound connection, the firewall maintains this address mapping. The address mapping structure is called an xlate, and remains in memory for a period of time. During this time, outside hosts can initiate connections to the inside host using the translated address from the pool, if allowed by the ACL. Normally, outside-to-inside connections require a static translation so that the inside host always uses the same IP address.
- Service—Names the service and protocol specified by the rule.
- Action—Specifies whether this filter permits or denies traffic flow.
- Logging—Shows the logging level and the interval in seconds between log messages (if you enable logging for the ACL). To set logging options, including enabling and disabling logging, right-click this column, and click Edit Log Option. The Log Options dialog box appears.
- Time—Specifies the name of the time range to be applied in this rule.
- Description—Shows the description you typed when you added the rule. An implicit rule includes the following description: “Implicit outbound rule.”

Add/Edit/Paste ACE

ACL Manager > Add/Edit/Paste Extended ACE

The Add/Edit/Paste ACE dialog box lets you create a new extended access list rule, or modify an existing rule. The Paste option becomes available only when you cut or copy a rule.

Fields

- Action—Determines the action type of the new rule. Select either permit or deny.
  - Permit—Permits all matching traffic.
  - Deny—Denies all matching traffic.

- Source/Destination—Specifies the source or destination type and, depending on that type, the other relevant parameters describing the source or destination host/network IP Address. Possible values are: any, IP address, Network Object Group, and Interface IP. The availability of subsequent fields depends upon the value of the Type field:
  - any—Specifies that the source or destination host/network can be any type. For this value of the Type field, there are no additional fields in the Source or Destination area.
  - IP Address—Specifies the source or destination host or network IP address. Both IPv4 and IPv6 addresses are supported. With this selection, the IP Address, ellipsis button, and Netmask fields become available. Choose an IP address or host name from the drop-down list in the IP Address field or click the ellipsis (...) button to browse for an IP address or name. Select a network mask from the drop-down list.
  - Network Object Group—Specifies the name of the network object group. Choose a name from the drop-down list or click the ellipsis (...) button to browse for a network object group name.
  - Interface IP—Specifies the interface on which the host or network resides. Select an interface from the drop-down list. The default values are inside and outside. There is no browse function.
- Protocol and Service—Specifies the protocol and service to which this ACE filter applies. Service groups let you identify multiple non-contiguous port numbers that you want the ACL to match. For example, if you want to filter HTTP, FTP, and port numbers 5, 8, and 9, define a service group that includes all these ports. Without service groups, you would have to create a separate rule for each port.

  You can create service groups for TCP, UDP, TCP-UDP, ICMP, and other protocols. A service group with the TCP-UDP protocol contains services, ports, and ranges that might use either the TCP or UDP protocol.
  - Protocol—Selects the protocol to which this rule applies. Possible values are ip, tcp, udp, icmp, and other. The remaining available fields in the Protocol and Service area depend upon the protocol you select. The next few bullets describe the consequences of each of these selections:
  - Protocol: TCP and UDP—Selects the TCP/UDP protocol for the rule. The Source Port and Destination Port areas allow you to specify the ports that the ACL uses to match packets.
  - Source Port/Destination Port—(*Available only for TCP and UDP protocols*) Specifies an operator and a port number, a range of ports, or a well-known service name from a list of services, such as HTTP or FTP. The operator list specifies how the ACL matches the port. Choose one of the following operators: = (equals the port number), not = (does not equal the port number), > (greater than the port number), < (less than the port number), range (equal to one of the port numbers in the range).
  - Group—(*Available only for TCP and UDP protocols*) Selects a source port service group. The Browse (...) button opens the Browse Source Port or Browse Destination Port dialog box.
  - Protocol: ICMP—Lets you choose an ICMP type or ICMP group from a preconfigured list or browse (...) for an ICMP group. The Browse button opens the Browse ICMP dialog box.
  - Protocol: IP—Specifies the IP protocol for the rule in the IP protocol box. No other fields are available when you make this selection.
  - Protocol: Other—Lets you choose a protocol from a drop-down list, choose a protocol group from a drop-down list, or browse for a protocol group. The Browse (...) button opens the Browse Other dialog box.
- Rule Flow Diagram—(*Display only*) Provides a graphical representation of the configured rule flow. This same diagram appears on the ACL Manager dialog box unless you explicitly close that display.
- Options—Sets optional features for this rule, including logging parameters, time ranges, and description.

- Logging—Enables or disables logging or specifies the use of the default logging settings. If logging is enabled, the Syslog Level and Log Interval fields become available.
- Syslog Level—Selects the level of logging activity. The default is Informational.
- Log Interval—Specifies the interval for permit and deny logging. The default is 300 seconds. The range is 1 through 6000 seconds.
- Time Range—Selects the name of the time range to use with this rule. The default is (any). Click the Browse (...) button to open the Browse Time Range dialog box to select or add a time range.
- Description—(*Optional*) Provides a brief description of this rule. A description line can be up to 100 characters long, but you can break a description into multiple lines.

Browse Source/Destination Address

ACL Manager > Add/Edit Extended Access List Rule > Source or Destination > Browse button

The Browse Source or Destination Address dialog box lets you select an object to use as a source or destination for this rule.

Fields

- Type—Determines the type of object to use as the source or destination for this rule. Selections are IP Address Objects, IP Names, Network Object Groups, and All. The contents of the table following this field change, depending upon your selection.
- Source/Destination Object Table—Displays the objects from which you can select a source or destination object. If you choose All in the type field, each category of object appears under its own heading. The table has the following headings:
  - Name—Displays the network name (which may be an IP address) for each object.
  - IP address—Displays the IP address of each object.
  - Netmask—Displays the network mask to use with each object.
  - Description—Displays the description entered in the Add/Edit/Paste Extended Access List Rule dialog box.

Browse Source/Destination Port

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: tcp or udp >Source or Destination Port > Group option > Browse button

The Browse Source or Destination Port dialog box lets you select a source or destination port for this protocol in this rule.

Fields

- Add—Opens the Add TCP Service Group dialog box, in which you can configure a new TCP service group.
- Find—Opens the Filter field.
- Filter/Clear—Specifies a filter criterion that you can use to search for items in the Name list, thus displaying only those items that match that criterion. When you make an entry in the Filter field, the Filter button becomes active. Clicking the Filter button performs the search. After you perform the search, the Filter button is dimmed, and the Clear button becomes active. Clicking the Clear button clears the filter field and dims the Clear button.

- Type—Determines the type of object to use as the source or destination for this rule. Selections are IP Address Objects, IP Names, Network Object Groups, and All. The contents of the table following this field change, depending upon your selection.
- Name—Lists the predefined protocols and service groups for your selection.

Add TCP Service Group

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: tcp or udp >Source or Destination Port > Group option > Browse button > Browse Source or Destination Port > Add button

The Add TCP Service Group dialog box lets you configure a new a TCP service group or port to add to the browsable source or destination port list for this protocol in this rule. Selecting a member of either the Members not in Group or the Members in Group list activates the Add and Remove buttons.

Fields

- Group Name—Specifies the name of the new TCP service group.
- Description—(Optional) Provides a brief description of this group.
- Members not in Group—Presents the option to select either a service/service group or a port number to add to the Members in Group list.
- Service/Service Group—Selects the option to select the name of a TCP service or service group to add to the Members in Group list.
- Port #—Selects the option to specify a range of port numbers to add to the Members in Group list.
- Add—Moves a selected item from the Members not in Group list to the Members in Group list.
- Remove—Moves a selected item from the Members in Group list to the Members not in Group list.
- Members in Group—Lists the members already configured in this service group.

Browse ICMP

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: icmp >ICMP > Group option > Browse button

The Browse ICMP dialog box lets you select an ICMP group for this rule.

Fields

- Add—Opens the Add ICMP Group dialog box, in which you can configure a new TCP service group.
- Find—Opens the Filter field.
- Filter/Clear—Specifies a filter criterion that you can use to search for items in the Name list, thus displaying only those items that match that criterion. When you make an entry in the Filter field, the Filter button becomes active. Clicking the Filter button performs the search. After you perform the search, the Filter button is dimmed, and the Clear button becomes active. Clicking the Clear button clears the filter field and dims the Clear button.
- Type—Determines the type of object to use as the ICMP group for this rule. Selections are IP Address Objects, IP Names, Network Object Groups, and All. The contents of the table following this field change, depending upon your selection.
- Name—Lists the predefined ICMP groups for your selection.

Add ICMP Group

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: icmp >ICMP > Group option > Browse button > Browse ICMP > Add button

The Add ICMP Group dialog box lets you configure a new a ICMP group by name or by number to add to the browsable ICMP list for this protocol in this rule. Choosing a member of either the Members not in Group or the Members in Group list activates the Add and Remove buttons.

Fields

- Group Name—Specifies the name of the new TCP service group.
- Description—(Optional) Provides a brief description of this group.
- Members not in Group—Presents the option to select either an ICMP type/ICMP group or an ICMP number to add to the Members in Group list.
- ICMP Type/ICMP Group—Selects the option to select the name of an ICMP group to add to the Members in Group list.
- ICMP #—Selects the option to specify an ICMP member by number to add to the Members in Group list.
- Add—Moves a selected item from the Members not in Group list to the Members in Group list.
- Remove—Moves a selected item from the Members in Group list to the Members not in Group list.
- Members in Group—Lists the members already configured in this service group.

Browse Other

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: other >Other > Group option > Browse button

The Browse Other dialog box lets you select a protocol group for this rule.

Fields

- Add—Opens the Add Protocol Group dialog box, in which you can configure a new service group.
- Find—Opens the Filter field.
- Filter/Clear—Specifies a filter criterion that you can use to search for items in the Name list, thus displaying only those items that match that criterion. When you make an entry in the Filter field, the Filter button becomes active. Clicking the Filter button performs the search. After you perform the search, the Filter button is dimmed, and the Clear button becomes active. Clicking the Clear button clears the filter field and dims the Clear button.
- Type—Determines the type of object to use as the protocol group for this rule. Selections are IP Address Objects, IP Names, Network Object Groups, and All. The contents of the table following this field change, depending upon your selection.
- Name—Lists the predefined protocol groups for your selection.

Add Protocol Group

ACL Manager > Add/Edit Extended Access List Rule > Protocol and Service > Protocol: other > Group option > Browse button > Browse Other > Add button

The Add Protocol Group dialog box lets you configure a new a protocol group by name or by number to add to the browsable protocol list for this rule. Selecting a member of either the Members not in Group or the Members in Group list activates the Add and Remove buttons.

Fields

- Group Name—Specifies the name of the new TCP service group.
- Description—(Optional) Provides a brief description of this group.
- Members not in Group—Presents the option to select either a protocol/protocol group or a protocol number to add to the Members in Group list.
- Protocol/Protocol Group—Selects the option to select the name of a protocol or protocol group to add to the Members in Group list.
- Protocol #—Selects the option to specify a protocol by number to add to the Members in Group list.
- Add—Moves a selected item from the Members not in Group list to the Members in Group list.
- Remove—Moves a selected item from the Members in Group list to the Members not in Group list.
- Members in Group—Lists the members already configured in this service group.

Client Firewall with Local Printer and Tethered Device Support

When users connect to the ASA, all traffic is tunneled through the connection and users cannot access resources on their local network. This includes printers, cameras, and Windows Mobile devices (tethered devices) that synchronize with the local computer. Enabling Local LAN Access in the client profile resolves this problem, however it can introduce a security or policy concern for some enterprises as a result of unrestricted access to the local network. You can use the ASA to deploy endpoint OS firewall capabilities to restrict access to particular types of local resources, such as printers and tethered devices.

To do so, enable client firewall rules for specific ports for printing. The client distinguishes between inbound and outbound rules. For printing capabilities, the client opens ports required for outbound connections, but blocks all incoming traffic.

Note Be aware that users logged in as administrators have the ability to modify the firewall rules deployed to the client by the ASA. Users with limited privileges cannot modify the rules. For either user, the client reapplies the firewall rules when the connection terminates.

If you configure the client firewall, and the user authenticates to an Active Directory (AD) server, the client still applies the firewall policies from the ASA. However, the rules defined in the AD group policy take precedence over the rules of the client firewall.

The following sections describe procedures on how to do this:

- Deploying a Client Firewall for Local Printer Support, page 87-38
- Tethered Devices Support, page 87-39

Usage Notes about Firewall Behavior

The following notes clarify how the AnyConnect client uses the firewall:

- The source IP is not used for firewall rules. The client ignores the source IP information in the firewall rules sent from the ASA. The client determines the source IP depending on whether the rules are public or private. Public rules are applied to all interfaces on the client. Private rules are applied to the Virtual Adapter.

- The ASA supports many protocols for ACL rules. However, the AnyConnect firewall feature supports only TCP, UDP, ICMP, and IP. If the client receives a rule with a different protocol, it treats it as an invalid firewall rule, and then disables split tunneling and uses full tunneling for security reasons.
- Starting in ASA 9.0, the Public Network Rule and Private Network Rule support unified access control lists. These access control lists can be used to define IPv4 and IPv6 traffic in the same rule.

Be aware of the following differences in behavior for each operating system:

- For Windows computers, deny rules take precedence over allow rules in Windows Firewall. If the ASA pushes down an allow rule to the AnyConnect client, but the user has created a custom deny rule, the AnyConnect rule is not enforced.
- On Windows Vista, when a firewall rule is created, Vista takes the port number range as a comma-separated string. The port range can be a maximum of 300 ports. For example, from 1-300 or 5000-5300. If you specify a range greater than 300 ports, the firewall rule is applied only to the first 300 ports.
- Windows users whose firewall service must be started by the AnyConnect client (not started automatically by the system) may experience a noticeable increase in the time it takes to establish a VPN connection.
- On Mac computers, the AnyConnect client applies rules sequentially in the same order the ASA applies them. Global rules should always be last.
- For third-party firewalls, traffic is passed only if both the AnyConnect client firewall and the third-party firewall allow that traffic type. If the third-party firewall blocks a specific traffic type that the AnyConnect client allows, the client blocks the traffic.

Deploying a Client Firewall for Local Printer Support

The ASA supports the AnyConnect client firewall feature with ASA version 8.3(1) or later, and ASDM version 6.3(1) or later. This section describes how to configure the client firewall to allow access to local printers, and how to configure the client profile to use the firewall when the VPN connection fails.

Limitations and Restrictions of the Client Firewall

The following limitations and restrictions apply to using the client firewall to restrict local LAN access:

- Due to limitations of the OS, the client firewall policy on computers running Windows XP is enforced for inbound traffic only. Outbound rules and bidirectional rules are ignored. This would include firewall rules such as 'permit ip any any'.
- Host Scan and some third-party firewalls can interfere with the firewall.

Table 72-1 clarifies what direction of traffic is affected by the source and destination port settings:

Source Port	Destination Port	Traffic Direction Affected
Specific port number	Specific port number	Inbound and outbound
A range or 'All' (value of 0)	A range or 'All' (value of 0)	Inbound and outbound
Specific port number	A range or 'All' (value of 0)	Inbound only
A range or 'All' (value of 0)	Specific port number	Outbound only

Example ACL Rules for Local Printing

Table 87-1 shows example ACL rules for local printing:

Table 87-1 Example ACL Rules for Local Printing

Description	Permission	Interface	Protocol	Source Port	Destination Address	Destination Port
Deny all	Deny	Public	Any	Default[1]	Any	Default
LPD	Allow	Public	TCP	Default	Any	515
IPP	Allow	Public	TCP	Default	Any	631
Printer	Allow	Public	TCP	Default	Any	9100
mDNS	Allow	Public	UDP	Default	224.0.0.251	5353
LLMNR	Allow	Public	UDP	Default	224.0.0.252	5355
NetBios	Allow	Public	TCP	Default	Any	137
NetBios	Allow	Public	UDP	Default	Any	137

1. The port range is 1 to 65535.

Note To enable local printing, you must enable the **Local LAN Access** feature in the client profile with a defined ACL rule *allow Any Any.*

Configuring Local Print Support

Step 1 Enable the AnyConnect client firewall in a group policy. Go to **Configuration > Remote Access VPN > Network (Client) Access > Group Policies**.

Step 2 Select a group policy and click **Edit**. The Edit Internal Group Policy window displays.

Step 3 Select **Advanced > AnyConnect Client > Client Firewall**. Click **Manage** for the Private Network Rule.

Step 4 Create an ACL and specify an ACE using the rules in Table 87-1. Add this ACL as a PrivateNetwork Rule.

Step 5 If you enabled the Automatic VPN Policy always-on and specified a closed policy, in the event of a VPN failure, users have no access to local resources. You can apply the firewall rules in this scenario by going to **Preferences (Cont) in the profile editor and** checking **Apply last local VPN resource rules**.

Tethered Devices Support

To support tethered devices and protect the corporate network, create a standard ACL in the group policy, specifying destination addresses in the range that the tethered devices use. Then specify the ACL for split tunneling as a network list to exclude from tunneled VPN traffic. You must also configure the client profile to use the last VPN local resource rules in case of VPN failure.

Note For Windows Mobile devices that need to sync with the computer running AnyConnect, specify the IPv4 destination address as 169.254.0.0, or the IPv6 destination address fe80::/64 in the ACL.

Follow these steps:

Step 1 In ASDM, go to **Group Policy > Advanced > Split Tunneling**.

Step 2 Uncheck **Inherit** next to the Network List field and click **Manage**. The ACL Manager displays.

Step 3 Click the **Extended ACL** tab.

Step 4 Click **Add** and then **Add ACL**. Specify a name for the new ACL.

Step 5 Choose the new ACL in the table and click **Add** and then **Add ACE**. The Edit ACE window displays.

Step 6 For Action, choose the **Permit** radio button.

Step 7 In the destination criteria area, specify the IPv4 destination address as 169.254.0.0 or the IPv6 destination address fe80::/64.

Step 8 For Service, choose *IP*.

Step 9 Click **OK**.

Step 10 Click OK to save the ACL.

Step 11 In the Split Tunneling pane for the internal group policy, uncheck Inherit for the Policy or IPv6 Policy, depending on the IP address you specified in step 7, and choose **Exclude Network List Below**. For Network List, choose the ACL you created.

Step 12 Click **OK**.

Step 13 Click **Apply**.

Fields

- Public Network Rule—Use the drop-down list to choose from the existing defined ACLs.

  Manage—Displays the ACL Manager dialog box, with which you can add, edit, and delete Access Control Lists (ACLs) and Extended Access Control Lists (ACEs).

- Private Network Rule—Use the drop-down list to choose from the existing defined ACLs.

  Manage—Displays the ACL Manager dialog box, with which you can add, edit, and delete Access Control Lists (ACLs) and Extended Access Control Lists (ACEs).

Configuring a Web ACLs

Configuration > Remote Access > Clientless SSL VPN Access > Advanced > Web ACLs

Configuration > Remote Access > Clientless SSL VPN Access > Group Policies > General > More Options > Web ACL

This dialog box lets you configure ACLs for Clientless SSL VPN connections.

Fields

- View (Unlabeled)—Indicates whether the selected entry is expanded (minus sign) or contracted (plus sign).
- # column—Specifies the ACE ID number.
- Enable—Indicates whether this ACL is enabled or disabled. You can enable or disable the ACL using this check box.
- Action—Specifies whether this ACL permits or denies access.

- Type—Specifies whether this ACL applies to a URL or a TCP address/port.
- Filter—Specifies the type of filter being applied.
- Syslog Level (Interval)—Specifies the syslog parameters for this ACL.
- Time Range—Specifies the name of the time range, if any, for this ACL. The time range can be a single interval or a series of periodic ranges.
- Description—Specifies the description, if any, of the ACL.
- Add ACL—Displays the Add Web Type ACL dialog box, in which you can specify an ACL ID.
- Add ACE—Displays the Add Web Type ACE dialog box, in which you specify parameters for the named ACL. This button is active only if there are one or more entries in the Web Type ACL table.
- Edit ACE/Delete—Click to edit or delete the highlighted ACL or ACE. When you delete an ACL, you also delete all of its ACEs. No warning or undelete.
- Move Up/Move Down—Highlight an ACL or ACE and click these buttons to change the order of ACLs and ACEs. The ASA checks ACLs and their ACEs in priority order according to their position in the ACLs list box until it finds a match.

Add/Edit Standard Access List Rule

ACL Manager > Add or Edit Standard Access List Rule

The Add/Edit Standard Access List Rule dialog box lets you create a new rule, or modify an existing rule.

Fields

- Action—Determines the action type of the new rule. Choose either Permit or Deny.
  - Permit—Permits all matching traffic.
  - Deny—Denies all matching traffic.
- Host/Network IP Address—Identifies the networks by IP address.
  - IP address—The IP address of the host or network.
  - Mask—The subnet mask of the host or network
- Description—(Optional) Enter a description of the access rule.

Add/Edit Server and URL List

Configuration > VPN > General > Group Policy > Add/Edit > Internal Group Policy > Web VPN Tab > Other Tab > Add or Edit Server and URL List

The Add or Edit Server and URL List dialog box lets you add, edit, delete, and order the items in the designated URL list.

Fields

- List Name—Specifies the name of the list to be added or selects the name of the list to be modified or deleted.
- URL Display Name—Specifies the URL name displayed to the user.
- URL—Specifies the actual URL associated with the display name.

- Add—Opens the Add Server or URL dialog box, in which you can configure a new server or URL and display name.
- Edit—Opens the Edit Server or URL dialog box, in which you can configure a new server or URL and display name.
- Delete—Removes the selected item from the server and URL list. There is no confirmation or undo.
- Move Up/Move Down—Changes the position of the selected item in the server and URL list.

Add/Edit Server or URL

Configuration > VPN > General > Group Policy > Add/Edit > Internal Group Policy > Web VPN Tab > Other Tab > Add or Edit Server and URL

The Add or Edit Server or URL dialog box lets you add or edit, delete, and order the items in the designated URL list.

Fields

- URL Display Name—Specifies the URL name displayed to the user.
- URL—Specifies the actual URL associated with the display name.

Configuring AnyConnect VPN Client Connections

The Cisco AnyConnect VPN client provides secure SSL or IPsec (IKEv2) connections to the ASA for remote users. The client gives remote users the benefits of a VPN client without the need for network administrators to install and configure clients on remote computers.

Without a previously-installed client, remote users enter the IP address in their browser of an interface configured to accept SSL VPN connections. Unless the ASA is configured to redirect http:// requests to https://, users must enter the URL in the form https://<*address*>.

After entering the URL, the browser connects to that interface and displays the login screen. If the user satisfies the login and authentication, and the ASA identifies the user as requiring the client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a VPN connection and either remains or uninstalls itself (depending on the ASA configuration) when the connection terminates.

In the case of a previously installed client, when the user authenticates, the ASA examines the revision of the client, and upgrades the client as necessary.

The AnyConnect client can be downloaded from the ASA, or it can be installed manually on the remote PC by the system administrator. For more information about installing the client manually, see the *AnyConnect Administrators Guide*.

The ASA downloads the client based on the group policy or username attributes of the user establishing the connection. You can configure the ASA to automatically download the client, or you can configure it to prompt the remote user about whether to download the client. In the latter case, if the user does not respond, you can configure the ASA to either download the client after a timeout period or present the login page.

Fields

- Keep Installer on Client System—Enable to allow permanent client installation on the remote computer. Enabling disables the automatic uninstalling feature of the client. The client remains installed on the remote computer for subsequent connections, reducing the connection time for the remote user.

Note Keep Installer on Client System is not supported after version 2.5 of the AnyConnect client.

- Compression—Compression increases the communications performance between the security appliance and the client by reducing the size of the packets being transferred.
- Datagram TLS—Datagram Transport Layer Security avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.
- Ignore Don't Defrag (DF) Bit—This feature allows the force fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel. An example use case is for servers in your network that do not respond correctly to TCP MSS negotiations.
- Client Bypass Protocol—The Client Protocol Bypass feature allows you to configure how the ASA manages IPv4 traffic when it is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic.

  When the AnyConnect client makes a VPN connection to the ASA, the ASA could assign it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the ASA assigns the AnyConnect connection only an IPv4 address or only an IPv6 address, you can now configure the Client Bypass Protocol to drop network traffic for which the ASA did not assign an IP address, or allow that traffic to bypass the ASA and be sent from the client unencrypted or "in the clear".

  For example, assume that the ASA assigns only an IPv4 address to an AnyConnect connection and the endpoint is dual stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.
- FQDN of This Device—This information is used by the client after network roaming in order to resolve the ASA IP address used for re-establishing the VPN session. This setting is critical to support roaming between networks of different IP protocols (such as IPv4 to IPv6).

  Note You cannot use the ASA FQDN present in the AnyConnect profile to derive the ASA IP address after roaming. The addresses may not match the correct device (the one the tunnel was established to) in the load balancing scenario.

  If the device FQDN is not pushed to the client, the client will try to reconnect to whatever IP address the tunnel had previously established. In order to support roaming between networks of different IP protocols (from IPv4 to IPv6), AnyConnect must perform name resolution of the device FQDN after roaming, so that it can determine which ASA address to use for re-establishing the tunnel. The client uses the ASA FQDN present in its profile during the initial connection. During subsequent session reconnects, it always uses the device FQDN pushed by ASA (and configured by the administrator in the group policy), when available. If the FQDN is not configured, the ASA derives the device FQDN (and sends it to the client) from whatever is set under Device Setup > Device Name/Password and Domain Name.

  If the device FQDN is not pushed by the ASA, the client cannot re-establish the VPN session after roaming between networks of different IP protocols.

- MTU—Adjusts the MTU size for SSL connections. Enter a value in bytes, from 256 to 1410 bytes. By default, the MTU size is adjusted automatically based on the MTU of the interface that the connection uses, minus the IP/UDP/DTLS overhead.
- Keepalive Messages—Enter a number, from 15 to 600 seconds, in the Interval field to enable and adjust the interval of keepalive messages to ensure that an connection through a proxy, firewall, or NAT device remains open, even if the device limits the time that the connection can be idle. Adjusting the interval also ensures that the client does not disconnect and reconnect when the remote user is not actively running a socket-based application, such as Microsoft Outlook or Microsoft Internet Explorer.
- **Optional Client Modules to Download**—To minimize download time, the AnyConnect client requests downloads (from the ASA) only of modules that it needs for each feature that it supports. You must specify the names of modules that enable other features. The AnyConnect client, version 3.0, includes the following modules (previous versions have fewer modules):
  - AnyConnect DART—The Diagnostic AnyConnect Reporting Tool (DART) captures a snapshot of system logs and other diagnostic information and creates a .zip file on your desktop so you can conveniently send troubleshooting information to Cisco TAC.
  - AnyConnect Network Access Manager—Formerly called the Cisco Secure Services Client, this module provides 802.1X (Layer 2) and device authentication for access to both wired and wireless network is integrated into AnyConnect 3.0.
  - AnyConnect SBL—Start Before Logon (SBL) forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting AnyConnect before the Windows login dialog box appears.
  - AnyConnect Web Security Module—Formerly called ScanSafe Hostscan, this module is integrated into the AnyConnect 3.0.
  - AnyConnect Telemetry Module—Sends information about the origin of malicious content to the web filtering infrastructure of the Cisco IronPort Web Security Appliance (WSA), which uses this data to provide better URL filtering rules.
  - AnyConnect Posture Module—Formerly called the Cisco Secure Desktop HostScan feature, the posture module is integrated into AnyConnect 3.0 and provides AnyConnect the ability to gather credentials for posture assessment prior to creating a remote access connection to the ASA.
- Always-On VPN—Determine if the always-on VPN flag setting in the AnyConnect service profile is disabled or if the AnyConnect service profile setting should be used. The always-on VPN feature lets AnyConnnect automatically establish a VPN session after the user logs onto a computer. The VPN session remains up until the user logs off the computer. If the physical connection is lost, the session remains up, and AnyConnect continually attempts to reestablish the physical connection with the adaptive security appliance to resume the VPN session.

  Always-on VPN permits the enforcement of corporate policies to protect the device from security threats. You can use it to help ensure AnyConnect establishes a VPN session whenever the endpoint is not in a trusted network. If enabled, a policy is configured to determine how network connectivity is managed in the absence of a connection.

Note Always-On VPN requires an AnyConnect release that supports AnyConnect Secure Mobility features. Refer to the *Cisco AnyConnect VPN Client Administrator Guide* for additional information.

- Client Profiles to Download—A profile is a group of configuration parameters that the AnyConnect client uses to configure VPN, Network Access Manager, web security, and telemetry settings. Click Add to launch the Select Anyconnect Client Profiles window where you can specify previously-created profiles for this group policy.

Using AnyConnect Client Profiles

You enable Cisco AnyConnect Secure Mobility client features in the AnyConnect profiles—XML files that contain configuration settings for the core client with its VPN functionality and for the optional client modules Network Access Manager, telemetry, and web security. The ASA deploys the profiles during AnyConnect installation and updates. Users cannot manage or modify profiles.

You can configure a profile using the AnyConnect profile editor, a convenient GUI-based configuration tool launched from ASDM. The AnyConnect software package, version 2.5 and later (for all OSs), includes the editor, which activates when you load the AnyConnect package on the ASA as an AnyConnect client image. Alternatively, you can manually edit the XML file and import the file to the ASA as a profile.

You can configure the ASA to deploy profiles globally for all AnyConnect users or to users based on their group policy. Usually, a user has a single profile file for each AnyConnect module installed. In some cases, you might want to provide more than one profile for a user. Someone who works from multiple locations might need more than one profile. Be aware that some of the profile settings (such as SBL) control the connection experience at a global level. Other settings are unique to a particular host and depend on the host selected.

Some profile settings are stored locally on the user computer in a user preferences file or a global preferences file. The user file has information the client needs to display user-controllable settings in the Preferences tab of the client GUI and information about the last connection, such as the user, the group, and the host. The global file has information about user-controllable settings to be able to apply those settings before login (since there is no user). For example, the client needs to know if Start Before Logon and/or AutoConnect On Start are enabled before login. For more information about creating and deploying AnyConnect client profiles and controlling client features, see the *AnyConnect VPN Client Administrator Guide*.

Fields

Add—Displays the Add AnyConnect Client Profiles dialog box, where you can specify a file in flash memory as a profile, or where you can browse flash memory for a file to specify as a profile. You can also upload a file from a local computer to the flash memory.

Edit—Displays the Edit SSL VPN Client Profile window, where you can change the settings contained in the profile for AnyConnect client features.

Delete—Deletes a profile from the table. This does not delete the XML file from flash.

AnyConnect Client Profiles Table—Displays the XML files specified as AnyConnect client profiles:

- **Profile Name**—The name of the profile specified when the profile was added.
- **Profile Usage/Type**—Displays the use for this profile, such as VPN, Network Access Manager, or telemetry.

Specifying an AnyConnect Client Profile

Specify an AnyConnect client profile for this group policy.

For more information about creating and deploying AnyConnect client profiles and controlling client features, see the *AnyConnect VPN Client Administrator Guide*.

Fields

Profile Name—Specify an AnyConnect client profile for this group policy.

Profile Usage—Displays the usage assigned to the profile when originally created: VPN, Network Access Manager, web security, or telemetry. If ASDM does not recognize the usage specified in the XML file, the drop-down list becomes selectable and you can choose a usage type manually.

Profile Location—Specify a path to the profile file in the ASA flash memory. If the file does not exist, the ASA creates one based on the profile template.

Importing an AnyConnect Client Profile

Import a new AnyConnect client profile in this window. You can import a profile from a local device or a remote server.

For more information about creating and deploying AnyConnect client profiles and controlling client features, see the *AnyConnect VPN Client Administrator Guide*.

Fields

Profile Name—Specify a name for the profile you add.

Profile Usage—Displays the usage assigned to the profile when originally created: VPN, Network Access Manager, web security, or telemetry. If ASDM does not recognize the usage specified in the XML file, the drop-down list becomes selectable and you can choose a usage type manually.

Group Policy—Specify a group policy for this profile. The profile downloads to users belonging to the group policy along with the AnyConnect client.

Profile Location—Specify a path to the profile file in the ASA flash memory. If the file does not exist, the ASA creates one based on the profile template.

Exporting an AnyConnect Client Profile

Export an AnyConnect VPN client profile from this window. You can export to a local device or a remote server.

For more information about creating and deploying AnyConnect client profiles and controlling client features, see the *AnyConnect VPN Client Administrator Guide*.

Fields

Device Profile Path—Displays the path and filename of the profile file.

Local Path—Specify the path and filename to export the profile file.

Browse Local—Click to launch a window to browse the local device file system.

Exempting AnyConnect Traffic from Network Address Translation

If you have configured your ASA to perform network address translation (NAT), you must exempt your remote access AnyConnect client traffic from being translated so that the AnyConnect clients, internal networks, and corporate resources on a DMZ, can originate network connections to each other. Failing to exempt the AnyConnect client traffic from being translated prevents the AnyConnect clients and other corporate resources from communicating.

"Identity NAT" (also known as "NAT exemption") allows an address to be translated to itself, which effectively bypasses NAT. Identity NAT can be applied between two address pools, an address pool and a subnetwork, or two subnetworks.

This procedure illustrates how you would configure identity NAT between these hypothetical network objects in our example network topology: Engineering VPN address pool, Sales VPN address pool, inside network, a DMZ network, and the Internet. Each Identity NAT configuration requires one NAT rule.

Table 87-2 Network Addressing for Configuring Identity NAT for VPN Clients

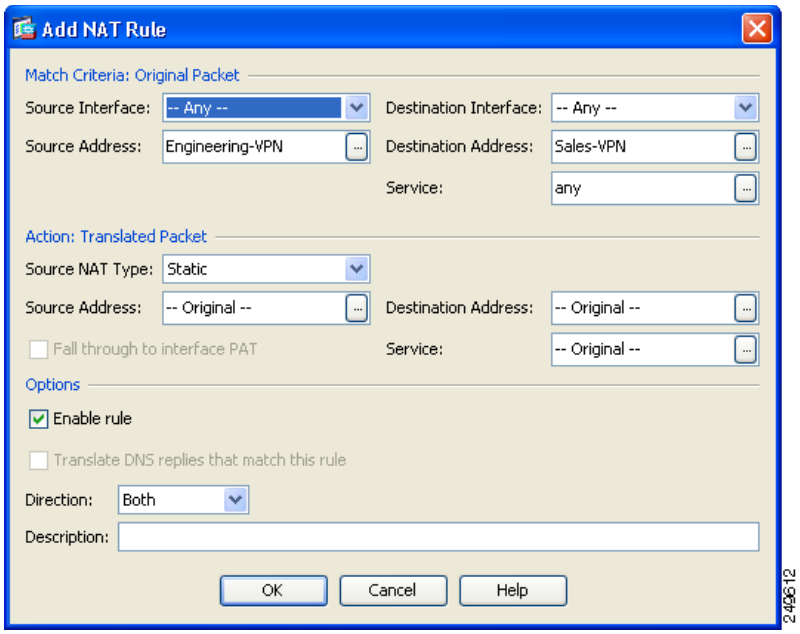
Network or Address Pool	Network or address pool name	Range of addresses
Inside network	inside-network	10.50.50.0 - 10.50.50.255
Engineering VPN address pool	Engineering-VPN	10.60.60.1 - 10.60.60.254
Sales VPN address pool	Sales-VPN	10.70.70.1 - 10.70.70.254
DMZ network	DMZ-network	192.168.1.0 - 192.168.1.255

Step 1 Log into the ASDM and select **Configuration > Firewall > NAT Rules**.

Step 2 Create a NAT rule so that the hosts in the Engineering VPN address pool can reach the hosts in the Sales VPN address pool. In the NAT Rules pane, select **Add > Add NAT Rule Before "Network Object" NAT rules** so that the ASA evaluates this rule before other rules in the Unified NAT table. See Figure 87-2 on page 87-48 for an example of the Add NAT rule dialog box.

Note NAT rule evaluation is applied on a top-down, first match basis. Once the ASA matches a packet to a particular NAT rule it does not perform any further evaluation. It is important that you place the most specific NAT rules at the top of the Unified NAT table so that the ASA does not prematurely match them to broader NAT rules.

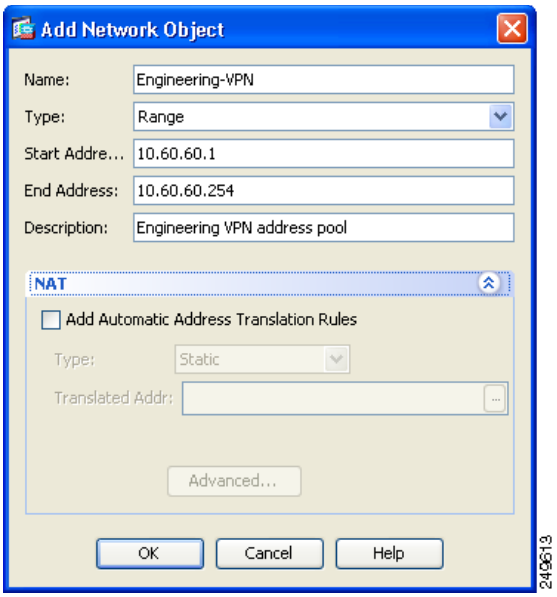
Figure 87-2 Add NAT rule dialog box



a. In the **Match criteria: Original Packet** area, configure these fields:

- Source Interface: Any
- Destination Interface: Any
- Source Address: Click the Source Address browse button and create the network object that represents the Engineering VPN address pool. Define the object type as a **Range** of addresses. Do not add an automatic address translation rule. See Figure 87-3 for an example.
- Destination Address: Click the Destination Address browse button and create the network object that represents the Sales VPN address pool. Define the object type as a **Range** of addresses. Do not add an automatic address translation rule.

Figure 87-3 Create Network Object for a VPN address pool



b. In the **Action Translated Packet** area, configure these fields:
   - Source NAT Type: Static
   - Source Address: Original
   - Destination Address: Original
   - Service: Original

c. In the **Options** area, configure these fields:
   - Check **Enable rule**.
   - Uncheck or leave empty the **Translate DNS replies that match this rule**.
   - Direction: Both
   - Description: Add a Description for this rule.

d. Click **OK**.

e. Click **Apply**. Your rule should look like rule 1 in the Unified NAT table in Figure 87-5 on page 87-52.

   CLI example:

```
nat source static Engineering-VPN Engineering-VPN destination static Sales-VPN
Sales-VPN
```

f. Click **Send**.

Step 3 When ASA is performing NAT, in order for two hosts in the same VPN pool to connect to each other, or for those hosts to reach the Internet through the VPN tunnel, you must enable the **Enable traffic between two or more hosts connected to the same interface** option. To do this, in ASDM, select **Configuration > Device Setup > Interfaces**. At the bottom of the Interface panel, check **Enable traffic between two or more hosts connected to the same interface** and click **Apply**.

CLI example:

```
same-security-traffic permit inter-interface
```

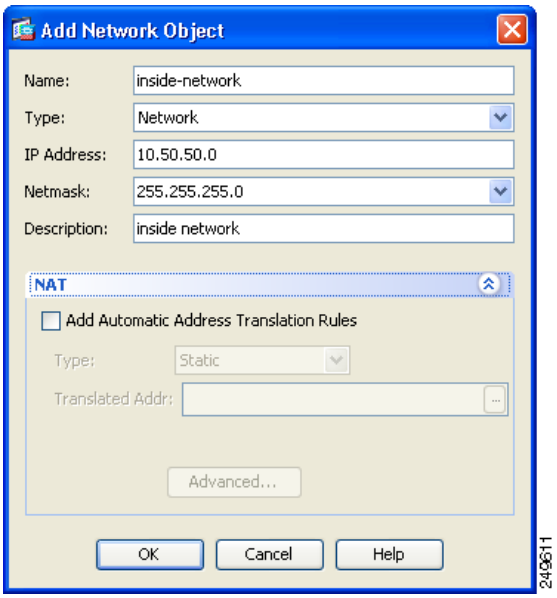
Step 4 Create a NAT rule so that the hosts in the Engineering VPN address pool can reach other hosts in the Engineering VPN address pool. Create this rule just as you created the rule in Step 2 except that you specify the Engineering VPN address pool as both the Source address and the Destination Address in the **Match criteria: Original Packet** area.

Step 5 Create a NAT rule so that the Engineering VPN remote access clients can reach the "inside" network. In the NAT Rules pane, select **Add > Add NAT Rule Before "Network Object" NAT rules** so that this rule will be processed before other rules.

a. In the **Match criteria: Original Packet** area configure these fields:

- Source Interface: Any
- Destination Interface: Any
- Source Address: Click the Source Address browse button and create a network object that represents the inside network. Define the object type as a **Network** of addresses. Do not add an automatic address translation rule.
- Destination Address: Click the Destination Address browse button and select the network object that represents the Engineering VPN address pool.

Figure 87-4 Add inside-network object



b. In the **Action: Translated Packet** area, configure these fields:

- Source NAT Type: Static
- Source Address: Original
- Destination Address: Original
- Service: Original

c. In the **Options** area, configure these fields:

- Check **Enable rule**.
- Uncheck or leave empty the **Translate DNS replies that match this rule**.
- Direction: Both

- Description: Add a Description for this rule.

d. Click **OK**.

e. Click **Apply**. Your rule should look like rule two in the Unified NAT table in Figure 87-5 on page 87-52.

CLI example

```
nat source static inside-network inside-network destination static Engineering-VPN
Engineering-VPN
```

Step 6 Create a new rule, following the method in Step 5, to configure identity NAT for the connection between the Engineering VPN address pool and the DMZ network. Use the DMZ network as the Source Address and use the Engineering VPN address pool as the Destination address.

Step 7 Create a new NAT rule to allow the Engineering VPN address pool to access the Internet through the tunnel. In this case, you do not want to use identity NAT because you want to change the source address from a private address to an Internet routable address. To create this rule, follow this procedure:

a. In the NAT Rules pane, select **Add > Add NAT Rule Before "Network Object" NAT rules** so that this rule will be processed before other rules.

b. In the **Match criteria: Original Packet** area configure these fields:

- Source Interface: Any
- Destination Interface: Any. This field will be automatically populated with "outside" after you select outside as the Source Address in the **Action: Translated Packet** area.
- Source Address: Click the Source Address browse button and select the network object that represents the Engineering VPN address pool.
- Destination Address: Any.

c. In the **Action: Translated Packet** area, configure these fields:

- Source NAT Type: Dynamic PAT (Hide)
- Source Address: Click the Source Address browse button and select the **outside** interface.
- Destination Address: Original
- Service: Original

d. In the **Options** area, configure these fields:

- Check **Enable rule**.
- Uncheck or leave empty the **Translate DNS replies that match this rule**.
- Direction: Both
- Description: Add a Description for this rule.

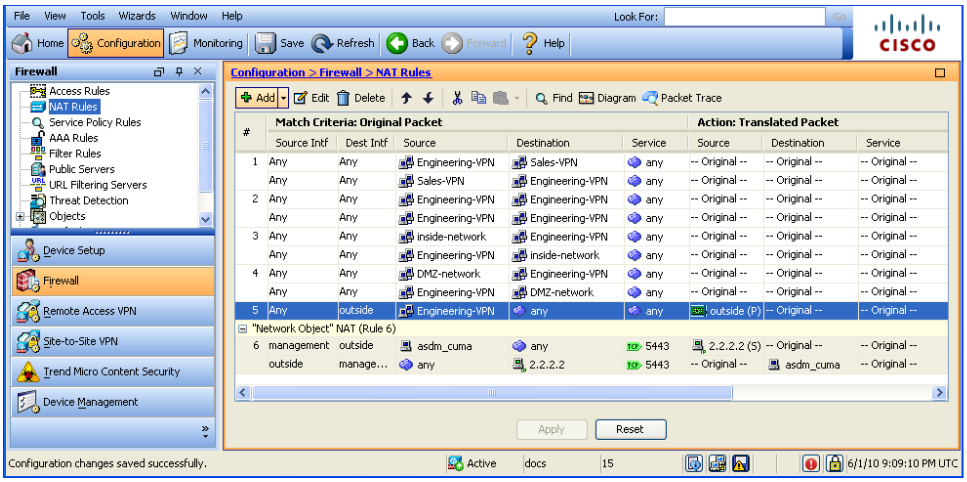
e. Click **OK**.

f. Click **Apply**. Your rule should look like rule five in the Unified NAT table in Figure 87-5 on page 87-52.

CLI example:

nat (any,outside) source dynamic Engineering-VPN interface

Figure 87-5 Unified NAT table



Step 8 After you have configured the Engineering VPN Address pool to reach itself, the Sales VPN address pool, the inside network, the DMZ network, and the Internet; you must repeat this process for the Sales VPN address pool. Use identity NAT to exempt the Sales VPN address pool traffic from undergoing network address translation between itself, the inside network, the DMZ network, and the Internet.

Step 9 From the **File** menu on the ASA, select **Save Running Configuration to Flash** to implement your identity NAT rules.

Configuring AnyConnect VPN Connections

Use the AnyConnect Connection Profiles pane and its child dialog boxes to specify VPN connection attributes for client-based connections. These attributes apply to the Cisco AnyConnect VPN client and to the legacy SSL VPN client.

The initial client deployment requires end-user administrative rights. The Cisco AnyConnect VPN client supports the HTTPS/TCP (SSL) and Datagram Transport Layer Security (DTLS) tunneling options.

In the main pane, you can enable client access on the interfaces you select and you can select, add, edit, and delete connections (tunnel groups). You can also specify whether you want to allow a user to select a particular connection at login.

Fields

- Access Interfaces—Lets you select from a table the interfaces on which to enable access. The fields in this table include the interface name and check boxes specifying whether to allow access.
  - In the Interface table, in the row for the interface you are configuring for AnyConnect connections, check the protocols you want to enable on the interface. You can allow SSL Access, IPsec access, or both.

    When checking SSL, DTLS (Datagram Transport Layer Security) is enabled by default. DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

When checking IPsec (IKEv2) access, client services are enabled by default. Client services include enhanced Anyconnect features including software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy. If you disable client services, the AnyConnect client still establishes basic IPsec connections with IKEv2.

  - Device Certificate—Lets you specify a certificate for authentication for either an RSA key or an ECDSA key. See Specifying a Device Certificate for AnyConnect Access, page 87-53.
  - Port Setting—Configure port numbers for clientless SSL and IPsec (IKEv2) connections. See Configuring Port Settings, page 87-54.
  - Enable inbound VPN sessions to bypass interface access lists is checked by default.— The security appliance allows all VPN traffic to pass through the interface ACLs. For example, even if the outside interface ACL does not permit the decrypted traffic to pass through, the security appliance trusts the remote private network and permits the decrypted packets to pass through. You can change this default behavior. If you want the interface ACL to inspect the VPN protected traffic, uncheck this box.

- Login Page Setting
  - Allow the user to select a connection profile, identified by its alias, on the login page. If you do not check this check box, the default connection profile is DefaultWebVPNGroup.
  - Shutdown portal login page.—Shows the web page when the login is disabled.
- Connection Profiles—Configure protocol-specific attributes for connections (tunnel groups).
  - Add/Edit—Click to Add or Edit a Connection Profile (tunnel group).
  - Name—The name of the Connection Profile.
  - Aliases—Other names by which the Connection Profile is known.
  - SSL VPN Client Protocol—Specifies whether SSL VPN client have access.
  - Group Policy—Shows the default group policy for this Connection Profile.
  - Allow user to select connection, identified by alias in the table above, at login page—Check to enable the display of Connection Profile (tunnel group) aliases on the Login page.
- Let group URL take precedence if group URL and certificate map match different connection profiles. Otherwise, the connection profile matches the certificate map will be used.—This option specifies the relative preference of the group URL and certificate values during the connection profile selection process. If the ASA fails to match the preferred value, it chooses the connection profile that matches the other value. Check this option only if you want to rely on the preference used by many older ASA software releases to match the group URL specified by the VPN endpoint to the connection profile that specifies the same group URL. This option is unchecked by default. If it is unchecked, the ASA prefers to match the certificate field value specified in the connection profile to the field value of the certificate used by the endpoint to assign the connection profile.

Specifying a Device Certificate for AnyConnect Access

The **Specify Device Certificate** screen allows you to specify an RSA or ECDSA certificate that will identify the ASA to the AnyConnect client when it attempts to create a VPN connection. Certain AnyConnect features, such as Always-on IPsec/IKEv2, require that a valid and trusted device certificate be available on the ASA.

If your AnyConnect clients are configured to use only SSL, then you only need to specify an RSA certificate as AnyConnect does not support ECDSA certificates for SSL VPN. If your AnyConnect clients are configured to use IPsec or SSL, or both IPsec and SSL, you can configure both kinds of certificates.

ECDSA certificates are only supported on IPsec connections.

Prerequisites

RSA or ECDSA certificates need to be stored on the ASA.

Detailed Steps

Step 1 In the Certificate with RSA Key area, perform one of these tasks:

- Keep the **Use the same device certificate for SSL and IPsec IKEv2** box checked if you want to choose one certificate to authenticate clients using either protocol. You can select the certificate from those available in the list box or click **Manage** to create an identity certificate to use.
- Uncheck the **Use the same device certificate for SSL and IPsec IKEv2** check box to specify separate certificates for SSL connections or IPsec connections.

Step 2 In the Certificate with ECDSA key field select the ECDSA certificate from the list box or click **Manage** to create an ECDSA identity certificate.

Step 3 Click **OK**.

Configuring Port Settings

Configure port numbers for SSL and IPsec (IKEv2) connections in this window:

Fields

- SSL Ports:
  - HTTPS Port—The port to enable HTTPS for clientless (browser-based) SSL connections. The range is 1-65535. The default is port 443.
  - DTLS Port—The port to enable DTLS for SSL connections. The range is 1-65535. The default is port 443.
- IPsec Client Services Port—The port to enable client services for IKEv2 connections. The range is 1-65535. The default is port 443.

Setting the Basic Attributes for an AnyConnect VPN Connection

To set the basic attributes for an AnyConnect VPN connection, choose Add or Edit in the Anyconnect Connection Profiles section. The Add (or Edit) Anyconnect Connection Profile > Basic dialog box opens.

Fields

Set the attributes in the Add AnyConnect Connection Profile > Basic dialog box as follows:

- Name—For Add, specify the name of the connection profile you are adding. For Edit, this field is not editable.
- Aliases—(Optional) Enter one or more alternative names for the connection. You can spaces or punctuation to separate the names.
- Authentication—Choose one of the following methods to use to authenticate the connection and specify a AAA server group to use in authentication.
  - AAA, Certificate, or Both—Select the type of authentication to use: AAA, Certificate, or Both. If you choose either Certificate or Both, the user must provide a certificate in order to connect.
  - AAA Server Group—Choose a AAA server group from the drop-down list. The default setting is LOCAL, which specifies that the ASA handles the authentication. Before making a selection, you can click **Manage** to open a dialog box over this dialog box to view or make changes to the ASA configuration of AAA server groups.
  - Choosing something other than LOCAL makes available the Use LOCAL if Server Group Fails check box.
  - Use LOCAL if Server Group fails—Check to enable the use of the LOCAL database if the group specified by the Authentication Server Group attribute fails.
- Client Address Assignment—Select the DHCP servers, client address pools, and client IPv6 address pools to use.
  - DHCP Servers—Enter the name or IP address of a DHCP server to use.
  - Client Address Pools—Enter pool name of an available, configured pool of IPv4 addresses to use for client address assignment. Before making a selection, you can click **Select** to open a dialog box over this dialog box to view or make changes to the address pools. See Configuring Local IP Address Pools, page 88-3 for more information on adding or editing an IPv4 address pool.
  - Client IPv6 Address Pools—Enter the pool name of an available, configured pool of IPv6 addresses to use for client address assignment. Before making a selection, you can click **Select** to open a dialog box over this dialog box to view or make changes to the address pools. See Configuring Local IP Address Pools, page 88-3 for more information on adding or editing an IPv6 address pool.
- Default Group Policy—Select the group policy to use.
  - Group Policy—Select the VPN group policy that you want to assign as the default group policy for this connection. A VPN group policy is a collection of user-oriented attribute-value pairs that can be stored internally on the device or externally on a RADIUS server. The default value is DfltGrpPolicy. You can click **Manage** to open a dialog box over this one to make changes to the group policy configuration.
  - Enable SSL VPN client protocol—Check to enable SSL for this VPN connection.
  - Enable IPsec (IKEv2) client protocol—Check to enable IPsec using IKEv2 for this connection.
  - DNS Servers—Enter the IP address(s) of DNS servers for this policy.
  - WINS Servers—Enter the IP address(s) of WINS servers for this policy.
  - Domain Name—Enter a default domain name.
- Find—Enter a GUI label or a CLI command to use as a search string, then click Next or Previous to begin the search.

Setting Advanced Attributes for a Connection Profile

The Advanced menu items and their dialog boxes let you configure the following characteristics for this connection:

- General attributes
- Client Addressing attributes
- Authentication attributes
- Authorization attributes
- Accounting attributes
- Name server attributes
- Clientless SSL VPN attributes

Note SSL VPN and secondary authentication attributes apply only to SSL VPN connection profiles.

Setting General Attributes for an AnyConnect SSL VPN Connection

Configure the General attributes to specify the password management parameters.

Fields

Set the Advanced General attributes as follows:

- Enable Simple Certificate Enrollment (SCEP) for this Connection Profile
- Strip the realm from username before passing it on to the AAA server
- Strip the group from username before passing it on to the AAA server
- Group Delimiter—Changing the group delimiter value makes the change globally on all other remote connection profiles.
- Enable Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.

  The ASA supports password management for the RADIUS and LDAP protocols. It supports the "password-expire-in-days" option only for LDAP. This parameter is valid for AAA servers that support such notification. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

  You can configure password management for IPsec remote access and SSL VPN tunnel-groups.

  Note Some RADIUS servers that support MS-CHAP currently do not support MS-CHAPv2. This feature requires MS-CHAPv2, so please check with your vendor.

  The ASA, releases 7.1 and later, generally supports password management for the following connection types when authenticating with LDAP or with any RADIUS configuration that supports MS-CHAPv2:

  - AnyConnect VPN client
  - IPsec VPN client
  - Clientless SSL VPN

Password management is *not* supported for any of these connection types for Kerberos/Active Directory (Windows password) or NT 4.0 Domain. The RADIUS server (for example, Cisco ACS) could proxy the authentication request to another authentication server. However, from the ASA perspective, it is talking only to a RADIUS server.

Note For LDAP, the method to change a password is proprietary for the different LDAP servers on the market. Currently, the ASA implements the proprietary password management logic only for Microsoft Active Directory and Sun LDAP servers.

Native LDAP requires an SSL connection. You must enable LDAP over SSL before attempting to do password management for LDAP. By default, LDAP uses port 636.

Note Allowing override account-disabled is a potential security risk.

- Notify user __ days prior to password expiration—Specifies that ASDM must notify the user at login a specific number of days before the password expires. The default is to notify the user 14 days prior to password expiration and every day thereafter until the user changes the password. The range is 1 through 180 days.
- Notify user on the day password expires—Notifies the user only on the day that the password expires.

  In either case, and, if the password expires without being changed, the ASA offers the user the opportunity to change the password. If the current password has not expired, the user can still log in using that password.

Note This does not change the number of days before the password expires, but rather, it enables the notification. If you select this option, you must also specify the number of days.

- Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

- Translate Assigned IP Address to Public IP Address—In rare situations, you might want to use a VPN peer's real IP address on the inside network instead of an assigned local IP address. Normally with VPN, the peer is given an assigned local IP address to access the inside network. However, you might want to translate the local IP address back to the peer's real public IP address if, for example, your inside servers and network security is based on the peer's real IP address. You can enable this feature on one interface per tunnel group.
  - Enable the address translation on interface—Enables the address translation and allows you to choose which interface the address appears on. *Outside* is the interface to which the AnyConnect client connects, and *inside* is the interface specific to the new tunnel group.

Note Because of routing issues and other limitations, we do not recommend using this feature unless you know you need it.

- Find—Enter a GUI label or a CLI command to use as a search string, then click Next or Previous to begin the search.

Setting Client Addressing Attributes for an AnyConnect SSL VPN Connection

The Client Addressing attributes let you configure interface-specific address pools that your connection can use. Click Add to add a new address pool or Edit to modify an existing pool. The Select Address Pools dialog box opens, showing a table listing the pool name, starting and ending address (or number of addresses), and subnet mask/prefix length of any existing pools. For a complete description of Client Addressing see Configuring Client Addressing, page 87-87.

Configuring Authentication Attributes for a Connection Profile

- Interface-specific Authentication Server Groups—Manages the assignment of authentication server groups to specific interfaces.
  - Add or Edit—Opens the Assign Authentication Server Group to Interface dialog box, in which you can specify the interface and server group, and specify whether to allow fallback to the LOCAL database if the selected server group fails. The Manage button on this dialog box opens the Configure AAA Server Groups dialog box. Your selections appear in the Interface/Server Group table.
  - Delete—Removes the selected server group from the table. There is no confirmation or undo.
- Username Mapping from Certificate—Lets you specify the methods and fields in a digital certificate from which to extract the username.
  - Pre-fill Username from Certificate—Extracts the username from the specified certificate field and uses it for username/password authentication and authorization, according to the options that follow in this panel.
  - Hide username from end user—Specifies to not display the extracted username to the end user.
  - Use script to select username—Specify the name of a script to use to select a username from a digital certificate. The default is --None--.
  - Add or Edit—Opens the Add or Edit Script Content dialog box, in which you can define a script to use in mapping the username from the certificate.
  - Delete—Deletes the selected script. There is no confirmation or undo.
  - Use the entire DN as the username—Specifies that you want to use the entire Distinguished Name field of the certificate as the username.
  - Specify the certificate fields to be used as the username—Specifies one or more fields to combine into the username.

    Possible values for primary and secondary attributes include the following:

Attribute	Definition
C	Country: the two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
CN	Common Name: the name of a person, system, or other entity. Not available a s a secondary attribute.
DNQ	Domain Name Qualifier.
EA	E-mail address.
GENQ	Generational Qualifier.
GN	Given Name.

Attribute	Definition
I	Initials.
L	Locality: the city or town where the organization is located.
N	Name.
O	Organization: the name of the company, institution, agency, association or other entity.
OU	Organizational Unit: the subgroup within the organization (O).
SER	Serial Number.
SN	Surname.
SP	State/Province: the state or province where the organization is located
T	Title.
UID	User Identifier.
UPN	User Principal Name.

  - Primary Field—Selects the first field to use from the certificate for the username. If this value is found, the secondary field is ignored.
  - Secondary Field—Selects the field to us if the primary field is not found.
- Find—Enter a GUI label or a CLI command to use as a search string, then click Next or Previous to begin the search.

Configuring Secondary Authentication Attributes for an SSL VPN Connection Profile

The Secondary Authentication dialog box lets you configure secondary or "double" authentication for this connection profile. With double authentication enabled, the end user must present two sets of valid authentication credentials in order to log on. You can use secondary authentication in conjunction with pre-filling the username from a certificate. The fields in this dialog box are similar to those you configure for primary authentication, but these fields relate only to secondary authentication.

When double authentication is enabled, these attributes select one or more fields in a certificate to use as the username. Configuring the secondary username from certificate attribute forces the security appliance to use the specified certificate field as the second username for the second username/password authentication.

Note If you also specify the secondary authentication server group, along with the secondary username from certificate, only the primary username is used for authentication.

Fields

- Secondary Authorization Server Group—Specifies an authorization server group from which to extract secondary credentials.
  - Server Group—Select an authorization server group to use as the secondary server AAA group. The default is none. The secondary server group cannot be an SDI server group.
  - Manage—Opens the Configure AAA Server Groups dialog box.

  - Use LOCAL if Server Group fails—Specifies to fall back to the LOCAL database if the specified server group fails.
  - Use primary username—Specifies that the login dialog must request only one username.
  - Attributes Server—Select whether this is the primary or secondary attributes server.

Note If you also specify an authorization server for this connection profile, the authorization server settings take precedence—the ASA ignores this secondary authentication server.

  - Session Username Server—Select whether this is the primary or secondary session username server.

- Interface-Specific Authorization Server Groups—Manages the assignment of authorization server groups to specific interfaces.
  - Add or Edit—Opens the Assign Authentication Server Group to Interface dialog box, in which you can specify the interface and server group, and specify whether to allow fallback to the LOCAL database if the selected server group fails. The Manage button on this dialog box opens the Configure AAA Server Groups dialog box. Your selections appear in the Interface/Server Group table.
  - Delete—Removes the selected server group from the table. There is no confirmation or undo.
- Username Mapping from Certificate—Specify the fields in a digital certificate from which to extract the username.
- Pre-fill Username from Certificate—Check to extract the names to be used for secondary authentication from the primary and secondary fields specified in this panel. You must configure the authentication method for both AAA and certificates before checking this attribute. To do so, return to the Basic panel in the same window and check Both next to Method.
- Hide username from end user—Check to hide the username to be used for secondary authentication from the VPN user.
- Fallback when a certificate is unavailable —This attribute is configurable only if “Hide username from end user” is checked. Uses Cisco Secure Desktop Host Scan data to pre-fill the username for secondary authentication if a certificate is unavailable.
- Password—Choose one of the following methods to retrieve the password to be used for secondary authentication:
  - Prompt—Prompt the user for the password.
  - Use Primary—Reuse the primary authentication password for all secondary authentications.
  - Use—Enter a common secondary password for all secondary authentications.
- Specify the certificate fields to be used as the username—Specifies one or more fields to match as the username. To use this username in the pre-fill username from certificate feature for the secondary username/password authentication or authorization, you must also configure the pre-fill-username and secondary-pre-fill-username.
  - Primary Field—Selects the first field to use from the certificate for the username. If this value is found, the secondary field is ignored.
  - Secondary Field—Selects the field to us if the primary field is not found.

  The options for primary and secondary field attributes include the following:

Attribute	Definition
C	Country: the two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
CN	Common Name: the name of a person, system, or other entity. Not available a s a secondary attribute.
DNQ	Domain Name Qualifier.
EA	E-mail address.
GENQ	Generational Qualifier.
GN	Given Name.
I	Initials.
L	Locality: the city or town where the organization is located.
N	Name.
O	Organization: the name of the company, institution, agency, association or other entity.
OU	Organizational Unit: the subgroup within the organization (O).
SER	Serial Number.
SN	Surname.
SP	State/Province: the state or province where the organization is located
T	Title.
UID	User Identifier.
UPN	User Principal Name.

- Use the entire DN as the username—Uses the entire subject DN (RFC1779) to derive a name for an authorization query from a digital certificate.
- Use script to select username—Names the script from which to extract a username from a digital certificate. The default is --None--.
  - Add or Edit—Opens the Add or Edit Script Content dialog box, in which you can define a script to use in mapping the username from the certificate.
  - Delete—Deletes the selected script. There is no confirmation or undo.

Configuring Authorization Attributes for an SSL VPN Connection Profile

The Authorization dialog box lets you view, add, edit, or delete interface-specific authorization server groups. Each row of the table on this dialog box shows the status of one interface-specific server group: the interface name, its associated server group, and whether fallback to the local database is enabled if the selected server group fails.

Fields

- Authorization Server Group—Specifies an authorization server group from which to draw authorization parameters.
  - Server Group—Selects an authorization server group to use. The default is none.

  - Manage—Opens the Configure AAA Server Groups dialog box.
  - Users must exist in the authorization database to connect—Select this check box to require that users meet this criterion.
- Interface-specific Authorization Server Groups—Manages the assignment of authorization server groups to specific interfaces.
  - Add or Edit—Opens the Assign Authentication Server Group to Interface dialog box, in which you can specify the interface and server group, and specify whether to allow fallback to the LOCAL database if the selected server group fails. The Manage button on this dialog box opens the Configure AAA Server Groups dialog box. Your selections appear in the Interface/Server Group table.
  - Delete—Removes the selected server group from the table. There is no confirmation or undo.
- Username Mapping from Certificate—Specify the fields in a digital certificate from which to extract the username.
  - Use script to select username—Specifies the name of a script to use to select a username from a digital certificate. The default is --None--.
  - Add or Edit—Opens the Add or Edit Script Content dialog box, in which you can define a script to use in mapping the username from the certificate.
  - Delete—Deletes the selected script. There is no confirmation or undo.
  - Use the entire DN as the username—Specifies that you want to use the entire Distinguished Name field of the certificate as the username.
  - Specify the certificate fields to be used as the username—Specifies one or more fields to combine into the username.
  - Primary Field—Selects the first field to use in the certificate for the username. If this value is found, the secondary field is ignored.
  - Secondary Field—Selects the field to use if the primary field is not found.
- Find—Enter a GUI label or a CLI command to use as a search string, then click Next or Previous to begin the search.

Adding or Editing Content to a Script for Certificate Pre-Fill-Username

The Add or Edit Script Content dialog box lets you create an authentication or authorization script.

Note Both AnyConnect client and clientless WebVPN display “Unknown” in the username field when pre-fill-username from certificate using a script cannot find the username in the client certificate.

Fields

- Script Name—Specify the name of the script. The script name must be the same in both authorization and authentication.You define the script here, and CLI uses the same script to perform this function.
- Select script parameters—Specify the attributes and content of the script.
- Value for Username—Select an attribute from the drop-down list of standard DN attributes to use as the username (Subject DN).
- No Filtering—Specify that you want to use the entire specified DN name.

- Filter by substring— Specify the Starting Index (the position in the string of the first character to match) and Ending Index (number of characters to search). If you choose this option, the starting index cannot be blank. If you leave the ending index blank, it defaults to -1, indicating that the entire string is searched for a match.

  For example, suppose you selected the DN attribute Common Name (CN), which contains a value of host/user. Table 72-1 shows some possible ways you might filter this value using the substring option to achieve various return values. The Return Value is what is actually pre-filled as the username.

Table 87-3 Filtering by Substring

Starting Index	Ending Index	Return Value
1	5	host/
6	10	user
6	-1	user

Using a negative index, as in the third row of this table, specifies to count from the end of the string backwards to the end of the substring, in this case, the “r” of “user”.

When using filtering by substrings, you should know the length of the substring that you are seeking. From the following examples, use either the regular expression matching or the custom script in Lua format:

- Example 1: Regular Expression Matching—Enter a regular expression to apply to the search in the Regular Expression field. Standard regular expression operators apply. For example, suppose you want to use a regular expression to filter everything up to the @ symbol of the “Email Address (EA)” DN value. The regular expression ^[^@]* would be one way to do this. In this example, if the DN value contained a value of user1234@example.com, the return value after the regular expression would be user1234.
- Example 2: Use custom script in Lua format—Specify a custom script written in the Lua programming language to parse the search fields. Selecting this option makes available a field in which you can enter your custom Lua script; for example, the script:

  ```
  return cert.subject.cn..'/'..cert.subject.l
  ```

  combines two DN fields, username (cn) and locality (l), to use as a single username and inserts the slash (/) character between the two fields.

  Table 87-4 lists the attribute names and descriptions that you can use in a Lua script.

Note Lua is case-sensitive.

Table 87-4 Attribute Names and Descriptions

Attribute Name	Description
cert.subject.c	Country
cert.subject.cn	Common Name
cert.subject.dnq	DN qualifier
cert.subject.ea	E-mail Address
cert.subject.genq	Generational qualified

Table 87-4 Attribute Names and Descriptions

cert.subject.gn	Given Name
cert.subject.i	Initials
cert.subject.l	Locality
cert.subject.n	Name
cert.subject.o	Organization
cert.subject.ou	Organization Unit
cert.subject.ser	Subject Serial Number
cert.subject.sn	Surname
cert.subject.sp	State/Province
cert.subject.t	Title
cert.subject.uid	User ID
cert.issuer.c	Country
cert.issuer.cn	Common Name
cert.issuer.dnq	DN qualifier
cert.issuer.ea	E-mail Address
cert.issuer.genq	Generational qualified
cert.issuer.gn	Given Name
cert.issuer.i	Initials
cert.issuer.l	Locality
cert.issuer.n	Name
cert.issuer.o	Organization
cert.issuer.ou	Organization Unit
cert.issuer.ser	Issuer Serial Number
cert.issuer.sn	Surname
cert.issuer.sp	State/Province
cert.issuer.t	Title
cert.issuer.uid	User ID
cert.serialnumber	Certificate Serial Number
cert.subjectaltname.upn	User Principal Name

If an error occurs while activating a tunnel group script, causing the script not to activate, the administrator's console displays an error message.

Configuring AnyConnect Secure Mobility

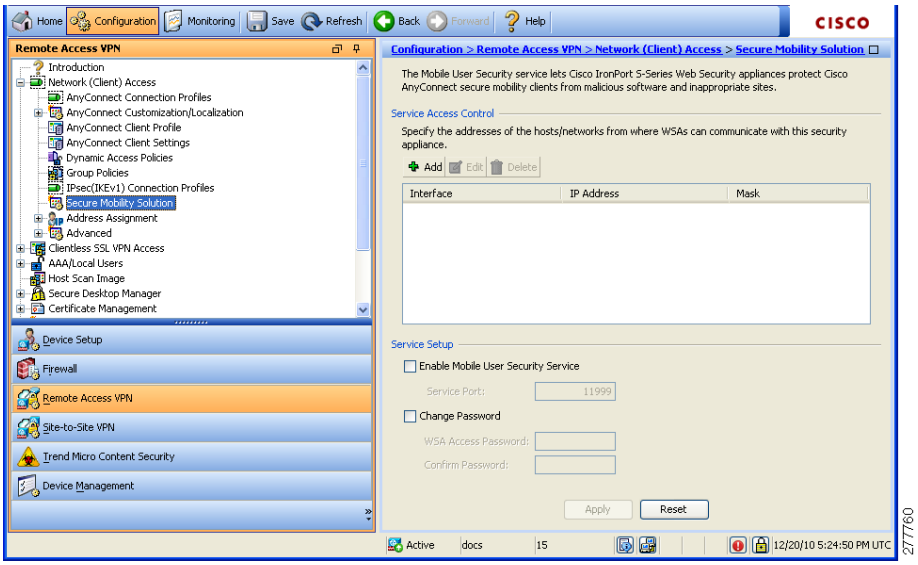
AnyConnect Secure Mobility protects corporate interests and assets from Internet threats when employees are mobile. Use the Mobile User Security dialog box to configure this feature. AnyConnect Secure Mobility lets Cisco IronPort S-Series Web Security appliances scan Cisco AnyConnect secure

mobility clients to ensure that clients are protected from malicious software and/or inappropriate sites. The client periodically checks to ensure that Cisco IronPort S-Series Web Security appliance protection is enabled.

To configure secure mobility solutions, choose **Configuration > Remote Access VPN > Network (Client) Access > Mobile User Security**.

Note This feature requires a release of the Cisco IronPort Web Security appliance that provides AnyConnect Secure Mobility licensing support for the Cisco AnyConnect secure mobility client. It also requires an AnyConnect release that supports the AnyConnect Secure Mobility feature.

Figure 87-6 Mobile User Security Window



Fields

- Service Access Control—Specifies from which host or network address the WSAs can communicate.
  - Add—Opens the Add MUS Access Control Configuration dialog box for the selected connection.
  - Edit—Opens the Edit MUS Access Control Configuration dialog box for the selected connection.
  - Delete—Removes the selected connection from the table. There is no confirmation or undo.
- Enable Mobile User Security Service—Starts the connection with the client through the VPN. If enabled, you are required to enter a password, used by the WSA when contacting the ASA. If no WSA is present, the status is disabled.
- Service Port—If you choose to enable the service, specify which port number for the service to use. The port must be between 1 and 65535 and must match the corresponding value provisioned into the WSA with the management system. The default is 11999.
- Change Password—Enables you to change the WSA access password.

- WSA Access Password—Specify the shared secret password required for authentication between the ASA and WSA. This password must match the corresponding password provisioned into the WSA with the management system.
- Confirm Password—Re-enter the specified password.
- Show WSA Sessions—Allows you to view session information of WSAs connected to the ASA.The host IP address of the WSA that is connected (or has been connected) and the duration of the connection is returned in a dialog box.

Add or Edit MUS Access Control

The Add or Edit MUS Access Control dialog box lets you configure MUS access.

Fields

- Interface Name—Use the drop-down menu to choose which interface name you are adding or editing.
- IP Address—Enter either an IPv4 or IPv6 address.
- Mask—Use the drop-down menu to choose the appropriate mask.

Configuring Clientless SSL VPN Connections

Use the Clientless SSL VPN Access Connections dialog box to configure clientless SSL VPN access parameters. This dialog box also records the configuration choices you make in its child dialog boxes.

Fields

- Access Interfaces—Lets you select from a table the interfaces on which to enable access. The fields in this table include the interface name and check boxes specifying whether to allow access.
  - Device Certificate—Lets you specify a certificate for authentication for either an RSA key or an ECDSA key or trustpoint. You have the option to configure two trustpoints. The client indicates ECDSA support with a vendor ID payload. The ASA scans the configured trustpoint list and chooses the first one that the client supports. If ECDSA is preferred, you should configure that trustpoint before the RSA trustpoint.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can add, edit, delete, export, and show details for a selected certificate.
  - Port Setting—Configure port numbers for clientless SSL and IPsec (IKEv2) connections. The range is 1-65535. The default is port 443.
- Login Page Setting
  - Allow user to select connection profile, identified by its alias, on the login page. Otherwise, DefaultWebVPN Group will be the connection profile.—Specifies that the user login page presents the user with a drop-down menu from which the user can select a particular tunnel group with which to connect.
  - Allow user to enter internal password on the login page.—Adds an option to input a different password when accessing internal servers.
  - Shutdown portal login page.—Shows the web page when the login is disabled.

- Connection Profiles—Provides a connection table that shows the records that determine the connection policy for this connection (tunnel group). Each record identifies a default group policy for the connection and contains protocol-specific connection parameters.
  - Add—Opens the Add Clientless SSL VPN dialog box for the selected connection.
  - Edit—Opens the Edit Clientless SSL VPN dialog box for the selected connection.
  - Delete—Removes the selected connection from the table. There is no confirmation or undo.
  - Name—The name of the Connection Profile.
  - Enabled—Checkmark when enabled.
  - Aliases—Other names by which the Connection Profile is known.
  - Authentication Method—Specifies which authentication method is used.
  - Group Policy—Shows the default group policy for this Connection Profile.
- Let group URL take precedence if group URL and certificate map match different connection profiles. Otherwise, the connection profile matches the certificate map will be used.—This option specifies the relative preference of the group URL and certificate values during the connection profile selection process. If the ASA fails to match the preferred value specified by the endpoint to that specified by a connection profile, it chooses the connection profile that matches the other value. Check this option only if you want to rely on the preference used by many older ASA software releases to match the group URL specified by the VPN endpoint to the connection profile that specifies the same group URL. This option is unchecked by default. If it is unchecked, the ASA prefers to match the certificate field value specified in the connection profile to the field value of the certificate used by the endpoint to assign the connection profile.

Add or Edit Clientless SSL VPN Connections

The Add or Edit SSL VPN dialog box consists of Basic and Advanced sections, accessible through the expandable menu on the left of the box.

Add or Edit Clientless SSL VPN Connections > Basic

The Basic dialog box lets you configure essential characteristics for this connection.

Fields

- Name—Specifies the name of the connection. For the edit function, this field is read-only.
- Aliases—(Optional) Specifies one or more alternate names for this connection. The aliases appear on the login page if you configure that option on the Clientless SSL VPN Access Connections dialog box.
- Authentication—Specifies the authentication parameters.
  - Method—Specifies whether to use AAA authentication, certificate authentication, or both methods for this connection. The default is AAA authentication.
  - AAA server Group—Selects the AAA server group to use for authenticating this connection. The default is LOCAL.
  - Manage—Opens the Configure AAA Server Groups dialog box.
- DNS Server Group—Selects the server to use as the DNS server group for this connection. The default is DefaultDNS.

- Default Group Policy—Specifies the default group policy parameters to use for this connection.
  - Group Policy—Selects the default group policy to use for this connection. The default is DfltGrpPolicy.
  - Clientless SSL VPN Protocol—Enables or disables the Clientless SSL VPN protocol for this connection.

Add or Edit Clientless SSL VPN Connections > Advanced

The Advanced menu items and their dialog boxes let you configure the following characteristics for this connection:

- General attributes.
- Authentication attributes.
- Authorization attributes.
- Accounting attributes.
- Name server attributes.
- Clientless SSL VPN attributes.

Add or Edit Clientless SSL VPN Connections > Advanced > General

Use this dialog box to specify whether to strip the realm and group from the username before passing them to the AAA server, and to specify password management options.

Fields

- Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.
  - Enable notification password management—Checking this check box makes the following two parameters available. You can select either to notify the user at login a specific number of days before the password expires or to notify the user only on the day that the password expires. The default is to notify the user 14 days prior to password expiration and every day thereafter until the user changes the password. The range is 1 through 180 days.

Note This does not change the number of days before the password expires, but rather, it enables the notification. If you select this option, you must also specify the number of days.

In either case, and, if the password expires without being changed, the ASA offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This parameter is valid for AAA servers that support such notification; that is, RADIUS, RADIUS with an NT server, and LDAP servers. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

  - Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

Note Allowing override account-disabled is a potential security risk.

Add or Edit Clientless or SSL VPN Client Connection Profile or IPsec Connection Profiles> Advanced > Authentication

The Authentication dialog box lets you view, add, edit, or delete interface-specific authentication server groups. Each row of the table on this dialog box shows the status of one interface-specific server group: the interface name, its associated server group, and whether fallback to the local database is enabled if the selected server group fails.

Fields

- Interface-specific Authorization Server Groups—Manages the assignment of authorization server groups to specific interfaces.
  - Add or Edit—Opens the Assign Authentication Server Group to Interface dialog box, in which you can specify the interface and server group, and specify whether to allow fallback to the LOCAL database if the selected server group fails. The Manage button on this dialog box opens the Configure AAA Server Groups dialog box. Your selections appear in the Interface/Server Group table.
  - Delete—Removes the selected server group from the table. There is no confirmation or undo.

Assign Authentication Server Group to Interface

This dialog box lets you associate an interface with a AAA server group. The results appear in the table on the Authentication dialog box.

Fields

- Interface—Selects an interface, DMZ, Outside, or Inside. The default is DMZ.
- Server Group—Selects a server group to assign to the selected interface. The default is LOCAL.
- Manage—Opens the Configure AAA Server Groups dialog box.
- Fallback—Enables or disables fallback to LOCAL if the selected server group fails.

Add or Edit SSL VPN Connections > Advanced > Authorization

This dialog box lets you configure the default authorization server group, interface-specific authorization server groups, and user name mapping attributes. The attributes are the same for SSL VPN and Clientless SSL VPN connections.

Fields

- Default Authorization Server Group—Configures default authorization server group attributes.
  - Server Group—Selects the authorization server group to use for this connection. The default is --None--.
  - Manage—Opens the Configure AAA Server Groups dialog box.
  - Users must exist in the authorization database to connect—Enables or disables this requirement.

- Interface-specific Authorization Server Groups
  - Table—Lists each configured interface and the server group with which it is associated.
  - Add or Edit—Opens the Assign Authorization Server Group to Interface dialog box.
  - Delete—Removes the selected row from the table.
- User Name Mapping—Specifies user name mapping attributes.
- Username Mapping from Certificate—Lets you specify the fields in a digital certificate from which to extract the username.
  - Pre-fill Username from Certificate —Enables the use of a username extracted from the specified certificate field as the username for username/password authentication and authorization, using the options that follow in this dialog box.
  - Hide username from end user—Specifies not to display the extracted username to the end user.
  - Use script to select username—Specify the name of a script to use to select a username from a digital certificate. There is no default.
  - Add or Edit—Opens the Add or Edit Script Content dialog box, in which you can define a script to use in mapping the username from the certificate.
  - Delete—Deletes the selected script. There is no confirmation or undo.
  - Use the entire DN as the username—Enables or disables the requirement to use the entire DN as the username.
  - Specify individual DN fields as the username. You can select both the primary DN field, for which the default is CN (Common Name) and the secondary DN field, for which the default is OU (Organization Unit).
  - Primary Field—Selects the first field to use in the username.
  - Secondary Field—Selects the second field to use in the username.

Assign Authorization Server Group to Interface

This dialog box lets you associate an interface with a AAA server group. The results appear in the table on the Authorization dialog box.

Fields

- Interface—Selects an interface, DMZ, Outside, or Inside. The default is DMZ.
- Server Group—Selects a server group to assign to the selected interface. The default is LOCAL.
- Manage—Opens the Configure AAA Server Groups dialog box.

Add or Edit SSL VPN Connections > Advanced > SSL VPN

This dialog box lets you configure attributes that affect what the remote user sees upon login.

Fields

- Portal Page Customization—Configures the look and feel of the user login page by specifying which preconfigured customization attributes to apply. The default is DfltCustomization.
- Enable the display of Radius Reject-Message on the login screen—Select this check box to display the RADIUS-reject message on the login dialog box when authentication is rejected.

- Enable the display of SecurId message on the login screen—Select this check box to display SecurID messages on the login dialog box.
- Manage—Opens the Configure GUI Customization Objects dialog box.
- Connection Aliases—Lists in a table the existing connection aliases and their status and lets you add or delete items in that table. A connection alias appears on the user login page if the connection is configured to allow users to select a particular connection (tunnel group) at login. The rows in this table are editable in place, so there is no Edit button. Clicking the "i" icon above the table opens a tooltip for the edit function.
  - Add—Opens the Add Connection Alias dialog box, on which you can add and enable a connection alias.
  - Delete—Removes the selected row from the connection alias table. There is no confirmation or undo.
  - To edit an alias listed in the table, double-click the line.
- Group URLs—Lists in a table the existing group URLs and their status and lets you add or delete items in that table. A group URL appears on the user login page if the connection is configured to allow users to select a particular group at login. The rows in this table are editable in place, so there is no Edit button. Clicking the "i" icon above the table opens a tooltip for the edit function.
  - Add—Opens the Add Group URL dialog box, on which you can add and enable a group URL.
  - Delete—Removes the selected row from the connection alias table. There is no confirmation or undo.
  - To edit a URL listed in the table, double-click the line.
- Do not run Cisco Secure Desktop (CSD) on client machine when using group URLs defined above to access the ASA. (If a client connects using a connection alias, this setting is ignored.)—Check if you want to exempt users from running CSD who use a URL that matches an entry in the Group URLs table. Be aware that doing so stops the security appliance from receiving endpoint criteria from these users, so you might have to change the DAP configuration to provide them with VPN access.

Add or Edit Clientless SSL VPN Connections > Advanced > Clientless SSL VPN

This dialog box lets you configure attributes that affect what the remote user sees upon login.

Fields

- Portal Page Customization—Configures the look and feel of the user login page by specifying which preconfigured customization attributes to apply. The default is DfltCustomization.
- Enable the display of Radius Reject-Message on the login screen—Select this check box to display the RADIUS-reject message on the login dialog box when authentication is rejected.
- Enable the display of SecurId message on the login screen—Select this check box to display SecurID messages on the login dialog box.
- Manage—Opens the Configure GUI Customization Objects dialog box.
- Connection Aliases—Lists in a table the existing connection aliases and their status and lets you add or delete items in that table. A connection alias appears on the user login page if the connection is configured to allow users to select a particular connection (tunnel group) at login.
  - Add—Opens the Add Connection Alias dialog box, on which you can add and enable a connection alias.

  - Delete—Removes the selected row from the connection alias table. There is no confirmation or undo.
- Group URLs—Lists in a table the existing group URLs and their status and lets you add or delete items in that table. A group URL appears on the user login page if the connection is configured to allow users to select a particular group at login.
  - Add—Opens the Add Group URL dialog box, on which you can add and enable a group URL.
  - Delete—Removes the selected row from the connection alias table. There is no confirmation or undo.
- Do not run Cisco Secure Desktop (CSD) on client machine when using group URLs defined above to access the ASA. (If a client connects using a connection alias, this setting is ignored.)—Check if you want to exempt users from running CSD who use a URL that matches an entry in the Group URLs table. Be aware that doing so stops the security appliance from receiving endpoint criteria from these users, so you might have to change the DAP configuration to provide them with VPN access.

Add or Edit Clientless SSL VPN Connections > Advanced > NetBIOS Servers

The table on this dialog box shows the attributes of the already-configured NetBIOS servers. The Add or Edit Tunnel Group dialog box for Clientless SSL VPN access, NetBIOS dialog box, lets you configure the NetBIOS attributes for the tunnel group. Clientless SSL VPN uses NetBIOS and the Common Internet File System protocol to access or share files on remote systems. When you attempt a file-sharing connection to a Windows computer by using its computer name, the file server you specify corresponds to a specific NetBIOS name that identifies a resource on the network.

The ASA queries NetBIOS name servers to map NetBIOS names to IP addresses. Clientless SSL VPN requires NetBIOS to access or share files on remote systems.

To make the NBNS function operational, you must configure at least one NetBIOS server (host). You can configure up to 3 NBNS servers for redundancy. The ASA uses the first server on the list for NetBIOS/CIFS name resolution. If the query fails, it uses the next server.

Fields

- IP Address—Displays the IP addresses of configured NetBIOS servers.
- Master Browser—Shows whether a server is a WINS server or one that can also be a CIFS server (that is, a master browser).
- Timeout (seconds)—Displays the initial time in seconds that the server waits for a response to an NBNS query before sending the query to the next server.
- Retries—Shows the number of times to retry sending an NBNS query to the configured servers, in order. In other words, this is the number of times to cycle through the list of servers before returning an error. The minimum number of retries is 0. The default number of retries is 2. The maximum number of retries is 10.
- Add/Edit—Click to add a NetBIOS server. This opens the Add or Edit NetBIOS Server dialog box.
- Delete—Removes the highlighted NetBIOS row from the list.
- Move Up/Move Down—The ASA sends NBNS queries to the NetBIOS servers in the order in which they appear in this box. Use this box to change the priority order of the servers by moving them up or down in the list.

Configure DNS Server Groups

This dialog box displays the configured DNS servers in a table, including the server group name, servers, timeout in seconds, number of retries allowed, and domain name. You can add, edit, or delete DNS server groups on this dialog box.

Fields

- Add or Edit—Opens the Add or Edit DNS Server Group dialog box.
- Delete—Removes the selected row from the table. There is no confirmation or undo.
- DNS Server Group—Selects the server to use as the DNS server group for this connection. The default is DefaultDNS.
- Manage—Opens the Configure DNS Server Groups dialog box.

Add or Edit Clientless SSL VPN Connections > Advanced > Clientless SSL VPN

This dialog box lets you specify portal-related attributes for Clientless SSL VPN connections.

Fields

- Portal Page Customization—Selects the customization to apply to the user interface.
- Manage—Opens the Configure GUI Customization Objects dialog box.

IPsec Remote Access Connection Profiles

Configuration > VPN > General > Tunnel Group

The parameters in the IPsec Connection Profiles dialog box let you configure IPsec remote access connections. Most of the parameters in this section were formerly configured under tunnel groups. An IPsec connection represents a connection-specific record for IPsec and Clientless SSL VPN connections.

The IPsec group uses the IPsec connection parameters to create a tunnel. An IPsec connection can be either remote-access or Site-to-Site. The IPsec group is configured on the internal server or on an external RADIUS server. For ASA 5505 in client mode or VPN 3002 hardware client parameters, which enable or disable interactive hardware client authentication and individual user authentication, the IPsec connection parameters take precedence over parameters set for users and groups.

The Clientless SSL VPN tunnel-group parameters are the parameters of the Clientless SSL VPN group that you want to apply to this IPsec connection. You configure Clientless SSL VPN access on the Configuration > Clientless SSL VPN dialog box.

Fields

- Access Interfaces—Selects the interfaces to enable for IPsec access. The default is that no access is selected.
- Connections—Shows in tabular format the configured parameters for existing IPsec connections. The Connections table contains records that determine connection policies. A record identifies a default group policy for the connection and contains protocol-specific connection parameters. The table contains the following columns:
  - Name—Specifies the name or IP address of the IPsec connection.
  - ID Certificate—Specifies the name of the ID certificate, if available.

  - IPsec Protocol—Indicates whether the IPsec protocol is enabled. You enable this protocol on the Add or Edit IPsec Remote Access Connection, Basic dialog box.
  - L2TP/IPsec Protocol—Indicates whether the L2TP/IPsec protocol is enabled. You enable this protocol on the Add or Edit IPsec Remote Access Connection, Basic dialog box.
  - Group Policy—Indicates the name of the group policy for this IPsec connection.
- Add or Edit—Opens the Add or Edit IPsec Remote Access Connection Profile dialog box.
- Delete—Removes the selected server group from the table. There is no confirmation or undo.

Add or Edit an IPsec Remote Access Connection Profile

The Add or Edit IPsec Remote Access Connection Profile dialog box has a navigation pane that lets you select basic or advanced elements to configure.

Add or Edit IPsec Remote Access Connection Profile Basic

The Add or Edit IPsec Remote Access Connection Profile Basic dialog box lets you configure common attributes for IPsec connections.

Fields

- Name—Identifies the name of the connection.
- IKE Peer Authentication—Configures IKE peers.
  - Pre-shared key—Specifies the value of the pre-shared key for the connection. The maximum length of a pre-shared key is 128 characters.
  - Identity Certificate—Selects the name of an identity certificate, if any identity certificates are configured and enrolled.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can add, edit, delete, export, and show details for a selected certificate.
- User Authentication—Specifies information about the servers used for user authentication. You can configure more authentication information in the Advanced section.
  - Server Group—Selects the server group to use for user authentication. the default is LOCAL. If you select something other than LOCAL, the Fallback check box becomes available.
  - Manage—Opens the Configure AAA Server Groups dialog box.
  - Fallback—Specifies whether to use LOCAL for user authentication if the specified server group fails.
- Client Address Assignment—Specifies attributes relevant to assigning client attributes.
  - DHCP Servers—Specifies the IP address of a DHCP server to use. You can add up to 10 servers, separated by spaces.
  - Client Address Pools—Specifies up to 6 predefined address pools. To define an address pool, go to Configuration > Remote Access VPN > Network Client Access > Address Assignment > Address Pools.
  - Select—Opens the Select Address Pools dialog box.
- Default Group Policy—Specifies attributes relevant to the default group policy.

- Group Policy—Selects the default group policy to use for this connection. The default is DfltGrpPolicy.
- Manage—Opens the Configure Group Policies dialog box, from which you can add, edit, or delete group policies.
- Client Protocols—Selects the protocol or protocols to use for this connection. By default, both IPsec and L2TP over IPsec are selected.

Mapping Certificates to IPsec or SSL VPN Connection Profiles

When the ASA receives an IPsec connection request with client certificate authentication, it assigns a connection profile to the connection according to policies you configure. That policy can be to use rules you configure, use the certificate OU field, use the IKE identity (i.e. hostname, IP address, key ID), the peer IP address, or a default connection profile. For SSL connections, the ASA only uses the rules you configure.

For IPsec or SSL connections using rules, the ASA evaluates the attributes of the certificate against the rules until it finds a match. When it finds a match, it assigns the connection profile associated with the matched rule to the connection. If it fails to find a match, it assigns the default connection profile (DefaultRAGroup for IPsec and DefaultWEBVPNGroup for SSL VPN) to the connection and lets the user choose the connection profile from a drop-down menu displayed on the portal page (if it is enabled). The outcome of the connection attempt once in this connection profile depends on whether or not the certificate is valid and the authentication settings of the connection profile.

A certificate group matching policy defines the method to use for identifying the permission groups of certificate users. You can use any or all of these methods.

First configure the policy for matching a certificate to a connection profile at Configuration > Remote Access VPN > Network (Client) Access > Advanced > IPsec > Certificate to Connection Profile Maps. If you choose to use rules you configure, go to Rules to specify the rules. The following procedures shows how you create the certificate-based criteria for each IPsec and SSL VPN connection profile:

Step 1 Use the table at the top (Certificate to Connection Profile Maps) to do one of the following:

- Create a list name, called a “map,” specify the priority of the list, and assign the list to a connection profile.

  ASDM highlights the list after you add it to the table.
- Confirm that a list is assigned to the connection profile for which you want to add certificate-based rules.

  ASDM highlights the list after you add it to the table and displays any associated list entries in the table at the bottom of the pane.

Step 2 Use the table at the bottom (Mapping Criteria) to view, add, change or delete entries to the selected list.

Each entry in the list consists of one certificate-based rule. All of the rules in the mapping criteria list need to match the contents of the certificate for the ASA to choose the associated map index. To assign a connection if one criterion or another matches, create one list for each matching criterion.

To understand the fields, see the following sections:

- Setting a Certificate Matching Policy
- Add/Edit Certificate Matching Rule

- Add/Edit Certificate Matching Rule Criterion

Setting a Certificate Matching Policy

For IPsec connections, a certificate group matching policy defines the method to use for identifying the permission groups of certificate users. You can use any or all of these methods:

Fields

- Use the configured rules to match a certificate to a group—Lets you use the rules you have defined under Rules.
- Use the certificate OU field to determine the group—Lets you use the organizational unit field to determine the group to which to match the certificate. This is selected by default.
- Use the IKE identity to determine the group—Lets you use the identity you previously defined under Configuration > VPN > IKE > Global Parameters. The IKE identity can be hostname, IP address, key ID, or automatic.
- Use the peer IP address to determine the group—Lets you use the peer's IP address. This is selected by default.
- Default to group—Lets you select a default group for certificate users that is used when none of the preceding methods resulted in a match. This is selected by default. Click the default group in the Default to group list. The group must already exist in the configuration. If the group does not appear in the list, you must define it by using Configuration > VPN > General > Tunnel Group.

Add/Edit Certificate Matching Rule

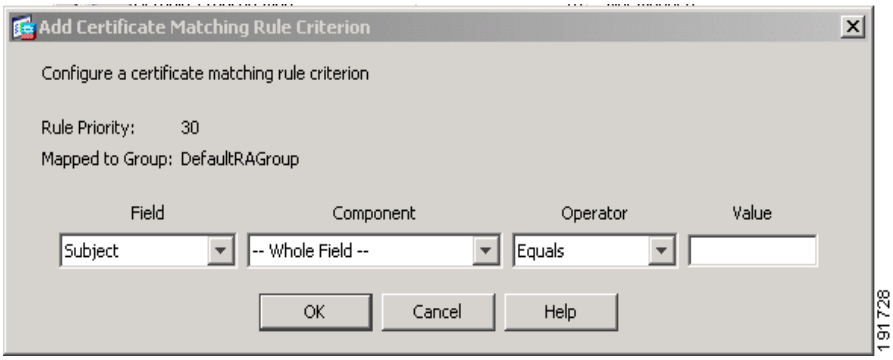
Configuration > VPN > IKE > Certificate Group Matching > Rules > Add/Edit Certificate Matching Rule

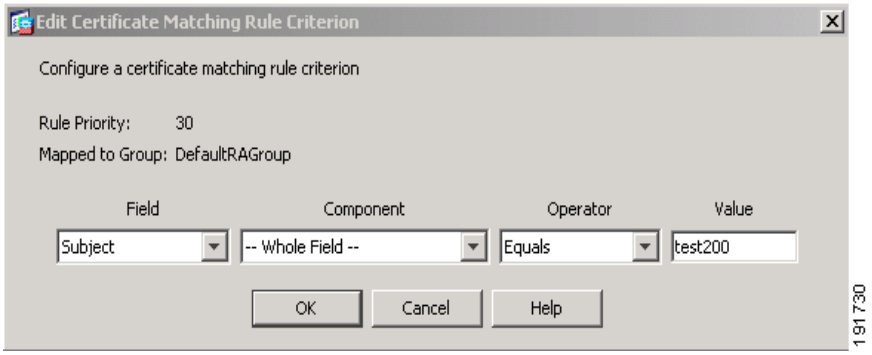
Use the **Add/Edit Certificate Matching Rule** dialog box to assign the name of a list (map) to a connection profile.

Fields

- **Map**—Choose one of the following:
  - **Existing**—Select the name of the map to include the rule.
  - **New**—Enter a new map name for a rule.
- **Rule Priority**—Type a decimal to specify the sequence with which the ASA evaluates the map when it receives a connection request. For the first rule defined, the default priority is 10. The ASA evaluates each connection against the map with the lowest priority number first.
- **Mapped to Connection Profile**—Select the connection profile, formerly called a “tunnel group,” to map to this rule.

If you do not assign a rule criterion to the map, as described in the next section, the ASA ignores the map entry.





Add/Edit Certificate Matching Rule Criterion

Configuration > VPN > IKE > Certificate Group Matching > Rules > Add/Edit Certificate Matching Rule Criterion

Use the **Add/Edit Certificate Matching Rule Criterion** dialog box to configure a certificate matching rule criterion for the selected connection profile.

Fields

- **Rule Priority**—(Display only). Sequence with which the ASA evaluates the map when it receives a connection request. The ASA evaluates each connection against the map with the lowest priority number first.
- **Mapped to Group**—(Display only). Connection profile to which the rule is assigned.
- **Field**—Select the part of the certificate to be evaluated from the drop-down list.
  - **Subject**—The person or system that uses the certificate. For a CA root certificate, the Subject and Issuer are the same.
  - **Alternative Subject**—The subject alternative names extension allows additional identities to be bound to the subject of the certificate.
  - **Issuer**—The CA or other entity (jurisdiction) that issued the certificate.
  - **Extended Key Usage**—An extension of the client certificate that provides further criteria that you can choose to match.

- **Component**—(Applies only if Subject of Issuer is selected.) Select the distinguished name component used in the rule:

DN Field	Definition
Whole Field	The entire DN.
Country (C)	The two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
Common Name (CN)	The name of a person, system, or other entity. This is the lowest (most specific) level in the identification hierarchy.
DN Qualifier (DNQ)	A specific DN attribute.
E-mail Address (EA)	The e-mail address of the person, system or entity that owns the certificate.
Generational Qualifier (GENQ)	A generational qualifier such as Jr., Sr., or III.
Given Name (GN)	The first name of the certificate owner.
Initials (I)	The first letters of each part of the certificate owner's name.
Locality (L)	The city or town where the organization is located.
Name (N)	The name of the certificate owner.
Organization (O)	The name of the company, institution, agency, association, or other entity.
Organizational Unit (OU)	The subgroup within the organization.
Serial Number (SER)	The serial number of the certificate.
Surname (SN)	The family name or last name of the certificate owner.
State/Province (S/P)	The state or province where the organization is located.
Title (T)	The title of the certificate owner, such as Dr.
User ID (UID)	The identification number of the certificate owner.
Unstructured Name (UNAME)	The unstructuredName attribute type specifies the name or names of a subject as an unstructured ASCII string.
IP Address (IP)	IP address field.

- **Operator**—Select the operator used in the rule:
  - **Equals**—The distinguished name field must exactly match the value.
  - **Contains**—The distinguished name field must include the value within it.
  - **Does Not Equal**—The distinguished name field must not match the value
  - **Does Not Contain**—The distinguished name field must not include the value within it.
- **Value**—Enter up to 255 characters to specify the object of the operator. For Extended Key Usage, select one of the pre-defined values in the drop-down list, or you can enter OIDs for other extensions. The pre-defined values include the following:

Selection	Key Usage Purpose	OID String
clientauth	Client Authentication	1.3.6.1.5.5.7.3.2
codesigning	Code Signing	1.3.6.1.5.5.7.3.3
emailprotection	Secure Email Protection	1.3.6.1.5.5.7.3.4
ocspsigning	OCSP Signing	1.3.6.1.5.5.7.3.9
serverauth	Server Authentication	1.3.6.1.5.5.7.3.1
timestamping	Time Stamping	1.3.6.1.5.5.7.3.8

Site-to-Site Connection Profiles

The Connection Profiles dialog box shows the attributes of the currently configured Site-to-Site connection profiles (tunnel groups), lets you select the delimiter to use when parsing connection profile names, and lets you add, modify, or delete connection profiles.

The security appliance supports IPsec LAN-to-LAN VPN connections for IPv4 or IPv6 using IKEv1 or IKEv2 and supports both inside and outside networks using the inner and outer IP headers.

Fields

- Access Interfaces—Displays a table of device interfaces where you can enable access by a remote peer device on the interface:
  - Interface—The device interface to enable or disable access.
  - Allow IKEv1 Access—Check to enable IPsec IKEv1 access by a peer device.
  - Allow IKEv2 Access—Check to enable IPsec IKEv2 access by a peer device.
- Connection Profiles—Displays a table of connection profiles where you can add, edit, or delete profiles:
  - Add—Opens the Add IPsec Site-to-Site connection profile dialog box.
  - Edit—Opens the Edit IPsec Site-to-Site connection profile dialog box.
  - Delete—Removes the selected connection profile. There is no confirmation or undo.
  - Name—The name of the connection profile.
  - Interface—The interface the connection profile is enabled on.
  - Local Network—Specifies the IP address of the local network.
  - Remote Network—Specifies the IP address of the remote network.
  - IKEv1 Enabled—Shows IKEv1 enabled for the connection profile.
  - IKEv2 Enabled—Shows IKEv2 enabled for the connection profile.
  - Group Policy—Shows the default group policy of the connection profile.

Add/Edit Site-to-Site Connection

You can get to this panel through various paths.

The Add or Edit IPsec Site-to-Site Connection dialog box lets you create or modify an IPsec Site-to-Site connection. These dialog boxes let you specify the peer IP address (IPv4 or IPv6), specify a connection name, select an interface, specify IKEv1 and IKEv2 peer and user authentication parameters, specify protected networks, and specify encryption algorithms.

The ASA supports LAN-to-LAN VPN connections to Cisco or third-party peers when the two peers have IPv4 inside and outside networks (IPv4 addresses on the inside and outside interfaces).

For LAN-to-LAN connections using mixed IPv4 and IPv6 addressing, or all IPv6 addressing, the security appliance supports VPN tunnels if both peers are Cisco ASA 5500 series security appliances, and if both inside networks have matching addressing schemes (both IPv4 or both IPv6).

Specifically, the following topologies are supported when both peers are Cisco ASA 5500 series ASAs:

- The ASAs have IPv4 inside networks and the outside network is IPv6 (IPv4 addresses on the inside interfaces and IPv6 addresses on the outside interfaces).
- The ASAs have IPv6 inside networks and the outside network is IPv4 (IPv6 addresses on the inside interface and IPv4 addresses on the outside interfaces).
- The ASAs have IPv6 inside networks and the outside network is IPv6 (IPv6 addresses on the inside and outside interfaces).

Fields

- Peer IP Address—Lets you specify an IP address (IPv4 or IPv6) and whether that address is static.
- Connection Name—Specifies the name assigned to this connection profile. For the Edit function, this field is display-only. You can specify that the connection name is the same as the IP address specified in the Peer IP Address field.
- Interface—Selects the interface to use for this connection.
- Protected Networks—Selects or specifies the local and remote network protected for this connection.
  - IP Address Type—Specifies the address is an IPv4 or IPv6 address.
  - Local Network—Specifies the IP address of the local network.
  - ...—Opens the Browse Local Network dialog box, in which you can select a local network.
  - Remote Network—Specifies the IP address of the remote network.
- IPsec Enabling—Specifies the group policy for this connection profile and the key exchange protocol specified in that policy:
  - Group Policy Name—Specifies the group policy associated with this connection profile.
  - Manage—Opens the Browse Remote Network dialog box, in which you can select a remote network.
  - Enable IKEv1—Enables the key exchange protocol IKEv1 in the specified group policy.
  - Enable IKEv2—Enables the key exchange protocol IKEv2 in the specified group policy.
- IKEv1 Settings tab—Specifies authentication and encryption settings for IKEv1:
  - Pre-shared Key—Specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.

  - Device Certificate—Specifies the name of the identity certificate, if available, to use for authentication.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can see the certificates that are already configured, add new certificates, show details for a certificate, and edit or delete a certificate.
  - IKE Policy—Specifies one or more encryption algorithms to use for the IKE proposal.
  - Manage—Opens the Configure IKEv1 Proposals dialog box.
  - IPsec Proposal—Specifies one or more encryption algorithms to use for the IPsec IKEv1 proposal.
- IKEv2 Settings tab—Specifies authentication and encryption settings for IKEv2:
  - Local Pre-shared Key—Specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
  - Local Device Certificate—Specifies the name of the identity certificate, if available, to use for authentication.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can see the certificates that are already configured, add new certificates, show details for a certificate, and edit or delete a certificate.
  - Remote Peer Pre-shared Key—Specify the value of the remote peer pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
  - Remote Peer Certificate Authentication—Check *Allowed* to allow certificate authentication for IKEv2 connections for this connection profile.
  - Manage—Opens the Manage CA Certificates dialog where you can view certificates and add new ones.
  - IKE Policy—Specifies one or more encryption algorithms to use for the IKE proposal.
  - Manage—Opens the Configure IKEv1 Proposals dialog box.
  - IPsec Proposal—Specifies one or more encryption algorithms to use for the IPsec IKEv1 proposal.
  - Select—Opens the Select IPsec Proposals (Transform Sets) dialog box, where you can assign a proposal to the connection profile for IKEv2 connections.

Adding or Editing a Site-to-Site Tunnel Group

You can get to this panel through various paths.

The Add or Edit IPsec Site-to-Site Tunnel Group dialog box lets you specify attributes for the IPsec site-to-site connection that you are adding. In addition, you can select IKE peer and user authentication parameters, configure IKE keepalive monitoring, and select the default group policy.

Fields

- Name—Specifies the name assigned to this tunnel group. For the Edit function, this field is display-only.
- IKE Authentication—Specifies the pre-shared key and Identity certificate parameters to use when authenticating an IKE peer.
  - Pre-shared Key—Specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.

  - Identity Certificate—Specifies the name of the ID certificate to use for authentication, if available.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can see the certificates that are already configured, add new certificates, show details for a certificate, and edit or delete a certificate.
  - IKE Peer ID Validation—Specifies whether to check IKE peer ID validation. The default is Required.
- IPsec Enabling—Specifies the group policy for this connection profile and the key exchange protocol specified in that policy:
  - Group Policy Name—Specifies the group policy associated with this connection profile.
  - Manage—Opens the Browse Remote Network dialog box, in which you can select a remote network.
  - Enable IKEv1—Enables the key exchange protocol IKEv1 in the specified group policy.
  - Enable IKEv2—Enables the key exchange protocol IKEv2 in the specified group policy.
- IKEv1 Settings tab—Specifies authentication and encryption settings for IKEv1:
  - Pre-shared Key—Specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
  - Device Certificate—Specifies the name of the identity certificate, if available, to use for authentication.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can see the certificates that are already configured, add new certificates, show details for a certificate, and edit or delete a certificate.
  - IKE Policy—Specifies one or more encryption algorithms to use for the IKE proposal.
  - Manage—Opens the Configure IKEv1 Proposals dialog box.
  - IPsec Proposal—Specifies one or more encryption algorithms to use for the IPsec IKEv1 proposal.
- IKEv2 Settings tab—Specifies authentication and encryption settings for IKEv2:
  - Local Pre-shared Key—Specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
  - Local Device Certificate—Specifies the name of the identity certificate, if available, to use for authentication.
  - Manage—Opens the Manage Identity Certificates dialog box, on which you can see the certificates that are already configured, add new certificates, show details for a certificate, and edit or delete a certificate.
  - Remote Peer Pre-shared Key—Specify the value of the remote peer pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
  - Remote Peer Certificate Authentication—Check *Allowed* to allow certificate authentication for IKEv2 connections for this connection profile.
  - Manage—Opens the Manage CA Certificates dialog where you can view certificates and add new ones.
  - IKE Policy—Specifies one or more encryption algorithms to use for the IKE proposal.
  - Manage—Opens the Configure IKEv1 Proposals dialog box.

  - IPsec Proposal—Specifies one or more encryption algorithms to use for the IPsec IKEv1 proposal.
  - Select—Opens the Select IPsec Proposals (Transform Sets) dialog box, where you can assign a proposal to the connection profile for IKEv2 connections.
- IKE Keepalive —Enables and configures IKE keepalive monitoring. You can select only one of the following attributes.
  - Disable Keep Alives—Enables or disables IKE keep alives.
  - Monitor Keep Alives—Enables or disables IKE keep alive monitoring. Selecting this option makes available the Confidence Interval and Retry Interval fields.
  - Confidence Interval—Specifies the IKE keep alive confidence interval. This is the number of seconds the ASA should allow a peer to idle before beginning keepalive monitoring. The minimum is 10 seconds; the maximum is 300 seconds. The default for a remote access group is 10 seconds.
  - Retry Interval—Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds.
  - Head end will never initiate keepalive monitoring—Specifies that the central-site ASA never initiates keepalive monitoring.

Crypto Map Entry

In this dialog box, specify crypto parameters for the Connection Profile.

Fields

- **Priority**—A unique priority (1 through 65,543, with 1 the highest priority). When IKE negotiation begins, the peer that initiates the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order.
- **Perfect Forward Secrecy**—Ensures that the key for a given IPsec SA was not derived from any other secret (like some other keys). If someone were to break a key, PFS ensures that the attacker would not be able to derive any other key. If you enable PFS, the Diffie-Hellman Group list becomes active.
  - **Diffie-Hellman Group**—An identifier which the two IPsec peers use to derive a shared secret without transmitting it to each other. The choices are Group 1 (768-bits), Group 2 (1024-bits), and Group 5 (1536-bits).
- **Enable NAT-T**— Enables NAT Traversal (NAT-T) for this policy, which lets IPsec peers establish both remote access and LAN-to-LAN connections through a NAT device.
- **Enable Reverse Route Injection**—Provides the ability for static routes to be automatically inserted into the routing process for those networks and hosts that are protected by a remote tunnel endpoint.
- **Security Association Lifetime**—Configures the duration of a Security Association (SA). This parameter specifies how to measure the lifetime of the IPsec SA keys, which is how long the IPsec SA lasts until it expires and must be renegotiated with new keys.
  - **Time**—Specifies the SA lifetime in terms of hours (hh), minutes (mm) and seconds (ss).
  - **Traffic Volume**—Defines the SA lifetime in terms of kilobytes of traffic. Enter the number of kilobytes of payload data after which the IPsec SA expires. Minimum is 100 KB, default is 10000 KB, maximum is 2147483647 KB.

Crypto Map Entry for Static Peer Address

In this dialog box, specify crypto parameters for the Connection Profile when the Peer IP Address is a static address.

Fields

- **Priority**—A unique priority (1 through 65,543, with 1 the highest priority). When IKE negotiation begins, the peer that initiates the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order.
- **Perfect Forward Secrecy**—Ensures that the key for a given IPsec SA was not derived from any other secret (like some other keys). If someone were to break a key, PFS ensures that the attacker would not be able to derive any other key. If you enable PFS, the Diffie-Hellman Group list becomes active.
  - **Diffie-Hellman Group**—An identifier which the two IPsec peers use to derive a shared secret without transmitting it to each other. The choices are Group 1 (768-bits), Group 2 (1024-bits), and Group 5 (1536-bits).
- **Enable NAT-T**— Enables NAT Traversal (NAT-T) for this policy, which lets IPsec peers establish both remote access and LAN-to-LAN connections through a NAT device.
- **Enable Reverse Route Injection**—Provides the ability for static routes to be automatically inserted into the routing process for those networks and hosts that are protected by a remote tunnel endpoint.
- **Security Association Lifetime**—Configures the duration of a Security Association (SA). This parameter specifies how to measure the lifetime of the IPsec SA keys, which is how long the IPsec SA lasts until it expires and must be renegotiated with new keys.
  - **Time**—Specifies the SA lifetime in terms of hours (hh), minutes (mm) and seconds (ss).
  - **Traffic Volume**—Defines the SA lifetime in terms of kilobytes of traffic. Enter the number of kilobytes of payload data after which the IPsec SA expires. Minimum is 100 KB, default is 10000 KB, maximum is 2147483647 KB.
- **Static Crypto Map Entry Parameters**—Configure these additional parameters when the Peer IP Address is specified as Static:
  - **Connection Type**—Specify the allowed negotiation as bidirectional, answer-only, or originate-only.
  - **Send ID Cert. Chain**—Enables transmission of the entire certificate chain.
  - **IKE Negotiation Mode**—Sets the mode for exchanging key information for setting up the SAs, Main or Aggressive. It also sets the mode that the initiator of the negotiation uses; the responder auto-negotiates. Aggressive Mode is faster, using fewer packets and fewer exchanges, but it does not protect the identity of the communicating parties. Main Mode is slower, using more packets and more exchanges, but it protects the identities of the communicating parties. This mode is more secure and it is the default selection. If you select Aggressive, the Diffie-Hellman Group list becomes active.
  - **Diffie-Hellman Group**—An identifier which the two IPsec peers use to derive a shared secret without transmitting it to each other. The choices are Group 1 (768-bits), Group 2 (1024-bits), and Group 5 (1536-bits).

Managing CA Certificates

Clicking Manage under IKE Peer Authentication opens the Manage CA Certificates dialog box. Use this dialog box to view, add, edit, and delete entries on the list of CA certificates available for IKE peer authentication.

The Manage CA Certificates dialog box lists information about currently configured certificates, including information about whom the certificate was issued to, who issued the certificate, when the certificate expires, and usage data.

Fields

- Add or Edit—Opens the Install Certificate dialog box or the Edit Certificate dialog box, which let you specify information about and install a certificate.
- Show Details—Displays detailed information about a certificate that you select in the table.
- Delete—Removes the selected certificate from the table. There is no confirmation or undo.

Install Certificate

Use this dialog box to install a new CA certificate. You can get the certificate in one of the following ways:

- Install from a file by browsing to the certificate file.
- Paste the previously acquired certificate text in PEM format into the box on this dialog box.
- Use SCEP—Specifies the use of the Simple Certificate Enrollment Protocol (SCEP) Add-on for Certificate Services runs on the Windows Server 2003 family. It provides support for the SCEP protocol, which allows Cisco routers and other intermediate network devices to obtain certificates.
  - SCEP URL: http://—Specifies the URL from which to download SCEP information.
  - Retry Period—Specifies the number of minutes that must elapse between SCEP queries.
  - Retry Count—Specifies the maximum number of retries allowed.
- More Options—Opens the Configure Options for CA Certificate dialog box.

:

Configure Options for CA Certificate

Use this dialog box to specify details about retrieving CA Certificates for this IPsec remote access connection. The dialog boxes on this dialog box are: Revocation Check, CRL Retrieval Policy, CRL Retrieval Method, OCSP Rules, and Advanced.

Revocation Check Dialog Box

Use this dialog box to specify information about CA Certificate revocation checking.

Fields

- The radio buttons specify whether to check certificates for revocation. The values of these buttons are as follows:

  - Do not check certificates for revocation
  - Check Certificates for revocation
- Revocation Methods area—Lets you specify the method–CRL or OCSP–to use for revocation checking, a nd the order in which to use these methods. You can choose either or both methods.

Add/Edit Remote Access Connections > Advanced > General

Use this dialog box to specify whether to strip the realm and group from the username before passing them to the AAA server, and to specify password management parameters.

Fields

- Strip the realm from username before passing it on to the AAA server—Enables or disables stripping the realm (administrative domain) from the username before passing the username on to the AAA server. Check the Strip Realm check box to remove the realm qualifier of the username during authentication. You can append the realm name to the username for AAA: authorization, authentication and accounting. The only valid delimiter for a realm is the @ character. The format is username@realm, for example, JaneDoe@example.com. If you check this Strip Realm check box, authentication is based on the username alone. Otherwise, authentication is based on the full username@realm string. You must check this box if your server is unable to parse delimiters.

Note You can append both the realm and the group to a username, in which case the ASA uses parameters configured for the group *and* for the realm for AAA functions. The format for this option is *username[@realm]]<#or!>group]*, for example, *JaneDoe@example.com#VPNGroup*. If you choose this option, you must use either the # or ! character for the group delimiter because the ASA cannot interpret the @ as a group delimiter if it is also present as the realm delimiter.

A Kerberos realm is a special case. The convention in naming a Kerberos realm is to capitalize the DNS domain name associated with the hosts in the Kerberos realm. For example, if users are in the example.com domain, you might call your Kerberos realm EXAMPLE.COM.

The ASA does not include support for the user@grouppolicy, as the VPN 3000 Concentrator did. Only the L2TP/IPsec client supports the tunnel switching via user@tunnelgroup.

- Strip the group from the username before passing it on to the AAA server—Enables or disables stripping the group name from the username before passing the username on to the AAA server. Check Strip Group to remove the group name from the username during authentication. This option is meaningful only when you have also checked the Enable Group Lookup box. When you append a group name to a username using a delimiter, and enable Group Lookup, the ASA interprets all characters to the left of the delimiter as the username, and those to the right as the group name. Valid group delimiters are the @, #, and ! characters, with the @ character as the default for Group Lookup. You append the group to the username in the format *username<delimiter>group*, the possibilities being, for example, *JaneDoe@VPNGroup, JaneDoe#VPNGroup*, and *JaneDoe!VPNGroup*.
- Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.
  - Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

Note Allowing override account-disabled is a potential security risk.

– Enable notification upon password expiration to allow user to change password—Checking this check box makes the following two parameters available. You can select either to notify the user at login a specific number of days before the password expires or to notify the user only on the day that the password expires. The default is to notify the user 14 days prior to password expiration and every day thereafter until the user changes the password. The range is 1 through 180 days.

Note This does not change the number of days before the password expires, but rather, it enables the notification. If you select this option, you must also specify the number of days.

In either case, and, if the password expires without being changed, the ASA offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This parameter is valid for AAA servers that support such notification; that is, RADIUS, RADIUS with an NT server, and LDAP servers. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

This feature requires the use of MS-CHAPv2.

Configuring Client Addressing

To specify the client IP address assignment policy and assign address pools to all IPsec and SSL VPN connections, open ASDM and select Configuration > Remote Access VPN > Network (Client) Access > IPsec or SSL VPN Connections > Add or Edit > Advanced > Client Addressing. The Add IPsec Remote Access Connection or Add SSL VPN Access Connection opens. Use this dialog box to add address pools and assign them to interfaces, and view, edit, or delete them. The table at the bottom of the dialog box lists the configured interface-specific address pools.

To understand the fields in this dialog box or its descendent dialog boxes, see the sections that follow this one. You can view or change the configuration of address pools and their assignment to interfaces, as follows:

- To view or change the configuration of address pools, click **Add** or **Edit** in the Add IPsec Remote Access Connection or Add SSL VPN Access Connection dialog box. The Assign Address Pools to Interface dialog box opens. This dialog box lets you assign IP address pools to the interfaces configured on the ASA. Click **Select**. The Select Address Pools dialog box opens. Use this dialog box to view the configuration of address pools. You can change their address pool configuration as follows:
  – To add an address pool to the ASA, choose **Add**. The Add IP Pool dialog box opens.
  – To change the configuration of an address pool on the ASA, choose **Edit**. The Edit IP Pool dialog box opens if the addresses in the pool are not in use.

Note You cannot modify an address pool if it is already in use. If you click **Edit** and the address pool is in use, ASDM displays an error message and lists the connection names and usernames that are using the addresses in the pool.

– To remove address pool on the ASA, select the entry in the table and click **Delete**.

Note You cannot remove an address pool if it is already in use. If you click **Delete** and the address pool is in use, ASDM displays an error message and lists the connection names that are using the addresses in the pool.

- To assign address pools to an interface, click **Add** in the Add IPsec Remote Access Connection or Add SSL VPN Access Connection dialog box. The Assign Address Pools to Interface dialog box opens. Select the interface to be assigned an address pool. Click **Select** next to the Address Pools field. The Select Address Pools dialog box opens. Double-click each unassigned pool you want to assign to the interface or choose each unassigned pool and click **Assign**. The adjacent field displays the list of pool assignments. Click OK to populate the Address Pools field with the names of these address pools, then **OK** again to complete the configuration of the assignment.
- To change the address pools assigned to an interface, double-click the interface, or choose the interface in the Add IPsec Remote Access Connection or Add SSL VPN Access Connection dialog box and click Edit. The Assign Address Pools to Interface dialog box opens. To remove address pools, double-click each pool name and press the Delete button on the keyboard. Click **Select** next to the Address Pools field if you want to assign additional fields to the interface. The Select Address Pools dialog box opens. Note that the Assign field displays the address pool names that remained assigned to the interface. Double-click each unassigned pool you want to add to the interface. The Assign field updates the list of pool assignments. Click **OK** to revise the Address Pools field with the names of these address pools, then **OK** again to complete the configuration of the assignment.
- To remove an entry from the Add IPsec Remote Access Connection or Add SSL VPN Access Connection dialog box, choose the entry and click **Delete**.

The Add IPsec Remote Access Connection and Add SSL VPN Access Connection dialog boxes and their descendent dialog boxes are identical. Use the following sections to understand or assign values to the fields in these dialog boxes:

- Add IPsec Remote Access Connection and Add SSL VPN Access Connection
- Assign Address Pools to Interface
- Select Address Pools
- Add or Edit IP Pool

Add IPsec Remote Access Connection and Add SSL VPN Access Connection

To access the Add IPsec Remote Access Connection and Add SSL VPN Access Connection dialog boxes, choose Config > Remote Access VPN > Network (Client) Access > IPsec or SSL VPN Connections > Add or Edit > Advanced > Client Addressing.

Fields

Use the following descriptions to assign values to the fields in this dialog box:

- Global Client Address Assignment Policy—Configures a policy that affects all IPsec and SSL VPN Client connections (including AnyConnect client connections). The ASA uses the selected sources in order, until it finds an address:
  - Use authentication server—Specifies that the ASA should attempt to use the authentication server as the source for a client address.
  - Use DHCP—Specifies that the ASA should attempt to use DHCP as the source for a client address.

  - Use address pool—Specifies that the ASA should attempt to use address pools as the source for a client address.
- Interface-Specific Address Pools—Lists the configured interface-specific address pools.

Assign Address Pools to Interface

Use the Assign Address Pools to Interface dialog box to select an interface and assign one or more address pools to that interface. To access this dialog box, choose Config > Remote Access VPN > Network (Client) Access > IPsec or SSL VPN Connections > Add or Edit > Advanced > Client Addressing > Add or Edit.

Fields

Use the following descriptions to assign values to the fields in this dialog box:

- Interface—Select the interface to which you want to assign an address pool. The default is DMZ.
- Address Pools—Specify an address pool to assign to the specified interface.
- Select—Opens the Select Address Pools dialog box, in which you can select one or more address pools to assign to this interface. Your selection appears in the Address Pools field of the Assign Address Pools to Interface dialog box.

Select Address Pools

The Select Address Pools dialog box shows the pool name, starting and ending addresses, and subnet mask of address pools available for client address assignment and lets you add, edit, or delete entries from that list. To access this dialog box, choose Config > Remote Access VPN > Network (Client) Access > IPsec or SSL VPN Connections > Add or Edit > Advanced > Client Addressing > Add or Edit > Select.

Fields

Use the following descriptions to assign values to the fields in this dialog box:

- Add—Opens the Add IP Pool dialog box, on which you can configure a new IP address pool.
- Edit—Opens the Edit IP Pool dialog box, on which you can modify a selected IP address pool.
- Delete—Removes the selected address pool. There is no confirmation or undo.
- Assign—Displays the address pool names that remained assigned to the interface. Double-click each unassigned pool you want to add to the interface. The Assign field updates the list of pool assignments.

Add or Edit IP Pool

The Add or Edit IP Pool dialog box lets you specify or modify a range of IP addresses for client address assignment. To access this dialog box, choose Config > Remote Access VPN > Network (Client) Access > IPsec or SSL VPN Connections > Add or Edit > Advanced > Client Addressing > Add or Edit > Select > Add or Edit.

Fields

Use the following descriptions to assign values to the fields in this dialog box:

- Name—Specifies the name assigned to the IP address pool.
- Starting IP Address—Specifies the first IP address in the pool.
- Ending IP Address—Specifies the last IP address in the pool.

- Subnet Mask—Selects the subnet mask to apply to the addresses in the pool.

Add/Edit Connection Profile > General > Authentication

You can get to this panel through various paths.

This dialog box is available for IPsec on Remote Access and Site-to-Site tunnel groups. The settings on this dialog box apply to the tunnel group globally across the ASA. To set authentication server group settings per interface, click Advanced. This dialog box lets you configure the following attributes:

- Authentication Server Group—Lists the available authentication server groups, including the LOCAL group (the default). You can also select None. Selecting something other than None or Local makes available the Use LOCAL if Server Group Fails check box. To set the authentication server group per interface, click Advanced.
- Use LOCAL if Server Group fails—Enables or disables fallback to the LOCAL database if the group specified by the Authentication Server Group attribute fails.

Add/Edit SSL VPN Connection > General > Authorization

You can get to this panel through various paths.

The settings on this dialog box apply to the connection (tunnel group) globally across the ASA. This dialog box lets you configure the following attributes:

- Authorization Server Group—Lists the available authorization server groups, including the LOCAL group. You can also select None (the default). Selecting something other than None makes available the check box for Users must exist in authorization database to connect.
- Users must exist in the authorization database to connect—Tells the ASA to allow only users in the authorization database to connect. By default this feature is disabled. You must have a configured authorization server to use this feature.
- Interface-Specific Authorization Server Groups—(Optional) Lets you configure authorization server groups on a per-interface basis. Interface-specific authorization server groups take precedence over the global server group. If you do not explicitly configure interface-specific authorization, authorization takes place only at the group level.
  - Interface—Select the interface on which to perform authorization. The standard interfaces are outside (the default), inside, and DMZ. If you have configured other interfaces, they also appear in the list.
  - Server Group—Select an available, previously configured authorization server group or group of servers, including the LOCAL group. You can associate a server group with more than one interface.
  - Add—Click Add to add the interface/server group setting to the table and remove the interface from the available list.
  - Remove—Click Remove to remove the interface/server group from the table and restore the interface to the available list.
- Authorization Settings—Lets you set values for usernames that the ASA recognizes for authorization. This applies to users that authenticate with digital certificates and require LDAP or RADIUS authorization.
  - Use the entire DN as the username—Allows the use of the entire Distinguished Name (DN) as the username.

- Specify individual DN fields as the username—Enables the use of individual DN fields as the username.
- Primary DN Field—Lists all of the DN field identifiers for your selection.

DN Field	Definition
Country (C)	Two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
Common Name (CN)	Name of a person, system, or other entity. This is the lowest (most specific) level in the identification hierarchy.
DN Qualifier (DNQ)	Specific DN attribute.
E-mail Address (EA)	E-mail address of the person, system or entity that owns the certificate.
Generational Qualifier (GENQ)	Generational qualifier such as Jr., Sr., or III.
Given Name (GN)	First name of the certificate owner.
Initials (I)	First letters of each part of the certificate owner's name.
Locality (L)	City or town where the organization is located.
Name (N)	Name of the certificate owner.
Organization (O)	Name of the company, institution, agency, association, or other entity.
Organizational Unit (OU)	Subgroup within the organization.
Serial Number (SER)	Serial number of the certificate.
Surname (SN)	Family name or last name of the certificate owner.
State/Province (S/P)	State or province where the organization is located.
Title (T)	Title of the certificate owner, such as Dr.
User ID (UID)	Identification number of the certificate owner.
User Principal Name (UPN)	Used with Smart Card certificate authentication.

- Secondary DN Field—Lists all of the DN field identifiers (see the foregoing table) for your selection and adds the option None for no selection.

Add/Edit SSL VPN Connections > Advanced > Accounting

You can get to this panel through various paths.

The settings on this dialog box apply to the connection (tunnel group) globally across the ASA. This dialog box lets you configure the following attribute:

- Accounting Server Group—Lists the available accounting server groups. You can also select None (the default). LOCAL is not an option.
- Manage—Opens the Configure AAA Server Groups dialog box.

Add/Edit Tunnel Group > General > Client Address Assignment

You can get to this panel through various paths.

To specify whether to use DHCP or address pools for address assignment, go to Configuration > VPN > I P Address Management > Assignment. The Add or Edit Tunnel Group dialog box > General > Client Address Assignment dialog box, lets you configure the following Client Address Assignment attributes:

- DHCP Servers—Specifies a DHCP server to use. You can add up to 10 servers, one at a time.
  - IP Address—Specifies the IP address of a DHCP server.
  - Add—Adds the specified DHCP server to the list for client address assignment.
  - Delete—Deletes the specified DHCP server from the list for client address assignment. There is no confirmation or undo.
- Address Pools—Lets you specify up to 6 address pools, using the following parameters:
  - Available Pools—Lists the available, configured address pools you can choose.
  - Add—Adds the selected address pool to the list for client address assignment.
  - Remove—Moves the selected address pool from the Assigned Pools list to the Available Pools list.
  - Assigned Pools—Lists the address pools selected for address assignment.

Note To configure interface-specific address pools, click Advanced.

Add/Edit Tunnel Group > General > Advanced

You can get to this panel through various paths.

The Add or Edit Tunnel Group dialog box, General, Advanced dialog box, lets you configure the following interface-specific attributes:

- Interface-Specific Authentication Server Groups—Lets you configure an interface and server group for authentication.
  - Interface—Lists available interfaces for selection.
  - Server Group—Lists authentication server groups available for this interface.
  - Use LOCAL if server group fails—Enables or disables fallback to the LOCAL database if the server group fails.
  - Add—Adds the association between the selected available interface and the authentication server group to the assigned list.
  - Remove—Moves the selected interface and authentication server group association from the assigned list to the available list.
  - Interface/Server Group/Use Fallback—Show the selections you have added to the assigned list.
- Interface-Specific Client IP Address Pools—-Lets you specify an interface and Client IP address pool. You can have up to 6 pools.
  - Interface—Lists the available interfaces to add.
  - Address Pool—Lists address pools available to associate with this interface.
  - Add—Adds the association between the selected available interface and the client IP address pool to the assigned list.

- Remove—Moves the selected interface/address pool association from the assigned list to the available list.
- Interface/Address Pool—Shows the selections you have added to the assigned list.

Add/Edit Tunnel Group > IPsec for Remote Access > IPsec

Configuration > VPN > General > Tunnel Group > Add/Edit Tunnel Group > IPSec for Remote Access > IPSec Tab

On the Add or Edit Tunnel Group dialog box for IPsec for Remote Access, the IPsec dialog box lets you configure or edit IPsec-specific tunnel group parameters.

Fields

- Pre-shared Key—Lets you specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
- Trustpoint Name—Selects a trustpoint name, if any trustpoints are configured. A trustpoint is a representation of a certificate authority. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.
- Authentication Mode—Specifies the authentication mode: none, xauth, or hybrid.
  - none—Specifies no authentication mode.
  - xauth—Specifies the use of IKE Extended Authentication mode, which provides the capability of authenticating a user within IKE using TACACS+ or RADIUS.
  - hybrid—Specifies the use of Hybrid mode, which lets you use digital certificates for security appliance authentication and a different, legacy method—such as RADIUS, TACACS+ or SecurID—for remote VPN user authentication. This mode breaks phase 1 of the Internet Key Exchange (IKE) into the following steps, together called hybrid authentication:

1. The security appliance authenticates to the remote VPN user with standard public key techniques. This establishes an IKE security association that is unidirectionally authenticated.
2. An extended authentication (xauth) exchange then authenticates the remote VPN user. This extended authentication can use one of the supported legacy authentication methods.

Note Before setting the authentication type to hybrid, you must configure the authentication server and create a pre-shared key.

- IKE Peer ID Validation—Selects whether IKE peer ID validation is ignored, required, or checked only if supported by a certificate.
- Enable sending certificate chain—Enables or disables sending the entire certificate chain. This action includes the root certificate and any subordinate CA certificates in the transmission.
- ISAKMP Keep Alive—Enables and configures ISAKMP keep alive monitoring.
  - Disable Keep Alives—Enables or disables ISAKMP keep alives.
  - Monitor Keep Alives—Enables or disables ISAKMP keep alive monitoring. Selecting this option makes available the Confidence Interval and Retry Interval fields.
  - Confidence Interval—Specifies the ISAKMP keep alive confidence interval. This is the number of seconds the ASA should allow a peer to idle before beginning keepalive monitoring. The minimum is 10 seconds; the maximum is 300 seconds. The default for a remote access group is 300 seconds.

  - Retry Interval—Specifies number of seconds to wait between ISAKMP keep alive retries. The default is 2 seconds.
  - Head end will never initiate keepalive monitoring—Specifies that the central-site ASA never initiates keepalive monitoring.
- Interface-Specific Authentication Mode—Specifies the authentication mode on a per-interface basis.
  - Interface—Lets you select the interface name. The default interfaces are inside and outside, but if you have configured a different interface name, that name also appears in the list.
  - Authentication Mode—Lets you select the authentication mode, none, xauth, or hybrid, as above.
  - Interface/Authentication Mode table—Shows the interface names and their associated authentication modes that are selected.
  - Add—Adds an interface/authentication mode pair selection to the Interface/Authentication Modes table.
  - Remove—Removes an interface/authentication mode pair selection from the Interface/Authentication Modes table.
- Client VPN Software Update Table—Lists the client type, VPN Client revisions, and image URL for each client VPN software package installed. For each client type, you can specify the acceptable client software revisions and the URL or IP address from which to download software upgrades, if necessary. The client update mechanism (described in detail under the Client Update dialog box) uses this information to determine whether the software each VPN client is running is at an appropriate revision level and, if appropriate, to provide a notification message and an update mechanism to clients that are running outdated software.
  - Client Type—Identifies the VPN client type.
  - VPN Client Revisions—Specifies the acceptable revision level of the VPN client.
  - Image URL—Specifies the URL or IP address from which the correct VPN client software image can be downloaded. For dialog boxes-based VPN clients, the URL must be of the form http:// or https://. For ASA 5505 in client mode or VPN 3002 hardware clients, the URL must be of the form tftp://.

Add/Edit Tunnel Group for Site-to-Site VPN

Configuration > VPN > General > Tunnel Group > Add/Edit Tunnel Group > IPSec for Remote Access > IPSec Tab

The Add or Edit Tunnel Group dialog box lets you configure or edit tunnel group parameters for this Site-to-Site connection profile.

Fields

- Certificate Settings—Sets the following certificate chain and IKE peer validation attributes:
  - Send certificate chain—Enables or disables sending the entire certificate chain. This action includes the root certificate and any subordinate CA certificates in the transmission.
  - IKE Peer ID Validation—Selects whether IKE peer ID validation is ignored, required, or checked only if supported by a certificate.
- IKE Keep Alive—Enables and configures IKE (ISAKMP) keepalive monitoring.
  - Disable Keepalives—Enables or disables IKE keep alives.

  - Monitor Keepalives—Enables or disables IKE keep alive monitoring. Selecting this option makes available the Confidence Interval and Retry Interval fields.
  - Confidence Interval—Specifies the IKE keepalive confidence interval. This is the number of seconds the ASA should allow a peer to idle before beginning keepalive monitoring. The minimum is 10 seconds; the maximum is 300 seconds. The default for a remote access group is 300 seconds.
  - Retry Interval—Specifies number of seconds to wait between IKE keepalive retries. The default is 2 seconds.
  - Head end will never initiate keepalive monitoring—Specifies that the central-site ASA never initiates keepalive monitoring.
- Default Group Policy—Specifies the following group-policy attributes:
  - Group Policy—Selects a group policy to use as the default group policy. The default value is DfltGrpPolicy.
  - Manage—Opens the Configure Group Policies dialog box.
  - IPsec Protocol—Enables or disables the use of the IPsec protocol for this connection profile.

Add/Edit Tunnel Group > PPP

Configuration > VPN > General > Tunnel Group > Add/Edit Tunnel Group > PPP Tab

On the Add or Edit Tunnel Group dialog box for a IPsec remote access tunnel group, the PPP dialog box lets you configure or edit the authentication protocols permitted of a PPP connection. This dialog box applies *only* to IPsec remote access tunnel groups.

Fields

- CHAP—Enables the use of the CHAP protocol for a PPP connection.
- MS-CHAP-V1—Enables the use of the MS-CHAP-V1 protocol for a PPP connection.
- MS-CHAP-V2—Enables the use of the MS-CHAP-V2 protocol for a PPP connection.
- PAP—Enables the use of the PAP protocol for a PPP connection.
- EAP-PROXY—Enables the use of the EAP-PROXY protocol for a PPP connection. EAP refers to the Extensible Authentication protocol.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	—	•	—	—

Add/Edit Tunnel Group > IPsec for LAN to LAN Access > General > Basic

Configuration > VPN > General > Tunnel Group > Add/Edit Tunnel Group > IPSec for LAN to LAN Access > General Tab > Basic Tab

On the Add or Edit Tunnel Group dialog box for Site-to-Site Remote Access, the General, Basic dialog box you can specify a name for the tunnel group that you are adding (Add function only) and select the group policy.

On the Edit Tunnel Group dialog box, the General dialog box displays the name and type of the tunnel group you are modifying.

Fields

- Name—Specifies the name assigned to this tunnel group. For the Edit function, this field is display-only.
- Type—(*Display-only*) Displays the type of tunnel group you are adding or editing. The contents of this field depend on your selection on the previous dialog box.
- Group Policy—Lists the currently configured group policies. The default value is the default group policy, DfltGrpPolicy.
- Strip the realm (administrative domain) from the username before passing it on to the AAA server—Enables or disables stripping the realm from the username before passing the username on to the AAA server. Check the Strip Realm check box to remove the realm qualifier of the username during authentication. You can append the realm name to the username for AAA: authorization, authentication and accounting. The only valid delimiter for a realm is the @ character. The format is username@realm, for example, JaneDoe@example.com. If you check this Strip Realm check box, authentication is based on the username alone. Otherwise, authentication is based on the full username@realm string. You must check this box if your server is unable to parse delimiters.

Note You can append both the realm and the group to a username, in which case the ASA uses parameters configured for the group *and* for the realm for AAA functions. The format for this option is *username[@realm]]<#or!>group]*, for example, *JaneDoe@example.com#VPNGroup*. If you choose this option, you must use either the # or ! character for the group delimiter because the ASA cannot interpret the @ as a group delimiter if it is also present as the realm delimiter.

A Kerberos realm is a special case. The convention in naming a Kerberos realm is to capitalize the DNS domain name associated with the hosts in the Kerberos realm. For example, if users are in the example.com domain, you might call your Kerberos realm EXAMPLE.COM.

The ASA does not include support for the user@grouppolicy, as the VPN 3000 Concentrator did. Only the L2TP/IPsec client supports the tunnel switching via user@tunnelgroup.

- Strip the group from the username before passing it on to the AAA server—Enables or disables stripping the group name from the username before passing the username on to the AAA server. Check Strip Group to remove the group name from the username during authentication. This option is meaningful only when you have also checked the Enable Group Lookup box. When you append a group name to a username using a delimiter, and enable Group Lookup, the ASA interprets all characters to the left of the delimiter as the username, and those to the right as the group name. Valid group delimiters are the @, #, and ! characters, with the @ character as the default for Group Lookup. You append the group to the username in the format *username<delimiter>group*, the possibilities being, for example, *JaneDoe@VPNGroup, JaneDoe#VPNGroup*, and *JaneDoe!VPNGroup*.
- Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.
  - Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

Note Allowing override account-disabled is a potential security risk.

- Enable notification upon password expiration to allow user to change password—Checking this check box makes the following two parameters available. If you do not also check the Enable notification prior to expiration check box, the user receives notification only after the password has expired.
- Enable notification prior to expiration—When you check this option, the ASA notifies the remote user at login that the current password is about to expire or has expired, then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password. This parameter is valid for AAA servers that support such notification; that is, RADIUS, RADIUS with an NT server, and LDAP servers. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

  Note that this does not change the number of days before the password expires, but rather, it enables the notification. If you check this check box, you must also specify the number of days.
- Notify...days prior to expiration—Specifies the number of days before the current password expires to notify the user of the pending expiration. The range is 1 through 180 days.

Add/Edit Tunnel Group > IPsec for LAN to LAN Access > IPsec

Configuration > VPN > General > Tunnel Group > Add/Edit Tunnel Group > IPSec for LAN to LAN Access > IPSec Tab

The Add or Edit Tunnel Group dialog box for IPsec for Site-to-Site access, IPsec dialog box, lets you configure or edit IPsec Site-to-Site-specific tunnel group parameters.

Fields

- Name—Specifies the name assigned to this tunnel group. For the Edit function, this field is display-only.
- Type—(*Display-only*) Displays the type of tunnel group you are adding or editing. The contents of this field depend on your selection on the previous dialog box.
- Pre-shared Key—Lets you specify the value of the pre-shared key for the tunnel group. The maximum length of the pre-shared key is 128 characters.
- Trustpoint Name—Selects a trustpoint name, if any trustpoints are configured. A trustpoint is a representation of a certificate authority. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.
- Authentication Mode—Specifies the authentication mode: none, xauth, or hybrid.
  - none—Specifies no authentication mode.
  - xauth—Specifies the use of IKE Extended Authentication mode, which provides the capability of authenticating a user within IKE using TACACS+ or RADIUS.
  - hybrid—Specifies the use of Hybrid mode, which lets you use digital certificates for security appliance authentication and a different, legacy method—such as RADIUS, TACACS+ or SecurID—for remote VPN user authentication. This mode breaks phase 1 of the Internet Key Exchange (IKE) into the following steps, together called hybrid authentication:

1. The security appliance authenticates to the remote VPN user with standard public key techniques. This establishes an IKE security association that is unidirectionally authenticated.

2. An extended authentication (xauth) exchange then authenticates the remote VPN user. This extended authentication can use one of the supported legacy authentication methods.

Note Before setting the authentication type to hybrid, you must configure the authentication server and create a pre-shared key.

- IKE Peer ID Validation—Selects whether IKE peer ID validation is ignored, required, or checked only if supported by a certificate.
- Enable sending certificate chain—Enables or disables sending the entire certificate chain. This action includes the root certificate and any subordinate CA certificates in the transmission.
- ISAKMP Keep Alive—Enables and configures ISAKMP keep alive monitoring.
  - Disable Keep Alives—Enables or disables ISAKMP keep alives.
  - Monitor Keep Alives—Enables or disables ISAKMP keep alive monitoring. Selecting this option makes available the Confidence Interval and Retry Interval fields.
  - Confidence Interval—Specifies the ISAKMP keep alive confidence interval. This is the number of seconds the ASA should allow a peer to idle before beginning keepalive monitoring. The minimum is 10 seconds; the maximum is 300 seconds. The default for a remote access group is 300 seconds.
  - Retry Interval—Specifies number of seconds to wait between ISAKMP keep alive retries. The default is 2 seconds.
  - Head end will never initiate keepalive monitoring—Specifies that the central-site ASA never initiates keepalive monitoring.
- Interface-Specific Authentication Mode—Specifies the authentication mode on a per-interface basis.
  - Interface—Lets you select the interface name. The default interfaces are inside and outside, but if you have configured a different interface name, that name also appears in the list.
  - Authentication Mode—Lets you select the authentication mode, none, xauth, or hybrid, as above.
  - Interface/Authentication Mode table—Shows the interface names and their associated authentication modes that are selected.
  - Add—Adds an interface/authentication mode pair selection to the Interface/Authentication Modes table.
  - Remove—Removes an interface/authentication mode pair selection from the Interface/Authentication Modes table.
- Client VPN Software Update Table—Lists the client type, VPN Client revisions, and image URL for each client VPN software package installed. For each client type, you can specify the acceptable client software revisions and the URL or IP address from which to download software upgrades, if necessary. The client update mechanism (described in detail under the Client Update dialog box) uses this information to determine whether the software each VPN client is running is at an appropriate revision level and, if appropriate, to provide a notification message and an update mechanism to clients that are running outdated software.
  - Client Type—Identifies the VPN client type.
  - VPN Client Revisions—Specifies the acceptable revision level of the VPN client.

– Image URL—Specifies the URL or IP address from which the correct VPN client software image can be downloaded. For Windows-based VPN clients, the URL must be of the form http:// or https://. For ASA 5505 in client mode or VPN 3002 hardware clients, the URL must be of the form tftp://.

Clientless SSL VPN Access > Connection Profiles > Add/Edit > General > Basic

Configuration > VPN > General > Tunnel Group > Add/Edit> WebVPN Access > General Tab > Basic Tab

The Add or Edit pane, General, Basic dialog box lets you specify a name for the tunnel group that you are adding, lets you select the group policy, and lets you configure password management.

On the Edit Tunnel Group dialog box, the General dialog box displays the name and type of the selected tunnel group. All other functions are the same as for the Add Tunnel Group dialog box.

Fields

- Name—Specifies the name assigned to this tunnel group. For the Edit function, this field is display-only.
- Type—Displays the type of tunnel group you are adding or editing. For Edit, this is a display-only field whose contents depend on your selection in the Add dialog box.
- Group Policy—Lists the currently configured group policies. The default value is the default group policy, DfltGrpPolicy.
- Strip the realm —Not available for Clientless SSL VPN.
- Strip the group —Not available or Clientless SSL VPN.
- Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.
  - Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

Note Allowing override account-disabled is a potential security risk.

  - Enable notification upon password expiration to allow user to change password—Checking this check box makes the following two parameters available. If you do not also check the Enable notification prior to expiration check box, the user receives notification only after the password has expired.
  - Enable notification prior to expiration—When you check this option, the ASA notifies the remote user at login that the current password is about to expire or has expired, then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password. This parameter is valid for AAA servers that support such notification; that is, RADIUS, RADIUS with an NT server, and LDAP servers. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

    Note that this does not change the number of days before the password expires, but rather, it enables the notification. If you check this check box, you must also specify the number of days.
  - Notify...days prior to expiration—Specifies the number of days before the current password expires to notify the user of the pending expiration. The range is 1 through 180 days.

Configuring Internal Group Policy IPsec Client Attributes

Use this dialog box to specify whether to strip the realm and group from the username before passing them to the AAA server, and to specify password management options.

Fields

- Strip the realm from username before passing it on to the AAA server—Enables or disables stripping the realm (administrative domain) from the username before passing the username on to the AAA server. Check the Strip Realm check box to remove the realm qualifier of the username during authentication. You can append the realm name to the username for AAA: authorization, authentication and accounting. The only valid delimiter for a realm is the @ character. The format is username@realm, for example, JaneDoe@example.com. If you check this Strip Realm check box, authentication is based on the username alone. Otherwise, authentication is based on the full username@realm string. You must check this box if your server is unable to parse delimiters.

Note You can append both the realm and the group to a username, in which case the ASA uses parameters configured for the group *and* for the realm for AAA functions. The format for this option is *username[@realm]]<#or!>group]*, for example, *JaneDoe@example.com#VPNGroup*. If you choose this option, you must use either the # or ! character for the group delimiter because the ASA cannot interpret the @ as a group delimiter if it is also present as the realm delimiter.

A Kerberos realm is a special case. The convention in naming a Kerberos realm is to capitalize the DNS domain name associated with the hosts in the Kerberos realm. For example, if users are in the example.com domain, you might call your Kerberos realm EXAMPLE.COM.

The ASA does not include support for the user@grouppolicy, as the VPN 3000 Concentrator did. Only the L2TP/IPsec client supports the tunnel switching via user@tunnelgroup.

- Strip the group from the username before passing it on to the AAA server—Enables or disables stripping the group name from the username before passing the username on to the AAA server. Check Strip Group to remove the group name from the username during authentication. This option is meaningful only when you have also checked the Enable Group Lookup box. When you append a group name to a username using a delimiter, and enable Group Lookup, the ASA interprets all characters to the left of the delimiter as the username, and those to the right as the group name. Valid group delimiters are the @, #, and ! characters, with the @ character as the default for Group Lookup. You append the group to the username in the format *username<delimiter>group*, the possibilities being, for example, *JaneDoe@VPNGroup, JaneDoe#VPNGroup*, and *JaneDoe!VPNGroup*.
- Password Management—Lets you configure parameters relevant to overriding an account-disabled indication from a AAA server and to notifying users about password expiration.
  - Override account-disabled indication from AAA server—Overrides an account-disabled indication from a AAA server.

Note Allowing override account-disabled is a potential security risk.

  - Enable notification upon password expiration to allow user to change password—Checking this check box makes the following two parameters available. You can select either to notify the user at login a specific number of days before the password expires or to notify the user only on the

day that the password expires. The default is to notify the user 14 days prior to password expiration and every day thereafter until the user changes the password. The range is 1 through 180 days.

Note This does not change the number of days before the password expires, but rather, it enables the notification. If you select this option, you must also specify the number of days.

In either case, and, if the password expires without being changed, the ASA offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This parameter is valid for AAA servers that support such notification; that is, RADIUS, RADIUS with an NT server, and LDAP servers. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

Configuring Client Addressing for SSL VPN Connections

Use this dialog box to specify the global client address assignment policy and to configure interface-specific address pools. You can also add, edit, or delete interface-specific address pools using this dialog box. The table at the bottom of the dialog box lists the configured interface-specific address pools.

Fields

- Interface-Specific IPv4 Address Pools—Lists the configured interface-specific address pools.
- Interface-Specific IPv6 Address Pools—Lists the configured interface-specific address pools.
- Add—Opens the Assign Address Pools to Interface dialog box, on which you can select an interface and select an address pool to assign.
- Edit—Opens the Assign Address Pools to Interface dialog box with the interface and address pool fields filled in.
- Delete—Deletes the selected interface-specific address pool. There is no confirmation or undo.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	—	•	—	—

Assign Address Pools to Interface

Use this dialog box to select an interface and assign one or more address pools to that interface.

Fields

- Interface—Select the interface to which you want to assign an address pool. The default is DMZ.

- Address Pools—Specify an address pool to assign to the specified interface.
- Select—Opens the Select Address Pools dialog box, in which you can select one or more address pools to assign to this interface. Your selection appears in the Address Pools field of the Assign Address Pools to Interface dialog box.

Select Address Pools

The Select Address Pools dialog box shows the pool name, starting and ending addresses, and subnet mask of address pools available for client address assignment and lets you add, edit, or delete entries from that list.

Fields

- Add—Opens the Add IP Pool dialog box, on which you can configure a new IP address pool.
- Edit—Opens the Edit IP Pool dialog box, on which you can modify a selected IP address pool.
- Delete—Removes the selected address pool. There is no confirmation or undo.
- Assign—Displays the address pool names that remained assigned to the interface. Double-click each unassigned pool you want to add to the interface. The Assign field updates the list of pool assignments.

Add or Edit an IP Address Pool

Configures or modifies an IP address pool.

Fields

- Name—Specifies the name assigned to the IP address pool.
- Starting IP Address—Specifies the first IP address in the pool.
- Ending IP Address—Specifies the last IP address in the pool.
- Subnet Mask—Selects the subnet mask to apply to the addresses in the pool.

Authenticating SSL VPN Connections

The SSL VPN Connections > Advanced > Authentication dialog box lets you configure authentication attributes for SSL VPN connections.

System Options

This field can be reached by navigating these paths:

- Configuration > Site-to-Site VPN > Advanced > System Options
- Configuration > Remote Access VPN > Network (Client) Access > Advanced > IPsec > System Options

The System Options pane lets you configure features specific to VPN sessions on the ASA.

Fields

- Limit the maximum number of active IPsec VPN sessions—Enables or disables limiting the maximum number of active IPsec VPN sessions. The range depends on the hardware platform and the software license.
  - Maximum IPsec Sessions—Specifies the maximum number of active IPsec VPN sessions allowed. This field is active only when you select the preceding check box to limit the maximum number of active IPsec VPN sessions.
- L2TP Tunnel Keep-alive Timeout—Specifies the frequency, in seconds, of keepalive messages. The range is 10 through 300 seconds. The default is 60 seconds. This is an advanced system option for Network (Client) Access only.
- Reclassify existing flows when VPN tunnels establish
- Preserve stateful VPN flows when the tunnel drops—Enables or disables preserving IPsec tunneled flows in Network-Extension Mode (NEM). With the persistent IPsec tunneled flows feature enabled, as long as the tunnel is recreated within the timeout dialog box, data continues flowing successfully because the security appliance still has access to the state information. This option is disabled by default.

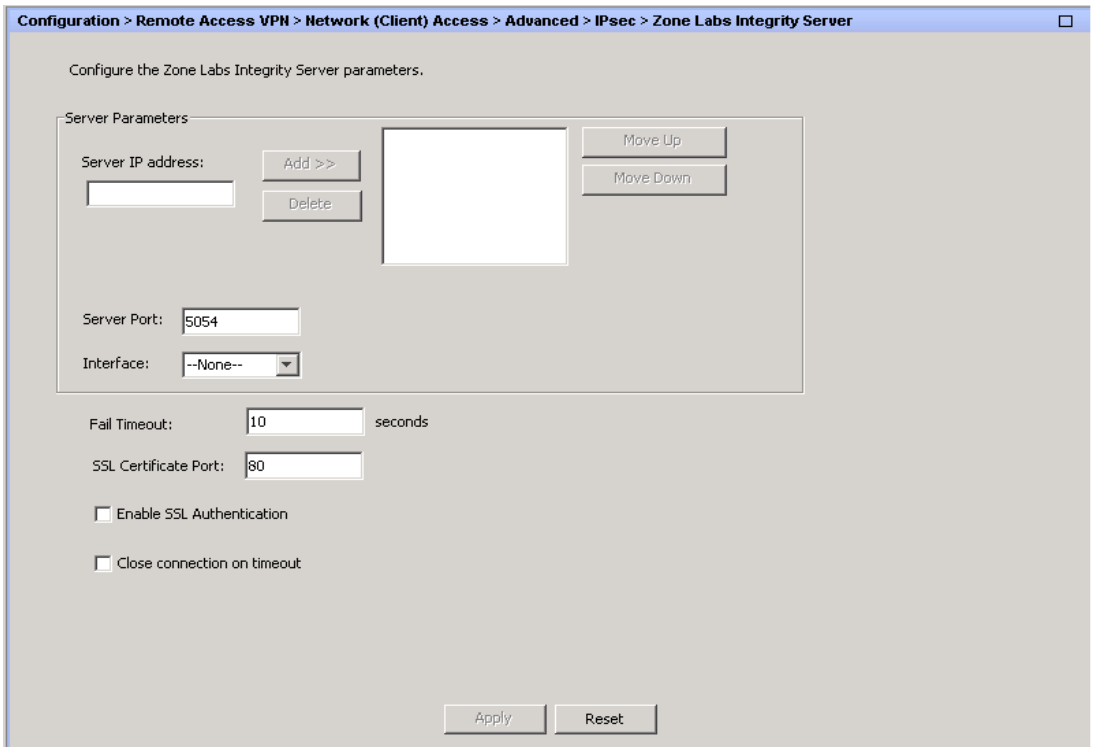
Note Tunneled TCP flows are not dropped, so they rely on the TCP timeout for cleanup. However, if the timeout is disabled for a particular tunneled flow, that flow remains in the system until being cleared manually or by other means (for example, by a TCP RST from the peer).

- IPsec Security Association Lifetime—Configures the duration of a Security Association (SA). This parameter specifies how to measure the lifetime of the IPsec SA keys, which is how long the IPsec SA lasts until it expires and must be renegotiated with new keys.
  - **Time**—Specifies the SA lifetime in terms of hours (hh), minutes (mm) and seconds (ss).
  - **Traffic Volume**—Defines the SA lifetime in terms of kilobytes of traffic. Enter the number of kilobytes of payload data after which the IPsec SA expires. Minimum is 100 KB, default is 10000 KB, maximum is 2147483647 KB.
- Enable PMTU (Path Maximum Transmission Unit) Aging—Allows an administrator to enable PMTU aging.
  - Interval to Reset PMTU of an SA (Security Association)—Enter the number of seconds at which the PMTU value is reset to its original value.

Zone Labs Integrity Server

Configuration > Remote Access VPN > Network (Client) Access > Advanced > IPsec > Zone Labs Integrity Server

The Zone Labs Integrity Server panel lets you configure the ASA to support a Zone Labs Integrity Server. This server is part of the Integrity System, a system designed to enforce security policies on remote clients entering the private network. In essence, the ASA acts as a proxy for the client PC to the Firewall Server and relays all necessary Integrity information between the Integrity client and the Integrity server.



Note The current release of the security appliance supports one Integrity Server at a time even though the user interfaces support the configuration of up to five Integrity Servers. If the active Server fails, configure another Integrity Server on the ASA and then reestablish the client VPN session.

Fields

- Server IP address—Type the IP address of the Integrity Server. Use dotted decimal notation.
- Add—Adds a new server IP address to the list of Integrity Servers. This button is active when an address is entered in the Server IP address field.
- Delete—Deletes the selected server from the list of Integrity Servers.
- Move Up—Moves the selected server up in the list of Integrity Servers. This button is available only when there is more than one server in the list.
- Move Down—Moves the selected server down in the list of Integrity Servers. This button is available only when there is more than one server in the list.
- Server Port—Type the ASA port number on which it listens to the active Integrity server. This field is available only if there is at least one server in the list of Integrity Servers. The default port number is 5054, and it can range from 10 to 10000. This field is only available when there is a server in the Integrity Server list.
- Interface—Choose the interface ASA interface on which it communicates with the active Integrity Server. This interface name menu is only available when there is a server in the Integrity Server list.
- Fail Timeout—Type the number of seconds that the ASA should wait before it declares the active Integrity Server to be unreachable. The default is 10 and the range is from 5 to 20.

- SSL Certificate Port: Specify the ASA port to be used for SSL Authorization. The default is port 80.
- Enable SSL Authentication—Check to enable authentication of the remote client SSL certificate by the ASA. By default, client SSL authentication is disabled.
- Close connection on timeout—Check to close the connection between the ASA and the Integrity Server on a timeout. By default, the connection remains open.
- Apply—Click to apply the Integrity Server setting to the ASA running configuration.
- Reset—Click to remove Integrity Server configuration changes that have not yet been applied.

Easy VPN Remote

Configuration > VPN > Easy VPN Remote

Easy VPN Remote lets the ASA 5505 act as an Easy VPN client device. The ASA 5505 can then initiate a VPN tunnel to an Easy VPN server, which can be an ASA, a Cisco VPN 3000 Concentrator, a Cisco IOS-based router, or a firewall acting as an Easy VPN server.

The Easy VPN client supports one of two modes of operation: Client Mode or Network Extension Mode (NEM). The mode of operation determines whether the Easy VPN Client inside hosts are accessible from the Enterprise network over the tunnel. Specifying a mode of operation is mandatory before making a connection because Easy VPN Client does not have a default mode.

Client mode, also called Port Address Translation (PAT) mode, isolates all devices on the Easy VPN Client private network from those on the enterprise network. The Easy VPN Client performs Port Address Translation (PAT) for all VPN traffic for its inside hosts. IP address management is neither required for the Easy VPN Client inside interface or the inside hosts.

NEM makes the inside interface and all inside hosts routable across the enterprise network over the tunnel. Hosts on the inside network obtain their IP addresses from an accessible subnet (statically or via DHCP) pre-configured with static IP addresses. PAT does not apply to VPN traffic in NEM. This mode does not require a VPN configuration for each client. The Cisco ASA 5505 configured for NEM mode supports automatic tunnel initiation. The configuration must store the group name, user name, and password. Automatic tunnel initiation is disabled if secure unit authentication is enabled.

The network and addresses on the private side of the Easy VPN Client are hidden, and cannot be accessed directly.

Fields

- Enable Easy VPN Remote—Enables the Easy VPN Remote feature and makes available the rest of the fields on this dialog box for configuration.
- Mode—Selects either Client mode or Network extension mode.
  - Client mode—Uses Port Address Translation (PAT) mode to isolate the addresses of the inside hosts, relative to the client, from the enterprise network.
  - Network extension mode—Makes those addresses accessible from the enterprise network.

Note If the Easy VPN Remote is using NEM and has connections to secondary servers, establish an ASDM connection to each headend and check Enable Reverse Route Injection on the Configuration > VPN > IPsec > IPsec Rules > Tunnel Policy (Crypto Map) - Advanced dialog box to configure dynamic announcements of the remote network using RRI.

  - Auto connect—The Easy VPN Remote establishes automatic IPsec data tunnels unless both of the following are true: Network extension mode is configured locally, and split-tunneling is configured on the group policy pushed to the Easy VPN Remote. If both are true, checking this attribute automates the establishment of IPsec data tunnels. Otherwise, this attribute has no effect.

- Group Settings—Specifies whether to use a pre-shared key or an X.509 certificate for user authentication.
  - Pre-shared key—Enables the use of a pre-shared key for authentication and makes available the subsequent Group Name, Group Password, and Confirm Password fields for specifying the group policy name and password containing that key.
  - Group Name—Specifies the name of the group policy to use for authentication.
  - Group Password—Specifies the password to use with the specified group policy.
  - Confirm Password—Requires you to confirm the group password just entered.
  - X.509 Certificate—Specifies the use of an X.509 digital certificate, supplied by a Certificate Authority, for authentication.
  - Select Trustpoint—Lets you select a trustpoint, which can be an IP address or a hostname, from the drop-down list. To define a trustpoint, click the link to Trustpoint(s) configuration at the bottom of this area.
  - Send certificate chain—Enables sending a certificate chain, not just the certificate itself. This action includes the root certificate and any subordinate CA certificates in the transmission.
- User Settings—Configures user login information.
  - User Name—Configures the VPN username for the Easy VPN Remote connection. Xauth provides the capability of authenticating a user within IKE using TACACS+ or RADIUS. Xauth authenticates a user (in this case, the Easy VPN hardware client) using RADIUS or any of the other supported user authentication protocols. The Xauth username and password parameters are used when secure unit authentication is disabled and the server requests Xauth credentials. If secure unit authentication is enabled, these parameters are ignored, and the ASA prompts the user for a username and password.
  - User Password—Configures the VPN user password for the Easy VPN Remote connection.
  - Confirm Password—Requires you to confirm the user password just entered.
- Easy VPN Server To Be Added—Adds or removes an Easy VPN server. Any ASA or VPN 3000 Concentrator Series can act as a Easy VPN server. A server must be configured before a connection can be established. The ASA supports IPv4 addresses, the names database, or DNS names and resolves addresses in that order. The first server in the Easy VPN Server(s) list is the primary server. You can specify a maximum of ten backup servers in addition to the primary server.
  - Name or IP Address—The name or IP address of an Easy VPN server to add to the list.
  - Add—Moves the specified server to the Easy VPN Server(s) list.
  - Remove—Moves the selected server from the Easy VPN Server(s) list to the Name or IP Address file. Once you do this, however, you cannot re-add the same address unless you re-enter the address in the Name or IP Address field.
  - Easy VPN Server(s)—Lists the configured Easy VPN servers in priority order.
  - Move Up/Move Down—Changes the position of a server in the Easy VPN Server(s) list. These buttons are available only when there is more than one server in the list.

Advanced Easy VPN Properties

Configuration > VPN > Easy VPN Remote > Advanced

Device Pass-Through

Certain devices like Cisco IP phones, printers, and the like are incapable of performing authentication, and therefore of participating in individual unit authentication. To accommodate these devices, the device pass-through feature, enabled by the MAC Exemption attributes, exempts devices with the specified MAC addresses from authentication when Individual User Authentication is enabled.

The first 24 bits of the MAC address indicate the manufacturer of the piece of equipment. The last 24 bits are the unit's serial number in hexadecimal format.

Tunneled Management

When operating an ASA model 5505 device behind a NAT device, use the Tunneled Management attributes to specify how to configure device management— in the clear or through the tunnel—and specify the network or networks allowed to manage the Easy VPN Remote connection through the tunnel. The public address of the ASA 5505 is not accessible when behind the NAT device unless you add static NAT mappings on the NAT device.

When operating a Cisco ASA 5505 behind a NAT device, use the **vpnclient management** command to specify how to configure device management— with additional encryption or without it—and specify the hosts or networks to be granted administrative access. The public address of the ASA 5505 is not accessible when behind the NAT device unless you add static NAT mappings on the NAT device.

Fields

- MAC Exemption—Configures a set of MAC addresses and masks used for device pass-through for the Easy VPN Remote connection
  - MAC Address—Exempts the device with the specified MAC address from authentication. The format for specifying the MAC address this field uses three hex digits, separated by periods; for example, 45ab.ff36.9999.
  - MAC Mask—The format for specifying the MAC mask in this field uses three hex digits, separated by periods; for example, the MAC mask ffff.ffff.ffff matches just the specified MAC address. A MAC mask of all zeroes matches no MAC address, and a MAC mask of ffff.ff00.0000 matches all devices made by the same manufacturer.
  - Add—Adds the specified MAC address and mask pair to the MAC Address/Mask list.
  - Remove—Moves the selected MAC address and mask pair from the MAC Address/MAC list to the individual MAC Address and MAC Mask fields.
- Tunneled Management—Configures IPsec encryption for device management and specifies the network or networks allowed to manage the Easy VPN hardware client connection through the tunnel. Selecting Clear Tunneled Management merely removes that IPsec encryption level and does not affect any other encryption, such as SSH or https, that exists on the connection.
  - Enable Tunneled Management—Adds a layer of IPsec encryption to the SSH or HTTPS encryption already present in the management tunnel.
  - Clear Tunneled Management—Uses the encryption already present in the management tunnel, without additional encryption.
  - IP Address— Specifies the IP address of the host or network to which you want to grant administrative access to the Easy VPN hardware client through the VPN tunnel. You can individually add one or more IP addresses and their respective network masks.

  - Mask—Specifies the network mask for the corresponding IP address.
  - Add—Moves the specified IP address and mask to the IP Address/Mask list.
  - Remove—Moves the selected IP address and mask pair from the IP Address/Mask list to the individual IP Address and Mask fields in this area.
  - IP Address/Mask—Lists the configured IP address and mask pairs to be operated on by the Enable or Clear functions in this area.
- IPsec Over TCP—Configure the Easy VPN Remote connection to use TCP-encapsulated IPsec.
  - Enable—Enables IPsec over TCP.

Note Choose Configuration > VPN > IPsec > Pre-Fragmentation, double-click the outside interface, and set the DF Bit Setting Policy to Clear if you configure the Easy VPN Remote connection to use TCP-encapsulated IPsec. The Clear setting lets the ASA send large packets.

  - Enter Port Number—Specifies the port number to use for the IPsec over TCP connection.
- Server Certificate—Configures the Easy VPN Remote connection to accept only connections to Easy VPN servers with the specific certificates specified by the certificate map. Use this parameter to enable Easy VPN server certificate filtering. To define a certificate map, go to Configuration > VPN > IKE > Certificate Group Matching > Rules.

AnyConnect Custom Attributes

Custom attributes are added here to support special features that are not defined in the ASDM. Deferred upgrade is the feature in AnyConnect 3.1 that uses custom attributes. See Configuring AnyConnect Client Custom Attributes for an Internal Group Policy, page 87-17

AnyConnect Essentials

AnyConnect Essentials is a separately licensed SSL VPN client, entirely configured on the ASA, that provides the full AnyConnect capability, with the following exceptions:

- No CSD (including HostScan/Vault/Cache Cleaner)
- No clientless SSL VPN
- Optional Windows Mobile Support (requires AnyConnect for Windows Mobile license)

The AnyConnect Essentials client provides remote end users running Microsoft Windows Vista, Windows Mobile, Windows XP or Windows 2000, Linux, or Macintosh OS X, with the benefits of a Cisco SSL VPN client.

To enable AnyConnect Essentials, check the **Enable AnyConnect Essentials** check box on the AnyConnect Essentials pane, which appears only if the AnyConnect Essentials license is installed on the ASA.

When AnyConnect Essentials is enabled, AnyConnect clients use Essentials mode, and clientless SSL VPN access is disabled. When AnyConnect Essentials is disabled, AnyConnect clients use the full AnyConnect SSL VPN Client.

Note The status information about the AnyConnect Essentials license on the Configuration > Device Management > Licensing > Activation Key pane simply reflects whether the AnyConnect Essentials license is installed. This status is not affected by the setting of the Enable AnyConnect Essentials License check box.

AnyConnect Essentials mode cannot be enabled when active clientless sessions exist to the device. To view SSL VPN session details click the **Monitoring > VPN > VPN Sessions** link in the SSL VPN Sessions section. This opens the Monitoring > VPN > VPN > VPN Statistics > Sessions pane. To see session details, choose **Filter By: Clientless SSL VPN** and click **Filter**. This displays session details.

To see how many clientless SSL VPN sessions are currently active, without showing session details, click **Check Number of Clientless SSL Sessions**. If the SSL VPN session count is zero, you can enable AnyConnect Essentials.

Note Secure Desktop does not work when AnyConnect Essentials is enabled. You can, however, disable AnyConnect Essentials when you enable Secure Desktop.

DTLS Settings

Enabling Datagram Transport Layer Security (DTLS) allows the AnyConnect VPN client establishing an SSL VPN connection to use two simultaneous tunnels—an SSL tunnel and a DTLS tunnel. Using DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

If you do not enable DTLS, AnyConnect client users establishing SSL VPN connections connect with an SSL VPN tunnel only.

Fields

- Interface—Displays a list of interfaces on the ASA.
- DTLS Enabled—Click to enable DTLS connections with the AnyConnect client on the interfaces.
- UDP Port (default 443)—(Optional) Specify a separate UDP port for DTLS connections.

SSL VPN Client Settings

The Cisco AnyConnect VPN client provides secure SSL connections to the ASA for remote users. The client gives remote users the benefits of an SSL VPN client without the need for network administrators to install and configure clients on remote computers.

Without a previously-installed client, remote users enter the IP address in their browser of an interface configured to accept SSL VPN connections. Unless the ASA is configured to redirect http:// requests to https://, users must enter the URL in the form https://<*address*>.

If you need to redirect http:// requests to https://, go to **Configuration > Remote Access VPN > Advanced**, then click **HTTP Redirect**. Choose the interface you want to redirect, then click **Edit** to display the Edit HTTP/HTTPS Settings dialog box. Check the **Redirect HTTP to HTTPS** check box, and change the HTTP Port value, if necessary. Click **OK** to close this dialog box, then click **Apply** to save your settings.

After entering the URL, the browser connects to that interface and displays the login screen. If the user satisfies the login and authentication, and the ASA identifies the user as requiring the client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure SSL connection and either remains or uninstalls itself (depending on the ASA configuration) when the connection terminates.

In the case of a previously installed client, when the user authenticates, the ASA examines the revision of the client, and upgrades the client as necessary.

When the client negotiates an SSL VPN connection with the ASA, it connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

The AnyConnect client can be downloaded from the ASA, or it can be installed manually on the remote PC by the system administrator. For more information about installing the client manually, see the *Cisco AnyConnect VPN Client Administrator Guide*.

The ASA downloads the client based on the group policy or local user policy attributes. You can configure the ASA to automatically download the client, or you can configure it to prompt the remote user about whether to download the client. In the latter case, if the user does not respond, you can configure the ASA to either download the client after a timeout period or present the login page.

Fields

- SSL VPN Client Images table—Displays the package files specified as SSL VPN client images, and allows you to establish the order that the ASA downloads the images to the remote PC.
  - Add—Displays the Add SSL VPN Client Image dialog box, where you can specify a file in flash memory as a client image file, or where you can browse flash memory for a file to specify as a client image. You can also upload a file from a local computer to the flash memory.
  - Replace—Displays the Replace SSL VPN Client Image dialog box, where you can specify a file in flash memory as an client image to replace an image highlighted in the SSL VPN Client Images table. You can also upload a file from a local computer to the flash memory.
  - Delete—Deletes an image from the table. This does not delete the package file from flash.
  - Move Up and Move Down—changes the order in which the ASA downloads the client images to the remote PC. It downloads the image at the top of the table first. Therefore, you should move the image used by the most commonly-encountered operating system to the top.
- SSL VPN Client Profiles table—Displays the XML files specified as SSL VPN client profiles. These profiles display host information in the AnyConnect VPN Client user interface.
  - Add—Displays the Add SSL VPN Client Profiles dialog box, where you can specify a file in flash memory as a profile, or where you can browse flash memory for a file to specify as a profile. You can also upload a file from a local computer to the flash memory.
  - Edit—Displays the Edit SSL VPN Client Profiles dialog box, where you can specify a file in flash memory as a profile to replace a profile highlighted in the SSL VPN Client Profiles table. You can also upload a file from a local computer to the flash memory.
  - Delete—Deletes a profile from the table. This does not delete the XML file from flash.
- Cache File System—The security appliance expands SSL VPN client and CSD images in cache memory. Adjust the size of cache memory to ensure the images have enough space to expand.

Add/Replace SSL VPN Client Image

In this pane, you can specify a filename for a file on the ASA flash memory that you want to add as an SSL VPN client image, or to replace an image already listed in the table. You can also browse the flash memory for a file to identify, or you can upload a file from a local computer.

Fields

- Flash SVC Image—Specify the file in flash memory that you want to identify as an SSL VPN client image.
- Browse Flash—Displays the Browse Flash dialog box where you can view all the files on flash memory.
- Upload—Displays the Upload Image dialog box where you can upload a file from a local PC that you want to identify as an client image.
- Regular expression to match user-agent—Specifies a string that the ASA uses to match against the User-Agent string passed by the browser. For mobile users, you can decrease the connection time of the mobile device by using the feature. When the browser connects to the ASA, it includes the User-Agent string in the HTTP header. When the ASA receives the string, if the string matches an expression configured for an image, it immediately downloads that image without testing the other client images.

Upload Image

In this pane, you can specify the path of a file on the local computer or in flash memory of the security appliance that you want to identify as an SSL VPN client image. You can also browse the local computer or the flash memory of the security appliance for a file to identify.

Fields

- Local File Path—Identifies the filename of the file in on the local computer that you want to identify as an SSL VPN client image.
- Browse Local Files—Displays the Select File Path dialog box where you can view all the files on local computer and where you can select a file to identify as a client image.
- Flash File System Path—Identifies the filename of the file in the flash memory of the security appliance that you want to identify as an SSL VPN client image.
- Browse Flash—Displays the Browse Flash Dialog dialog box where you can view all the files on flash memory of the security appliance and where you can choose a file to identify as a client image.
- Upload File—Initiates the file upload.

Add/Edit SSL VPN Client Profiles

In this pane you can specify the path of a file on the local computer or in flash memory of the ASA that you want to identify as an SSL VPN client profile. These profiles display host information in the AnyConnect VPN client user interface. You can also browse the local computer or the flash memory of the security appliance for a file to identify.

Fields

- Profile Name—Associates a name with the XML file that appears in the table. Provide any name that makes it easy for you to remember the hosts identified in the XML profile file.
- Profile Package—Identifies the filename of the file in flash memory on the local computer that you want to identify as an SSL VPN client profile.
- Browse Flash—Displays the Browse Flash Dialog dialog box where you can view all the files on flash memory of the security appliance and where you can choose a file to identify as a profile.
- Upload File—Initiates the file upload.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	—	•	—	—

Upload Package

In this pane, you can specify the path of a file on the local computer or in flash memory of the security appliance that you want to identify as an SSL VPN client profile. You can also browse the local computer or the flash memory of the security appliance for a file to identify.

Fields

- Local File Path—Identifies the filename of the file in on the local computer that you want to identify as an SSL VPN client profile.
- Browse Local Files—Displays the Select File Path dialog box where you can view all the files on local computer and where you can select a file to identify as a client profile.
- Flash File System Path—Identifies the filename of the file in the flash memory of the security appliance that you want to identify as an client profile.
- Browse Flash—Displays the Browse Flash dialog box where you can view all the files on flash memory of the security appliance and where you can choose a file to identify as a client profile.
- Upload File—Initiates the file upload.

Bypass Interface Access List

You can require an access rule to apply to the local IP addresses by unchecking this check box. The access rule applies to the local IP address, and not to the original client IP address used before the VPN packet was decrypted.

- Enable inbound IPsec sessions to bypass interface access-lists. Group policy and per-user authorization access lists still apply to the traffic—By default, the ASA allows VPN traffic to terminate on an ASA interface; you do not need to allow IKE or ESP (or other types of VPN packets) in an access rule. When this check box is checked, you also do not need an access rule for local IP addresses of decrypted VPN packets. Because the VPN tunnel was terminated successfully using

VPN security mechanisms, this feature simplifies configuration and maximizes the ASA performance without any security risks. (Group policy and per-user authorization access lists still apply to the traffic.)

Configuring AnyConnect Host Scan

Configuration > Remote Access VPN > Host Scan Image

The AnyConnect Posture Module provides the AnyConnect Secure Mobility Client the ability to identify the operating system, anti-virus, anti-spyware, and firewall software installed on the host. The Host Scan application gathers this information.

Using the secure desktop manager tool in the Adaptive Security Device Manager (ASDM), you can create a prelogin policy which evaluates the operating system, anti-virus, anti-spyware, and firewall software Host Scan identifies. Based on the result of the prelogin policy's evaluation, you can control which hosts are allowed to create a remote access connection to the security appliance.

The Host Scan support chart contains the product name and version information for the anti-virus, anti-spyware, and firewall applications you use in your prelogin policies. We deliver Host Scan and the Host Scan support chart, as well as other components, in the Host Scan package.

Starting with AnyConnect Secure Mobility Client, release 3.0, Host Scan is available separately from CSD. This means you can deploy Host Scan functionality without having to install CSD and you will be able to update your Host Scan support charts by upgrading the latest Host Scan package.

Posture assessment and the AnyConnect telemetry module require Host Scan to be installed on the host.

This chapter contains the following sections:

- Host Scan Dependencies and System Requirements, page 87-113
- Host Scan Packaging, page 87-114
- Installing and Enabling Host Scan on the ASA, page 87-115
- Other Important Documentation Addressing Host Scan, page 87-119

Host Scan Dependencies and System Requirements

Dependencies

The AnyConnect Secure Mobility Client with the posture module requires these minimum ASA components:

- ASA 8.4
- ASDM 6.4

These AnyConnect features require that you install the posture module.

- SCEP authentication
- AnyConnect Telemetry Module

System Requirements

The posture module can be installed on any of these platforms:

- Windows XP (x86 and x86 running on x64)
- Windows Vista (x86 and x86 running on x64)
- Windows 7 (x86 and x86 running on x64)
- Mac OS X 10.5,10.6 (32-bit and 32-bit running on 64-bit)
- Linux (32-bit and 32-bit running on 64-bit)
- Windows Mobile

Licensing

These are the AnyConnect licensing requirements for the posture module:

- AnyConnect Premium for basic Host Scan.
- Advanced Endpoint Assessment license is required for
  - Remediation
  - Mobile Device Management

Entering an Activation Key to Support Advanced Endpoint Assessment

Advanced Endpoint Assessment includes all of the Endpoint Assessment features and lets you configure an attempt to update noncompliant computers to meet version requirements. You can use ASDM to activate a key to support Advanced Endpoint Assessment after acquiring it from Cisco, as follows:

Step 1 Choose **Configuration > Device Management > Licensing > Activation Key**.

Step 2 Enter the key in the **New Activation Key** field.

Step 3 Click **Update Activation Key**.

Step 4 Choose **File > Save Running Configuration to Flash**.

An Advanced Endpoint Assessment entry appears and the Configure button becomes active in the Host Scan Extensions area of the **Configuration > Remote Access VPN > Secure Desktop Manager > Host Scan** pane, which is accessible only if CSD is enabled.

Host Scan Packaging

You can load the Host Scan package on to the ASA in one of these ways:

- You can upload it as a standalone package: **hostscan-*version*.pkg**
- You can upload it by uploading an AnyConnect Secure Mobility package: **anyconnect-NGC-win-*version*-k9.pkg**
- You can upload it by uploading a Cisco Secure Desktop package: **csd_version-k9.pkg**

File	Description
hostscan-*version*.pkg	This file contains the Host Scan software as well as the Host Scan library and support charts.
anyconnect-NGC-win-*version*-k9.pkg	This package contains all the Cisco AnyConnect Secure Mobility Client features including the hostscan-*version*.pkg file.
csd_*version*-k9.pkg	This file contains all Cisco Secure Desktop features including Host Scan software as well as the Host Scan library and support charts. This method requires a separate license for Cisco Secure Desktop.

Installing and Enabling Host Scan on the ASA

These tasks describe installing and enabling Host Scan on the ASA:

- Installing or Upgrading Host Scan
- Enabling or Disabling Host Scan
- Enabling or Disabling CSD on the ASA
- Viewing the Host Scan Version Enabled on the ASA
- Uninstalling Host Scan
- Uninstalling CSD from the ASA
- Assigning AnyConnect Posture Module to a Group Policy

Installing or Upgrading Host Scan

Use this procedure to upload, or upgrade, and enable a new Host Scan image on the ASA. This image can enable the host scan functionality for AnyConnect, or you can use it to upgrade the host scan support chart for an existing deployment of Cisco Secure Desktop (CSD).

You can specify a standalone Host Scan package or an AnyConnect Secure Mobility Client version 3.0 or later package in the field.

If you previously uploaded a CSD image to the ASA, the Host Scan image you specify will upgrade or downgrade the existing Host Scan files that were delivered with that CSD package.

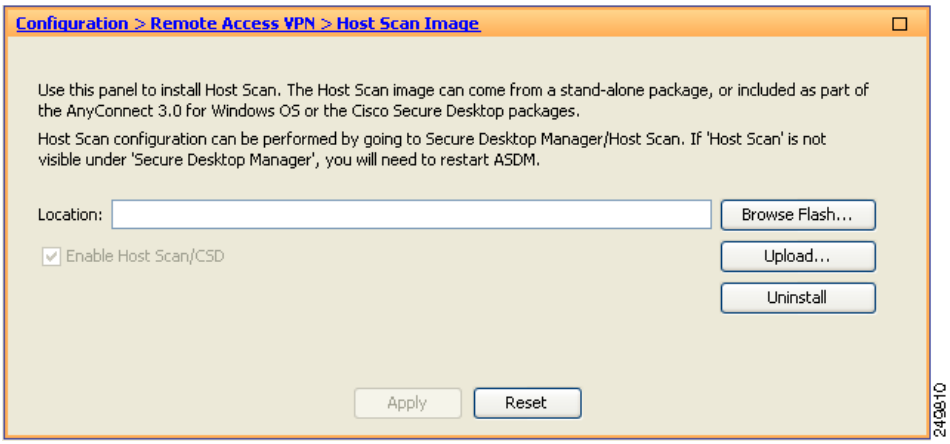
You do not need to restart the security appliance after you install or upgrade Host Scan; however, you must exit and restart Adaptive Security Device Manager (ASDM) to access Secure Desktop Manager.

Note Host scan requires an AnyConnect Secure Mobility Client premium license.

Step 1 Use your Internet browser to download the **hostscan_*version*-k9.pkg** file or **anyconnect-NGC-win-*version*-k9.pkg** file to your computer. You cannot use a csd_*version*-k9.pkg with this procedure.

Step 2 Open ASDM and choose **Configuration > Remote Access VPN > Host Scan Image.** ASDM opens the Host Scan Image panel (Figure 87-7).

Figure 87-7 Host Scan Image Panel



Step 3 Click **Upload** to prepare to transfer a copy of the Host Scan package from your computer to a drive on the ASA.

Step 4 In the Upload Image dialog box, click **Browse Local Files** to search for the Host Scan package on your local computer.

Step 5 Select the **hostscan_*version*.pkg** file or **anyconnect-NGC-win-*version*-k9.pkg** file you downloaded in Step 1 and click **Select**. The path to the file you selected is in the Local File Path field and the Flash File System Path field reflects the destination path of the Host Scan package. If your ASA has more than one flash drive, you can edit the Flash File System Path to indicate another flash drive.

Step 6 Click **Upload File**. ASDM transfers a copy of the file to the flash card. An Information dialog box displays the following message:

```
File has been uploaded to flash successfully.
```

Step 7 Click **OK**.

Step 8 In the Use Uploaded Image dialog, click **OK** to use the Host Scan package file you just uploaded as the current image.

Step 9 Check **Enable Host Scan/CSD** if it is not already checked.

Step 10 Click **Apply**.

Note If AnyConnect Essentials is enabled on the ASA, you receive a message that CSD will not work with it. You have the choice to **Disable** or **Keep** AnyConnect Essentials.

Step 11 From the File menu, select **Save Running Configuration To Flash**.

Enabling or Disabling Host Scan

When you first install or upgrade a Host Scan image using ASDM, you enable the image as part of that procedure. See "Installing and Enabling Host Scan on the ASA" section on page 87-115.

Otherwise, to enable or disable a Host Scan image using ASDM, follow this procedure:

Step 1 Open ASDM and choose **Configuration > Remote Access VPN > Host Scan Image.** ASDM opens the Host Scan Image panel (Figure 87-7).

Step 2 Check **Enable Host Scan/CSD** to enable Host Scan or uncheck **Enable Host Scan/CSD to disable Host Scan.**

Step 3 Click **Apply**.

Enabling or Disabling CSD on the ASA

Enabling CSD loads the CSD configuration file, data.xml, from the flash device to the running configuration.

Disabling CSD does not alter the CSD configuration.

Use ASDM to enable or disable CSD as follows:

Step 1 Choose **Configuration > Clientless SSL VPN > Secure Desktop > Setup**.

ASDM opens the Setup pane (Figure 87-7).

Note The Secure Desktop Image field displays the image (and version) that is currently installed. The Enable Secure Desktop check box indicates whether CSD is enabled.

Step 2 Check or uncheck **Enable Secure Desktop** and click **Apply**.

ASDM enables or disables CSD.

Step 3 Click the **X** in the upper right corner of the ASDM window to exit.

A window displays the following message:

```
The configuration has been modified. Do you want to save the running configuration to
flash memory?
```

Step 4 Click **Save**. ASDM saves the configuration and closes.

Viewing the Host Scan Version Enabled on the ASA

Open ASDM and select **Configuration > Remote Access VPN > Host Scan Image**.

If there is a Host Scan image designated in the Host Scan Image location field, and the Enable HostScan/CSD box is checked, the version of that image is the Host Scan version being used by the ASA.

If the Host Scan Image filed is empty, and the Enable HostScan/CSD box is checked, select **Configuration > Remote Access VPN > Secure Desktop Manager**. The version of CSD in the Secure Desktop Image Location field is the Host Scan version being used by the ASA.

Uninstalling Host Scan

Uninstalling Host Scan package removes it from view on the ASDM interface and prevents the ASA from deploying it even if Host Scan or CSD is enabled. Uninstalling Host Scan does not delete the Host Scan package from the flash drive.

Uninstall Host Scan on the security appliance as follows:

Step 1 Open ASDM and select **Configuration > Remote Access VPN > Host Scan Image**.

Step 2 In the Host Scan Image pane, click **Uninstall**. ASDM removes the text from the Location text box.

Step 3 From the File menu select **Save Running Configuration to Flash**.

Uninstalling CSD from the ASA

Uninstalling CSD removes the CSD configuration file, data.xml, from the desktop directory on the flash card. If you want to retain the file, copy it using an alternative name or download it to your workstation before you uninstall CSD.

Uninstall CSD on the security appliance as follows:

Step 1 Open ASDM and choose **Configuration > Remote Access VPN > Secure Desktop Manager > Setup**.

ASDM opens the Setup pane (Figure 87-7).

Step 2 Click **Uninstall**.

A confirmation window displays the following message:

```
Do you want to delete disk0:/csd_<n>.<n>.*.pkg and all CSD data files?
```

Step 3 Click **Yes**.

ASDM removes the text from the Location text box and removes the Secure Desktop Manager menu options below Setup.

Step 4 Click the **X** in the upper right corner of the ASDM window to exit.

A window displays the following message:

```
The configuration has been modified. Do you want to save the running configuration to
flash memory?
```

Step 5 Click **Save**. ASDM saves the configuration and closes.

Assigning AnyConnect Posture Module to a Group Policy

Step 1 Open ASDM and choose **Configuration > Remote Access VPN > Network (Client) Access > Group Policies.**

Step 2 In the Group Policies panel, click **Add** to create a new group policy or select the group policy to which you want to assign the Host Scan package and click **Edit**.

Step 3 In the Edit Internal Group Policy panel, expand the **Advanced** navigation tree on the left side of the panel and select **AnyConnect Client**.

Step 4 Uncheck the Optional Client Modules to Download **Inherit** checkbox.

Step 5 In the Optional Client Modules to Download drop down menu, check the AnyConnect Posture Module and click **OK**.

Step 6 Click **OK**.

Other Important Documentation Addressing Host Scan

Once Host Scan gathers the posture credentials from the endpoint computer, you will need to understand subjects like, configuring prelogin policies, configuring dynamic access policies, and using Lua expressions to make use of the information.

These topics are covered in detail in these documents:

- Cisco Secure Desktop Configuration Guides
- Cisco Adaptive Security Device Manager Configuration Guides

See also the Cisco *AnyConnect Secure Mobility Client Administrator Guide, Release 3.0* for more information about how Host Scan works with AnyConnect clients.

Configuring Maximum VPN Sessions

To specify the maximum allowed number of VPN sessions or AnyConnect client VPN sessions, perform the following steps:

Step 1 Choose **Configuration > Remote Access VPN > Advanced > Maximum VPN Sessions**.

Step 2 In the Maximum AnyConnect Sessions field, enter the maximum number of sessions allowed.

Valid values range from 1 to the maximum number of sessions that are allowed by your license.

Step 3 In the Maximum Other VPN Sessions field, enter the maximum number of VPN sessions allowed, which includes Cisco VPN client (IPsec IKEv1) LAN-to-LAN VPN, and clientless SSL VPN sessions.

Valid values range from 1 to the maximum number of sessions that are allowed by your license.

Step 4 Click **Apply**.

Configuring the Pool of Cryptographic Cores

You can change the allocation of cryptographic cores on Symmetric Multi-Processing (SMP) platforms to give you better throughput performance for AnyConnect TLS/DTLS traffic. These changes can accelerate the SSL VPN datapath and provide customer-visible performance gains in AnyConnect, smart tunnels, and port forwarding. To configure the pool of cryptographic cores, perform the following steps.

Limitations

- Cryptographic core rebalancing is available on the following platforms:
  - 5585-X
  - 5580
  - 5545-X

  - 5555-X
  - ASASM
- The large modulus operation is only available for 5510, 5520, 5540, and 5550 platforms.

Detailed Steps

Step 1 Choose **Configuration > Remote Access VPN > Advanced > Crypto Engine**.

Step 2 Check **Enable Large Modulus Acceleration** if you want to perform large modulus operations in the hardware.

Step 3 From the Accelerator Bias drop-down menu, choose one of the following:

Note This field only shows up if the feature is available in ASA.

- **balanced**—Equally distributes cryptography hardware resources (Admin/SSL and IPsec cores).
- **ipsec**—Allocates cryptography hardware resources to favor IPsec (includes SRTP encrypted voice traffic).
- **ssl**—Allocates cryptography hardware resources to favor Admin/SSL.

Step 4 Click **Apply**.

Configuring IP Addresses for VPNs

This chapter describes IP address assignment methods.

IP addresses make internetwork connections possible. They are like telephone numbers: both the sender and receiver must have an assigned number to connect. But with VPNs, there are actually two sets of addresses: the first set connects client and server on the public network. Once that connection is made, the second set connects client and server through the VPN tunnel.

In ASA address management, we are dealing with the second set of IP addresses: those private IP addresses that connect a client with a resource on the private network, through the tunnel, and let the client function as if it were directly connected to the private network. Furthermore, we are dealing only with the private IP addresses that get assigned to clients. The IP addresses assigned to other resources on your private network are part of your network administration responsibilities, not part of VPN management. Therefore, when we discuss IP addresses here, we mean those IP addresses available in your private network addressing scheme that let the client function as a tunnel endpoint.

This chapter includes the following sections:

- Configuring an IP Address Assignment Policy, page 88-1
- Configuring Local IP Address Pools, page 88-3
- Configuring AAA Addressing, page 88-5
- Configuring DHCP Addressing, page 88-6

Configuring an IP Address Assignment Policy

The ASA can use one or more of the following methods for assigning IP addresses to remote access clients. If you configure more than one address assignment method, the ASA searches each of the options until it finds an IP address. By default, all methods are enabled.

- **Use authentication server** — Retrieves addresses from an external authentication, authorization, and accounting server on a per-user basis. If you are using an authentication server that has IP addresses configured, we recommend using this method. You can configure AAA servers in the Configuration > AAA Setup pane.This method is available for IPv4 and IPv6 assignment policies.
- **Use DHCP** — Obtains IP addresses from a DHCP server. If you want to use DHCP, you must configure a DHCP server. You must also define the range of IP addresses that the DHCP server can use. If you use DHCP, configure the server in the Configuration > Remote Access VPN > DHCP Server pane. This method is available for IPv4 assignment policies.

- **Use an internal address pool —** Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, configure the IP address pools in Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Address Pools pane. This method is available for IPv4 and IPv6 assignment policies.
  - Allow the reuse of an IP address so many minutes after it is released—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, this is unchecked, meaning the ASA does not impose a delay. If you want one, check the box and enter the number of minutes in the range 1 - 480 to delay IP address reassignment.This configurable element is available for IPv4 assignment policies.

Use one of these methods to specify a way to assign IP addresses to remote access clients.

- Configuring IPv4 and IPv6 Address Assignments using ASDM

Configuring IPv4 and IPv6 Address Assignments using ASDM

Step 1 Select **Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Assignment Policy**

Step 2 In the IPv4 Policy area, check the address assignment method to enabled it or uncheck the address assignment method to disable it. These methods are enabled by default:

- Use Authentication server. Enables the use of a Authentication Authorization and Accounting (AAA) server you have configured to provide IP addresses.
- Use DHCP. Enables the use of a Dynamic Host Configuration Protocol (DHCP) server you have configured to provide IP addresses.
- Use internal address pools: Enables the use of a local address pool configured on the ASA.

If you enable **Use internal address pools**, you can also enable the reuse of an IPv4 address after it has been released. You can specify a range of minutes from 0-480 after which the IP v4 address can be reused.

Step 3 In the IPv6 Policy area, check the address assignment method to enable it or uncheck the address assignment method to disable it. These methods are enabled by default:

- Use Authentication server. Enables the use of a Authentication Authorization and Accounting (AAA) server you have configured to provide IP addresses.
- Use internal address pools: Enables the use of a local address pool configured on the ASA.

Step 4 Click **Apply**.

Step 5 Click **OK**.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	—	•	—	—

Viewing Address Assignment Methods

Use one of these methods to view the address assignment method configured on the ASA:

Viewing IPv4 and IPv6 Address Assignments using ASDM

Select **Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Assignment Policy**

Configuring Local IP Address Pools

To configure IPv4 or IPv6 address pools for VPN remote access tunnels, open ASDM and select **Configuration > Remote Access VPN > Network (Client) Access > Address Management > Address Pools > Add/Edit IP Pool**. To delete an address pool, open ASDM and select **Configuration > Remote Access VPN > Network (Client) Access > Address Management > Address Pools**. Select the address pool you want to delete and click **Delete**.

The ASA uses address pools based on the connection profile or group policy for the connection. The order in which you specify the pools is important. If you configure more than one address pool for a connection profile or group policy, the ASA uses them in the order in which you added them to the ASA.

If you assign addresses from a non-local subnet, we suggest that you add pools that fall on subnet boundaries to make adding routes for these networks easier.

Use one of these methods to configure a local IP address pool:

- Configuring Local IPv4 Address Pools Using ASDM, page 88-3
- Configuring Local IPv6 Address Pools Using ASDM, page 88-4

Configuring Local IPv4 Address Pools Using ASDM

The IP Pool area shows each configured address pool by name with their IP address range, for example: 10.10.147.100 to 10.10.147.177. If no pools exist, the area is empty. The ASA uses these pools in the order listed: if all addresses in the first pool have been assigned, it uses the next pool, and so on.

If you assign addresses from a non-local subnet, we suggest that you add pools that fall on subnet boundaries to make adding routes for these networks easier.

Step 1 **Select Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Address Pools.**

Step 2 To add an IPv4 address, click **Add > IPv4 Address pool**. To edit an existing address pool, select the address pool in the address pool table and click **Edit**.

Step 3 In the Add/Edit IP Pool dialog box enter this information:

- Pool Name—Enter the name of the address pool. It can be up to 64 characters
- Starting Address—Enter the first IP address available in each configured pool. Use dotted decimal notation, for example: 10.10.147.100.
- Ending Address—Enter the last IP address available in each configured pool. User dotted decimal notation, for example: 10.10.147.177.
- Subnet Mask—Identifies the subnet on which this IP address pool resides.

Step 4 Click **Apply**.

Step 5 Click **OK**.

Configuring Local IPv6 Address Pools Using ASDM

The IP Pool area shows each configured address pool by name with a starting IP address range, the address prefix, and the number of addresses configurable in the pool. If no pools exist, the area is empty. The ASA uses these pools in the order listed: if all addresses in the first pool have been assigned, it uses the next pool, and so on.

If you assign addresses from a non-local subnet, we suggest that you add pools that fall on subnet boundaries to make adding routes for these networks easier.

Step 1 **Select Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Address Pools.**

Step 2 To add an IPv6 address, click **Add > IPv6 Address pool**. To edit an existing address pool, select the address pool in the address pool table and click **Edit**.

Step 3 In the Add/Edit IP Pool dialog box enter this information:

- Name—Displays the name of each configured address pool.
- Starting IP Address—Enter the first IP address available in the configured pool. For example: 2001:DB8::1.
- Prefix Length— Enter the IP address prefix length in bits. For example 32 represents /32 in CIDR notation. The prefix length defines the subnet on which the pool of IP addresses resides.
- Number of Addresses—Identifies the number of IPv6 addresses, starting at the Starting IP Address, there are in the pool.

Step 4 Click **Apply**.

Step 5 Click **OK**.

Modes

The following table shows the modes in which this feature is available:

Firewall Mode		Security Context		
			Multiple	
Routed	Transparent	Single	Context	System
•	—	•	—	—

Configuring AAA Addressing

To use a AAA server to assign addresses for VPN remote access clients, you must first configure a AAA server or server group. See the **aaa-server protocol** command in the command reference and the "Configuring AAA Server Groups" section on page 46-11.

In addition, the user must match a connection profile configured for RADIUS authentication.

The following examples illustrate how to define a AAA server group called RAD2 for the tunnel group named firstgroup. It includes one more step than is necessary, in that previously you might have named the tunnel group and defined the tunnel group type. This step appears in the following example as a reminder that you have no access to subsequent tunnel-group commands until you set these values.

An overview of the configuration that these examples create follows:

```
hostname(config)# vpn-addr-assign aaa
hostname(config)# tunnel-group firstgroup type ipsec-ra
hostname(config)# tunnel-group firstgroup general-attributes
hostname(config-general)# authentication-server-group RAD2
```

To configure AAA for IP addressing, perform the following steps:

Step 1 To configure AAA as the address assignment method, enter the **vpn-addr-assign** command with the **aaa** argument:

```
hostname(config)# vpn-addr-assign aaa
hostname(config)#
```

Step 2 To establish the tunnel group called firstgroup as a remote access or LAN-to-LAN tunnel group, enter the **tunnel-group** command with the **type** keyword. The following example configures a remote access tunnel group.

```
hostname(config)# tunnel-group firstgroup type ipsec-ra
hostname(config)#
```

Step 3 To enter general-attributes configuration mode, which lets you define a AAA server group for the tunnel group called firstgroup, enter the **tunnel-group** command with the **general-attributes** argument.

```
hostname(config)# tunnel-group firstgroup general-attributes
hostname(config-general)#
```

Step 4 To specify the AAA server group to use for authentication, enter the **authentication-server-group** command.

```
hostname(config-general)# authentication-server-group RAD2
hostname(config-general)#
```

This command has more arguments that this example includes. For more information, see the command reference.

Configuring DHCP Addressing

To use DHCP to assign addresses for VPN clients, you must first configure a DHCP server and the range of IP addresses that the DHCP server can use. Then you define the DHCP server on a connection profile basis. Optionally, you can also define a DHCP network scope in the group policy associated with a connection profile or username. This is either an IP network number or IP Address that identifies to the DHCP server which pool of IP addresses to use.

The following examples define the DHCP server at IP address 172.33.44.19 for the connection profile named **firstgroup**. They also define a DHCP network scope of 192.86.0.0 for the group policy called **remotegroup**. (The group policy called remotegroup is associated with the connection profile called firstgroup). If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

The following configuration includes more steps than are necessary, in that previously you might have named and defined the connection profile type as remote access, and named and identified the group policy as internal or external. These steps appear in the following examples as a reminder that you have no access to subsequent tunnel-group and group-policy commands until you set these values.

Guidelines and Limitations

You can only use an IPv4 address to identify a DHCP server to assign client addresses.

Configuring DHCP Addressing Using ASDM

Detailed Steps

Step 1 Select **Configuration > Remote Access VPN > Network (Client) Access> AnyConnect Connection Profiles**.

Step 2 In the Connection Profiles Area click **Add** or **Edit**.

Step 3 Click **Basic** in the configuration tree for the connection profile.

Step 4 In the Client Address Assignment area, enter the IPv4 address of the DHCP server you want to use to assign IP addresses to clients. For example, **172.33.44.19**.

Step 5 Edit the group-policy associated with the connection profile to define the DHCP scope. Select **Configuration > Remote Access VPN > Network (Client) Access> Group Policies.**

Step 6 Double-click the group policy you want to edit.

Step 7 Click **Servers** in the configuration tree.

Step 8 Expand the **More Options** area by clicking the down arrow.

Step 9 Uncheck DHCP Scope **Inherit**.

Step 10 Enter the IP network number or IP Address that identifies to the DHCP server which pool of IP addresses to use. For example, **192.86.0.0**.

Step 11 Click **OK**.

Step 12 Click **Apply**.

Configuring Dynamic Access Policies

This chapter describes how to configure dynamic access policies. It includes the following sections.

- Information About Dynamic Access Policies, page 89-1
- Licensing Requirements for Dynamic Access Policies, page 89-3
- Dynamic Access Policies Interface, page 89-4
- Configuring Dynamic Access Policies, page 89-6
- Testing Dynamic Access Policies, page 89-8
- DAP and Authentication, Authorization, and Accounting Services, page 89-9
- Configuring Endpoint Attributes Used in DAPs, page 89-13
- Configuring DAP Access and Authorization Policy Attributes, page 89-27
- Guide to Creating DAP Logical Expressions using LUA, page 89-31

Information About Dynamic Access Policies

VPN gateways operate in dynamic environments. Multiple variables can affect each VPN connection, for example, intranet configurations that frequently change, the various roles each user may inhabit within an organization, and logins from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

Dynamic access policies (DAP) on the ASA let you configure authorization that addresses these many variables. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security. That is, the ASA grants access to a particular user for a particular session based on the policies you define. The ASA generates a DAP at the time the user connects by selecting and/or aggregating attributes from one or more DAP records. It selects these DAP records based on the endpoint security information of the remote device and the AAA authorization information for the authenticated user. It then applies the DAP record to the user tunnel or session.

The DAP system includes the following components that require your attention:

- DAP Selection Configuration File—A text file containing criteria that the ASA uses for selecting and applying DAP records during session establishment. Stored on the ASA. You can use ASDM to modify it and upload it to the ASA in XML data format. DAP selection configuration files include all of the attributes that you configure. These can include AAA attributes, endpoint attributes, and access policies as configured in network and web-type ACL filter, port forwarding and URL lists.

- DfltAccess Policy—Always the last entry in the DAP summary table, always with a priority of 0. You can configure Access Policy attributes for the default access policy, but it does not contain—and you cannot configure—AAA or endpoint attributes. You cannot delete the DfltAccessPolicy, and it must be the last entry in the summary table.

Refer to the *Dynamic Access Deployment Guide* (https://supportforums.cisco.com/docs/DOC-1369) for additional information.

DAP and Endpoint Security

The ASA obtains endpoint security attributes by using posture assessment tools that you configure. These posture assessment tools include the AnyConnect posture module, the independent Host Scan package, Cisco Secure Desktop, and NAC.

Table 89-1 identifies each of the remote access protocols DAP supports, the posture assessment tools available for that method, and the information that tool provides.

Table 89-1 DAP Posture Assessment

Remote Access Protocol	AnyConnect Posture Module Host Scan package Cisco Secure Desktop (without Endpoint Assessment Host Scan Extension enabled)	AnyConnect Posture Module Host Scan package Cisco Secure Desktop (with Endpoint Assessment Host Scan Extension enabled)	NAC	Cisco NAC Appliance
	Returns file information, registry key values, running processes, operating system	Returns antivirus, antispyware, and personal firewall software information	Returns NAC status	Returns VLAN Type and VLAN IDs
IPsec VPN	No	No	Yes	Yes
Cisco AnyConnect VPN	Yes	Yes	Yes	Yes
Clientless VPN	Yes	Yes	No	No
PIX Cut-through Proxy	No	No	No	No

DAP Support for Remote Access Connection Types

The DAP system supports the following remote access methods:

- IPsec VPN
- Clientless (browser-based) SSL VPN
- Cisco AnyConnect Secure Mobility Client (SSL VPN)
- PIX cut-through proxy (posture assessment not available)

Remote Access Connection Sequence with DAPs

The following sequence outlines a typical remote access connection establishment.

1. A remote client attempts a VPN connection.
2. The ASA performs posture assessment, using configured NAC and Cisco Secure Desktop Host Scan values.

3. The ASA authenticates the user via AAA. The AAA server also returns authorization attributes for the user.
4. The ASA applies AAA authorization attributes to the session, and establishes the VPN tunnel.
5. The ASA selects DAP records based on the user AAA authorization information and the session posture assessment information.
6. The ASA aggregates DAP attributes from the selected DAP records, and they become the DAP policy.
7. The ASA applies the DAP policy to the session.

Licensing Requirements for Dynamic Access Policies

The following tables shows the licensing requirements for enforcing Dynamic Access Policies.

Advanced Endpoint Assessment license

Note This feature is not available on No Payload Encryption models.

Model	License Requirement
All models	Advanced Endpoint Assessment License.

SSL VPN license (client)

Note This feature is not available on No Payload Encryption models.

Model	License Requirement
All models	AnyConnect Premium License

AnyConnect Mobile License

Note This feature is not available on No Payload Encryption models.

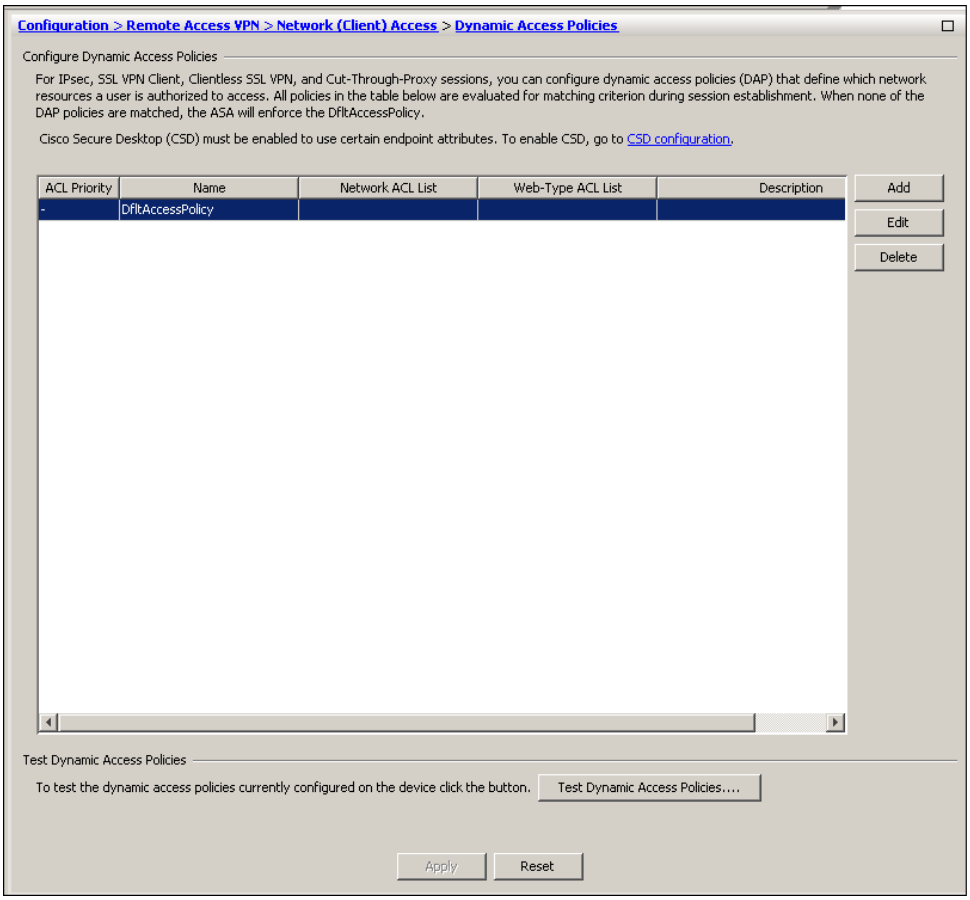
Model	License Requirement
All models	AnyConnect Mobile license.[1]

1. This license requires activation of one of the following licenses to specify the total number of SSL VPN sessions permitted: AnyConnect Essentials or AnyConnect Premium.

Dynamic Access Policies Interface

Figure 89-1 shows the Dynamic Access Policies pane.

Figure 89-1 Dynamic Access Policies ASDM pane



Fields

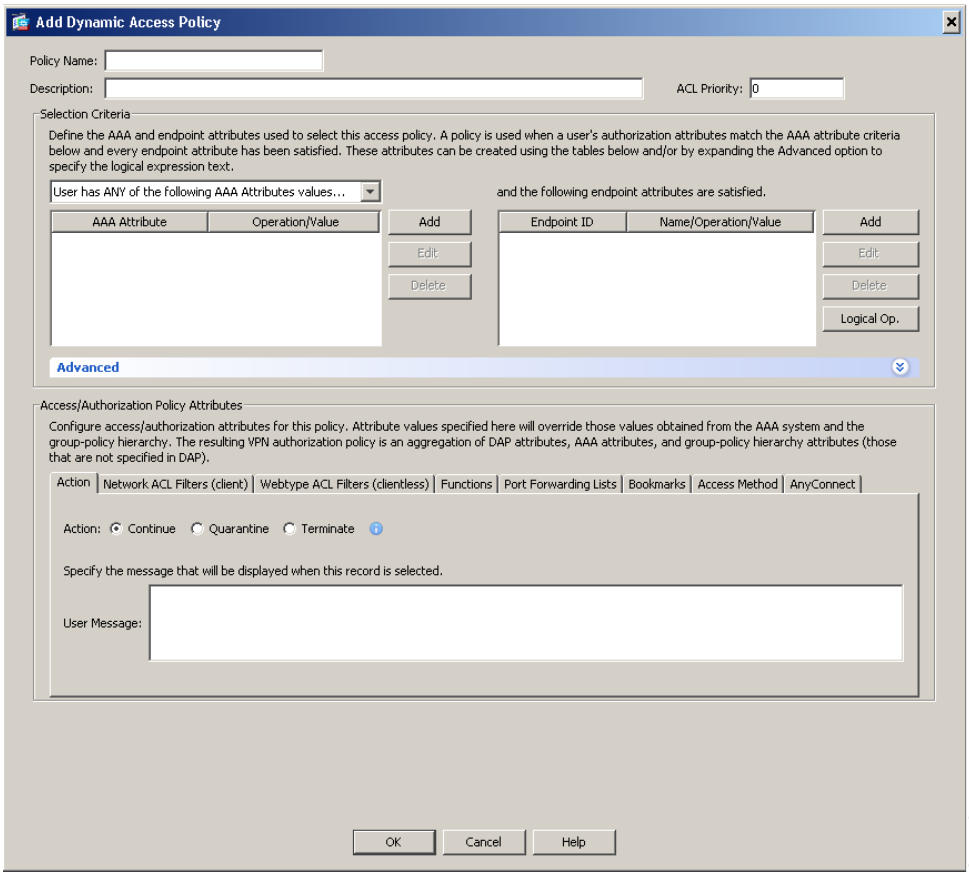
- ACL Priority—Displays the priority of the DAP record. The ASA uses this value to logically sequence the access lists when aggregating the network and web-type ACLs from multiple DAP records. The ASA orders the records from highest to lowest priority number, with lowest at the bottom of the table. Higher numbers have a higher priority, that is a DAP record with a value of 4 has a higher priority than a record with a value of 2. You cannot manually sort them.
- Name—Displays the name of the DAP record.

- Network ACL List—Displays the name of the firewall access list that applies to the session.
- Web-Type ACL List—Displays the name of the SSL VPN access list that applies to the session.
- Description—Describes the purpose of the DAP record.
- Test Dynamic Access Policies button—Click to test already configured DAP records.
- Find — You can search for a Dynamic Access Policy (DAP) by using the **Find** field. Start typing in the field and the tool will search the beginning characters of every field of the DAP table for a match. You can use wild cards to expand your search.

  For example typing `sal` in the **Find** field will match a DAP named `Sales` but not a DAP named `Wholesalers`. If you type `*sal` in the **Find** field, the search will find the first instance of either Sales or Wholesalers in the table.
- Find Arrows — Use the up and down arrows to skip up or down to the next string match.
- Match Case — Checking the Match Case check box will make your search case-sensitive.

Figure 89-2 shows the Add Dynamic Access Policy pane.

Figure 89-2 Add/Edit Dynamic Access Policies Pane



Configuring Dynamic Access Policies

Prerequisites

- Other than where noted, you must install Cisco Secure Desktop or Host Scan before configuring DAP endpoint attributes.
- Before configuring File, Process, and Registry endpoint attributes, configure File, Process, and Registry Basic Host Scan attributes. For instructions, start ASDM and select **Configuration > Remote Access VPN > Secure Desktop Manager > Host Scan** and click **Help**.

Guidelines and Limitations

DAP supports only ASCII characters.

Mobile Device Guidelines

ASA administrators will use AnyConnect Mobile Posture DAP Attributes differently depending on the AnyConnect license they have installed. See Adding Mobile Posture Attributes to a DAP, page 89-16 for more information.

Detailed Steps

Step 1 Start ASDM and select **Configuration > Remote Access VPN > Network (Client) Access** or **Clientless SSL VPN Access > Dynamic Access Policies.**

The Configure Dynamic Access Policies pane opens.

Step 2 To include certain antivirus, antispyware, or personal firewall endpoint attributes, click the CSD configuration link near the top of the pane. Then enable Cisco Secure Desktop *and* Host Scan extensions. This link does not display if you have previously enabled both of these features.

If you enable Cisco Secure Desktop, but do not enable Host Scan extensions, when you apply your changes ASDM includes a link to enable Host Scan configuration.

Step 3 To create a new dynamic access policy, click **Add**. To modify an existing policy, click **Edit**.

The Add/Edit Dynamic Access Policy pane opens.

Step 4 At the top of the Add/Edit Dynamic Access Policy pane, provide a name (required) and a description (optional) of this dynamic access policy.

- The **Policy Name** is a string of 4 through 32 characters, no spaces allowed.
- You are allowed a maximum of 80 charaters in the DAP **Description** field.

Step 5 In the **ACL Priority** field, set a priority for the dynamic access policy.

The security appliance applies access policies in the order you set here, highest number having the highest priority. Values of 0 to 2147483647 are valid. The default value is 0.

Step 6 In the Add/Edit AAA Attributes field, use the ANY/ALL/NONE drop-down list (unlabeled) to choose whether a user must have any, all, or none of the AAA attribute values you configure to use this dynamic access policy, as well as satisfying every endpoint attribute.

Duplicate entries are not allowed. If you configure a DAP record with no AAA or endpoint attributes, the ASA always selects it since all selection criteria are satisfied.

Step 7 To Set AAA attributes, click **Add** or **Edit** in the AAA Attributes field. Use one or more of these procedures: See the "Configuring AAA Attributes in a DAP" section on page 89-9 for more information.

Step 8 Use one or more of these procedures to **add** or **edit** endpoint attributes to the DAP policy:

- Adding an Anti-Spyware or Anti-Virus Endpoint Attribute to a DAP, page 89-14
- Adding an Application Attribute to a DAP, page 89-15
- Adding Mobile Posture Attributes to a DAP, page 89-16
- Adding a File Endpoint Attribute to a DAP, page 89-17
- Adding a Device Endpoint Attribute to a DAP, page 89-18
- Adding a NAC Endpoint Attribute to a DAP, page 89-19
- Adding an Operating System Endpoint Attribute to a DAP, page 89-20
- Adding a Personal Firewall Endpoint Attribute to a DAP, page 89-20
- Adding a Policy Endpoint Attribute to a DAP, page 89-21
- Adding a Process Endpoint Attribute to a DAP, page 89-22
- Adding a Registry Endpoint Attribute to a DAP, page 89-23

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR). To set this value for each of the end point attributes, click the **Logical Op.** button.

Step 9 In the **Advanced** field you can enter one or more logical expressions to set AAA or endpoint attributes other than what is possible in the AAA and Endpoint areas above. This feature that requires knowledge of the Lua programming language.

- AND/OR—Click to define the relationship between the basic selection rules and the logical expressions you enter here, that is, whether the new attributes add to or substitute for the AAA and endpoint attributes already set. The default is AND.
- Logical Expressions—You can configure multiple instances of each type of endpoint attribute. Enter free-form Lua text that defines new AAA and/or endpoint selection attributes. ASDM does not validate text that you enter here; it just copies this text to the DAP XML file, and the ASA processes it, discarding any expressions it cannot parse.
- Guide—Click to display online help for creating these logical operations or see Guide to Creating DAP Logical Expressions using LUA, page 89-31.

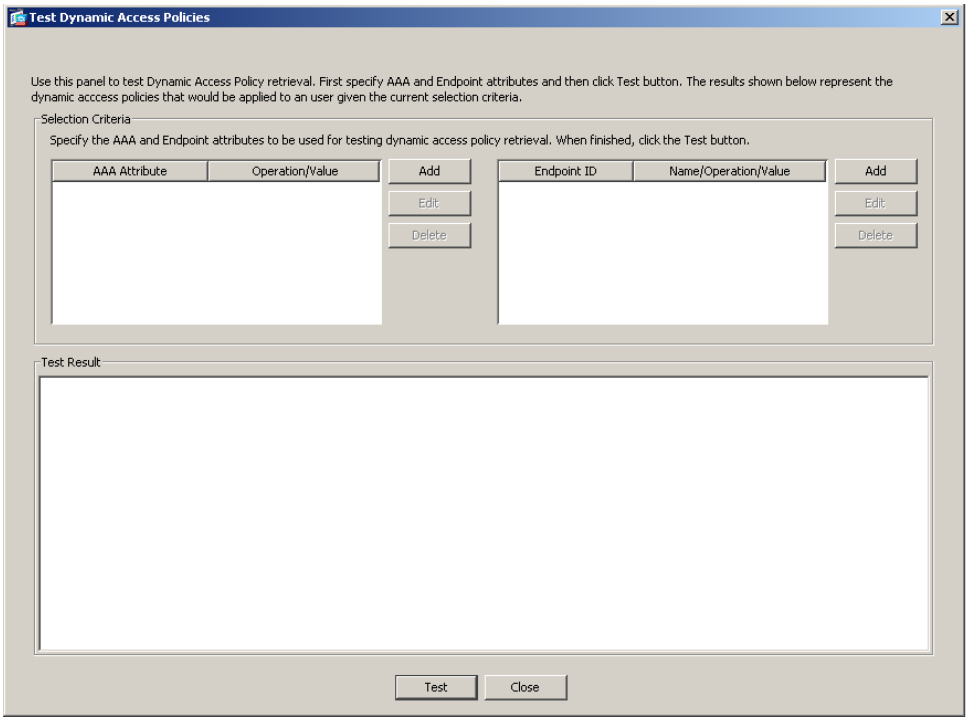
Step 10 To configure network and webtype ACLs, file browsing, file server entry, HTTP proxy, URL entry, port forwarding lists and URL lists, set values in the **Access Policy Attributes** fields. Attribute values that you configure here override authorization values in the AAA system, including those in existing user, group, tunnel group, and default group records. See Configuring DAP Access and Authorization Policy Attributes, page 89-27 for more information.

Step 11 Click **OK**.

Tip If you want to test your Dynamic Access Policy, in the Configure Dynamic Access Policies dialog box, click **Test Dynamic Access Policies** and add the attributes to the test interface. See Testing Dynamic Access Policies, page 89-8.

Testing Dynamic Access Policies

Figure 89-3 Test Dynamic Access Policies Pane



This pane lets you test the retrieval of the set of DAP records configured on the device by specifying authorization attribute value pairs. To specify these pairs, use the Add/Edit buttons associated with the AAA Attribute and Endpoint Attribute tables. The dialogs that display when you click these Add/Edit buttons are similar to those in the Add/Edit AAA Attributes and Add/Edit Endpoint Attributes dialog boxes.

When you enter attribute value pairs and click the “Test” button, the DAP subsystem on the device references these values when evaluating the AAA and endpoint selection attributes for each record. The results display in the “Test Results” text area.

Fields

- Selection Criteria—Determine the AAA and endpoint attributes to test for dynamic access policy retrieval.
- AAA Attributes
  - AAA Attribute—Identifies the AAA attribute.
  - Operation Value—Identifies the attribute as =/!= to the given value.
  - Add/Edit—Click to add or edit a AAA attribute.
- Endpoint Attributes—Identifies the endpoint attribute.
  - Endpoint ID—Provides the endpoint attribute ID.
  - Name/Operation/Value—
  - Add/Edit/Delete—Click to add, edit or delete and endpoint attribute.

- Test Result—Displays the result of the test.
- Test—Click to test the retrieval of the policies you have set.
- Close—Click to close the pane.

DAP and Authentication, Authorization, and Accounting Services

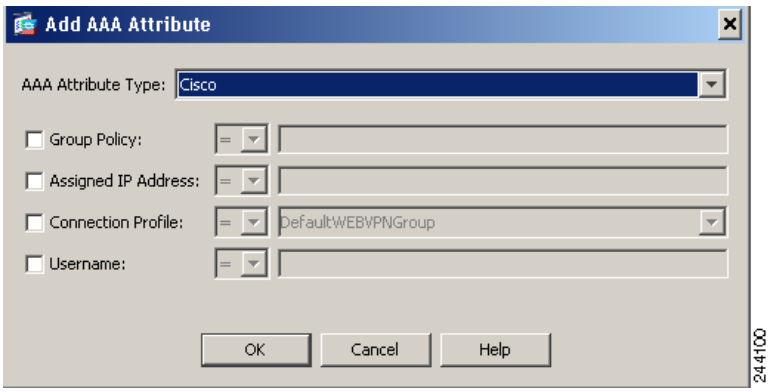
DAP complements AAA services. It provides a limited set of authorization attributes that can override those AAA provides. The ASA selects DAP records based on the AAA authorization information for the user and posture assessment information for the session. The ASA can select multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

You can specify AAA attributes from the Cisco AAA attribute hierarchy, or from the full set of response attributes that the ASA receives from a RADIUS or LDAP server. For more information about DAP and AAA, see the section, Configuring AAA Attributes in a DAP.

Configuring AAA Attributes in a DAP

Figure 89-4 shows the Add AAA Attribute dialog box.

Figure 89-4 Add AAA Attribute Dialog Box



To configure AAA attributes as selection criteria for DAP records, in the Add/Edit AAA Attributes dialog box, set the Cisco, LDAP, or RADIUS attributes that you want to use. You can set these attributes either to = or != the value you enter. There is no limit for the number of AAA attributes for each DAP record. For detailed information about AAA attributes, see AAA Attribute Definitions.

Fields

AAA Attributes Type—Use the drop-down list to select Cisco, LDAP or RADIUS attributes:

- Cisco—Refers to user authorization attributes that are stored in the AAA hierarchical model. You can specify a small subset of these attributes for the AAA selection attributes in the DAP record.These include:
  - Group Policy —The group policy name associated with the VPN user session. Can be set locally on the security appliance or sent from a RADIUS/LDAP server as the IETF-Class (25) attribute. Maximum 64 characters.

  - Assigned IP Address—Enter the IPv4 address you want to specify for the policy. The assigned IP address for full tunnel VPN clients (IPsec, L2TP/IPsec, SSL VPN AnyConnect) does not apply to Clientless SSL VPN, since there is no address assignment for clientless sessions.
  - Assigned IPv6 Address—Enter the IPv6 address you want to specify for the policy.
  - Connection Profile—The connection or tunnel group name. Maximum 64 characters.
  - Username—The username of the authenticated user. Maximum 64 characters. Applies if you are using Local, RADIUS, LDAP authentication/authorization or any other authentication type (for example, RSA/SDI), NT Domain, etc).
  - =/!=—Equal to/Not equal to.

- LDAP—The LDAP client (security appliance) stores all native LDAP response attribute value pairs in a database associated with the AAA session for the user. The LDAP client writes the response attributes to the database in the order in which it receives them. It discards all subsequent attributes with that name. This scenario might occur when a user record and a group record are both read from the LDAP server. The user record attributes are read first, and always have priority over group record attributes.

  To support Active Directory group membership, the AAA LDAP client provides special handling of the LDAP memberOf response attribute. The AD memberOf attribute specifies the DN string of a group record in AD. The name of the group is the first CN value in the DN string. The LDAP client extracts the group name from the DN string and stores it as the AAA memberOf attribute, and in the response attribute database as the LDAP memberOf attribute. If there are additional memberOf attributes in the LDAP response message, then the group name is extracted from those attributes and is combined with the earlier AAA memberOf attribute to form a comma separated string of group names, also updated in the response attribute database.

  In the case where the VPN remote access session to an LDAP authentication/authorization server returns the following three Active directory groups (memberOf enumerations):

  cn=Engineering,ou=People,dc=company,dc=com

  cn=Employees,ou=People,dc=company,dc=com

  cn=EastCoastast,ou=People,dc=company,dc=com

  the ASA processes three Active Directory groups: Engineering, Employees, and EastCoast which could be used in any combination as aaa.ldap selection criteria.

  LDAP attributes consist of an attribute name and attribute value pair in the DAP record. The LDAP attribute name is syntax/case sensitive. If for example you specify LDAP attribute Department instead of what the AD server returns as department, the DAP record will not match based on this attribute setting.

  Note To enter multiple values in the Value field, use the semicolon (;) as the delimiter. For example:

  eng;sale; cn=Audgen VPN,ou=USERS,o=OAG

- RADIUS—The RADIUS client stores all native RADIUS response attribute value pairs in a database associated with the AAA session for the user. The RADIUS client writes the response attributes to the database in the order in which it receives them. It discards all subsequent attributes with that name. This scenario might occur when a user record and a group record are both read from the RADIUS server. The user record attributes are read first, and always have priority over group record attributes.

RADIUS attributes consist of an attribute number and attribute value pair in the DAP record. See Security Appliance Supported RADIUS Attributes and Values for a table that lists RADIUS attributes that the security appliance supports.

Note For RADIUS attributes, DAP defines the Attribute ID = 4096 + RADIUS ID.

For example:

The RADIUS attribute "Access Hours" has a Radius ID = 1, therefore DAP attribute value = 4096 + 1 = 4097.

The RADIUS attribute "Member Of" has a Radius ID = 146, therefore DAP attribute value = 4096 + 146 = 4242.

- LDAP and RADIUS attributes include:
  - Attribute ID—Names/numbers the attribute. Maximum 64 characters.
  - Value—The attribute name (LDAP) or number (RADIUS).

    To enter multiple values in the Value field, use the semicolon (;) as the delimiter. For example:

    eng;sale; cn=Audgen VPN,ou=USERS,o=OAG
  - =/!=—Equal to/Not equal to.
- LDAP includes the Get AD Groups button. This button queries the Active Directory LDAP server for the list of groups the user belong to (memberOf enumerations). It retrieves the AD groups using the CLI show-ad-groups command in the background

The **show ad-groups** command applies only to Active Directory servers using LDAP. Use this command to display AD groups that you can use for dynamic access policy AAA selection criteria.

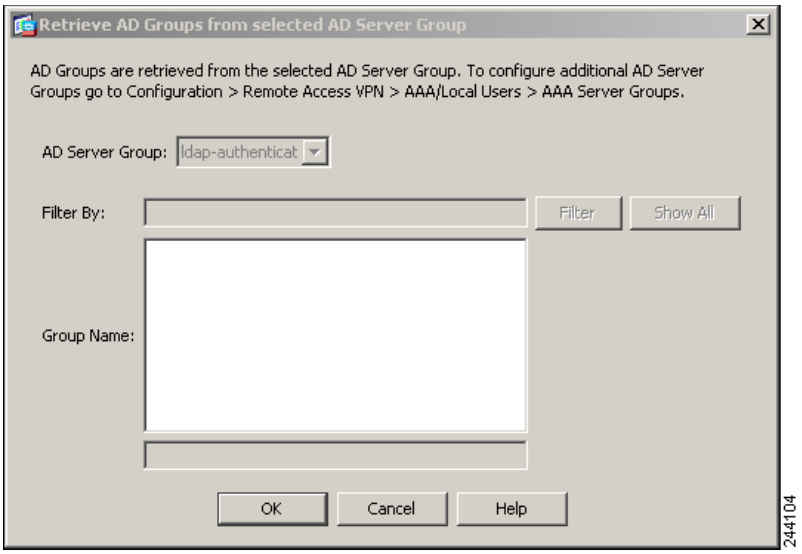
The default time that the ASA waits for a response from the server is 10 seconds. You can adjust this time using the **group-search-timeout** command in aaa-server host configuration mode.

Note If the Active Directory server has a large number of groups, the output of the **show ad-groups** command might be truncated based on limitations to the amount of data the server can fit into a response packet. To avoid this problem, use the filter option to reduce the number of groups reported by the server.

Retrieving Active Directory Groups

Figure 89-5 shows the Retrieve AD Groups from Selected AD Server Group pane.

Figure 89-5 Retrieve AD Groups Dialog Box



You can query an Active Directory server for available AD groups in this pane. This feature applies only to Active Directory servers using LDAP. Use the group information to specify dynamic access policy AAA selection criteria.

You can change the level in the Active Directory hierarchy where the search begins by changing the Group Base DN in the Edit AAA Server pane. You can also change the time that the ASA waits for a response from the server in the window. To configure these features, choose Configuration > Remote Access VPN > AAA/Local Users > AAA Server Groups > Edit AAA Server.

Note If the Active Directory server has a large number of groups, the list of AD groups retrieved may be truncated based on limitations of the amount of data the server can fit into a response packet. To avoid this problem, use the filter feature to reduce the number of groups reported by the server.

Fields

AD Server Group—The name of the AAA server group to retrieve AD groups.

Filter By—Specify a group or the partial name of a group to reduce the groups displayed.

Group Name—A list of AD groups retrieved from the server.

AAA Attribute Definitions

Table 74-2 defines the AAA selection attribute names that are available for DAP use. The Attribute Name field shows you how to enter each attribute name in a Lua logical expression, which you might do in the Advanced section of the Add/Edit Dynamic Access Policy pane.

Attribute Type	Attribute Name	Source	Value	Max String Length	Description
Cisco	aaa.cisco.grouppolicy	AAA	string	64	Group policy name on the ASA or sent from a Radius/LDAP server as the IETF-CLass (25) attribute

	aaa.cisco.ipaddress	AAA	number	-	Assigned IP address for full tunnel VPN clients (IPsec, L2TP/IPsec, SSL VPN AnyConnect)
	aaa.cisco.tunnelgroup	AAA	string	64	Connection profile (tunnel group) name
	aaa.cisco.username	AAA	string	64	Name of the authenticated user (applies if using Local authentication/authorization)
LDAP	aaa.ldap.<*label*>	LDAP	string	128	LDAP attribute value pair
RADIUS	aaa.radius.<number>	RADIUS	string	128	Radius attribute value pair

See Security Appliance Supported RADIUS Attributes and Values for a table that lists RADIUS attributes that the security appliance supports.

Configuring Endpoint Attributes Used in DAPs

Endpoint attributes contain information about the endpoint system environment, posture assessment results, and applications. The ASA dynamically generates a collection of endpoint attributes during session establishment and stores these attributes in a database associated with the session. There is no limit for the number of endpoint attributes for each DAP record.

Each DAP record specifies the endpoint selection attributes that must be satisfied for the ASA to select it. The ASA selects only DAP records that satisfy every condition configured.

For detailed information about Endpoint attributes, see Endpoint Attribute Definitions.

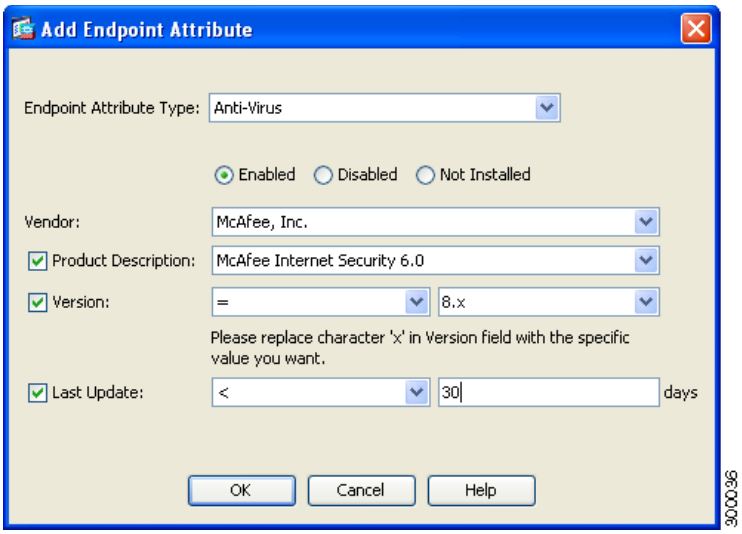
Configuring endpoint attributes as selection criteria for DAP records is part of the larger process of Configuring Dynamic Access Policies. Read Configuring Dynamic Access Policies, page 89-6 before you configuring endpoint attributes in DAPs.

This section includes the following topics:

- Adding an Anti-Spyware or Anti-Virus Endpoint Attribute to a DAP, page 89-14
- Adding an Application Attribute to a DAP, page 89-15
- Adding Mobile Posture Attributes to a DAP, page 89-16
- Adding a File Endpoint Attribute to a DAP, page 89-17
- Adding a Device Endpoint Attribute to a DAP, page 89-18
- Adding a NAC Endpoint Attribute to a DAP, page 89-19
- Adding an Operating System Endpoint Attribute to a DAP, page 89-20
- Adding a Personal Firewall Endpoint Attribute to a DAP, page 89-20
- Adding a Policy Endpoint Attribute to a DAP, page 89-21
- Adding a Process Endpoint Attribute to a DAP, page 89-22
- Adding a Registry Endpoint Attribute to a DAP, page 89-23

Figure 89-6 shows the Add Endpoint Attributes dialog box.

Figure 89-6 Add Endpoint Attributes Dialog Box



Adding an Anti-Spyware or Anti-Virus Endpoint Attribute to a DAP

Prerequisites

Configuring Anti-Spyware and Anti-Virus endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Anti-Spyware and Anti-Virus endpoint attributes.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match Any** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select Anti-Spyware or Anti-Virus.

Step 2 Click the appropriate **Enabled, Disabled, or Not Installed** button to indicate whether the selected endpoint attribute and its accompanying qualifiers (fields below the Enabled/Disabled/Not Installed buttons) must be enabled, disabled, or are not installed.

Step 3 From the **Vendor ID** list box, click the name of the anti-spyware or anti-virus vendor you are testing for.

Step 4 Check the **Product Description** check box and select from the list box the vendor's product name you are testing for.

Step 5 Check the **Version** checkbox and set the operation field to equal to (=), not equal (!=), less than (<), greater than (>), less that or equal to (<=), or greater than or equal to (>=) the product version number you select from ther **Version** list box.

If the choice in the version list box has an x, such as 3.x, replace the x with a specific release number, for example, 3.5.

Step 6 Check the Last Update check box. Specify the number of days since the last update. You might want to indicate that an update should occur in less than (<) or more than (>) the number of days you enter here.

Step 7 Click **OK**.

Step 8 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

- See Endpoint Attribute Definitions, page 89-24 for additional information on the antispyware and antivirus endpoint attribute requirements.
- See DAP and AntiVirus, AntiSpyware, and Personal Firewall Programs, page 89-24 for information on how Host Scan checks for antivirus, antispyware, and personal firewall programs that are memory-resident.

Adding an Application Attribute to a DAP

Prerequisites

Configuring Application endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Application endpoint attributes.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match Any** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Application**.

Step 2 In the Client Type operation field, select equals (=) or does not eaqual (!=).

Step 3 In the Client type list box, indicate the type of remote access connection you are testing for.

Step 4 Click **OK**.

Step 5 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Application endpoint attribute requirements.

Adding Mobile Posture Attributes to a DAP

Licensing

Mobile posture requires an AnyConnect Mobile license and an AnyConnect Premium license installed on the ASA. Enterprises that install these licenses will be able to enforce DAP policies on supported mobile devices based on DAP attributes and other existing endpoint attributes. This includes allowing or denying remote access from a mobile device.

Prerequisites

Configuring mobile posture attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Anti-Spyware and Anti-Virus endpoint attributes.

Guidelines

- These mobile posture attributes can be included in a dynamic access polciy and enforced without installing Host Scan or Cisco Secure Desktop on the endpoint.
- Some mobile posture attributes are relevant to the AnyConnect client running on mobile devices only, some mobile posture attributes are relevant to both AnyConnect clients running on mobile devices and AnyConnect desktop clients.
- When specifying mobile posture attributes and application attributes in a dynamic access policy, they both should be set to AnyConnect.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **AnyConnect**.

Step 2 Check the **Client Version** check box and set the operation field to be equal to (=), not equal to (!=), less than (<), greater than (>), less than or equal to (<=), or greater than or equal to (>=) the AnyConnect client version number you then specify in the **Client Version** field.

You can use this field to evaluate the client version on mobile devices, such as mobile phones and tablets, or desktop and laptop devices.

Step 3 Check the **Platform** check box and set the operation field to be equal to (=), or not equal to (!=) the operating system you then select from the **Platform** list box.

You can use this field to evaluate the operating system on mobile devices, such as mobile phones and tablets, as well as the operating system on desktop and laptop devices. Selecting Apple iOS or Android platforms activates the additional attribute fields for Device Type and Device Unique ID.

Step 4 Check the **Platform Version** check box and set the operation field to be equal to (=), not equal to (!=), less than (<), greater than (>), less than or equal to (<=), or greater than or equal to (>=) the operating system version number you then specify in the **Platform Version** field.

If you want to create a DAP record that contains this attribute, be sure to also specify a Platform in the previous step.

Step 5 If you selected the Platform checkbox and selected the Apple iOS or Android platform, you can check the **Device Type** checkbox. Set the operation field to be equal to (=) or not equal to (!=) the mobile device you then select in the **Device Type** field.

When you specify Android in the **Platform** field, you will be able to pick from a list of supported Android devices in the **Device Type** field. When you specify Apple iOS in the Platform field you will be able to pick from a list of supported Apple devices in the Device Type field. In both cases, the proper Android or Apple iOS device type information is substituted for the device type you choice from the list box.

If you have a supported device which is not listed in the Device Type field, you can enter the Android or Apple iOS device type information in the Device Type field. The most reliable way to obtain the device type information is to install the AnyConnect client on the endpoint and perform a DAP Trace. In the DAP trace results, look for the value of **endpoint.anyconnect.devicetype**. That is the value that you need to enter in the Device Type field.

Step 6 If you selected the Platform checkbox and selected the Apple iOS or Android platform, you can check the **Device Unique ID** checkbox. Set the operation field to be equal to (=) or not equal to (!=) the mobile device's unique ID you then specify in the **Device Unique ID** field.

The Device Unique ID distinguishes individual devices allowing you to set policies for a particular mobile device. To obtain a device's unique ID you will need the device to connect to the ASA and perform a DAP trace. See Performing a DAP Trace, page 89-31 for more information.

Step 7 Click **OK**.

Step 8 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the AnyConnect endpoint attribute requirements.

Adding a File Endpoint Attribute to a DAP

Prerequisites

- Configuring File endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure File endpoint attributes.
- Before configuring a File endpoint attribute, define the file for which you want to scan in the Host Scan window for Cisco Secure Desktop. In ASDM select **Configuration > Remote Access VPN > Secure Desktop Manager > Host Scan**. Click **Help** on that page for more information.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match All** is used by default.

Detailed Steps

You only need to configure one AnyConnect attribute in the Add Endpoint Attribute field except where noted.

Step 1 In the **Endpoint Attribute Type** list box, select **File**.

Step 2 Select the appropriate **Exists** or **Does not exist** radio button to indicate whether the selected endpoint attribute and its accompanying qualifiers (fields below the Exists/Does not exist buttons) should be present or not.

Step 3 In the **Endpoint ID** list box, choose from the drop-down list the endpoint ID that equates to the file entry for which you want to scan.

The file information is displayed below the Endpoint ID list box.

Step 4 Check the **Last Update** check box and set the operation field to be less than (<) or greater than (>) a certain number of days old. Enter the number of days old in the **days** field.

Step 5 Check the **Checksum** checkbox and set the operation field to be equal to (=) or not equal to (!=) the checksum value of the file you are testing for.

Step 6 Click **Compute CRC32 Checksum** to determine the checksum value of the file you are testing for.

Step 7 Click OK.

Step 8 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the File endpoint attribute requirements.

Adding a Device Endpoint Attribute to a DAP

Prerequisites

Configuring Device endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Device endpoint attributes.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match Any** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Device**.

Step 2 Check the **Host Name** checkbox and set the operation field to be equal to (=) or not equal to (!=) the host name of the device you are testing for. Use the computer's host name only, not the fully qualified domain name (FQDN).

Step 3 Check the **MAC address** checkbox and set the operation field to be equal to (=) or not equal to (!=) the MAC address of the network interface card you are testing for. Only one MAC address per entry. The address must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.

Step 4 Check the **BIOS Serial Number** checkbox and set the operation field to be equal to (=) or not equal to (!=) the BIOS serial number value of the device you are testing for. The number format is manufacturer-specific. There is no format requirement.

Step 5 Check the **TCP/UDP Port Number** checkbox and set the operation field to be equal to (=) or not equal to (!=) the TCP or UDP port in listening state that you are testing for.

In the TCP/UDP combo box, select the kind of port you are testing for: TCP (IPv4), UDP(IPv4), TCP (IPv6), or UDP (IPv6). If you are testing for more than one port, make several individual endpoint attribute rules in the DAP and specify one port in each.

Step 6 Check the **Privacy Protection** checkbox and set the operation field to be equal to (=) or not equal to (!=) the component CSD uses to execute the PreLogin Policy.

Step 7 Check the **Version of Secure Desktop (CSD)** checkbox and set the operation field to be equal to (=) or not equal to (!=) the version of the Host Scan image running on the endpoint.

Step 8 Check the **Version of Endpoint Assessment** checkbox and set the operation field to be equal to (=) or not equal to (!=) the version of endpoint assessment (OPSWAT) you are testing for.

Step 9 Click OK.

Step 10 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Device endpoint attribute requirements.

Adding a NAC Endpoint Attribute to a DAP

Prerequisites

Configuring NAC endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure NAC endpoint attributes.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match Any** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **NAC**.

Step 2 Check the **Posture Status** checkbox and set the operation field to be equal to (=) or not equal to (!=) the posture token string received by ACS. Enter the posture token string in the Posture Status text box.

Step 3 Click **OK**.

Step 4 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the NAC endpoint attribute requirements.

Adding an Operating System Endpoint Attribute to a DAP

Prerequisites

Configuring **Operating System** endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Operating System endpoint attributes.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Operating System**.

Step 2 Check the **OS Version** checkbox and set the operation field to be equal to (=) or not equal to (!=) the Windows, Mac, or Linux operating system you set in the **OS Version** list box.

Step 3 Check the **OS Update** checkbox and set the operation field to be equal to (=) or not equal to (!=) the Windows, Mac, or Linux service pack for the operating system you enter in the **OS Update** text box.

Step 4 Click **OK**.

Step 5 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Operating System endpoint attribute requirements.

Adding a Personal Firewall Endpoint Attribute to a DAP

Prerequisites

Configuring **Personal Firewall** endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Personal Firewall endpoint attributes.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Operating System**.

Step 2 Click the appropriate **Enabled, Disabled, or Not Installed** button to indicate whether the selected endpoint attribute and its accompanying qualifiers (fields below the Enabled/Disabled/Not Installed buttons) must be enabled, disabled, or are not installed.

Step 3 From the **Vendor ID** list box, click the name of the personal firewall vendor you are testing for.

Step 4 Check the **Product Description** check box and select from the list box the vendor's product name you are testing for.

Step 5 Check the **Version** checkbox and set the operation field to equal to (=), not equal (!=), less than (<), greater than (>), less that or equal to (<=), or greater than or equal to (>=) the product version number you select from ther **Version** list box.

If the choice in the **Version** list box has an x, such as 3.x, replace the x with a specific release number, for example, 3.5.

Step 6 Click **OK.**

Step 7 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

- See Endpoint Attribute Definitions, page 89-24 for additional information on the Personal Firewall endpoint attribute requirements.
- See DAP and AntiVirus, AntiSpyware, and Personal Firewall Programs, page 89-24 for information on how Host Scan checks for antivirus, antispyware, and personal firewall programs that are memory-resident.

Adding a Policy Endpoint Attribute to a DAP

Prerequisites

Configuring **Policy** endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure **Policy** endpoint attributes.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match Any** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Policy**.

Step 2 Check the **Location** checkbox and set the operation field to be equal to (=) or not equal to (!=) the Cisco Secure Desktop Microsoft Windows location profile. Enter the Cisco Secure Desktop Microsoft Windows location profile string in the **Location** text box.

Step 3 Click **OK**.

Step 4 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Policy endpoint attribute requirements.

Adding a Process Endpoint Attribute to a DAP

Prerequisites

- Configuring **Process** endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Personal Firewall endpoint attributes.
- Before configuring a Process endpoint attribute, define the process for which you want to scan in the Host Scan window for Cisco Secure Desktop. In ASDM select **Configuration > Remote Access VPN > Secure Desktop Manager > Host Scan**. Click **Help** on that page for more information.

Guidelines

You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match All** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Process**.

Step 2 Click the appropriate **Exists or Does not exist** button to indicate whether the selected endpoint attribute and its accompanying qualifiers (fields below the Exists and Does not exist buttons) should be present or not.

Step 3 In the **Endpoint ID** list box, choose from the drop-down list the endpoint ID for which you want to scan.

The endpoint ID process information is displayed below the list box.

Step 4 Click **OK**.

Step 5 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Process endpoint attribute requirements.

Adding a Registry Endpoint Attribute to a DAP

Prerequisites

- Configuring **Process** endpoint attributes as selection criteria for DAP records is part of a larger process. Read Configuring Dynamic Access Policies, page 89-6 before you configure Personal Firewall endpoint attributes.
- Before configuring a Registry endpoint attribute, define the registry key for which you want to scan in the Host Scan window for Cisco Secure Desktop. In ASDM select **Configuration > Remote Access VPN > Secure Desktop Manager > Host Scan**. Click **Help** on that page for more information.

Guidelines

- You can only scan for registry endpoint attributes on Windows operating systems.
- You can create multiple instances of each type of endpoint attribute. For each of these types, you need to decide whether the DAP policy should require that the user have all instances of a type (Match all = AND) or only one of them (Match Any = OR).

  To set this value, after you have defined all instances of the endpoint attribute, click the **Logical Op.** button and select the **Match Any** or **Match All** button. If you do not specify a Logical Operation, **Match All** is used by default.

Detailed Steps

Step 1 In the **Endpoint Attribute Type** list box, select **Registry**.

Step 2 Click the appropriate **Exists or Does not exist** button to indicate whether the **Registry** endpoint attribute and its accompanying qualifiers (fields below the Exists and Does not exist buttons) should be present or not.

Step 3 In the **Endpoint ID** list box, choose from the drop-down list the endpoint ID that equates to the registry entry for which you want to scan.

The registry information is displayed below the Endpoint ID list box.

Step 4 Check the **Value** checkbox and set the operation field to be equal to (=) or not equal to (!=).

Step 5 In the first **Value** list box, identify the registry key as a dword or a string.

Step 6 In the second Value operation list box, enter the value of the resgistry key you are scanning for.

Step 7 If you want to disregard the case of the registry entry when scanning, click the **Caseless** checkbox. If you want the search to be case-sensitive, do not ccheck the Caseless check box.

Step 8 Click **OK**.

Step 9 Return to Configuring Dynamic Access Policies, page 89-6.

Additional References

See Endpoint Attribute Definitions, page 89-24 for additional information on the Registry endpoint attribute requirements.

DAP and AntiVirus, AntiSpyware, and Personal Firewall Programs

The security appliance uses a DAP policy when the user attributes matches the configured AAA and endpoint attributes. The Prelogin Assessment and Host Scan modules of Cisco Secure Desktop return information to the security appliance about the configured endpoint attributes, and the DAP subsystem uses that information to select a DAP record that matches the values of those attributes.

Most, but not all, antivirus, antispyware, and personal firewall programs support active scan, which means that the programs are memory-resident, and therefore always running. Host Scan checks to see if an endpoint has a program installed, and if it is memory-resident as follows:

- If the installed program does not support active scan, Host Scan reports the presence of the software. The DAP system selects DAP records that specify the program.
- If the installed program does support active scan, and active scan is enabled for the program, Host Scan reports the presence of the software. Again the security appliance selects DAP records that specify the program.
- If the installed program does support active scan and active scan is disabled for the program, Host Scan ignores the presence of the software. The security appliance does not select DAP records that specify the program. Further, the output of the **debug trace** command, which includes a lot of information about DAP, does not indicate the program presence, even though it is installed.

Endpoint Attribute Definitions

Table 89-2 defines the endpoint selection attribute names that are available for DAP use.The Attribute Name field shows you how to enter each attribute name in a Lua logical expression, which you might do in the Advanced area in the Add/Edit Dynamic Access Policy pane. The *label* variable identifies the application, filename, process, or registry entry.

Table 89-2 Endpoint Attribute Definitions

Attribute Type	Attribute Name	Source	Value	Max String Length	Description
Antispyware (Requires Cisco Secure Desktop)	endpoint.as["*label*"].exists	Host Scan	true	—	Antispyware program exists
	endpoint.as["*label*"].version		string	32	Version
	endpoint.as["*label*"].description		string	128	Antispyware description
	endpoint.as["*label*"].lastupdate		integer	—	Seconds since update of antispyware definitions

Table 89-2 Endpoint Attribute Definitions (continued)

Attribute Type	Attribute Name	Source	Value	Max String Length	Description
Antivirus (Requires Cisco Secure Desktop)	endpoint.av["*label*"].exists	Host Scan	true	—	Antivirus program exists
	endpoint.av["*label*"].version		string	32	Version
	endpoint.av["*label*"].description		string	128	Antivirus description
	endpoint.av["*label*"].lastupdate		integer	—	Seconds since update of antivirus definitions
AnyConnect (Does not require Cisco Secure Desktop or Host Scan.)	endpoint.anyconnect.clientversion	Endpoint	version	—	AnyConnect client version.
	endpoint.anyconnect.platform		string	—	Operating system on which AnyConnect client is installed.
	endpoint.anyconnect.platformversion		version	64	Version of operating system on which AnyConnect client is installed.
	endpoint.anyconnect.devicetype		string	64	Mobile device type on which AnyConnect client is installed.
	endpoint.anyconnect.deviceuniqueid		caseless	64	Unique ID of mobile device on which AnyConnect client is installed.
Application	endpoint.application.clienttype	Application	string	—	Client type: CLIENTLESS ANYCONNECT IPSEC L2TP

Table 89-2 Endpoint Attribute Definitions (continued)

Attribute Type	Attribute Name	Source	Value	Max String Length	Description
Device	endpoint.device.hostname	Endpoint	string	64	Host Name only. Not FQDN.
	endpoint.device.MAC		string	Must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.	Mac Address for a network interface card. Only one Mac address per entry.
	endpoint.device.id		string	64	BIOS Serial Number. The number format is manufacturer-specific. There is no format requirement.
	endpoint.device.port		string	An integer between 1 and 65535.	TCP port in listening state. You can define a single port per line.
	endpoint.device.protection		None (Host Scan) Scure Desktop (either Cache Cleaner or Vault)	64	Defines which component of CSD will execute for the particular PreLogin Policy.
	endpoint.device.protection_version		string	64	Version of Host Scan image they are running.
	endpoint.device.protection_extension		string	64	Versionof Endpoint Assessment (OPSWAT)
File	endpoint.file["*label*"].exists	Secure Desktop	true	—	The files exists
	endpoint.file[“label”].endpointid				
	endpoint.file["*label*"].lastmodified		integer	—	Seconds since file was last modified
	endpoint.file["*label*"].crc.32		integer	—	CRC32 hash of the file
NAC	endpoint.nac.status	NAC	string	—	User defined status string
Operating System	endpoint.os.version	Secure Desktop	string	32	Operating system
	endpoint.os.servicepack		integer	—	Service pack for Windows

Table 89-2 Endpoint Attribute Definitions (continued)

Attribute Type	Attribute Name	Source	Value	Max String Length	Description
Personal firewall (Requires Secure Desktop)	endpoint.fw["*label*"].exists	Host Scan	true	—	The personal firewall exists
	endpoint.fw["*label*"].version		string	32	Version
	endpoint.fw["*label*"].description		string	128	Personal firewall description
Policy	endpoint.policy.location	Secure Desktop	string	64	Location value from Cisco Secure Desktop
Process	endpoint.process["*label*"].exists	Secure Desktop	true	—	The process exists
	endpoint.process["*label*"].path		string	255	Full path of the process
Registry	endpoint.registry["*label*"].type	Secure Desktop	*dword string*	—	dword
	endpoint.registry["*label*"].value		string	255	Value of the registry entry
VLAN	endoint.vlan.type	CNA	string	—	VLAN type: ACCESS AUTH ERROR GUEST QUARANTINE ERROR STATIC TIMEOUT

Configuring DAP Access and Authorization Policy Attributes

To Configure Access and Authorization Policy Attributes for a DAP, click each tab and configure the fields.

- Action Tab—Specifies special processing to apply to a specific connection or session.
  - Continue—(Default) Click to apply access policy attributes to the session.
  - Quarantine—Through the use of quarantine, you can restrict a particular client who already has an established tunnel through a VPN. ASA applies restricted ACLs to a session to form a restricted group, based on the selected DAP record. When an endpoint is not compliant with an administratively defined policy, the user can still access services for remediation (such as updating the antivirus and so on), but restrictions are placed upon the user. After the remediation occurs, the user can reconnect, which invokes a new posture assessment. If this assessment passes, the user connects.

    Note This parameter requires an AnyConnect release that supports AnyConnect Secure Mobility features.

  - Terminate—Click to terminate the session.

  - User Message—Enter a text message to display on the portal page when this DAP record is selected. Maximum 490 characters. A user message displays as a yellow orb. When a user logs on it blinks three times to attract attention, and then it is still. If several DAP records are selected, and each of them has a user message, all of the user messages display.

Note You can include in such messages URLs or other embedded text, which require that you use the correct HTML tags.

For example: All contractors please read Instructions for the procedure to upgrade your antivirus software.

- Network ACL Filters Tab—Lets you select and configure network ACLs to apply to this DAP record. An ACL for DAP can contain permit or deny rules, but not both. If an ACL contains both permit and deny rules, the ASA rejects it.
  - **Network ACL drop-down list**—Select already configured network ACLs to add to this DAP record. Only ACLs having all permit or all deny rules are eligible, and these are the only ACLs that display here. This field supports unified ACLs which can define access rules for IPv4 and IPv6 network traffic.
  - **Manage...**—Click to add, edit, and delete network ACLs.
  - **Network ACL list**—Displays the network ACLs for this DAP record.
  - **Add>>**— Click to add the selected network ACL from the drop-down list to the Network ACLs list on the right.
  - **Delete**—Click to delete a highlighted network ACL from the Network ACLs list. You cannot delete an ACL from the ASA unless you first delete it from DAP records.
- **Web-Type ACL Filters (clientless) Tab**—Lets you select and configure web-type ACLs to apply to this DAP record. An ACL for DAP can contain only permit or deny rules. If an ACL contains both permit and deny rules, the ASA rejects it.
  - **Web-Type ACL** drop-down list—Select already configured web-type ACLs to add to this DAP record. Only ACLs having all permit or all deny rules are eligible, and these are the only ACLs that display here.
  - **Manage...**—Click to add, edit, and delete web-type ACLs.
  - **Web-Type ACL** list—Displays the web-type ACLs for this DAP record.
  - **Add>>**—Click to add the selected web-type ACL from the drop-down list to the Web-Type ACLs list on the right.
  - **Delete**—Click to delete a web-type ACL from the Web-Type ACLs list. You cannot delete an ACL from the ASA unless you first delete it from DAP records.
- **Functions Tab**—Lets you configure file server entry and browsing, HTTP proxy, and URL entry for the DAP record.
  - **File Server Browsing**—Enables or disables CIFS browsing for file servers or shared features.

Note Browsing requires NBNS (Master Browser or WINS). If that fails or is not configured, we use DNS.

The CIFS browse feature does not support internationalization.

- **File Server Entry**—Lets or prohibits a user from entering file server paths and names on the portal page. When enabled, places the file server entry drawer on the portal page. Users can enter pathnames to Windows files directly. They can download, edit, delete, rename, and move files. They can also add files and folders. Shares must also be configured for user access on the applicable Windows servers. Users might have to be authenticated before accessing files, depending on network requirements.
- **HTTP Proxy**—Affects the forwarding of an HTTP applet proxy to the client. The proxy is useful for technologies that interfere with proper content transformation, such as Java, ActiveX, and Flash. It bypasses mangling while ensuring the continued use of the security appliance. The forwarded proxy modifies the browser's old proxy configuration automatically and redirects all HTTP and HTTPS requests to the new proxy configuration. It supports virtually all client side technologies, including HTML, CSS, JavaScript, VBScript, ActiveX, and Java. The only browser it supports is Microsoft Internet Explorer.
- **URL Entry**—Allows or prevents a user from entering HTTP/HTTPS URLs on the portal page. If this feature is enabled, users can enter web addresses in the URL entry box, and use clientless SSL VPN to access those websites.

Using SSL VPN does not ensure that communication with every site is secure. SSL VPN ensures the security of data transmission between the remote user PC or workstation and the ASA on the corporate network. If a user then accesses a non-HTTPS web resource (located on the Internet or on the internal network), the communication from the corporate ASA to the destination web server is not secured.

In a clientless VPN connection, the ASA acts as a proxy between the end user web browser and target web servers. When a user connects to an SSL-enabled web server, the ASA establishes a secure connection and validates the server SSL certificate. The end user browser never receives the presented certificate, so therefore cannot examine and validate the certificate. The current implementation of SSL VPN does not permit communication with sites that present expired certificates. Neither does the ASA perform trusted CA certificate validation. Therefore, users cannot analyze the certificate an SSL-enabled web-server presents before communicating with it.

To limit Internet access for users, choose Disable for the URL Entry field. This prevents SSL VPN users from surfing the web during a clientless VPN connection.

- **Unchanged**—(default) Click to use values from the group policy that applies to this session.
- **Enable/Disable**—Click to enable or disable the feature.
- **Auto-start**—Click to enable HTTP proxy and to have the DAP record automatically start the applets associated with these features.

- **Port Forwarding Lists Tab**—Lets you select and configure port forwarding lists for user sessions.

  Port Forwarding provides access for remote users in the group to client/server applications that communicate over known, fixed TCP/IP ports. Remote users can use client applications that are installed on their local PC and securely access a remote server that supports that application. Cisco has tested the following applications: Windows Terminal Services, Telnet, Secure FTP (FTP over SSH), Perforce, Outlook Express, and Lotus Notes. Other TCP-based applications may also work, but Cisco has not tested them.

Note Port Forwarding does not work with some SSL/TLS versions.

Caution Make sure Sun Microsystems Java Runtime Environment (JRE) 1.4+ is installed on the remote computers to support port forwarding (application access) and digital certificates.

  - Port Forwarding—Select an option for the port forwarding lists that apply to this DAP record. The other attributes in this field are enabled only when you set Port Forwarding to Enable or Auto-start.
  - **Unchanged**—Click to remove the attributes from the running configuration.
  - **Enable/Disable**—Click to enable or disable port forwarding.
  - **Auto-start**—Click to enable port forwarding, and to have the DAP record automatically start the port forwarding applets associated with its port forwarding lists.
  - **Port Forwarding List** drop-down list—Select already configured port forwarding lists to add to the DAP record.
  - **New...**—Click to configure new port forwarding lists.
  - **Port Forwarding Lists** (unlabeled)—Displays the port forwarding lists for the DAP record.
  - **Add**—Click to add the selected port forwarding list from the drop-down list to the Port Forwarding list on the right.
  - **Delete**—Click to delete selected port forwarding list from the Port Forwarding list. You cannot delete a port forwarding list from the ASA unless you first delete it from DAP records.
- **Bookmarks Tab**—Lets you select and configure bookmarks for certain user session URLs.
  - **Enable bookmarks**—Click to enable. When unchecked, no bookmarks display in the portal page for the connection.
  - **Bookmark** drop-down list—select already configured bookmarks to add to the DAP record.
  - **Manage...**—Click to add, import, export, and delete bookmarks.
  - **Bookmarks (unlabeled)**—Displays the URL lists for the DAP record.
  - **Add>>**—Click to add the selected bookmark from the drop-down list to the URL area on the right.
  - **Delete**—Click to delete the selected bookmark from the URL list area. You cannot delete a bookmark from the ASA unless you first delete it from DAP records.
- **Access Method Tab**—Lets you configure the type of remote access permitted.
  - **Unchanged**—Continue with the current remote access method.
  - **AnyConnect Client**—Connect using the Cisco AnyConnect VPN Client.
  - **Web-Portal**—Connect with clientless VPN.
  - **Both-default-Web-Portal**—Connect via either clientless or the AnyConnect client, with a default of clientless.
  - **Both-default-AnyConnect Client**—Connect via either clientless or the AnyConnect client, with a default of AnyConnect.
- **AnyConnect Tab**—Lets you choose the status of the Always-on VPN flag.
  - Always-On VPN for AnyConnect client—Determine if the always-on VPN flag setting in the AnyConnect service profile is unchanged, disabled, or if the AnyConnect profile setting should be used.

Note This parameter requires a release of the Cisco IronPort Web Security appliance that provides Secure Mobility Solution licensing support for the Cisco AnyConnect VPN client. It also requires an AnyConnect release that supports "Secure Mobility Solution" features. Refer to the *Cisco AnyConnect VPN Client Administrator Guide* for additional information.

Performing a DAP Trace

By performing a DAP trace you can display the DAP endpoint attributes for all connected devices.

Prerequisites

Log on to the ASA from an SSH terminal and enter Privileged Exec mode. In Privileged Exec mode, the ASA displays this prompt: `hostname#`

Detailed Steps

	Command	Purpose

Step 1	**debug dap trace**
	
	Example
	`hostname# debug dap trace`
		Enables DAP debugs to display all DAP attributes for the session in the terminal window.
		
		Example output:
		This is a small fragment of the output one receives from running the debug dap trace command
		`endpoint.anyconnect.clientversion="0.16.0021";`
		`endpoint.anyconnect.platform="apple-ios";`
		`endpoint.anyconnect.platformversion="4.1";`
		`endpoint.anyconnect.devicetype="iPhone1,2";`
		`endpoint.anyconnect.deviceuniqueid="dd13ce3547f2fa1b2c3d4e5f6g7h8i9j0fa03f75";`

Additional References

In order to search the output of the DAP trace, send the output of the command to a sytem log. To learn more about logging on the ASA see Configuring Logging in the *Cisco ASA 5500 Series Configuration Guide using the CLI, 8.4*.

Guide to Creating DAP Logical Expressions using LUA

This section provides information about constructing logical expressions for AAA or Endpoint attributes. Be aware that doing so requires sophisticated knowledge of Lua (www.lua.org).

In the Advanced field you enter free-form Lua text that represents AAA and/or endpoint selection logical operations. ASDM does not validate text that you enter here; it just copies this text to the DAP policy file, and the ASA processes it, discarding any expressions it cannot parse.

This option is useful for adding selection criteria other than what is possible in the AAA and endpoint attribute areas above. For example, while you can configure the ASA to use AAA attributes that satisfy any, all, or none of the specified criteria, endpoint attributes are cumulative, and must all be satisfied. To let the security appliance employ one endpoint attribute or another, you need to create appropriate logical expressions in Lua and enter them here.

- For a list of AAA Selection attributes, including proper name syntax for creating logical expressions, see Table 74-1.
- For a list of endpoint selection attributes, including proper name syntax for creating logical expressions, see Table 89-2.

The following sections provide detailed explanations of creating Lua EVAL expressions, as well as examples.

- Syntax for Creating Lua EVAL Expressions
  - Constructing DAP EVAL Expressions
- The DAP CheckAndMsg Function
  - Checking for a Single Antivirus Program
  - Checking for Antivirus Definitions Within the Last 10 Days
  - Checking for a Hotfix on the User PC
  - Checking for Antivirus Programs
  - Checking for Antivirus Programs and Definitions Older than 1 1/2 Days
- Additional Lua Functions
  - OU-Based Match Example
  - Group Membership Example
  - Antivirus Example
  - Antispyware Example
  - Firewall Example
  - Antivirus, Antispyware, or any Firewall Example
- CheckAndMsg with Custom Function Example
- Further Information on Lua

Syntax for Creating Lua EVAL Expressions

This section provides information about the syntax for creating Lua EVAL expressions.

Note If you must use Advanced mode, we recommend that you use EVAL expressions whenever possible for reasons of clarity, which makes verifying the program straightforward.

EVAL(<*attribute*> , <comparison>, {<*value*> | <*attribute*>}, [<type>])

<attribute>	AAA attribute or an attribute returned from Cisco Secure Desktop, see Table 74-1 and Table 89-2 for attribute definitions	
<comparison>	One of the following strings (quotation marks required)	
	“EQ”	equal
	“NE”	not equal
	“LT”	less than
	“GT”	greater than
	“LE”	less than or equal
	“GE”	greater than or equal
<value>	A string in quotation marks that contains the value to compare the attribute against	
<type>	One of the following strings (quotation marks required)	
	“string”	case-sensitive string comparison
	“caseless”	case-insensitive string comparison
	“integer”	number comparison, converts string values to numbers
	“hex”	number comparison using hexadecimal values, converts hex string to hex numbers
	“version”	compares versions of the form X.Y.Z. where X, Y, and Z are numbers

Example:

EVAL(endpoint.os.version, “EQ”, “Windows XP”, “string”)

Constructing DAP EVAL Expressions

Study these examples for help in creating logical expressions in Lua.

- This endpoint expression tests for a match on CLIENTLESS OR CVC client types:

```
(EVAL(endpoint.application.clienttype,”EQ”,"CLIENTLESS") or
EVAL(endpoint.application.clienttype, “EQ”,"CVC"))
```

- This endpoint expression tests for Norton Antivirus versions 10.x but excludes 10.5.x:

```
(EVAL(endpoint.av[“NortonAV”].version, “GE”, "10",”version”) and
(EVAL(endpoint.av[“NortonAV”].version,”LT”, "10.5", “version”) or
EVAL(endpoint.av[“NortonAV”].version, “GE”, "10.6", “version”)))
```

The DAP CheckAndMsg Function

CheckAndMsg is a Lua function that you can configure DAP to call. It generates a user message based on a condition.

You use ASDM to configure CheckAndMsg through the Advanced field in DAP. The ASA displays the message to the user only when the DAP record containing the LUA CheckAndMsg function is selected and results in a clientless SSL VPN or AnyConnect termination.

The syntax of the CheckAndMsg function follows:

```
CheckAndMsg(value, "<message string if value is true>", "<message string if value if
false>")
```

Be aware of the following when creating CheckAndMsg functions:

- CheckAndMsg returns the value passed in as its first argument.
- Use the EVAL function as the first argument if you do not want to use string comparison. For example:

  ```
  (CheckAndMsg((EVAL(...)) , "true msg", "false msg"))
  ```

  CheckandMsg returns the result of the EVAL function and the security appliances uses it to determine whether to select the DAP record. If the record is selected and results in termination, the security appliance displays the appropriate message.

Checking for a Single Antivirus Program

This example checks if a single antivirus program, in this case McAfee, is installed on the user PC, and displays a message if it is not.

```
(CheckAndMsg(EVAL(endpoint.av["McAfeeAV"].exists,"NE","true"),"McAfee AV was not
found on your computer", nil))
```

Checking for Antivirus Definitions Within the Last 10 Days

This example checks antivirus definitions within the last 10 days (864000 sec), in particular the last update of the McAfee AV dat file, and displays a message to a user lacking the appropriate update that they need an antivirus update:

```
((CheckAndMsg(EVAL(endpoint.av["McAfeeAV"].lastupdate,"GT","864000","integer"),"AV
Update needed! Please wait for the McAfee AV till it loads the latest dat file.",nil) ))
```

Checking for a Hotfix on the User PC

This example checks for a specific hotfix. If a user does not have the hotfix on their PC, a message that it is not installed displays.

```
(not CheckAndMsg(EVAL(endpoint.os.windows.hotfix["KB923414"],"EQ","true"),nil,"The
required hotfix is not installed on your PC."))
```

or you could define it this way (which makes more sense):

```
(CheckAndMsg(EVAL(endpoint.os.windows.hotfix["KB923414"],"NE","true"),"The required hotfix
is not installed on your PC.",nil))
```

You can build the expression in this example because the debug dap trace returns:

```
endpoint.os.windows.hotfix["KB923414"] = "true";
```

Checking for Antivirus Programs

You can configure messages so that the end user is aware of and able to fix problems with missing or not running AVs. As a result, if access is denied, the ASA collects all messages for the DAP that caused the "terminate" condition and displays them in the browser on the logon page. If access is allowed, the ASA displays all messages generated in the process of DAP evaluation on the portal page.

The following example shows how to use this feature to check on the Norton Antivirus program.

Step 1 Copy and paste the following Lua expression into the Advanced field of the Add/Edit Dynamic Access Policy pane (click the double arrow on the far right to expand the field).

```
(CheckAndMsg(EVAL(endpoint.av["NortonAV"].exists, "EQ", "false"),"Your Norton AV was found
but the active component of it was not enabled", nil) or
CheckAndMsg(EVAL(endpoint.av["NortonAV"].exists, "NE", "true"),"Norton AV was not found on
your computer", nil) )
```

Step 2 In that same Advanced field, click the **OR** button.

Step 3 In the Access Attributes section below, in the leftmost tab, Action**,** click **Terminate**.

Step 4 Connect from a PC that does not have or has disabled Norton Antivirus.

The expected result is that the connection is not allowed *and* the message appears as a blinking ! point.

Step 5 Click the blinking ! to see the message.

Checking for Antivirus Programs *and* Definitions Older than 1 1/2 Days

This example checks for the presence of the Norton and McAfee antivirus programs, and whether the virus definitions are older than 1 1/2 days (10,000 seconds). If the definitions are older than 1 1/2 days, the ASA terminates the session with a message and links for remediation. To accomplish this task, perform the following steps.

Step 1 Copy and paste the following Lua expression into the Advanced field of the Add/Edit Dynamic Access Policy pane (click the double arrow on the far right to expand the field):

```
((EVAL(endpoint.av["NortonAV"].exists,"EQ","true","string") and
CheckAndMsg(EVAL(endpoint.av["NortonAV"].lastupdate,"GT","10000",integer"),To
remediate <a href='http://www.symantec.com'>Click this link </a>",nil)) or
(EVAL(endpoint.av["McAfeeAV"].exists,"EQ","true","string") and
CheckAndMsg(EVAL(endpoint.av["McAfeeAV"].lastupdate,"GT","10000",integer"),To
remediate <a href='http://www.mcafee.com'>Click this link</a>",nil))
```

Step 2 In that same Advanced field, click **AND**.

Step 3 In the Access Attributes section below, in leftmost tab, Action**,** click **Terminate**.

Step 4 Connect from a PC that has Norton and McAfee antivirus programs with versions that are older than 1 1/2 days.

The expected result is that the connection is not allowed *and* the message appears as a blinking ! point.

Step 5 Click the blinking ! to see the message and links for remediation.

Additional Lua Functions

When working with dynamic access policies for clientless SSL VPN, you might need additional flexibility of match criteria. For example, you might want to apply a different DAP based on the following:

- Organizational Unit (OU) or other level of the hierarchy for the user object
- Group Name that follows a naming convention but has many possible matches—you might require the ability to use a wildcard on group names.

You can accomplish this flexibility by creating a Lua logical expression in the Advanced section of the DAP pane in ASDM.

OU-Based Match Example

DAP can use many attributes returned from an LDAP server in a logical expression. See the DAP trace section for example output of this, or run a debug dap trace.

The LDAP server returns the user Distinguished Name (DN). This implicitly identifies where in the directory the user object is located. For example, if the user DN is CN=Example User,OU=Admins,dc=cisco,dc=com this user is located in OU=Admins,dc=cisco,dc=com. If all administrators are in this OU (or any container below this level) you can use a logical expression to match on this criteria as follows:

```
assert(function()
   if ( (type(aaa.ldap.distinguishedName) == "string") and
        (string.find(aaa.ldap.distinguishedName, "OU=Admins,dc=cisco,dc=com$") ~= nil) )
then
       return true
   end
   return false
end)()
```

In this example, the string.find function allows for a regular expression. Use the $ at the end of the string to anchor this string to the end of the distinguishedName field.

Group Membership Example

You can create a basic logical expression for pattern matching of AD group membership. Because users can be members of multiple groups, DAP parses the response from the LDAP server into separate entries in a table. You need an advanced function to accomplish the following:

- Compare the memberOf field as a string (in the event the user belongs to only one group).
- Iterate through each returned memberOf field if the returned data is of type "table".

The function we have written and tested for this purpose is shown below. In this example, if a user is a member of any group ending with "-stu" they match this DAP.

```
assert(function()
   local pattern = "-stu$"
   local attribute = aaa.ldap.memberOf
   if ((type(attribute) == "string") and
       (string.find(attribute, pattern) ~= nil)) then
       return true
   elseif (type(attribute) == "table") then
       local k, v
       for k, v in pairs(attribute) do
           if (string.find(v, pattern) ~= nil) then
               return true
           end
       end
   end
   return false
end)()
```

Antivirus Example

The following example uses a custom function to check if CSD detects any antivirus software.

```
assert(function()
    for k,v in pairs(endpoint.av) do
         if (EVAL(v.exists, "EQ", "true", "string")) then
              return true
         end
    end
    return false
end)()
```

Antispyware Example

The following example uses a custom function to check if CSD detects any antispyware.

```
assert(function()
    for k,v in pairs(endpoint.as) do
         if (EVAL(v.exists, "EQ", "true", "string")) then
              return true
         end
    end
    return false
end)()
```

Firewall Example

The following example uses a custom function to check if CSD detects a firewall.

```
assert(function()
    for k,v in pairs(endpoint.fw) do
         if (EVAL(v.exists, "EQ", "true", "string")) then
              return true
         end
    end
    return false
end)()
```

Antivirus, Antispyware, *or* any Firewall Example

The following example uses a custom function to check if CSD detects any antivirus, antispyware, or any firewall.

```
assert(function()
       function check(antix)
           if (type(antix) == "table") then
               for k,v in pairs(antix) do
                   if (EVAL(v.exists, "EQ", "true", "string")) then
                       return true
                   end
               end
           end
           return false
       end
       return (check(endpoint.av) or check(endpoint.fw) or check(endpoint.as))
   end)()
```

CheckAndMsg with Custom Function Example

You can use the following function to deny access in the absence of an antivirus program. Use it with a DAP that has Action set to terminate.

```
assert( function()
for k,v in pairs(endpoint.av) do
    if (EVAL(v.exists, "EQ", "true", "string")) then
        return false
    end
    end
    return CheckAndMsg(true, "Please install antivirus software before connecting.", nil)
end)()
```

If a user lacking an antivirus program attempts to log in, DAP displays the following message:

```
Please install antivirus software before connecting.
```

Further Information on Lua

You can find detailed LUA programming information at http://www.lua.org/manual/5.1/manual.html.

Operator for Endpoint Category

You can configure multiple instances of each type of endpoint. In this pane, set each type of endpoint to require only one instance of a type (Match Any = OR) or to have all instances of a type (Match All = AND).

- If you configure only one instance of an endpoint category, you do not need to set a value.
- For some endpoint attributes, it makes no sense to configure multiple instances. For example, no users have more than one running OS.
- You are configuring the Match Any/Match All operation within each endpoint type.

The security appliance evaluates each type of endpoint attribute, and then performs a logical AND operation on all of the configured endpoints. That is, each user must satisfy the conditions of ALL of the endpoints you configure, as well as the AAA attributes.

DAP Examples

The following sections provide examples of useful dynamic access policies.

- Using DAP to Define Network Resources
- Using DAP to Apply a WebVPN ACL
- Enforcing CSD Checks and Applying Policies via DAP

Using DAP to Define Network Resources

This example shows how to configure dynamic access policies as a method of defining network resources for a user or group. The DAP policy named Trusted_VPN_Access permits clientless and AnyConnect VPN access. The policy named Untrusted_VPN_Access permits only clientless VPN access. Table 89-3 summarizes the configuration of each of these policies.

The ASDM path is Configuration > Remote Access VPN > Clientless SSL VPN Access > Dynamic Access Policies > Add/Edit Dynamic Access Policy > Endpoint

Table 89-3 A Simple DAP Configuration for Network Resources

Attribute	Trusted_VPN_Access	Untrusted_VPN_Access
Endpoint Attribute Type Policy	Trusted	Untrusted
Endpoint Attribute Process	ieexplore.exe	—
Advanced Endpoint Assessment	AntiVirus= McAfee Attribute	
CSD Location	Trusted	Untrusted
LDAP memberOf	Engineering, Managers	Vendors
ACL		Web-Type ACL
Access	**AnyConnect** *and* **Web Portal**	**Web Portal**

Using DAP to Apply a WebVPN ACL

DAP can directly enforce a subset of access policy attributes including Network ACLs (for IPsec and AnyConnect), clientless SSL VPN Web-Type ACLs, URL lists, and Functions. It cannot directly enforce, for example, a banner or the split tunnel list, which the group policy enforces. The Access Policy Attributes tabs in the Add/Edit Dynamic Access Policy pane provide a complete menu of the attributes DAP directly enforces.

Active Directory/LDAP stores user group policy membership as the "memberOf" attribute in the user entry. You can define a DAP such that for a user in AD group (memberOf) = Engineering the ASA applies a configured Web-Type ACL. To accomplish this task, perform the following steps:

Step 1 Navigate to the Add AAA attributes pane (Configuration > Remote Access VPN > Clientless SSL VPN Access > Dynamic Access Policies > Add/Edit Dynamic Access Policy > AAA Attributes section > Add AAA Attribute).

Step 2 For the AAA Attribute type, use the drop-down menu to choose LDAP.

Step 3 In the Attribute ID field, enter memberOf, exactly as you see it here. Case is important.

Step 4 In the Value field, use the drop-down menu to choose =, and in the adjacent field enter Engineering.

Step 5 In the Access Policy Attributes area of the pane, click the Web-Type ACL Filters tab.

Step 6 Use the Web-Type ACL drop-down menu to select the ACL you want to apply to users in the AD group (memberOf) = Engineering.

Enforcing CSD Checks and Applying Policies via DAP

This example creates a DAP that checks that a user belongs to two specific AD/LDAP groups (Engineering and Employees) and a specific ASA tunnel group. It then applies an ACL to the user.

The ACLs that DAP applies control access to the resources. They override any ACLS defined the group policy on the ASA. In addition, the ASA applied the regular AAA group policy inheritance rules and attributes for those that DAP does not define or control, examples being split tunneling lists, banner, and DNS. To accomplish this task, perform the following steps.

Step 1 Navigate to the Add AAA attributes pane (Configuration > Remote Access VPN > Clientless SSL VPN Access > Dynamic Access Policies > Add/Edit Dynamic Access Policy > AAA Attributes section > Add AAA Attribute).

Step 2 For the AAA Attribute type, use the drop-down menu to choose LDAP.

Step 3 In the Attribute ID field, enter memberOf, exactly as you see it here. Case is important.

Step 4 In the Value field, use the drop-down menu to choose =, and in the adjacent field enter Engineering.

Step 5 In the Attribute ID field, enter memberOf, exactly as you see it here. Case is important.

Step 6 In the Value field, use the drop-down menu to select =, and in the adjacent field enter Employees.

Step 7 For the AAA attribute type, use the drop-down menu to choose Cisco.

Step 8 Check the Tunnel group box, use the drop-down menu to choose =, and in the adjacent drop-down list select the appropriate tunnel group (connection policy).

Step 9 In the Network ACL Filters tab of the Access Policy Attributes area, choose the ACLs to apply to users who meet the DAP criteria defined in the previous steps.

Clientless SSL VPN End User Set-up

This section is for the system administrator who sets up Clientless (browser-based) SSL VPN for end users. It summarizes configuration requirements and tasks for the user remote system. It also specifies information to communicate to users to get them started using Clientless SSL VPN. This section includes the following topics:

- Requiring Usernames and Passwords
- Communicating Security Tips
- Configuring Remote Systems to Use Clientless SSL VPN Features
- Capturing Clientless SSL VPN Data

Note We assume you have already configured the ASA for Clientless SSL VPN. For further information see Configuring Clientless SSL VPN Access, page 91-6.

Requiring Usernames and Passwords

Depending on your network, during a remote session users may have to log in to any or all of the following: the computer itself, an Internet service provider, Clientless SSL VPN, mail or file servers, or corporate applications. Users may have to authenticate in many different contexts, requiring different information, such as a unique username, password, or PIN. Ensure users have the required access.

Table 90-1 lists the type of usernames and passwords that Clientless SSL VPN users might need to know.

Table 90-1 Usernames and Passwords to Give to Clientless SSL VPN Users

Login Username/ Password Type	Purpose	Entered When
Computer	Access the computer	Starting the computer
Internet Service Provider	Access the Internet	Connecting to an Internet service provider
Clientless SSL VPN	Access remote network	Starting a Clientless SSL VPN session
File Server	Access remote file server	Using the Clientless SSL VPN file browsing feature to access a remote file server

Table 90-1 Usernames and Passwords to Give to Clientless SSL VPN Users (continued)

Login Username/ Password Type	Purpose	Entered When
Corporate Application Login	Access firewall-protected internal server	Using the Clientless SSL VPN web browsing feature to access an internal protected website
Mail Server	Access remote mail server via Clientless SSL VPN	Sending or receiving e-mail messages

Communicating Security Tips

Advise users always to log out from the session. (To log out of Clientless SSL VPN, click the logout icon on the Clientless SSL VPN toolbar or close the browser.)

Advise users that using Clientless SSL VPN does not ensure that communication with every site is secure. Clientless SSL VPN ensures the security of data transmission between the remote PC or workstation and the ASA on the corporate network. If a user then accesses a non-HTTPS web resource (located on the Internet or on the internal network), the communication from the corporate ASA to the destination web server is not secure.

Configuring Remote Systems to Use Clientless SSL VPN Features

Table 90-2 includes the following information about setting up remote systems to use Clientless SSL VPN:

- Starting Clientless SSL VPN
- Using the Clientless SSL VPN Floating Toolbar
- Web Browsing
- Network Browsing and File Management
- Using Applications (Port Forwarding)
- Using email via Port Forwarding, Web Access, or Email Proxy

Table 90-2 also provides information about the following:

- Clientless SSL VPN requirements, by feature
- Clientless SSL VPN supported applications
- Client application installation and configuration requirements
- Information you might need to provide end users
- Tips and use suggestions for end users

It is possible you have configured user accounts differently and that different features are available to each Clientless SSL VPN user. Table 90-2 organizes information by user activity, so you can skip over the information for unavailable features.

Table 90-2 Clientless SSL VPN Remote System Configuration and End User Requirements

Task	Remote System or End User Requirements	Specifications or Use Suggestions
Starting Clientless SSL VPN	Connection to the Internet	Any Internet connection is supported, including: • Home DSL, cable, or dial-ups • Public kiosks • Hotel hook-ups • Airport wireless nodes • Internet cafes
	Clientless SSL VPN-supported browser	We recommend the following browsers for Clientless SSL VPN. Other browsers might not fully support Clientless SSL VPN features. On Microsoft Windows: • Internet Explorer 8 • Firefox 8 On Linux: • Firefox 8 On Mac OS X: • Safari 5 • Firefox 8
	Cookies enabled on browser	Cookies must be enabled on the browser in order to access applications via port forwarding.
	URL for Clientless SSL VPN	An https address in the following form: https://*address* where *address* is the IP address or DNS hostname of an interface of the ASA (or load balancing cluster) on which Clientless SSL VPN is enabled. For example: https://10.89.192.163 or https://cisco.example.com.
	Clientless SSL VPN username and password	
	[Optional] Local printer	Clientless SSL VPN does not support printing from a web browser to a network printer. Printing to a local printer is supported.

Table 90-2 Clientless SSL VPN Remote System Configuration and End User Requirements (continued)

Task	Remote System or End User Requirements	Specifications or Use Suggestions
Using the Floating Toolbar in a Clientless SSL VPN Connection		A floating toolbar is available to simplify the use of Clientless SSL VPN. The toolbar lets you enter URLs, browse file locations, and choose preconfigured web connections without interfering with the main browser window. If you configure your browser to block popups, the floating toolbar cannot display. The floating toolbar represents the current Clientless SSL VPN session. If you click the **Close** button, the ASA prompts you to confirm that you want to close the Clientless SSL VPN session. **Tip** TIP: To paste text into a text field, use Ctrl-V. (Right-clicking is disabled on the Clientless SSL VPN toolbar.)
Web Browsing	Usernames and passwords for protected websites	Using Clientless SSL VPN does not ensure that communication with every site is secure. See "Communicating Security Tips." The look and feel of web browsing with Clientless SSL VPN might be different from what users are accustomed to. For example: • The Clientless SSL VPN title bar appears above each web page. • You access websites by: – Entering the URL in the Enter Web Address field on the Clientless SSL VPN Home page. – Clicking on a preconfigured website link on the Clientless SSL VPN Home page. – Clicking a link on a webpage accessed via one of the previous two methods. Also, depending on how you configured a particular account, it might be that: • Some websites are blocked. • Only the web sites that appear as links on the Clientless SSL VPN Home page are available.

Table 90-2 Clientless SSL VPN Remote System Configuration and End User Requirements (continued)

Task	Remote System or End User Requirements	Specifications or Use Suggestions
Network Browsing and File Management	File permissions configured for shared remote access	Only shared folders and files are accessible via Clientless SSL VPN.
	Server name and passwords for protected file servers	—
	Domain, workgroup, and server names where folders and files reside	Users might not be familiar with how to locate their files through your organization network.
	—	Do not interrupt the **Copy File to Server** command or navigate to a different screen while the copying is in progress. Interrupting the operation can cause an incomplete file to be saved on the server.

Table 90-2 Clientless SSL VPN Remote System Configuration and End User Requirements (continued)

Task	Remote System or End User Requirements	Specifications or Use Suggestions
Using Applications (called Port Forwarding or Application Access)	**Note** On Macintosh OS X, only the Safari browser supports this feature.	
	Note Because this feature requires installing Oracle Java Runtime Environment (JRE) and configuring the local clients, and because doing so requires administrator permissions on the local system, it is unlikely that users will be able to use applications when they connect from public remote systems.	
	Caution Users should always close the Application Access window when they finish using applications by clicking the **Close** icon. Failure to quit the window properly can cause Application Access or the applications themselves to be disabled.	
	Client applications installed	—
	Cookies enabled on browser	—
	Administrator privileges	User must have administrator access on the PC if you use DNS names to specify servers because modifying the hosts file requires it.
	Oracle Java Runtime Environment (JRE) version 1.4.x and 1.5.x installed. JavaScript must be enabled on the browser. By default, it is enabled.	If JRE is not installed, a pop-up window displays, directing users to a site where it is available. On rare occasions, the port forwarding applet fails with Java exception errors. If this happens, do the following: 1. Clear the browser cache and close the browser. 2. Verify that no Java icons are in the computer task bar. Close all instances of Java. 3. Establish a Clientless SSL VPN session and launch the port forwarding Java applet.
	Client applications configured, if necessary. **Note** The Microsoft Outlook client does not require this configuration step. All non-Windows client applications require configuration. To see if configuration is necessary for a Windows application, check the value of the Remote Server. • If the Remote Server contains the server hostname, you do not need to configure the client application. • If the Remote Server field contains an IP address, you must configure the client application.	To configure the client application, use the server's locally mapped IP address and port number. To find this information: 1. Start Clientless SSL VPN on the remote system and click the Application Access link on the Clientless SSL VPN Home page. The Application Access window appears. 2. In the Name column, find the name of the server you want to use, then identify its corresponding client IP address and port number (in the Local column). 3. Use this IP address and port number to configure the client application. Configuration steps vary for each client application.
	Note Clicking a URL (such as one in an -e-mail message) in an application running over Clientless SSL VPN does not open the site over Clientless SSL VPN. To open a site over Clientless SSL VPN, cut and paste the URL into the Enter (URL) Address field.	

Table 90-2 Clientless SSL VPN Remote System Configuration and End User Requirements (continued)

Task	Remote System or End User Requirements	Specifications or Use Suggestions
Using E-mail via Application Access	Fulfill requirements for Application Access (See Using Applications)	To use mail, start Application Access from the Clientless SSL VPN Home page. The mail client is then available for use.
	Note If you are using an IMAP client and you lose your mail server connection or are unable to make a new connection, close the IMAP application and restart Clientless SSL VPN.	
	Other mail clients	We have tested Microsoft Outlook Express versions 5.5 and 6.0. Clientless SSL VPN should support other SMTPS, POP3S, or IMAP4S e-mail programs via port forwarding, such as Lotus Notes, and Eudora, but we have not verified them.
Using E-mail via Web Access	Web-based e-mail product installed	Supported products include: • Outlook Web Access For best results, use OWA on Internet Explorer 8.x or higher, or Firefox 8.x. • Lotus iNotes Other web-based e-mail products should also work, but we have not verified them.
Using E-mail via E-mail Proxy	SSL-enabled mail application installed Do not set the ASA SSL version to TLSv1 Only. Outlook and Outlook Express do not support TLS.	Supported mail applications: • Microsoft Outlook • Microsoft Outlook Express versions 5.5 and 6.0 Other SSL-enabled mail clients should also work, but we have not verified them.
	Mail application configured	

Capturing Clientless SSL VPN Data

The CLI capture command lets you log information about websites that do not display properly over a Clientless SSL VPN connection. This data can help your Cisco customer support engineer troubleshoot problems. The following sections describe how to use the capture command:

- Creating a Capture File
- Using a Browser to Display Capture Data

Note Enabling Clientless SSL VPN capture affects the performance of the security appliance. Be sure to disable the capture after you generate the capture files needed for troubleshooting.

Creating a Capture File

Perform the following steps to capture data about a Clientless SSL VPN session to a file.

Step 1 To start the Clientless SSL VPN capture utility, use the **capture** command from privileged EXEC mode.

capture *capture_name* **type webvpn user** *webvpn_username*

where:

- *capture_name* is a name you assign to the capture, which is also prepended to the name of the capture files.
- *webvpn_user* is the username to match for capture.

The capture utility starts.

Step 2 A user logs in to begin a Clientless SSL VPN session. The capture utility is capturing packets.

Stop the capture by using the **no** version of the command.

no capture *capture_name*

The capture utility creates a *capture_name*.zip file, which is encrypted with the password **koleso**.

Step 3 Send the .zip file to Cisco Systems, or attach it to a Cisco TAC service request.

Step 4 To look at the contents of the .zip file, unzip it using the password **koleso**.

The following example creates a capture named *hr*, which captures Clientless SSL VPN traffic for user2 to a file:

```
hostname# capture hr type webvpn user user2
WebVPN capture started.
   capture name   hr
   user name      user2
hostname# no capture hr
```

Using a Browser to Display Capture Data

Perform the following steps to capture data about a Clientless SSL VPN session and view it in a browser.

Step 1 To start the Clientless SSL VPN capture utility, use the **capture** command from privileged EXEC mode.

capture *capture_name* **type webvpn user** *webvpn_username*

where:

- *capture_name* is a name you assign to the capture, which is also prepended to the name of the capture files.
- *webvpn_username* is the username to match for capture.

The capture utility starts.

Step 2 A user logs in to begin a Clientless SSL VPN session. The capture utility is capturing packets.

Stop the capture by using the **no** version of the command.

Step 3 Open a browser and in the address box enter

https://*IP_address or hostname of the ASA***/webvpn_capture.html**

The captured content displays in a sniffer format.

Step 4 When you finish examining the capture content, stop the capture by using the **no** version of the command.

Configuring Clientless SSL VPN

This chapter describes how to configure clientless SSL VPN and includes the following sections:

- Information About Clientless SSL VPN, page 91-2
- Licensing Requirements, page 91-2
- Prerequisites for Clientless SSL VPN, page 91-5
- Guidelines and Limitations, page 91-5
- Configuring Clientless SSL VPN Access, page 91-6
- Configuring the Setup for Cisco Secure Desktop, page 91-13
- Configuring Application Profile Customization Framework, page 91-15
- Using Auto Signon, page 91-25
- Configuring Session Settings, page 91-28
- Java Code Signer, page 91-28
- Encoding, page 91-29
- Content Cache, page 91-30
- Content Rewrite, page 91-31

- Customizing the AnyConnect Client, page 91-131

- Configuring Bookmarks, page 91-140
- Sending an Administrator's Alert to Clientless SSL VPN Users, page 91-149

Information About Clientless SSL VPN

Note When the ASA is configured for clientless SSL VPN, you cannot enable security contexts (also called firewall multimode) or Active/Active stateful failover. Therefore, these features become unavailable.

Clientless SSL VPN lets users establish a secure, remote-access VPN tunnel to an ASA using a web browser. Users do not need a software or hardware client.

Clientless SSL VPN provides secure and easy access to a broad range of web resources and both web-enabled and legacy applications from almost any computer that can reach HTTP Internet sites. They include:

- Internal websites
- Web-enabled applications
- NT/Active Directory file shares
- E-mail proxies, including POP3S, IMAP4S, and SMTPS
- Microsoft Outlook Web Access Exchange Server 2000, 2003, and 2007
- Microsoft Web App to Exchange Server 2010 in 8.4(2) and later.
- Application Access (that is, smart tunnel or port forwarding access to other TCP-based applications)

Clientless SSL VPN uses Secure Sockets Layer Protocol and its successor, Transport Layer Security (SSL/TLS1) to provide the secure connection between remote users and specific, supported internal resources that you configure at an internal server. The ASA recognizes connections that need to be proxied, and the HTTP server interacts with the authentication subsystem to authenticate users.

The network administrator provides access to resources by users of clientless SSL VPN sessions on a group basis. Users have no direct access to resources on the internal network.

Licensing Requirements

The following table shows the licensing requirements for this feature:

Note This feature is not available on No Payload Encryption models.

Model	License Requirement[1,2]
ASA 5505	AnyConnect Premium license: • Base License or Security Plus license: 2 sessions. • *Optional permanent or time-based licenses: 10 or 25 sessions.* • *Shared licenses are not supported.*[3]
ASA 5510	AnyConnect Premium license: • Base and Security Plus License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, or 250 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5520	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, or 750 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5540	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, or 2500 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5550	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, or 5000 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5580	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, 5000, or 10000 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5512-X	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, or 250 sessions.* • *Optional Shared licenses*[3]*: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*

Model	License Requirement[1,2]
ASA 5515-X	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, or 250 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5525-X	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, or 750 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5545-X	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, or 2500 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5555-X	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, or 5000 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5585-X with SSP-10	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, or 5000 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASA 5585-X with SSP-20, -40, and -60	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, 5000, or 10000 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*
ASASM	AnyConnect Premium license: • Base License: 2 sessions. • *Optional permanent or time-based licenses: 10, 25, 50, 100, 250, 500, 750, 1000, 2500, 5000, or 10000 sessions.* • *Optional Shared licenses[3]: Participant or Server. For the Server license, 500-50,000 in increments of 500 and 50,000-545,000 in increments of 1000.*

1. If you start a clientless SSL VPN session and then start an AnyConnect client session from the portal, 1 session is used in total. However, if you start the AnyConnect client first (from a standalone client, for example) and then log into the clientless SSL VPN portal, then 2 sessions are used.
2. The maximum combined VPN sessions of *all* types cannot exceed the maximum sessions shown in this table.
3. A shared license lets the ASA act as a shared license server for multiple client ASAs. The shared license pool is large, but the maximum number of sessions used by each individual ASA cannot exceed the maximum number listed for permanent licenses.

Prerequisites for Clientless SSL VPN

See the *Supported VPN Platforms, Cisco ASA 5500 Series* for the platforms and browsers supported by ASA Release 9.0.

Guidelines and Limitations

- ActiveX pages require that you enable ActiveX Relay or enter **activex-relay** on the associated group policy. If you do so or assign a smart tunnel list to the policy, and the browser proxy exception list on the endpoint specifies a proxy, the user must add a “shutdown.webvpn.relay.” entry to that list.
- The ASA does not support clientless access to Windows Shares (CIFS) Web Folders from Windows 7, Vista, Internet Explorer 8-9, Mac OS X, and Linux.
- Certificate authentication, including the DoD Common Access Card and SmartCard, works with the Safari keychain only.
- The ASA does not support DSA or RSA certificates for clientless SSL VPN connections.
- Some domain-based security products have requirements above those requests that originate from the ASA.
- Inspecting configuration control and other inspection features under the Modular Policy Framework are not supported.
- Neither NAT or PAT is applicable to the client.
- Some components of Clientless SSL VPN require the Java Runtime Environment (JRE).With Mac OS X v10.7 and later Java is not installed by default. For details of how to install Java on Mac OS X see http://java.com/en/download/faq/java_mac.xml.
- If you have several group policies configured for the clientless portal, they are displayed in a drop-down on the logon page. If the top of the list of group policies is one that requires a certificate, then as soon as the user gets to the logon page, they must have a matching certificate. If not all your group policies use certificates, then configure the list to display a non-certificate policy first. Name your group polices to sort alphabetically, or prefix them with numbers so an AAA policy shows up first. For example, 1-AAA, 2-Certificate. Or, create a "dummy" group policy named Select-a-Group, and make sure that shows up first.

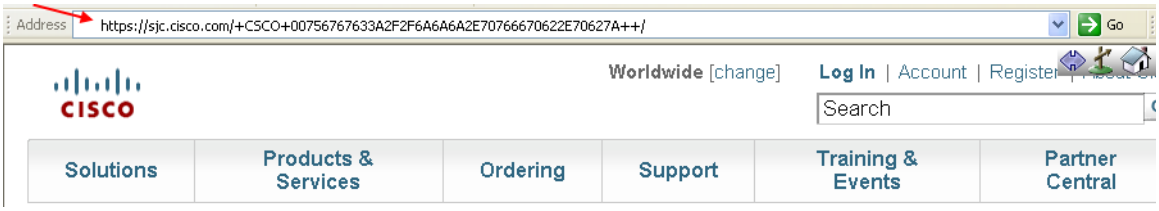
Observing Clientless SSL VPN Security Precautions

By default, the ASA permits all portal traffic to all web resources (e.g., HTTPS, CIFS, RDP, and plug-ins). The ASA clientless service rewrites each URL to one that is meaningful only to itself; the user cannot use the rewritten URL displayed on the page accessed to confirm that they are on the site they requested. To avoid placing users at risk, assign a web ACL to the policies configured for clientless

access – group-policies, dynamic access policies, or both – to control traffic flows from the portal. For example, without such an ACL, users could receive an authentication request from an outside fraudulent banking or commerce site. Also, we recommend disabling URL Entry on these policies to prevent user confusion over what is accessible.

Figure 91-1 Example URL Typed by User

Figure 91-2 Same URL Rewritten by Security Appliance and displayed on the Browser Window



Detailed Steps

We recommend that you do the following to minimize risks posed by clientless SSL VPN access:

Step 1 Configure a group policy for all users who need clientless SSL VPN access, and enable clientless SSL VPN only for that group policy.

Step 2 With the group policy open, choose **General > More Options > Web ACL** and click **Manage**.

Step 3 Create a web ACL to do one of the following: permit access only to specific targets within the private network, permit access only to the private network, deny Internet access, or permit access only to reputable sites.

Step 4 Assign the web ACL to any policies (group policies, dynamic access policies, or both) that you have configured for clientless access. To assign a web ACL to a DAP, edit the DAP record, and select the web ACL on the **Network ACL Filters** tab.

Step 5 Disable URL entry on the *portal page*, the page that opens upon the establishment of a browser-based connection. To do so, click **Disable** next to URL Entry on both the group policy Portal frame and the DAP **Functions** tab. To disable URL entry on a DAP, use ASDM to edit the DAP record, click the **Functions** tab, and check **Disable** next to URL Entry

Step 6 Instruct users to enter external URLs in the native browser address field above the portal page or open a separate browser window to visit external sites.

Configuring Clientless SSL VPN Access

When configuring Clientless SSL VPN access, you can do the following:

- Enable or disable ASA interfaces for clientless SSL VPN sessions.
- Choose a port for clientless SSL VPN connections.
- Set a maximum number of simultaneous clientless SSL VPN sessions.

Detailed Steps

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies** pane to configure or create a group policy for clientless access.

Step 2 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Connection Profiles**.

a. Enable or disable **Allow Access** for each ASA interface.

The Interface columns lists the configured interfaces. The WebVPN Enabled field displays the current status for clientless SSL VPN on the interface. (A green check next to Yes indicates that clientless SSL VPN is enabled. A red circle next to No indicates that clientless SSL VPN is disabled.

b. Click the **Port Setting** button, and enter the port number that you want to use for clientless SSL VPN sessions. The default port is 443, for HTTPS traffic; the range is 1 through 65535. If you change the port number, all current clientless SSL VPN connections terminate, and current users must reconnect. You also lose connectivity to ASDM, and a prompt displays, inviting you to reconnect.

Step 3 Navigate to **Configuration > Remote Access VPN > Advanced > Maximum VPN Sessions**, and enter the maximum number of clientless SSL VPN sessions you want to allow in the Maximum Other VPN Sessions field. Be aware that the different ASA models support clientless SSL VPN sessions as follows: ASA 5510 supports a maximum of 250; ASA 5520 maximum is 750; ASA 5540 maximum is 2500; ASA 5550 maximum is 5000.

Clientless SSL VPN Server Certificate Verification

When connecting to a remote SSL-enabled server through clientless SSL VPN, it is important to know that you can trust the remote server, and that it is in fact the server you are trying to connect to. ASA 9.0 introduces support for SSL server certificate verification against a list of trusted certificate authority (CA) certificates for clientless SSL VPN.

When you connect to a remote server via a web browser using the HTTPS protocol, the server will provide a digital certificate signed by a CA to identify itself. Web browsers ship with a collection of CA certificates which are used to verify the validity of the server certificate. This is a form of public key infrastructure (PKI).

Just as browsers provide certificate management facilities, so does the ASA in the form of trusted certificate pool management facility: trustpools. This can be thought of as a special case of trustpoint representing multiple known CA certificates. The ASA includes a default bundle of certificates, similar to that provided with web browsers, but it is inactive until activated by the administrator.

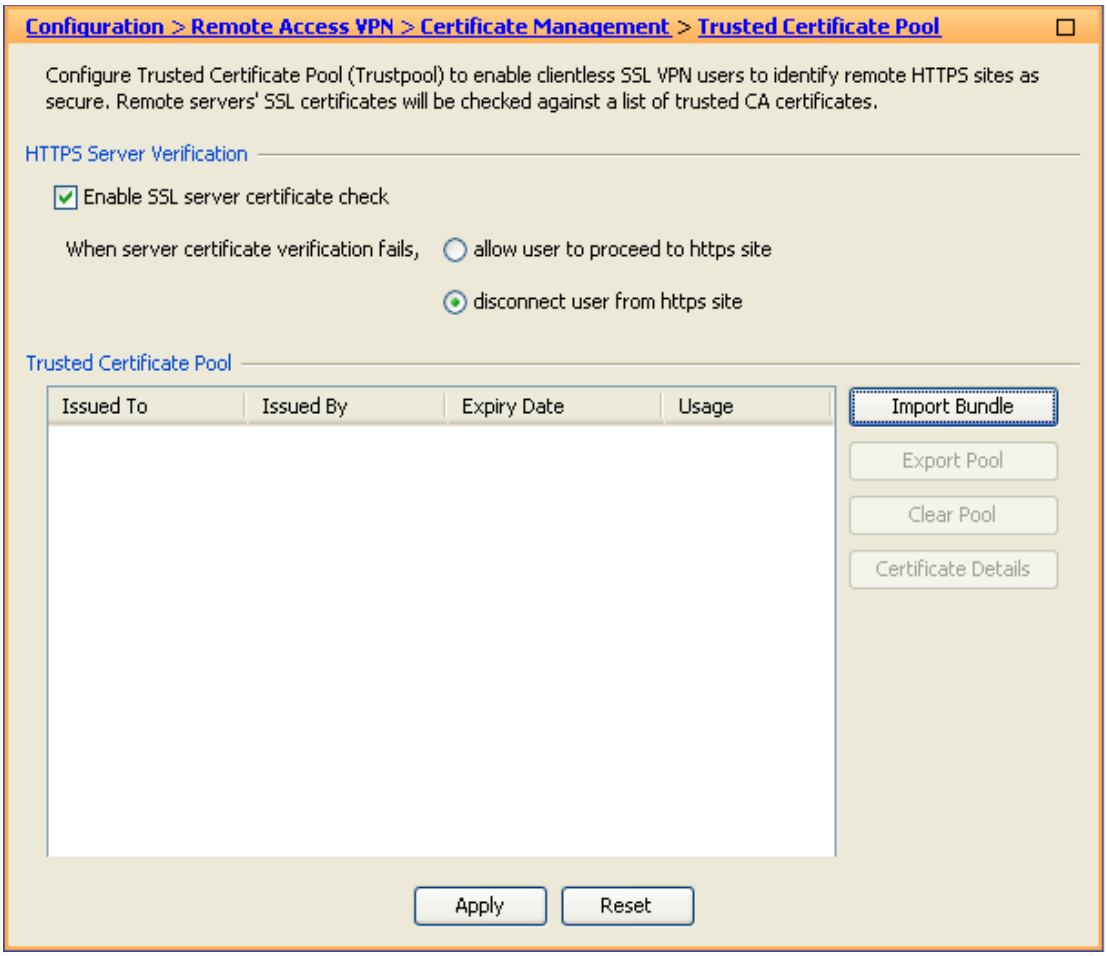
Note If you are already familiar with trustpools from Cisco IOS then you should be aware that the ASA version is similar, but not identical.

Enabling HTTP Server Verification

To enable HTTPS Server Verification for Clientless SSL VPN users:

Step 1 In the ASDM, navigate to **Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool**.

Figure 91-3 Enabling HTTPS Server Verification in the ASDM



Step 2 Select the **Enable SSL Certificate check** check box.

Step 3 You must decide which action you want to be taken if server certificate verification fails. Click **disconnect user from https site** to disconnect if the server could not be verified. Alternatively, click **allow user to proceed to https site** to allow the user to continue the connection, even if the check failed.

Step 4 Click **Apply** to save your changes.

Importing a Certificate Bundle

You can import individual certificates or bundles of certificates from a variety of locations in one of the following formats:

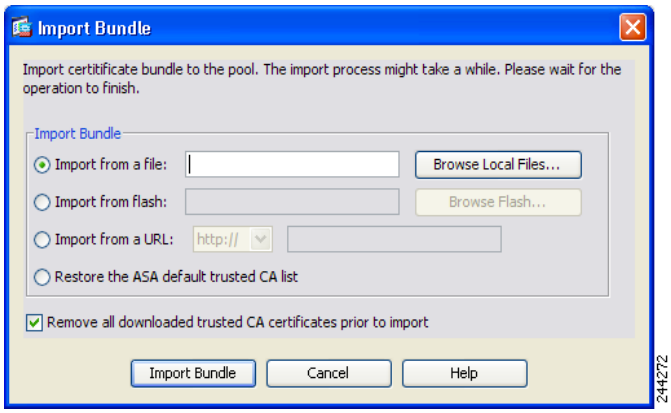
- x509 certificates in DER format wrapped in a pkcs7 structure

- a file of concatenated x509 certificates in PEM format (complete with PEM header)

To import a certificate or bundle:

Step 1 In the ASDM, navigate to **Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool**.

Step 2 Click **Import Bundle**.



Step 3 Select the location of the bundle:

- If the bundle is stored on your machine, click **Import from a file**, then click **Browse Local Files** and navigate to the bundle.
- If the bundle is stored on the ASA flash file system, click **Import from flash**, then click **Browse Flash** and navigate to the file.
- If the bundle is hosted on a server, click **Import from a URL**, select the protocol from the list, and enter the URL in the box.

Step 4 Click **Import Bundle**. Alternatively, click **Cancel** to abandon your changes.

Note You can select the **Remove all downloaded trusted CA certificates prior to import** check box to clear the trustpool before importing a new bundle.

Exporting the Trustpool

When you have correctly configured the Trustpool you should export the pool. This will enable you to restore the Trustpool to this point, for example if you wish to remove a certificate that was added to the trustpool after the export. You can export the pool to the ASA flash file system or your local file system.

In the ASDM, navigate to **Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool**, then click **Export Pool**.

To export to the local file system:

Step 1 Click **Export to a file**.

Step 2 Click **Browse Local Files.**

Step 3 Navigate to the folder where you want to save the trustpool.

Step 4 Enter a unique memorable name for the trustpool in the **File name** box.

Step 5 Click **Select**.

Step 6 Click **Export Pool** to save the file. Alternatively, click **Cancel** to stop saving.

Removing Certificates

To remove all certificates, in the ASDM, navigate to **Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool**, then click **Clear Pool**.

Note Before clearing the trustpool you should export the current trustpool to enable you to restore your current settings.

Restoring the Default Trusted Certificate Authority List

To restore the default trusted Certificate Authority (CA) list, in the ASDM, navigate to **Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool**, then click **Restore default trusted CA list** and click **Import Bundle**.

Updating the Trustpool

The trustpool should be updated if either of the following conditions exists:

- Any certificate in the trustpool is due to expire or has been re-issued.
- The published CA certificate bundle contains additional certificates that are required by a specific application.

A full update will replace all the certificates in the trustpool.

A practical update enables you to add new certificates or replace existing certificates.

Removing a Certificate Bundle

Clearing the trustpool removal will remove all certificates that are not part of the default bundle.

You cannot remove the default bundle. To clear the trustpool, in the ASDM, navigate to Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool, then click Clear Pool.

Note

	Command	Purpose
Step 1	`webvpn`	Switches to group policy webvpn configuration mode.
Step 2	`url-entry disable`	Disables URL entry.

Configuring ACLs

ACLs constrain user access to specific networks, subnets, hosts, and web servers. The Web ACLs table displays the filters configured on the ASA application to the clientless SSL VPN traffic. The table shows the name of each access control list (ACL), and below and indented to the right of the ACL name, the ACEs (access control entries) assigned to the ACL.

Each ACL permits or denies access to specific networks, subnets, hosts, and web servers. Each ACE specifies one rule that serves the function of the ACL.

Guidelines

If you do not define any filters, all connections are permitted.

Restrictions

- The ASA supports only an inbound ACL on an interface.
- At the end of each ACL, there is an implicit, unwritten rule that denies all traffic that is not permitted. If traffic is not explicitly permitted by an ACE (access control entry), the ASA denies it. ACEs are referred to as rules in this topic.

Detailed Steps

Web ACLs are configured on the page **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Web ACLs**.

Step 1 Click **Add ACL** to add an ACL or ACE. To insert a new ACE before or after an existing ACE, click **Insert** or **Insert After**.

Step 2 Click **Edit** to highlight the ACE you want to change.

Step 3 Highlight the ACL or ACE you want to remove and click **Delete**. When you delete an ACL, you must delete all of its ACEs. No warning is provided, and or undelete.

Step 4 Use the **Move Up** and **Move Down** buttons to change the order of ACLs or ACEs. The ASA checks ACLs to be applied to clientless SSL VPN sessions and their ACEs in the sequence determined by their position in the ACLs list until it finds a match.

Step 5 Click **+** to expand or **-** to collapse the list of ACEs under each ACL. The priority of the ACEs under each ACL is displayed. The order in the list determines priority.

Step 6 (Optional) Click **Find** to search for a web ACL. Start typing in the field, and the tool searches the beginning characters of every field for a match. You can use wild cards to expand your search. For example, typing *sal* in the Find field matches a web ACL named sales but not a customization object named wholesalers. If you type **sal* in the Find field, the search finds the first instance of either sales or wholesalers in the table.

Step 7 Use the up and down arrows to skip up or down to the next string match. Check the **Match Case** checkbox to make your search case sensitive.

Step 8 (Optional) Highlight a web ACL and click **Assign** to assign the selected web ACL to one or more VPN group policies, dynamic access policies, or user policies.

Step 9 When you create an ACE, by default it is enabled. Clear the check box to disable an ACE.

The IP address or URL of the application or service to which the ACE applies is displayed. The TCP service to which the ACE applies is also displayed. The Action field displays whether the ACE permits or denies clientless SSL VPN access. The time range associated with the ACE and the logging behavior (either disabled or with a specified level and time interval) is also displayed.

Adding or Editing ACEs

An Access Control Entry (or "access rule") permits or denies access to specific URLs and services. You can configure multiple ACEs for an ACL. ACLs apply ACEs in priority order, acting on the first match.

Detailed Steps

Step 1 Permit or deny access to specific networks, subnets, hosts, and web servers specified in the Filter group field.

Step 2 Specify a URL or an IP address to which you want to apply the filter (permit or deny user access):

- URL—Applies the filter to the specified URL.
- Protocols (unlabeled)—Specifies the protocol part of the URL address.
- ://x—Specifies the URL of the Web page to which to apply the filter.
- TCP—Applies the filter to the specified IP address, subnet, and port.
- IP Address—Specifies the IP address to which to apply the filter.
- Netmask—Lists the standard subnet mask to apply to the address in the IP Address field.
- Service—Identifies the service (such as https, kerberos, or any) to be matched. Displays a list of services from which you can select the service to display in the Service field.
- Boolean operator (unlabeled)—Lists the boolean conditions (equal, not equal, greater than, less than, or range) to use in matching the service specified in the service field.

Step 3 The Rule Flow Diagram graphically depicts the traffic flow using the filter. This area may be hidden.

Step 4 Specify the logging rules. The default is Default Syslog.

- Logging—Choose enable if you want to enable a specific logging level.
- Syslog Level—Grayed out until you select Enable for the Logging attribute. Lets you select the type of syslog messages you want the ASA to display.
- Log Interval—Lets you select the number of seconds between log messages.
- Time Range—Lets you select the name of a predefined time-range parameter set.
- ...—Click to browse the configured time ranges or to add a new one.

Configuration Examples for ACLs for Clientless SSL VPN

Examples

Here are examples of ACLs for clientless SSL VPN:

Action	Filter	Effect
Deny	url http://*.yahoo.com/	Denies access to all of Yahoo!
Deny	url cifs://fileserver/share/directory	Denies access to all files in the specified location.
Deny	url https://www.example.com/ directory/file.html	Denies access to the specified file.
Permit	url https://www.example.com/directory	Permits access to the specified location
Deny	url http://*:8080/	Denies HTTPS access to anywhere via port 8080.

Action	Filter	Effect
Deny	url http://10.10.10.10	Denies HTTP access to 10.10.10.10.
Permit	url any	Permits access to any URL. Usually used after an ACL that denies url access.

Configuring the Setup for Cisco Secure Desktop

The Cisco Secure Desktop Setup window displays the version and state of the Cisco Secure Desktop image if it is installed on the ASA, indicates whether it is enabled, and shows the size of the cache used to hold the Cisco Secure Desktop and SSL VPN Client on the ASA.

You can use the buttons in this window as follows:

To transfer a copy of a Cisco Secure Desktop image from your local computer to the flash device of the ASA, click **Upload**.

To prepare to install or upgrade Cisco Secure Desktop, use your Internet browser to download a securedesktop_asa_<*n*>_<*n*>*.pkg file from http://www.cisco.com/cgi-bin/tablebuild.pl/securedesktop to any location on your PC. Then use this button to transfer a copy from your local computer to the flash device. Click **Browse Flash** to install it into the running configuration. Finally, click **Enable Secure Desktop**.

- To install or replace the Cisco Secure Desktop image on the flash device of the ASA, click **Browse Flash**.

Note If you click **Browse Flash** to upgrade or downgrade the Cisco Secure Desktop image, select the package to install, and click **OK**, the Uninstall Cisco Secure Desktop dialog window asks you if you want to delete the Cisco Secure Desktop distribution currently in the running configuration from the flash device. Click **Yes** if you want to save space on the flash device, or click **No** to reserve the option to revert to this version of Cisco Secure Desktop.

- To remove the Cisco Secure Desktop image and configuration file (sdesktop/data.xml) from the running configuration, click **Uninstall**.

  If you click this button, the Uninstall Cisco Secure Desktop dialog window asks if you want to delete the Cisco Secure Desktop image that was named in the "Secure Desktop Image field" and all Cisco Secure Desktop data files (including the entire Cisco Secure Desktop configuration) from the flash device. Click **Yes** if you want to remove these files from both the running configuration and the flash device, or click **No** to remove them from the running configuration, but retain them on the flash device.

Detailed Steps

The Cisco Secure Desktop image loaded into the running configuration is displayed in the Location field. By default, the filename is in the format securedesktop_asa_<n>_<n>*.pkg.

Step 1 Click **Browse Flash** to insert or modify the value in this field.

Step 2 Click **Enable Secure Desktop** and click **Apply** to do the following:

a. Make sure the file is a valid Cisco Secure Desktop image.

b. Create an "sdesktop" folder on disk0 if one is not already present.

c. Insert a data.xml (Cisco Secure Desktop configuration) file into the sdesktop folder if one is not already present.

d. Load the data.xml file into the running configuration.

Note If you transfer or replace the data.xml file, disable and then enable Cisco Secure Desktop to load the file.

e. Enable Cisco Secure Desktop.

Uploading Images

The Upload Image dialog box lets you transfer a copy of a Cisco Secure Desktop image from your local computer to the flash device on the ASA. Use this window to install or upgrade Cisco Secure Desktop.

Prerequisites

- Before using this window, use your Internet browser to download a securedesktop_asa_<*n*>_<*n*>*.pkg file from http://www.cisco.com/cgi-bin/tablebuild.pl/securedesktop to any location on your local computer.

Detailed Steps

You can use the buttons in this window as follows:

- To choose the path of the securedesktop_asa_<*n*>_<*n*>*.pkg file to be transferred, click **Browse Local Files**. The Selected File Path dialog box displays the contents of the folder you last accessed on your local computer. Navigate to the securedesktop_asa_<*n*>_<*n*>*.pkg file, select it, and click **Open**.
- To select the target directory for the file, click **Browse Flash**. The Browse Flash dialog box displays the contents of the flash card.
- To uploads the securedesktop_asa_<*n*>_<*n*>*.pkg file from your local computer to the flash device, click **Upload File**. A Status window appears and remains open for the duration of the file transfer. Following the transfer, an Information window displays the message, “File is uploaded to flash successfully.” Click **OK**. The Upload Image dialog box removes the contents of the Local File Path and Flash File System Path fields.
- To close the Upload Image dialog box, click **Close**. Click this button after you upload the Cisco Secure Desktop image to the flash device or if you decide not to upload it. If you uploaded it, the filename appears in the Secure Desktop Image field of the Cisco Secure Desktop Setup window. If you did not upload it, a Close Message dialog box prompts, “Are you sure you want to close the dialog without uploading the file?” Click **OK** if you do not want to upload the file. The Close Message and Upload Image dialog boxes close, revealing the Cisco Secure Desktop Setup pane. Otherwise, click **Cancel** in the Close Message dialog box. The dialog box closes, revealing the Upload Image dialog box again, with the values in the fields intact. Click **Upload File**.

Step 1 Specify the path to the securedesktop_asa_<*n*>_<*n*>*.pkg file on your local computer. Click **Browse Local** to automatically insert the path in this field, or enter the path. For example:

D:\Documents and Settings*Windows_user_name*.AMER\My Documents\My Downloads\securedesktop_asa_3_1_1_16.pkg

ASDM inserts the file path into the Local File Path field.

Step 2 Specify the destination path on the flash device of the ASA and the name of the destination file. Click **Browse Flash** to automatically insert the path into this field, or enter the path. For example:

disk0:/securedesktop_asa_3_1_1_16.pkg

The file name of the Cisco Secure Desktop image that you selected on your local computer is displayed in the Browse Flash dialog box. We recommend that you use this name to prevent confusion. Confirm that this field displays the same name of the local file you selected and click **OK**. The Browse Flash dialog box closes. ASDM inserts the destination file path into the Flash File System Path field.

Configuring Application Profile Customization Framework

Clientless SSL VPN includes an Application Profile Customization Framework option that lets the ASA handle non-standard applications and web resources so they display correctly over a clientless SSL VPN connection. An APCF profile contains a script that specifies when (pre, post), where (header, body, request, response), and what (data) to transform for a particular application. The script is in XML and uses sed (stream editor) syntax to transform strings/text.

Multiple APCF profiles can run in parallel on an ASA. Within an APCF profile script, multiple APCF rules can apply. In this case, the ASA processes the oldest rule first (based on configuration history), then the next oldest rule, and so forth.

You can configure multiple APCF profiles on an ASA. Within an APCF profile script, multiple APCF rules can apply. The ASA processes the oldest rule first, based on configuration history, the next oldest rule next, and so forth.

You can store APCF profiles on the ASA flash memory, or on an HTTP, HTTPS, or TFTP server.

Restrictions

We recommend that you configure an APCF profile only with the assistance of Cisco personnel.

Managing APCF Profiles

You can store APCF profiles on the ASA flash memory or on an HTTP, HTTPS, FTP, or TFTP server. Use this pane to add, edit, and delete APCF packages, and to put them in priority order.

Step 1 Navigate to Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Application Helper, where you can perform the following functions.

- Click **Add/Edit** to create a new APCF profile or change an existing one.
  - Select **Flash file** to locate an APCF file stored on the ASA flash memory.

    Then click **Upload** to get an APCF file from a local computer to the ASA flash file system, or Browse to upload select an APCF file that is already in flash memory.
  - Select URL to retrieve the APCF file from an HTTP, HTTPS, FTP, or TFTP server.
- Click **Delete** to remove an existing APCF profile. No confirmation or undo exists.
- Click **Move Up** or **Move Down** to rearrange APCF profiles within the list. The order determines which the APCF profile is used.

Step 2 Click **Refresh** if you do not see the changes you made in the list.

Uploading APCF Packages

Detailed Steps

Step 1 The path to the APCF file on your computer is shown. Click **Browse Local** to automatically insert the path in this field, or enter the path.

Step 2 Click to locate and choose the APCF file on your computer that you want to transfer. The Select File Path dialog box displays the contents of the folder you last accessed on your local computer. Navigate to the APCF file, choose it, and click **Open**. ASDM inserts the file path into the Local File Path field.

Step 3 The path on the ASA to upload the APCF file is shown in the Flash File System Path. Click **Browse Flash** to identify the location on the ASA to which you want to upload the APCF file. The Browse Flash dialog box displays the contents of flash memory.

Step 4 The file name of the APCF file you selected on your local computer is displayed. We recommend that you use this name to prevent confusion. Confirm that this file displays the correct filename, and click **OK**. The Browse Flash dialog box closes. ASDM inserts the destination file path in the Flash File System Path field.

Step 5 Click **Upload File** when you have identified the location of the APCF file on your computer, and the location where you want to download it to the ASA.

Step 6 A Status window appears and remains open for the duration of the file transfer. Following the transfer, an Information window displays the message, "File is uploaded to flash successfully." Click **OK**. The Upload Image dialog window removes the contents of the Local File Path and Flash File System Path fields, indicating you can upload another file. To do so, repeat these instructions. Otherwise, click **Close**.

Step 7 Close the Upload Image dialog window. Click **Close** after you upload the APCF file to flash memory or if you decide not to upload it. If you do upload it, the filename appears in the APCF File Location field of the APCF window. If you do not upload it, a Close Message dialog box prompts, "Are you sure you want to close the dialog without uploading the file?" Click **OK** if you do not want to upload the file. The Close Message and Upload Image dialog boxes close, revealing the APCF Add/Edit pane. Otherwise, click **Cancel** in the Close Message dialog box. The dialog box closes, revealing the Upload Image dialog box again, with the values in the fields intact. Click **Upload File**.

Managing APCF Packets

Step 1 Use the following commands to add, edit, and delete APCF packets and put them in priority order:

- APCF File Location—Displays information about the location of the APCF package. This can be on the ASA flash memory, or on an HTTP, HTTPS, FTP, or TFTP server.
- Add/Edit—Click to add or edit a new or existing APCF profile.
- Delete—Click to remove an existing APCF profile. There is no confirmation or undo.
- Move Up—Click to rearrange APCF profiles within a list. The list determines the order in which the ASA attempts to use APCF profiles.

Step 2 Click **Flash file** to locate an APCF file stored on the ASA flash memory.

Step 3 Enter the path to an APCF file stored on flash memory. If you already added a path, it displays to an APCF file stored on flash memory after you browse to locate it.

Step 4 Click Browse Flash to browse flash memory to locate the APCF file. A Browse Flash Dialog pane displays. Use the Folders and Files columns to locate the APCF file. Highlight the APCF file and click **OK**. The path to the file then displays in the Path field.

Note If you do not see the name of an APCF file that you recently downloaded, click **Refresh**.

- Upload —Click to upload an APCF file from a local computer to the ASA flash file system. The Upload APCF package pane displays.
- URL—Click to use an APCF file stored on an HTTP, HTTPS or TFTP server.
- ftp, http, https, and tftp (unlabeled)—Identify the server type.
- URL (unlabeled)—Enter the path to the FTP, HTTP, HTTPS, or TFTP server.

APCF Syntax

APCF profiles use XML format, and sed script syntax, with the XML tags in Table 91-1.

Guidelines

Misuse of an APCF profile can result in reduced performance and undesired rendering of content. In most cases, Cisco Engineering supplies APCF profiles to solve specific application rendering issues.

Table 91-1 APCF XML Tags

Tag	Use
<APCF>...</APCF>	The mandatory root element that opens any APCF XML file.
<version>1.0</version>	The mandatory tag that specifies the APCF implementation version. Currently the only version is 1.0.
<application>...</application>	The mandatory tag that wraps the body of the XML description.
<id> text </id>	The mandatory tag that describes this particular APCF functionality.
<apcf-entities>...</apcf-entities>	The mandatory tag that wraps a single or multiple APCF entities.
<js-object>…</js-object> <html-object>…</html-object> <process-request-header>...</process-request-header> <process-response-header>...</process-response-header> <preprocess-response-body>...</preprocess-response-body> <postprocess-response-body>...</postprocess-response-body>	One of these tags specifies type of content or the stage at which the APCF processing should take place.

Table 91-1 APCF XML Tags (continued)

Tag	Use
<conditions>… </conditions>	A child element of the pre/post-process tags that specifies criteria for processing such as: http-version (such as 1.1, 1.0, 0.9) http-method (get, put, post, webdav) http-scheme (“http/”, “https/”, other) server-regexp regular expression containing ("a".."z" | "A".."Z" | "0".."9" | ".-_*[]?")) server-fnmatch (regular expression containing ("a".."z" | "A".."Z" | "0".."9" | ".-_*[]?+()\{},")), user-agent-regexp user-agent-fnmatch request-uri-regexp request-uri-fnmatch If more than one of condition tags is present, the ASA performs a logical AND for all tags.
<action> … </action>	Wraps one or more actions to perform on the content under specified conditions; you can use the following tags to define these actions (shown below): <do>, <sed-script>, <rewrite-header>, <add-header>, <delete-header>.
<do>…</do>	Child element of the action tag used to define one of the following actions: <no-rewrite/>—Do not mangle the content received from the remote server. <no-toolbar/>—Do not insert the toolbar. <no-gzip/>—Do not compress the content. <force-cache/>—Preserve the original caching instructions. <force-no-cache/>—Make object non-cacheable. < downgrade-http-version-on-backend>—Use HTTP/1.0 when sending the request to remote server.
<sed-script> TEXT </sed-script>	Child element of the action tag used to change the content of text-based objects. The Text must be a valid Sed script. The <sed-script> applies to the <conditions> tag defined before it.
<rewrite-header></rewrite-header>	Child element of the action tag. Changes the value of the HTTP header specified in the child element <header> tag shown below.
<add-header></add-header>	Child element of the action tag used to add a new HTTP header specified in the child element <header> tag shown below.

Table 91-1 APCF XML Tags (continued)

Tag	Use
<delete-header></delete-header>	Child element of the action tag used to delete the specified HTTP header specified by the child element <header> tag shown below.
<header></header>	Specifies the name HTTP header to be rewritten, added, or deleted. For example, the following tag changes the value of the HTTP header named Connection: <rewrite-header> <header>Connection</header> <value>close</value> </rewrite-header>

Configuration Examples for APCF

Example:

```
<APCF>
<version>1.0</version>
<application>
  <id>Do not compress content from example.com</id>
  <apcf-entities>
      <process-request-header>
         <conditions>
           <server-fnmatch>*.example.com</server-fnmatch>
         </conditions>
           <action>
             <do><no-gzip/></do>
           </action>
      </process-request-header>
  </apcf-entities>
</application>
</APCF>
```

Example:

```
<APCF>
<version>1.0</version>
<application>
 <id>Change MIME type for all .xyz objects</id>
 <apcf-entities>
      <process-response-header>
        <conditions>
            <request-uri-fnmatch>*.xyz</request-uri-fnmatch>
        </conditions>
         <action>
           <rewrite-header>
                <header>Content-Type</header>
                <value>text/html</value>
           </rewrite-header>
         </action>
      </process-response-header>
 </apcf-entities>
</application>
</APCF>
```

Managing Passwords

Optionally, you can configure the ASA to warn end users when their passwords are about to expire.

The ASA supports password management for the RADIUS and LDAP protocols. It supports the "password-expire-in-days" option for LDAP only.

You can configure password management for IPsec remote access and SSL VPN tunnel-groups.When you configure password management, the ASA notifies the remote user at login that the user's current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This command is valid for AAA servers that support such notification.

The ASA, releases 7.1 and later, generally supports password management for the following connection types when authenticating with LDAP or with any RADIUS configuration that supports MS-CHAPv2:

- AnyConnect VPN Client
- IPsec VPN Client
- Clientless SSL VPN

The RADIUS server (for example, Cisco ACS) could proxy the authentication request to another authentication server. However, from the ASA perspective, it is talking only to a RADIUS server.

Prerequisites

- Native LDAP requires an SSL connection. You must enable LDAP over SSL before attempting to do password management for LDAP. By default, LDAP uses port 636.

  If you are using an LDAP directory server for authentication, password management is supported with the Sun Java System Directory Server (formerly named the Sun ONE Directory Server) and the Microsoft Active Directory.

  Sun—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.

  Microsoft—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.Restrictions
- Some RADIUS servers that support MSCHAP currently do not support MSCHAPv2. This command requires MSCHAPv2 so check with your vendor.
- Password management is *not* supported for any of these connection types for Kerberos/Active Directory (Windows password) or NT 4.0 Domain.
- For LDAP, the method to change a password is proprietary for the different LDAP servers on the market. Currently, the ASA implements the proprietary password management logic only for Microsoft Active Directory and Sun LDAP servers.
- The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

Detailed Steps

Step 1 Navigate to Configuration > Remote Access VPN > Clientless SSL VPN Access > Connection Profiles > Add or Edit > Advanced > General > Password Management.

Step 2 Click the Enable password management option.

Adding the Cisco Authentication Scheme to SiteMinder

In addition to configuring the ASA for SSO with SiteMinder, you must also configure your CA SiteMinder Policy Server with the Cisco authentication scheme, a Java plug-in you download from the Cisco web site.

Prerequisites

Configuring the SiteMinder Policy Server requires experience with SiteMinder.

Detailed Steps

This section presents general tasks, not a complete procedure. To configure the Cisco authentication scheme on your SiteMinder Policy Server, perform the following steps:

Step 1 With the SiteMinder Administration utility, create a custom authentication scheme, being sure to use the following specific arguments:

- In the Library field, enter **smjavaapi**.
- In the Secret field, enter the same secret configured on the ASA.

  You configure the secret on the ASA using the **policy-server-secret** command at the command line interface.
- In the Parameter field, enter **CiscoAuthApi**.

Step 2 Using your Cisco.com login, download the file **cisco_vpn_auth.jar** from http://www.cisco.com/cisco/software/navigator.html and copy it to the default library directory for the SiteMinder server. This .jar file is also available on the Cisco ASA CD.

Configuring the SAML POST SSO Server

Use the SAML server documentation provided by the server software vendor to configure the SAML server in Relying Party mode.The following steps list the specific parameters required to configure the SAML Server for Browser Post Profile:

Detailed Steps

Step 1 Configure the SAML server parameters to represent the asserting party (the ASA):

- Recipient consumer URL (same as the assertion consumer URL configured on the ASA)
- Issuer ID, a string, usually the hostname of appliance
- Profile type -Browser Post Profile

Step 2 Configure certificates.

Step 3 Specify that asserting party assertions must be signed.

Step 4 Select how the SAML server identifies the user:

- Subject Name Type is DN
- Subject Name format is uid=<user>

Configuring SSO with the HTTP Form Protocol

This section describes using the HTTP Form protocol for SSO. HTTP Form protocol is an approach to SSO authentication that can also qualify as a AAA method. It provides a secure method for exchanging authentication information between users of clientless SSL VPN and authenticating web servers. You can use it in conjunction with other AAA servers such as RADIUS or LDAP servers.

Prerequisites

To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

Restrictions

As a common protocol, it is applicable only when the following conditions are met for the web server application used for authentication:

- The authentication cookie must be set for successful request and not set for unauthorized logons. In this case, ASA cannot distinguish successful from failed authentication.

Detailed Steps

The ASA again serves as a proxy for users of clientless SSL VPN to an authenticating web server but, in this case, it uses HTTP Form protocol and the POST method for requests. You must configure the ASA to send and receive form data. Figure 91-4 illustrates the following SSO authentication steps:

Step 1 A user of clientless SSL VPN first enters a username and password to log into the clientless SSL VPN server on the ASA.

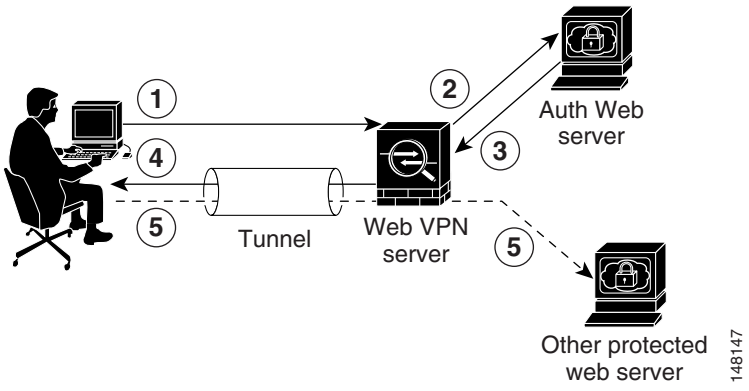
Step 2 The clientless SSL VPN server acts as a proxy for the user and forwards the form data (username and password) to an authenticating web server using a POST authentication request.

Step 3 If the authenticating web server approves the user data, it returns an authentication cookie to the clientless SSL VPN server where it is stored on behalf of the user.

Step 4 The clientless SSL VPN server establishes a tunnel to the user.

Step 5 The user can now access other websites within the protected SSO environment without reentering a username and password.

Figure 91-4 SSO Authentication Using HTTP Forms



While you would expect to configure form parameters that let the ASA include POST data such as the username and password, you initially might not be aware of additional hidden parameters that the web server requires. Some authentication applications expect hidden data which is neither visible to nor entered by the user. You can, however, discover hidden parameters the authenticating web server expects by making a direct authentication request to the web server from your browser without the ASA in the middle acting as a proxy. Analyzing the web server response using an HTTP header analyzer reveals hidden parameters in a format similar to the following:

```
<param name>=<URL encoded value>&<param name>=<URL encoded>
```

Some hidden parameters are mandatory and some are optional. If the web server requires data for a hidden parameter, it rejects any authentication POST request that omits that data. Because a header analyzer does not tell you if a hidden parameter is mandatory or not, we recommend that you include all hidden parameters until you determine which are mandatory.

Gathering HTTP Form Data

This section presents the steps for discovering and gathering necessary HTTP Form data. If you do not know what parameters the authenticating web server requires, you can gather parameter data by analyzing an authentication exchange using the following steps:

Prerequisites

These steps require a browser and an HTTP header analyzer.

Detailed Steps

Step 1 Start your browser and HTTP header analyzer, and connect directly to the web server login page without going through the ASA.

Step 2 After the web server login page has loaded in your browser, examine the login sequence to determine if a cookie is being set during the exchange. If the web server has loaded a cookie with the login page, configure this login page URL as the *start-URL*.

Step 3 Enter the username and password to log in to the web server, and press **Enter**. This action generates the authentication POST request that you examine using the HTTP header analyzer.

An example POST request—with host HTTP header and body—follows:

```
POST
/emco/myemco/authc/forms/MCOlogin.fcc?TYPE=33554433&REALMOID=06-000430e1-7443-125c-ac05
-83846dc90034&GUID=&SMAUTHREASON=0&METHOD=GET&SMAGENTNAME=$SM$5FZmjnk3DRNwNjk2KcqVCFbIr
NT9%2bJ0H0KPshFtg6rB1UV2PxkHqLw%3d%3d&TARGET=https%3A%2F%2Fwww.example.com%2Femco%2Fmye
mco%2FHTTP/1.1

Host: www.example.com

(BODY)

SMENC=ISO-8859-1&SMLOCALE=US-EN&USERID=Anyuser&USER_PASSWORD=XXXXXX&target=https%3A%2F%
2Fwww.example.com%2Femco%2Fmyemco%2F&smauthreason=0
```

Step 4 Examine the POST request and copy the protocol, host, and the complete URL to configure the action-uri parameter.

Step 5 Examine the POST request body and copy the following:

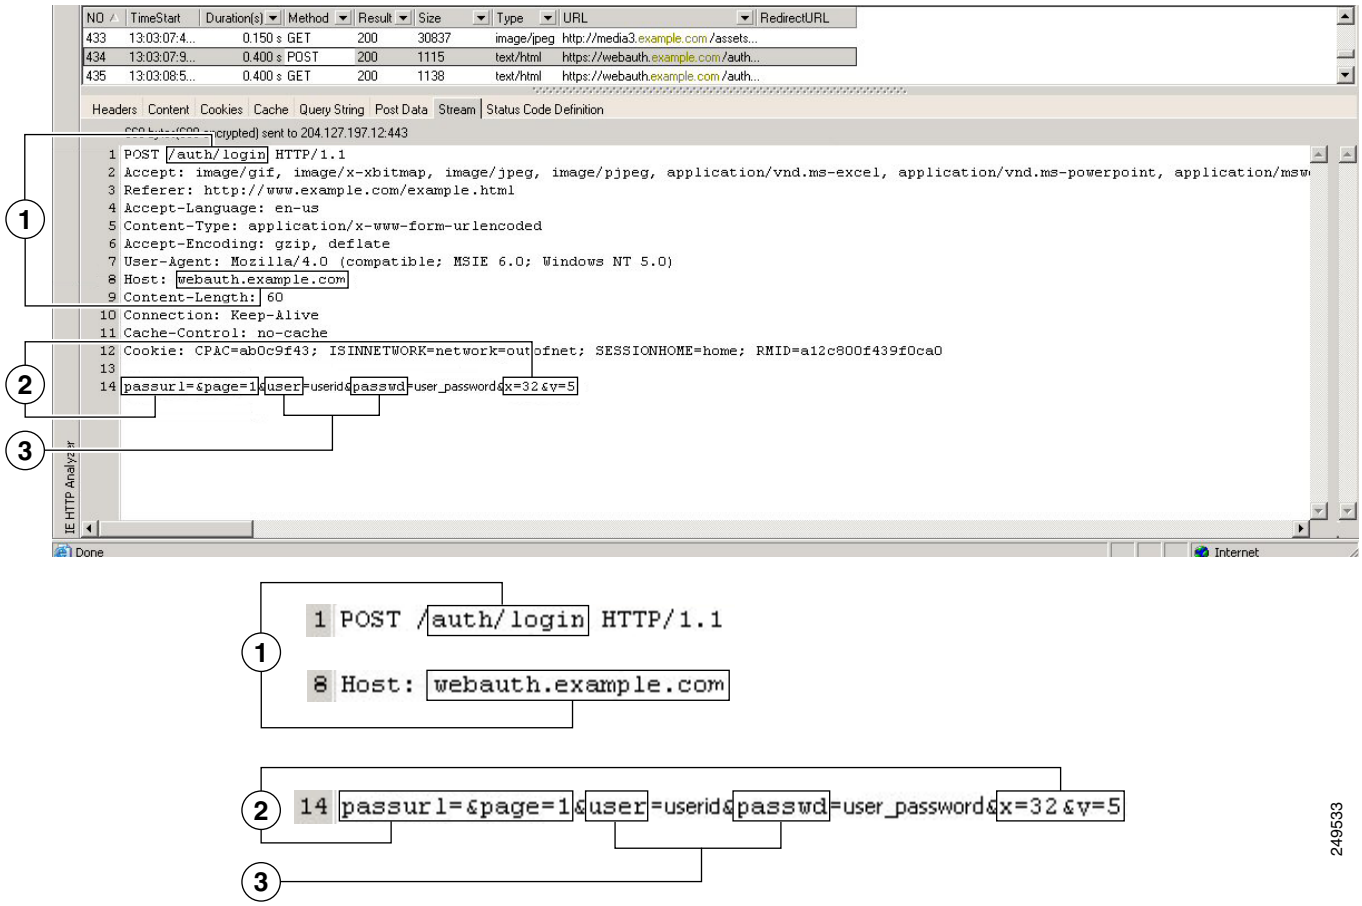
a. Username parameter. In the preceding example, this parameter is *USERID*, not the value *anyuser*.

b. Password parameter. In the preceding example, this parameter is *USER_PASSWORD*.

c. Hidden parameter. This parameter is everything in the POST body except the username and password parameters. In the preceding example, the hidden parameter is: SMENC=ISO-8859-1&SMLOCALE=US-EN&target=https%3A%2F%2Fwww.example.com%2Femco%2Fmyemco%2F&smauthreason=0

Figure 91-5 highlights the action URI, hidden, username and password parameters within sample output from an HTTP analyzer. This is only an example; output varies widely across different websites.

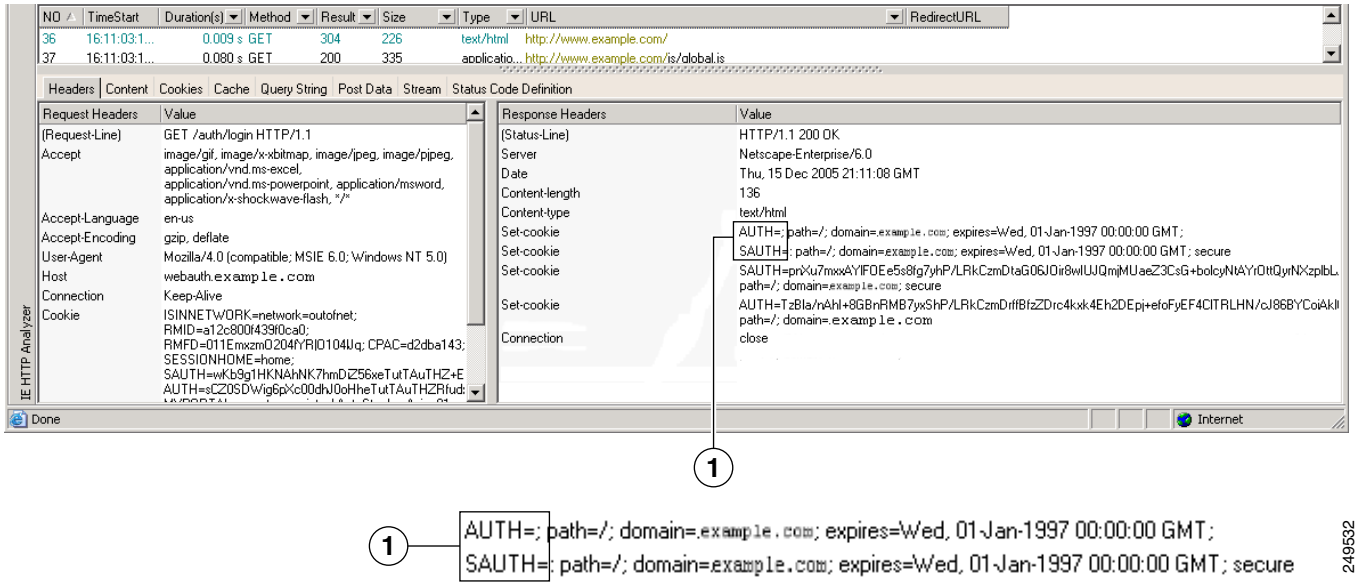
Figure 91-5 Action-uri, hidden, username and password parameters



Step 6 If you successfully log in to the web server, examine the server response with the HTTP header analyzer to locate the name of the session cookie set by the server in your browser. This is the **auth-cookie-name** parameter.

In the following server response header, the name of the session cookie is SMSESSION. You just need the name, not the value.Figure 91-6 shows an example of authorization cookies in HTTP analyzer output. This is only an example; output varies widely across different websites.

Figure 91-6 Authorization cookies in sample HTTP analyzer output



1	Authorization cookies

Step 7 In some cases, the server may set the same cookie regardless of whether the authentication was successful or not, and such a cookie is unacceptable for SSO purposes. To confirm that the cookies are different, repeat Step 1 through Step 6 using invalid login credentials and then compare the “failure” cookie with the “success” cookie.

You now have the necessary parameter data to configure the ASA for SSO with HTTP Form protocol.

Using Auto Signon

The Auto Signon window or tab lets you configure or edit auto signon for users of clientless SSL VPN. Auto signon is a simplified single signon method that you can use if you do not already have an SSO method deployed on your internal network. With auto signon configured for particular internal servers, the ASA passes the login credentials that the user of clientless SSL VPN entered to log in to the ASA (username and password) to those particular internal servers. You configure the ASA to respond to a specific authentication method for a particular range of servers. The authentication methods you can configure the ASA to respond to consists of authentication using Basic (HTTP), NTLM, FTP and CIFS, or all of these methods.

If the lookup of the username and password fails on the ASA, an empty string is substituted, and the behavior converts back as if no auto sign-on is available.

Auto signon is a straight-forward method for configuring SSO for particular internal servers. This section describes the procedure for setting up SSO with auto signon. If you already have SSO deployed using Computer Associates SiteMinder SSO server, or if you have Security Assertion Markup Language (SAML) Browser Post Profile SSO, and if you want to configure the ASA to support this solution, see the "SSO Servers" section on page 91-61.

The following fields are displayed:

- IP Address—In conjunction with the following Mask, displays the IP address range of the servers to be authenticated to as configured with the Add/Edit Auto Signon dialog box. You can specify a server using either the server URI or the server IP address and mask.
- Mask—In conjunction with the preceding IP Address, displays the IP address range of the servers configured to support auto signon with the Add/Edit Auto Signon dialog box.
- URI—Displays a URI mask that identifies the servers configured with the Add/Edit Auto Signon dialog box.
- Authentication Type—Displays the type of authentication—Basic (HTTP), NTLM, FTP and CIFS, or all of these methods—as configured with the Add/Edit Auto Signon dialog box.

Restrictions

- Do not enable auto signon for servers that do not require authentication or that use credentials different from the ASA. When auto signon is enabled, the ASA passes on the login credentials that the user entered to log into the ASA regardless of what credentials are in user storage.
- If you configure one method for a range of servers (for example, HTTP Basic) and one of those servers attempts to authenticate with a different method (for example, NTLM), the ASA does not pass the user login credentials to that server.

Detailed Steps

Step 1 Click to add or edit an auto signon instruction. An auto signon instruction defines a range of internal servers using the auto signon feature and the particular authentication method.

Step 2 Click to delete an auto signon instruction selected in the Auto Signon table.

Step 3 Click **IP Block** to specify a range of internal servers using an IP address and mask.

- IP Address—Enter the IP address of the first server in the range for which you are configuring auto sign-on.
- Mask—From the subnet mask menu, choose the subnet mask that defines the server address range of the servers supporting auto signon.

Step 4 Click URI to specify a server supporting auto signon by URI, then enter the URI in the field next to this button.

Step 5 Determine the authentication method assigned to the servers. For the specified range of servers, the ASA can be configured to respond to Basic HTTP authentication requests, NTLM authentication requests, FTP and CIFS authentication requests, or requests using any of these methods.

- Basic—Click this button if the servers support basic (HTTP) authentication.
- NTLM—Click this button if the servers support NTLMv1 authentication.

Note NTLM is not the most secure choice and other better alternatives exist. NTLM does not support recent cryptographic methods such as AES or SHA-256. Cisco recommends that applications not use NTLM.

- FTP/CIFS—Click this button if the servers support FTP and CIFS authentication
- Basic, NTLM, and FTP/CIFS—Click this button if the servers support all of the above.

Accessing Virtual Desktop Infrastructure (VDI)

In a VDI model, administrators publish enterprise applications or desktops pre-loaded with enterprise applications, and end users remotely access these applications. These virtualized resources appear just as any other resources, such as email, so that users do not need to go through a Citrix Access Gateway to access them. Users log onto the ASA using Citrix Receiver mobile client, and the ASA connects to a pre-defined Citrix XenApp or XenDesktop Server. The administrator must configure the Citrix server's address and logon credentials under Group Policy so that when users connect to their Citrix Virtualized resource, they enter the ASA's SSL VPN IP address and credentials instead of pointing to the Citrix Server's address and credentials. When the ASA has verified the credentials, the receiver client starts to retrieve entitled applications through the ASA.

Supported Mobile Devices

- iPad—Citrix Receiver version 4.x or later
- iPhone/iTouch—Citrix Receiver version 4.x or later
- Android 2.x/3.x/4.0/4.1 phone—Citrix Receiver version 2.x or later
- Android 4.0 phone—Citrix Receiver version 2.x or later

Limitations

Citrix Receiver clients access only one XenApp/XenDesktop server at a time.

Detailed Steps

Step 1 Browse to Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies.

Step 2 Edit the DfltGrpPolicy and expand the More options menu from the left-side menu.

Step 3 Choose **VDI Access**. Click **Add** or **Edit** to provide VDI server details.

- Server (Host Name or IP Address)—Address of the XenApp or XenDesktop server. This value can be a clientless macro.
- Port Number (Optional)—Port number for connecting to the Citrix server. This value can be a clientless macro.
- Active Directory Domain Name—Domain for logging into the virtualization infrastructure server. This value can be a clientless macro.
- Use SSL Connection—Check the checkbox if you want the server to connect using SSL.
- Username—Username for logging into the virtualization infrastructure server. This value can be a clientless macro.
- Password—Password for logging into the virtualization infrastructure server. This value can be a clientless macro.

Configuring Session Settings

The clientless SSL VPN Add/Edit Internal Group Policy > More Options > Session Settings window lets you specify personalized user information between clientless SSL VPN sessions. By default, each group policy inherits the settings from the default group policy. Use this window to specify personalized clientless SSL VPN user information for the default group policy and any group policies for which you want to differentiate these values.

Detailed Steps

Step 1 Click none or choose the file server protocol (smb or ftp) from the User Storage Location drop-down menu. If you choose smb or ftp, use the following syntax to enter the file system destination into the adjacent text field:

username:*password*@*host*:*port-number*/*path*

For example

mike:mysecret@ftpserver3:2323/public

Note Although the configuration shows the username, password, and preshared key, the ASA uses an internal algorithm to store the data in an encrypted form to safeguard it.

Step 2 Type the string, if required, for the security appliance to pass to provide user access to the storage location.

Step 3 Choose one of the following options from the Storage Objects drop-down menu to specify the objects the server uses in association with the user. The ASA store these objects to support clientless SSL VPN connections.

- cookies,credentials
- cookies
- credentials

Step 4 Enter the limit in KB transaction size over which to time out the session. This attribute applies only to a single transaction. Only a transaction larger than this value resets the session expiration clock.

Java Code Signer

Code signing appends a digital signature to the executable code itself. This digital signature provides enough information to authenticate the signer as well as to ensure that the code has not been subsequently modified since signed.

Code-signer certificates are special certificates whose associated private keys are used to create digital signatures. The certificates used to sign code are obtained from a CA, with the signed code itself revealing the certificate origin.

Choose the configured certificate that you want to employ in Java object signing from the drop down list.

To configure a Java Code Signer, choose Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Java Code Signer.

Java objects which have been transformed by clientless SSL VPN can subsequently be signed using a PKCS12 digital certificate associated with a trustpoint. In the Java Trustpoint pane, you can configure the clientless SSL VPN Java object signing facility to use a PKCS12 certificate and keying material from a specified trustpoint location.

To import a trustpoint, choose **Configuration > Properties > Certificate > Trustpoint > Import**.

Encoding

With encoding, you can view or specify the character encoding for clientless SSL VPN portal pages.

Character encoding, also called "character coding" and "a character set," is the pairing of raw data (such as 0s and 1s) with characters to represent the data. The language determines the character encoding method to use. Some languages use a single method, while others do not. Usually, the geographic region determines the default encoding method used by the browser, but the remote user can change it. The browser can also detect the encoding specified on the page, and render the document accordingly.

The encoding attribute lets you specify the value of the character-encoding method used on the portal page to ensure that the browser renders it properly, regardless of the region in which the user is using the browser, and regardless of any changes made to the browser.

By default, the ASA applies the "Global Encoding Type" to pages from Common Internet File System servers. The mapping of CIFS servers to their appropriate character encoding, globally with the "Global Encoding Type" attribute, and individually with the file-encoding exceptions displayed in the table, provides for the accurate handling and display of CIFS pages when the proper rendering of filenames or directory paths, as well as pages, is an issue.

Detailed Steps

Step 1 Global Encoding Type determines the character encoding that all clientless SSL VPN portal pages inherit except for those from the CIFS servers listed in the table. You can type the string or choose one of the options from the drop-down list, which contains the most common values, as follows:

- big5
- gb2312
- ibm-850
- iso-8859-1
- shift_jis

Note

- unicode
- windows-1252
- none

Note If you click **none** or specify a value that the browser on the clientless SSL VPN session does not support, it uses its own default encoding.

You can type a string consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. The string is case-insensitive. The command interpreter converts upper-case to lower-case when you save the ASA configuration.

Step 2 Enter the name or IP address of a CIFS server for which the encoding requirement differs from the "Global Encoding Type" attribute setting. The ASA retains the case you specify, although it ignores the case when matching the name to a server.

Step 3 Choose the character encoding that the CIFS server should provide for clientless SSL VPN portal pages. You can type the string, or choose one from the drop-down list, which contains only the most common values, as follows:

- big5
- gb2312
- ibm-850
- iso-8859-1
- shift_jis

Note If you are using Japanese Shift_jis Character encoding, click **Do not specify** in the Font Family area of the associated Select Page Font pane to remove the font family.

- unicode
- windows-1252
- none

If you click **none** or specify a value that the browser on the clientless SSL VPN session does not support, it uses its own default encoding.

You can type a string consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. The string is case-insensitive. The command interpreter converts upper-case to lower-case when you save the ASA configuration.

Content Cache

Caching enhances the performance of clientless SSL VPN. It stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content. The use of the cache reduces traffic, with the result that many applications run more efficiently.

Detailed Steps

Step 1 Select **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Content Cache**.

Step 2 If **Enable Cache** is unchecked, check it.

Step 3 Define the terms for caching.

- Maximum Object Size—Enter the maximum size in KB of a document that the ASA can cache. The ASA measures the original content length of the object, not rewritten or compressed content. The range is 0 to 10,000 KB; the default is 1000 KB
- Minimum Object Size—Enter the minimum size in KB of a document that the ASA can cache. The ASA measures the original content length of the object, not rewritten or compressed content. The range is 0 to 10,000 KB; the default is 0 KB.

Note The Maximum Object Size must be greater than the Minimum Object Size.

- Expiration Time—Enter an integer between 0 and 900 to set the number of minutes to cache objects without revalidating them. The default is one minute.
- LM Factor—Enter an integer between 1 and 100; the default is 20.

  The LM factor sets the policy for caching objects which have only the last-modified timestamp. This revalidates objects that have no server-set change values. The ASA estimates the length of time since the object has changed, also called the expiration time. The estimated expiration time equals the time elapsed since the last change multiplied by the LM factor. Setting the LM factor to 0 forces immediate revalidation, while setting it to 100 results in the longest allowable time until revalidation.

  The expiration time sets the amount of time to for the ASA to cache objects that have neither a last-modified time stamp nor an explicit server-set expiry time.
- Cache static content—Check to cache all content that is not subject to rewrite, for example, PDF files and images.
- Restore Cache Default—Click to restore default values for all cache parameters.

Content Rewrite

The Content Rewrite pane lists all applications for which content rewrite is enabled or disabled.

Clientless SSL VPN processes application traffic through a content transformation/rewriting engine that includes advanced elements such as JavaScript, VBScript, Java, and multi-byte characters to proxy HTTP traffic which may have different semantics and access control rules depending on whether the user is using an application within or independently of an SSL VPN device.

By default, the security appliance rewrites, or transforms, all clientless traffic. You might not want some applications and web resources (for example, public websites) to go through the ASA. The ASA therefore lets you create rewrite rules that let users browse certain sites and applications without going through the ASA. This is similar to split-tunneling in a VPN connection.

You can create multiple rewrite rules. The rule number is important because the security appliance searches rewrite rules by order number, starting with the lowest, and applies the first rule that matches.

"Configuration Example for Content Rewrite Rules" shows example content rewrite rules.

Note These improvements were made to Content Rewriter in ASA 9.0:

- Content rewrite added support for HTML5.

- The clientless SSL VPN rewriter engines were significantly improved to provide better quality and efficacy. As a result, you can expect a better end-user experience for clientless SSL VPN users.

Detailed Steps

The Content Rewrite table has the following columns:

- Rule Number—Displays an integer that indicates the position of the rule in the list.
- Rule Name—Provides the name of the application for which the rule applies.
- Rewrite Enabled—Displays content rewrite as enabled or disabled.
- Resource Mask—Displays the resource mask.

The following steps explain how to add a rewrite entry or edit a selected rewrite entry.

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Content Rewrite**.

Step 2 Click Add or Edit to create or update an content rewriting rule.

Step 3 Enable content rewrite must be checked to enable this rule.

Step 4 Enter a number for this rule. This number specifies the priority of the rule, relative to the others in the list. Rules without a number are at the end of the list. The range is 1 to 65534.

Step 5 (Optional) Provide an alphanumeric string that describes the rule, maximum 128 characters.

Step 6 Enter a string to match the application or resource to apply the rule to. The string can be up to 300 characters. You can use one of the following wildcards, but you must specify at least one alphanumeric character.

* — Matches everything. ASDM does not accept a mask that consists of a * or *.*

? —Matches any single character.

[!seq] — Matches any character not in sequence.

[seq] — Matches any character in sequence.

Configuration Example for Content Rewrite Rules

Table 91-2 Content Rewrite Rules

Function	Enable content rewrite	Rule Number	Rule Name	Resource Mask
Disable rewriter for HTTP URLs at youtube.com	Unchecked	1	no-rewrite-youtube	*.youtube.com/*
Enable rewriter for all HTTP URLs that do not match above rules	Check	65,535	rewrite-all	*

Configuring Browser Access to Plug-ins

The following sections describe the integration of browser plug-ins for clientless SSL VPN browser access:

- Preparing the Security Appliance for a Plug-in, page 91-34
- Installing Plug-ins Redistributed By Cisco, page 91-34
- Providing Access to a Citrix XenApp Server, page 91-36

A browser plug-in is a separate program that a web browser invokes to perform a dedicated function, such as connect a client to a server within the browser window. The ASA lets you import plug-ins for download to remote browsers in clientless SSL VPN sessions. Of course, Cisco tests the plug-ins it redistributes, and in some cases, tests the connectivity of plug-ins we cannot redistribute. However, we do not recommend importing plug-ins that support streaming media at this time.

The ASA does the following when you install a plug-in onto the flash device:

- (Cisco-distributed plug-ins only) Unpacks the jar file specified in the *URL*.
- Writes the file to the ASA file system.
- Populates the drop-down menu next to the URL attributes in ASDM.
- Enables the plug-in for all future clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down menu next to the Address field of the portal page.

Table 91-3 shows the changes to the main menu and address field of the portal page when you add the plug-ins described in the following sections.

* Not a recommended plug-in.

Table 91-3 Effects of Plug-ins on the Clientless SSL VPN Portal Page

Plug-in	Main Menu Option Added to Portal Page	Address Field Option Added to Portal Page
ica	Citrix MetaFrame Services	ica://
rdp	Terminal Servers	rdp://
rdp2*	Terminal Servers Vista	rdp2://
ssh,telnet	Secure Shell	ssh://
	Telnet services (supporting v1 and v2)	telnet://
vnc	Virtual Network Computing services	vnc://

When the user in a clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can select the protocol displayed in the drop-down menu and enter the URL in the Address field to establish a connection.The plug-ins support single sign-on (SSO). Refer to the "Configuring SSO with the HTTP Form Protocol" section on page 91-22 for implementation details.

The minimum access rights required for remote use belong to the guest privilege mode.

Prerequisites

- Clientless SSL VPN must be enabled on the ASA to provide remote access to the plug-ins.
- To configure SSO support for a plug-in, you install the plug-in, add a bookmark entry to display a link to the server, and specify SSO support when adding the bookmark.
- The minimum access rights required for remote use belong to the guest privilege mode.

- Plug-ins require ActiveX or Oracle Java Runtime Environment (JRE), see the compatibility matrix for version requirements.

Restrictions

Note The remote desktop protocol plug-in does not support load balancing with a session broker. Because of the way the protocol handles the redirect from the session broker, the connection fails. If a session broker is not used, the plug-in works.

- The plug-ins support single sign-on (SSO). They use the *same* credentials entered to open the clientless SSL VPN session. Because the plug-ins do not support macro substitution, you do not have the options to perform SSO on different fields such as the internal domain password or on an attribute on a RADIUS or LDAP server.
- A stateful failover does not retain sessions established using plug-ins. Users must reconnect following a failover.
- If you use stateless failover instead of stateful failover, clientless features such as bookmarks, customization, and dynamic access-policies are not synchronized between the failover ASA pairs. In the event of a failover, these features do not work.

Preparing the Security Appliance for a Plug-in

Before installing a plug-in, prepare the ASA as follows:

Prerequisites

Make sure clientless SSL VPN (“webvpn”) is enabled on an ASA interface.

Restrictions

Do not specify an IP address as the common name (CN) for the SSL certificate. The remote user attempts to use the FQDN to communicate with the ASA. The remote PC must be able to use DNS or an entry in the System32\drivers\etc\hosts file to resolve the FQDN.

Go to the section that identifies the type of plug-in you want to provide for clientless SSL VPN access.

- Installing Plug-ins Redistributed By Cisco, page 91-34
- Providing Access to a Citrix XenApp Server, page 91-36

Installing Plug-ins Redistributed By Cisco

Cisco redistributes the following open-source, Java-based components to be accessed as plug-ins for web browsers in clientless SSL VPN sessions.

Prerequisites

Make sure clientless SSL VPN (“webvpn”) is enabled on an interface on the ASA. To do so, enter the **show running-config** command.

Plug-ins Redistributed by Cisco

Table 91-4

Protocol	Description	Source of Redistributed Plug-in *
RDP	HOBLink JWT is a Native Java RDP client which supports RDP 7.0 for remote access to Windows Terminal services. **Note** Since properoRDP and HOBSoft both use RDP as the plugin protocol, customers will not be able to use HOBSoft for one set of users and properoRDP for the rest via GroupPolicy etc. Use this plug-in if you want to use a single plug-in for Windows, Mac OS X and Linux operating systems. See This Document for a list of all supported operating systems.	Customers can download this plugin from these locations: HOBSoft Cisco.com Proper Java RDP
RDP	Accesses Microsoft Terminal Services hosted by Windows Vista and Windows 2003 R2. Supports Remote Desktop ActiveX Control. We recommend using this plug-in that supports both RDP and RDP2. Only versions up to 5.2 of the RDP and RDP2 protocols are supported. Version 5.2 and later are not supported.	The original source of the redistributed plug-in is http://properjavardp.sourceforge.net/
RDP2	Accesses Microsoft Terminal Services hosted by Windows Vista and Windows 2003 R2. Supports Remote Desktop ActiveX Control. **Note** This legacy plug-in supports only RDP2. We do not recommend using this plug-in, instead, use the RDP plug-in above.	The original source of the redistributed plug-in is http://properjavardp.sourceforge.net/
SSH	The Secure Shell-Telnet plug-in lets the remote user establish a Secure Shell (v1 or v2) or Telnet connection to a remote computer. **Note** Because keyboard-interactive authentication is not supported by JavaSSH, it cannot be supported with SSH plugin. (Keyboard interactive is a generic authentication method used to implement different authentication mechanisms.)	The web site containing the source of the redistributed plug-in is http://javassh.org/
VNC	The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing (also known as VNC server or service) turned on. This version changes the default color of the text and contains updated French and Japanese help files.	The web site containing the source of the redistributed plug-in is http://www.tightvnc.com/

```
* Consult the plug-in documentation for information on deployment configuration and
restrictions.
```

These plug-ins are available on the Cisco Adaptive Security Appliance Software Download site.

Detailed Steps

Follow these steps to provide clientless SSL VPN browser access to a plug-in redistributed by Cisco.

Step 1 Create a temporary directory named plugins on the computer you use to establish ASDM sessions with the ASA, and download the plug-ins you want from the Cisco website to the plugins directory.

Step 2 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Client-Server Plug-ins**.

This pane displays the currently loaded plug-ins that are available to clientless SSL sessions. The hash and date of these plug-ins are also provided.

Step 3 Click **Import**.

The Import Client-Server Plug-in dialog box opens.

Step 4 Use the following descriptions to enter the Import Client-Server Plug-in dialog box field values.

- Plug-in Name—Select one of the following values:
  - **ica** to provide plug-in access to Citrix MetaFrame or Web Interface services
  - **rdp** to provide plug-in access to Remote Desktop Protocol services
  - **ssh,telnet** to provide plug-in access to *both* Secure Shell and Telnet services
  - **vnc** to provide plug-in access to Virtual Network Computing services

Note Any undocumented options in this menu are experimental and are not supported.

- Select the location of the plugin file—Select one of the following options and insert a path into its text field.
  - Local computer—Enter the location and name of the plug-in into the associated Path field, or click **Browse Local Files** and navigate to the plug-in, choose it, then click **Select**.
  - Flash file system—Enter the location and name of the plug-in into the associated Path field, or click **Browse Flash** and navigate to the plug-in, choose it, then click **OK**.
  - Remote Server—Choose **ftp**, **tftp**, or **HTTP** from the drop-down menu next to the associated Path attribute, depending on which service is running on the remote server. Enter the host name or address of the server and the path to the plug-in into the adjacent text field.

Step 5 Click **Import Now**.

Step 6 Click **Apply**.

The plug-in is now available for future clientless SSL VPN sessions.

Providing Access to a Citrix XenApp Server

As an example of how to provide clientless SSL VPN browser access to third-party plug-ins, this section describes how to add clientless SSL VPN support for the Citrix XenApp Server Client.

With a Citrix plug-in installed on the ASA, clientless SSL VPN users can use a connection to the ASA to access Citrix XenApp services.

A stateful failover does not retain sessions established using the Citrix plug-in. Citrix users must reauthenticate after failover.

To provide access to the Citrix plug-in, follow the procedures in the following sections.

- Preparing the Citrix XenApp Server for Clientless SSL VPN Access

- Creating and Installing the Citrix Plug-in

Preparing the Citrix XenApp Server for Clientless SSL VPN Access

You must configure the Citrix Web Interface software to operate in a mode that does not use the (Citrix) "secure gateway." Otherwise, the Citrix client cannot connect to the Citrix XenApp Server.

Note If you are not already providing support for a plug-in, you must follow the instructions in the"Preparing the Security Appliance for a Plug-in" section on page 91-34 before using this section.

Creating and Installing the Citrix Plug-in

To create and install the Citrix plug-in, perform the following steps:

Detailed Steps

Step 1 Download theICA plug-in file from the Cisco Software Download web site.

This file contains files that Cisco customized for use with the Citrix plug-in.

Step 2 Download the Citrix Java client from the Citrix site.

On Citrix download site, select Citrix Receiver, Receivers by Platform, and click Find. Expand Receiver for Other Platforms, and download Receiver for Java. JICAComponents.tar.gz a gzip'd tar file, which you can open with 7-Zip or other unix-compatible tools.

Step 3 Extract the following files from the Citrix Java client, then add them to the ica-plugin.zip file:

- JICA-configN.jar
- JICAEngN.jar

You can use WinZip to perform this step.

Step 4 Ensure the EULA included with the Citrix Java client grants you the rights and permissions to deploy the client on your web servers.

Step 5 Install the plug-in by using ASDM, or entering the following CLI command in privileged EXEC mode:

import webvpn plug-in protocol ica *URL*

URL is the host name or IP address and path to the ica-plugin.zip file.

Note We recommend that you add a bookmark to make it easy for users to connect. Adding a bookmark is required if you want to provide SSO support for Citrix sessions.
We also recommend that you use URL parameters in the bookmark the provide convenient viewing, for example:
ica://10.56.1.114/?DesiredColor=4&DesiredHRes=1024&DesiredVRes=768

Step 6 Establish an SSL VPN clientless session and click the bookmark or enter the URL for the Citrix server.

Use the Client for Java Administrator's Guide as needed.

Microsoft Kerberos Constrained Delegation Solution

Many organizations want to authenticate their Clientless VPN users and extend their authentication credentials seamlessly to web-based resources using authentication methods beyond what the ASA SSO feature can offer today. With the growing demand to authenticate remote access users with Smart Cards and One-time Passwords (OTP), the SSO feature falls short in meeting that demand, because it only forwards conventional user credentials, such as static username and password, to clientless web-based resources when authentication is required.

For example, neither certificate- or OTP-based authentication methods encompass a conventional username and password necessary for the ASA to seamlessly perform SSO access to web-based resources. When authenticating with a certificate, a username and password is not required for the ASA to extend to web-based resources, making it an unsupported authentication method for SSO. On the other hand, OTP does include a static username; however, the password is dynamic and will subsequently change throughout the VPN session. In general, Web-based resources are configured to accept static usernames and passwords, thus also making OTP an unsupported authentication method for SSO.

Microsoft's Kerberos Constrained Delegation (KCD), a new feature introduced in software release 8.4 of the ASA, provides access to Kerberos-protected Web applications in the private network. With this benefit, you can seamlessly extend certificate- and OTP-based authentication methods to web applications. Thus, with SSO and KCD working together although independently, many organizations can now authenticate their clientless VPN users and extend their authentication credentials seamlessly to web applications using all authentication methods supported by the ASA.

Requirements

In order for the **kcd-server** command to function, the ASA must establish a trust relationship between the *source* domain (the domain where the ASA resides) and the *target* or *resource* domain (the domain where the web services reside). The ASA, using its unique format, crosses the certification path from the source to the destination domain and acquires the necessary tickets on behalf of the remote access user to access the services.

This crossing of the certificate path is called cross-realm authentication. During each phase of cross-realm authentication, the ASA relies on the credentials at a particular domain and the trust relationship with the subsequent domain.

Understanding How KCD Works

Kerberos relies on a trusted third party to validate the digital identity of entities in a network. These entities (such as users, host machines, and services running on hosts) are called principals and must be present in the same domain. Instead of secret keys, Kerberos uses tickets to authenticate a client to a server. The ticket is derived from the secret key and consists of the client's identity, an encrypted session key, and flags. Each ticket is issued by the key distribution center and has a set lifetime.

The Kerberos security system is a network authentication protocol used to authenticate entities (users, computers, or applications) and protect network transmissions by scrambling the data so that only the device that the information was intended for can decrypt it. You can configure KCD to provide Clientless SSL VPN (also known as WebVPN) users with SSO access to any web services protected by Kerberos. Examples of such web services or applications include Outlook Web Access (OWA), Sharepoint, and Internet Information Server (IIS).

Two extensions to the Kerberos protocol were implemented: *protocol transition* and *constrained delegation*. These extensions allow the Clientless or WebVPN remote access users to access Kerberos authenticated applications in the private network.

The *protocol transition* provides you with increased flexibility and security by supporting different authentication mechanisms at the user authentication level and by switching to the Kerberos protocol for security features (such as mutual authentication and constrained delegation) in subsequent application layers. *Constrained delegation* provides a way for domain administrators to specify and enforce application trust boundaries by limiting where application services can act on a user's behalf. This flexibility improves application security designs by reducing the chance of compromise by an untrusted service.

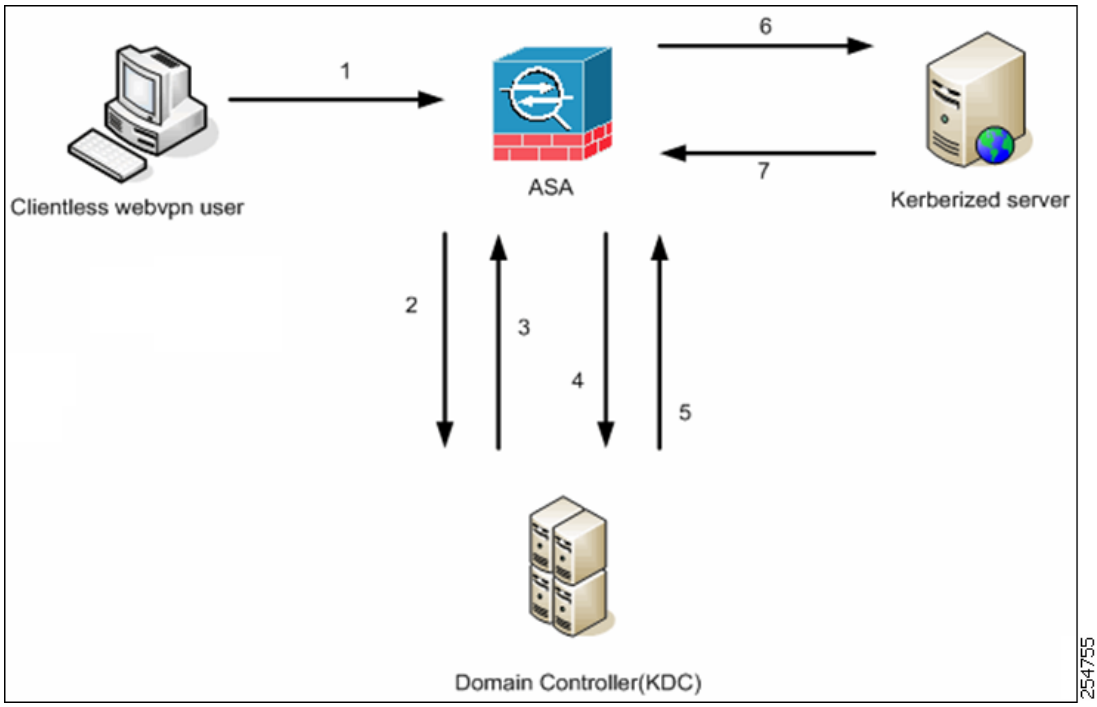
For more information on constrained delegation, see RFC 1510 via the IETF website (http://www.ietf.org).

Authentication Flow with KCD

Figure 91-7 depicts the packet and process flow a user will experience directly and indirectly when accessing resources trusted for delegation via the clientless portal. This process assumes that the following tasks have been completed:

- Configured KCD on ASA
- Joined the Windows Active Directory and ensured services are trusted for delegation
- Delegated ASA as a member of the Windows Active Directory domain

Figure 91-7 KCD Process



Note A clientless user session is authenticated by the ASA using the authentication mechanism configured for the user. (In the case of Smartcard credentials, ASA performs LDAP authorization with the userPrincipalName from the digital certificate against the Windows Active Directory).

1. After successful authentication, the user logs in to the ASA clientless portal page. The user accesses a Web service by entering a URL in the portal page or by clicking on the bookmark. If the Web service requires authentication, the server challenges ASA for credentials and sends a list of authentication methods supported by the server.

   Note KCD for Clientless SSL VPN is supported for all authentication methods (RADIUS, RSA/SDI, LDAP, digital certificates, and so on). Refer to the AAA Support table at http://www.cisco.com/en/US/partner/docs/security/asa/asa84/configuration/guide/access_aaa.html#wp1069492.

2. Based on the HTTP headers in the challenge, ASA determines whether the server requires Kerberos authentication. (This is part of the SPNEGO mechanism.) If connecting to a backend server requires Kerberos authentication, the ASA requests a service ticket for itself on behalf of the user from the key distribution center.
3. The key distribution center returns the requested tickets to the ASA. Even though these tickets are passed to the ASA, they contain the user's authorization data.ASA requests a service ticket from the KDC for the specific service that the user wants to access.

   Note Steps 1 to 3 comprise protocol transition. After these steps, any user who authenticates to ASA using a non-Kerberos authentication protocol is transparently authenticated to the key distribution center using Kerberos.

4. ASA requests a service ticket from the key distribution center for the specific service that the user wants to access.
5. The key distribution center returns a service ticket for the specific service to the ASA.
6. ASA uses the service ticket to request access to the web service.
7. The Web server authenticates the Kerberos service ticket and grants access to the service. The appropriate error message is displayed and requires acknowledgement if there is an authentication failure. If the Kerberos authentication fails, the expected behavior is to fall back to basic authentication.

Adding Windows Service Account in Active Directory

The KCD implementation on the ASA requires a service account, or in other words, an Active Directory user account with privileges necessary to add computers, such as adding the ASA to the domain. For our example, the Active Directory username JohnDoe depicts a service account with the required privileges. For more information on how to implement user privileges in Active Directory, contact Microsoft Support or visit http://microsoft.com.

Configuring DNS for KCD

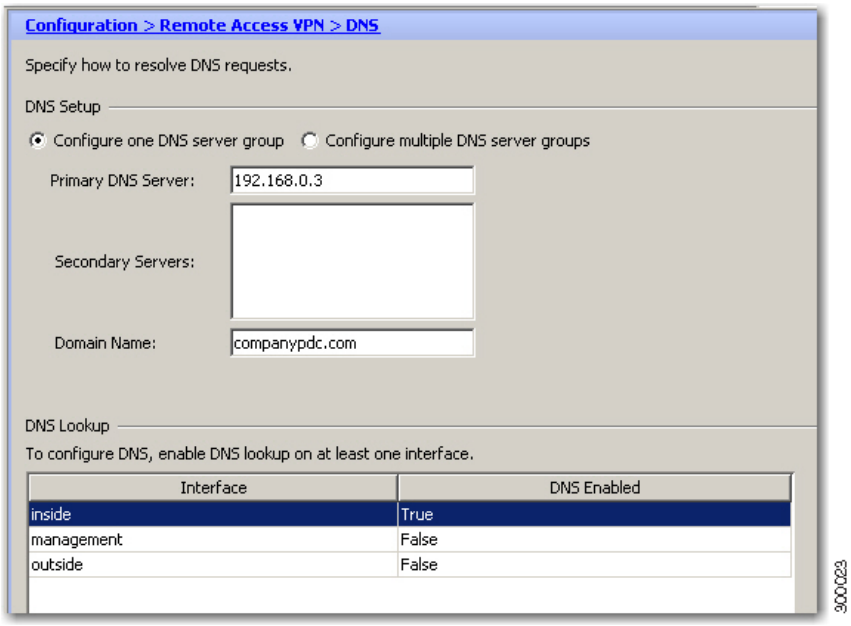
This section outlines configuration procedures necessary to configure DNS on the ASA. When using KCD as the authentication delegation method on the ASA, DNS is required to enable hostname resolution and communication between the ASA, Domain Controller (DC), and services trusted for delegation.

Step 1 From ASDM, navigate to **Configuration > Remote Access VPN > DNS** and configure the DNS setup as shown in Figure 91-8:

- DNS Server Group—Enter the DNS server IP address(es), such as 192.168.0.3.
- Domain Name—Enter the domain name in which the DC is a member.

Step 2 Enable DNS Lookup on the appropriate interface. Clientless VPN deployments require DNS Lookups via the internal corporate network, typically the *inside* interface.

Figure 91-8 ASA DNS Configuration Example



Configuring the ASA to Join the Active Directory Domain

This section outlines configuration procedures necessary to enable the ASA to act as part of the Active Directory domain. KCD requires the ASA to be a member of the Active Directory domain. This configuration enables the functionality necessary for constrained delegation transactions between the ASA and the KCD server.

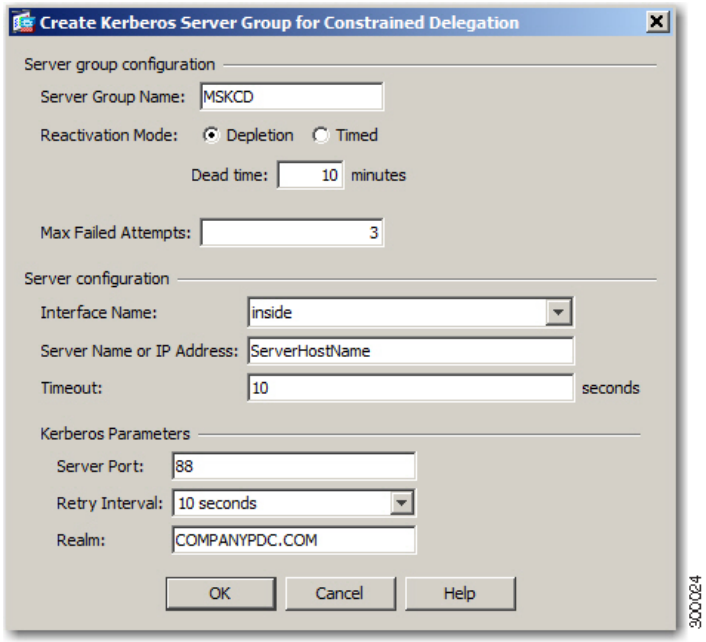
Step 1 From ASDM, navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Microsoft KCD Server**, as shown in Figure 91-9.

Step 2 Click **New** to add a Kerberos Server Group for Constrained Delegation and configure the following (see Figure 91-9):

- Server Group Configuration

  - Server Group Name—Define the name of the constrained delegation configuration on the ASA, such as MSKCD, which is the default value. You can configure multiple server groups for redundancy; however, you can only assign one server group to the KCD server configuration used to request service tickets on behalf of VPN users.
  - Reactivation Mode—Click the radio button for the mode you want to use (**Depletion** or **Timed**). In Depletion mode, failed servers are reactivated only after all of the servers in the group are inactive. In Timed mode, failed servers are reactivated after 30 seconds of down time. Depletion is the default configuration.
  - Dead Time—If you choose the Depletion reactivation mode, you must add a dead time interval. Ten minutes is the default configuration. The interval represents the duration of time, in minutes, that elapses between the disabling of the last server in a group and the subsequent re-enabling of all servers.
  - Max Failed Attempts—Set the number of failed connection attempts allowed before declaring an unresponsive server to be inactive. Three attempts is the default.
- Server Configuration
  - Interface Name—Choose the interface on which the server resides. In general, authentication server deployments reside on the internal corporate network, typically via the *inside* interface.
  - Server Name—Define the hostname of the domain controller, such as ServerHostName.
  - Timeout—Specify the maximum time, in seconds, to wait for a response from the server. Ten seconds is the default.
- Kerberos Parameter
  - Server Port—88 is the default and the standard port used for KCD.
  - Retry Interval—Choose the desired retry interval. Ten seconds is the default configuration.
  - Realm—Enter the domain name of the DC in all uppercase. The KCD configuration on the ASA requires the realm value to be in uppercase. A realm is an authentication domain. A service can accept authentication credentials only from entities in the same realm. The realm must match the domain name which the ASA joins.

Figure 91-9 KCD Server Group Configuration



Step 3 Click **OK** to apply your configuration and then configure the Microsoft KCD Server to request service tickets on behalf of the remote access user (see Figure 91-9). The Microsoft KCD Server configuration window appears upon clicking **OK**.

Configuring Kerberos Server Groups

The Kerberos Server Group for Constrained Delegation, MSKCD, is automatically applied to the KCD Server Configuration. You can also configure Kerberos Server groups and manage them under **Configuration > Remote Access VPN > AAA/Local User > AAA Server Groups**.

Step 1 Under the Server Access Credential section, configure the following:

- Username—Define a Service Account (Active Directory username) such as JohnDoe, which has been granted privileges necessary to add computer accounts to the Active Directory domain. The username does not correspond to a specific administrative user but simply a user with service-level privileges. This service account is used by the ASA to add a computer account for itself to the Active Directory domain at every reboot. You must configure the computer account separately to request Kerberos tickets on behalf of the remote users.

  Note Administrative privileges are required for initial join. A user with service-level priviledges on the domain controller will not get access.

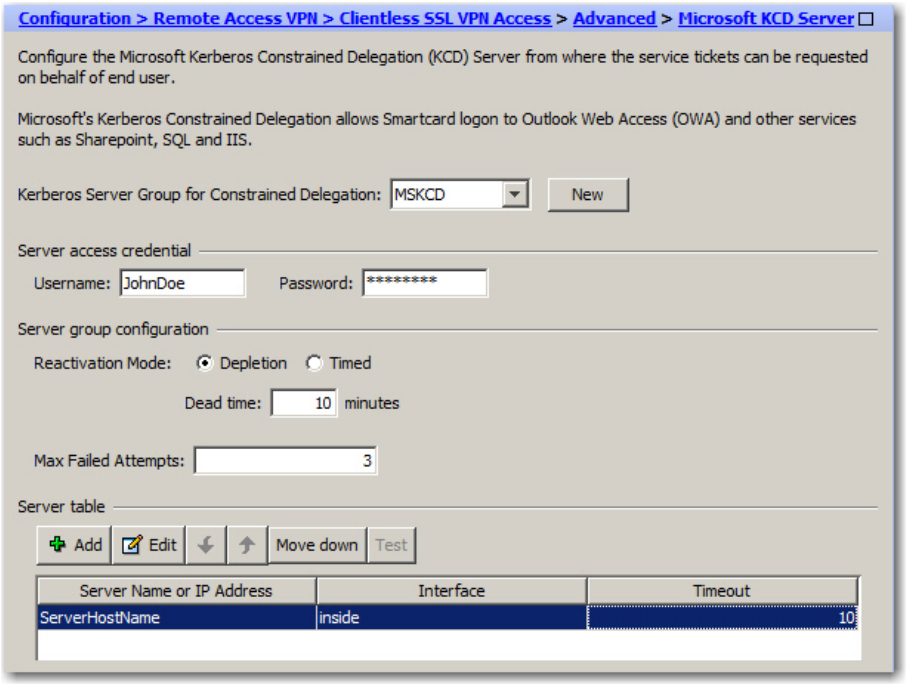
- Password—Define the password associated with the username (such as Cisco123). The password does not correspond to a specific password but simply a service-level password privilege to add a device on the Window domain controller.

Step 2 Under the Server Group Configuration section, configure the following:

- Reactivation Mode—Click the mode you want to use (**Depletion** or **Timed**). In Depletion mode, failed servers are reactivated only after all of the servers in the group are inactive. In Timed mode, failed servers are reactivated after 30 seconds of down time. Depletion is the default configuration.
- Dead Time—If you choose the Depletion reactivation mode, you must add a dead time interval. The interval represents the duration of time, in minutes, that elapses between the disabling of the last server in a group and the subsequent re-enabling of all servers. Ten minutes is the default.
- Max Failed Attempts—Set the number of failed connection attempts allowed before declaring a nonresponsive server to be inactive. Three attempts is the default.

Note Under the Server Table section, the previously configured DC hostname, ServerHostName, was automatically applied to the KCD Server configuration (see Figure 91-10).

Figure 91-10 KCD Server Configuration



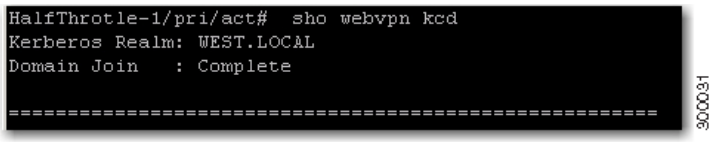
Step 3 Click **Apply**.

Note After applying your configuration, the ASA automatically starts the process of joining the Active Directory domain. The ASA's hostname appears in the Computers directory in Active Directory Users and Computers.

To confirm if the ASA has successfully joined the domain, execute the following command from the ASA prompt as shown in Figure 91-11:

show webvpn kcd

Figure 91-11 ASA Domain Membership Confirmation



Configuring Bookmarks to Access the Kerberos Authenticated Services

To access Kerberos Authenticated Services such as Outlook Web Access using the ASA clientless portal, you must configure bookmark lists. Bookmark Lists are assigned and displayed to remote access users based on the VPN security policies they are associated with.

Restriction

When creating a bookmark to an application that uses Kerberos constrained delegation (KCD), do not check Enable Smart Tunnel.

Detailed Steps

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless VPN Access > Portal > Bookmarks** on the ASDM GUI.

Step 2 In Bookmark List, enter the URL to reference for the service location.

Configuring Application Access

The following sections describe how to enable smart tunnel access and port forwarding on clientless SSL VPN sessions, specify the applications to be provided with such access, and provide notes on using it:

- Configuring Smart Tunnel Access
- Configuring Smart Tunnel Log Off

Configuring Smart Tunnel Access

To configure smart tunnel access, you create a smart tunnel list containing one or more applications eligible for smart tunnel access, and the endpoint operating system associated with the list. Because each group policy or local user policy supports one smart tunnel list, you must group the nonbrowser-based applications to be supported into a smart tunnel list. After creating a list, you assign it to one or more group policies or local user policies.

The following sections describe smart tunnels and how to configure them:

- About Smart Tunnels
- Why Smart Tunnels?
- Configuring a Smart Tunnel (Lotus example)

- Simplifying Configuration of Which Applications to Tunnel
- About Smart Tunnel Lists
- Creating a Smart Tunnel Auto Sign-On Server List
- Adding Servers to a Smart Tunnel Auto Sign-on Server List
- Enabling and Disabling Smart Tunnel Access

About Smart Tunnels

A smart tunnel is a connection between a TCP-based application and a private site, using a clientless (browser-based) SSL VPN session with the security appliance as the pathway, and the ASA as a proxy server. You can identify applications to which you want to grant smart tunnel access, and specify the local path to each application. For applications running on Microsoft Windows, you can also require a match of the SHA-1 hash of the checksum as a condition for granting smart tunnel access.

Lotus SameTime and Microsoft Outlook are examples of applications to which you might want to grant smart tunnel access.

Configuring smart tunnels requires one of the following procedures, depending on whether the application is a client or is a web-enabled application:

- Create one or more smart tunnel lists of the client applications, then assign the list to the group policies or local user policies for whom you want to provide smart tunnel access.
- Create one or more bookmark list entries that specify the URLs of the web-enabled applications eligible for smart tunnel access, then assign the list to the group policies or local user policies for whom you want to provide smart tunnel access.

You can also list web-enabled applications for which to automate the submission of login credentials in smart tunnel connections over clientless SSL VPN sessions.

Why Smart Tunnels?

Smart tunnel access lets a client TCP-based application use a browser-based VPN connection to access a service. It offers the following advantages to users, compared to plug-ins and the legacy technology, port forwarding:

- Smart tunnel offers better performance than plug-ins.
- Unlike port forwarding, smart tunnel simplifies the user experience by not requiring the user connection of the local application to the local port.
- Unlike port forwarding, smart tunnel does not require users to have administrator privileges.

The advantage of a plug-in is that it does not require the client application to be installed on the remote computer.

Prerequisites

See the *Supported VPN Platforms, Cisco ASA 5500 Series* for the platforms and browsers supported by ASA Release 9.0 smart tunnels.

The following requirements and limitations apply to smart tunnel access on Windows:

- ActiveX or Oracle Java Runtime Environment (JRE) 4 update 15 or later (JRE 6 or later recommended) on Windows must be enabled on the browser.
- Only Winsock 2, TCP-based applications are eligible for smart tunnel access.

- For Mac OS X only, Java Web Start must be enabled on the browser.

Restrictions

- Smart tunnel supports only proxies placed between computers running Microsoft Windows and the security appliance. Smart Tunnel uses the Internet Explorer configuration, which sets system-wide parameters in Windows. That configuration may include proxy information:
  - If a Windows computer requires a proxy to access the ASA, then there must be a static proxy entry in the client's browser, and the host to connect to must be in the client's list of proxy exceptions.
  - If a Windows computer does not require a proxy to access the ASA, but does require a proxy to access a host application, then the ASA must be in the client's list of proxy exceptions.

  Proxy systems can be defined the client's configuration of static proxy entry or automatic configuration, or by a PAC file. Only static proxy configurations are currently supported by Smart Tunnels.
- Kerberos constrained delegation (KCD) is not supported for smart tunnels.
- For Windows, if you want to add smart tunnel access to an application started from the command prompt, you must specify "cmd.exe" in the Process Name of one entry in the smart tunnel list, and specify the path to the application itself in another entry, because "cmd.exe" is the parent of the application.
- With HTTP-based remote access, some subnets may block user access to the VPN gateway. To fix this, place a proxy in front of the ASA to route traffic between the web and the end user. That proxy must support the CONNECT method. For proxies that require authentication, Smart Tunnel supports only the basic digest authentication type.
- When smart tunnel starts, the ASA by default passes all browser traffic through the VPN session if the browser process is the same. The ASA only also does this if a tunnel-all policy (the default) applies. If the user starts another instance of the browser process, it passes all traffic through the VPN session. If the browser process is the same and the security appliance does not provide access to a URL, the user cannot open it. As a workaround, assign a tunnel policy that is not tunnel-all.
- A stateful failover does not retain smart tunnel connections. Users must reconnect following a failover.
- The Mac version of smart tunnel does not support POST bookmarks, form-based auto sign-on, or POST macro substitution.
- For Mac OS X users, only those applications started from the portal page can establish smart tunnel connections. This requirement includes smart tunnel support for Firefox. Using Firefox to start another instance of Firefox during the first use of a smart tunnel requires the user profile named csco_st. If this user profile is not present, the session prompts the user to create one.
- In Mac OS X, applications using TCP that are dynamically linked to the SSL library can work over a smart tunnel.
- Smart tunnel does not support the following on Mac OS X:
  - Proxy services.
  - Auto sign-on.
  - Applications that use two-level name spaces.
  - Console-based applications, such as Telnet, SSH, and cURL.
  - Applications using dlopen or dlsym to locate libsocket calls.
  - Statically linked applications to locate libsocket calls.

- Mac OS X requires the full path to the process and is case-sensitive. To avoid specifying a path for each username, insert a tilde (~) before the partial path (e.g., ~/bin/vnc).

Configuring a Smart Tunnel (Lotus example)

To configure a Smart Tunnel, perform the following steps:

Note These example instructions provide the minimum instructions required to add smart tunnel support for an application. See the field descriptions in the sections that follow for more information.

Detailed Steps

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Smart Tunnels**.

Step 2 Double-click the smart tunnel list to which you want to add an application; or click **Add** to create a list of applications, enter a name for this list in the List Name field, and click **Add**.

For example, click **Add** in the Smart Tunnels pane, enter Lotus in the List Name field, and click **Add**.

Step 3 Click **Add** in the Add or Edit Smart Tunnel List dialog box.

Step 4 Enter a string in the Application ID field to serve as a unique index to the entry within the smart tunnel list.

Step 5 Enter the filename and extension of the application into the Process Name dialog box.

Table 91-5 shows example Application ID strings and the associated paths required to support Lotus.

Table 91-5 Smart Tunnel Example: Lotus 6.0 Thick Client with Domino Server 6.5.5

Application ID Example	Minimum Required Process Name
lotusnotes	notes.exe
lotusnlnotes	nlnotes.exe
lotusntaskldr	ntaskldr.exe
lotusnfileret	nfileret.exe

Step 6 Select **Windows** next to OS.

Step 7 Click **OK**.

Step 8 Repeat Steps 3–7 for each application to add to the list.

Step 9 Click **OK** in the Add or Edit Smart Tunnel List dialog box.

Step 10 Assign the list to the group policies and local user policies to which you want to provide smart tunnel access to the associated applications, as follows:

- To assign the list to a group policy, choose **Configuration > Remote Access VPN> Clientless SSL VPN Access > Group Policies > Add** or **Edit > Portal** and choose the smart tunnel name from the drop-down list next to the Smart Tunnel List attribute.

- To assign the list to a local user policy, choose **Configuration > Remote Access VPN> AAA Setup > Local Users > Add** or **Edit > VPN Policy > Clientless SSL VPN** and choose the smart tunnel name from the drop-down list next to the Smart Tunnel List attribute.

Simplifying Configuration of Which Applications to Tunnel

A smart tunnel application list is essentially a filter of what applications are granted access to the tunnel. The default is to allow access for all processes started by the browser. With Smart Tunnel enabled bookmark, the clientless session grants access only to processes initiated by the web browser. For non-browser applications, an administrator can choose to tunnel all applications and thus remove the need to know which applications an end user may invoke. Table 91-6 shows in which situations processes are granted access.

Table 91-6 Access for Smart Tunnel Applications and Enabled Bookmarks

	Smart Tunnel Enabled Bookmark	Smart Tunnel Application Access
Application list specified	Any processes that match a process name in the application list are granted access.	Only processes that match a process name in the application list are granted access.
Smart tunnel is disabled	All processes (and their child processes) are granted access.	No process is granted access.
Smart Tunnel all Applications check box is checked	All processes (and their child processes) are granted access. **Note** This includes processes initiated by non-Smart Tunnel web pages if the web page is served by the same browser process.	All processes owned by the user who started the browser are granted access but not child processes of those original processes.

Restrictions

This configuration is applicable to Windows platforms only.

Detailed Steps

Follow these steps to configure tunnel policy.

Step 1 Choose **Configuration > Remote Access VPN > AAA/Local Users > Local Users**.

Step 2 In the User Account window, highlight the username that you want to edit.

Step 3 Click **Edit**. The Edit User Account window appears.

Step 4 In the left sidebar of the Edit User Account window, click **VPN Policy > Clientless SSL VPN**.

Step 5 Perform one of the following:

- Check the **smart tunnel_all_applications** check box. All applications will be tunneled without making a list or knowing which executables an end user may invoke for external applications.
- Or choose from the following tunnel policy options:
  - Uncheck the **Inherit** check box at the Smart Tunnel Policy parameter.

– Choose from the network list and specify one of the tunnel options: use smart tunnel for the specified network, do not use smart tunnel for the specified network, or use tunnel for all network traffic.

Adding Applications to Be Eligible for Smart Tunnel Access

The clientless SSL VPN configuration of each ASA supports *smart tunnel lists*, each of which identifies one or more applications eligible for smart tunnel access. Because each group policy or username supports only one smart tunnel list, you must group each set of applications to be supported into a smart tunnel list.

The Add or Edit Smart Tunnel entry dialog box lets you specify the attributes of an application in a smart tunnel list.

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Smart Tunnels**, and choose a Smart Tunnel application list to edit, or add a new one.

Step 2 For a new list, enter a unique name for the list of applications or programs. Do not use spaces.

Following the configuration of the smart tunnel list, the list name appears next to the Smart Tunnel List attribute in the Clientless SSL VPN group policies and local user policies. Assign a name that will help you to distinguish its contents or purpose from other lists that you are likely to configure.

Step 3 Click Add and add as many applications as you need to this smart tunnel list. The parameters are described below:

- Application ID - Enter a string to name the entry in the smart tunnel list. This user-specified name is saved and then returned onto the GUI. The string is unique for the operating system. It typically names the application to be granted smart tunnel access. To support multiple versions of an application for which you choose to specify different paths or hash values, you can use this attribute to differentiate entries, specifying the operating system, and name and version of the application supported by each list entry. The string can be up to 64 characters.
- Process Name - Enter the filename or path to the application. The string can be up to 128 characters.

  Windows requires an exact match of this value to the right side of the application path on the remote host to qualify the application for smart tunnel access. If you specify only the filename for Windows, SSL VPN does not enforce a location restriction on the remote host to qualify the application for smart tunnel access.

  If you specify a path and the user installed the application in another location, that application does not qualify. The application can reside on any path as long as the right side of the string matches the value you enter.

  To authorize an application for smart tunnel access if it is present on one of several paths on the remote host, either specify only the name and extension of the application in this field; or create a unique smart tunnel entry for each path.

Note A sudden problem with smart tunnel access may be an indication that a *Process Name* value is not up-to-date with an application upgrade. For example, the default path to an application sometimes changes following the acquisition of the company that produces the application and the next application upgrade.

For Windows, if you want to add smart tunnel access to an application started from the command prompt, you must specify "cmd.exe" in the Process Name of one entry in the smart tunnel list, and specify the path to the application itself in another entry, because "cmd.exe" is the parent of the application.

- OS - Click **Windows** or **Mac** to specify the host operating system of the application.
- Hash (Optional and only applicable to Windows) - To obtain this value, enter the checksum of the application (that is, the checksum of the executable file) into a utility that calculates a hash using the SHA-1 algorithm. One example of such a utility is the Microsoft File Checksum Integrity Verifier (FCIV), which is available at http://support.microsoft.com/kb/841290/. After installing FCIV, place a temporary copy of the application to be hashed on a path that contains no spaces (for example, c:/fciv.exe), then enter **fciv.exe -sha1** *application* at the command line (for example, **fciv.exe -sha1 c:\msimn.exe**) to display the SHA-1 hash.

  The SHA-1 hash is always 40 hexadecimal characters.

  Before authorizing an application for smart tunnel access, clientless SSL VPN calculates the hash of the application matching the *Application ID*. It qualifies the application for smart tunnel access if the result matches the value of *Hash*.

  Entering a hash provides a reasonable assurance that SSL VPN does not qualify an illegitimate file that matches the string you specified in the *Application ID*. Because the checksum varies with each version or patch of an application, the *Hash* you enter can only match one version or patch on the remote host. To specify a hash for more than one version of an application, create a unique smart tunnel entry for each *Hash* value.

Note You must update the smart tunnel list in the future if you enter *Hash* values and you want to support future versions or patches of an application with smart tunnel access. A sudden problem with smart tunnel access may be an indication that the application list containing *Hash* values is not up-to-date with an application upgrade. You can avoid this problem by not entering a hash.

Step 4 Click **OK** to save the application, and create how ever many applications you need for this smart tunnel list.

Step 5 When you are done creating your smart tunnel list, you must assign it to a group policy or a local user policy for it to become active, as follows:

- To assign the list to a group policy, choose **Config > Remote Access VPN> Clientless SSL VPN Access > Group Policies > Add** or **Edit > Portal** and choose the smart tunnel name from the drop-down list next to the Smart Tunnel List attribute.
- To assign the list to a local user policy, choose **Config > Remote Access VPN> AAA Setup > Local Users > Add** or **Edit > VPN Policy > Clientless SSL VPN** and choose the smart tunnel name from the drop-down list next to the Smart Tunnel List attribute.

Table 91-7 Example Smart Tunnel Entries

Smart Tunnel Support	Application ID (Any unique string is OK.)	Process Name	OS
Mozilla Firefox.	firefox	firefox.exe	Windows
Microsoft Outlook Express.	outlook-express	msimn.exe	Windows

Table 91-7 Example Smart Tunnel Entries

Smart Tunnel Support	Application ID (Any unique string is OK.)	Process Name	OS
More restrictive alternative—Microsoft Outlook Express only if the executable file is in a predefined path.	outlook-express	\Program Files\Outlook Express\msimn.exe	Windows
Open a new Terminal window on a Mac. (Any subsequent application launched from within the same Terminal window fails because of the one-time-password implementation.)	terminal	Terminal	Mac
Start smart tunnel for a new window	new-terminal	Terminal open -a MacTelnet	Mac
Start application from a Mac Terminal window.	curl	Terminal curl www.example.com	Mac

About Smart Tunnel Lists

For each group policy and username, you can configure clientless SSL VPN to do one of the following:

- Start smart tunnel access automatically upon user login.
- Enable smart tunnel access upon user login, but require the user to start it manually, using the **Application Access > Start Smart Tunnels** button on the clientless SSL VPN Portal Page.

Restrictions

The smart tunnel logon options are mutually exclusive for each group policy and username. Use only one.

Creating a Smart Tunnel Auto Sign-On Server List

The Smart Tunnel Auto Sign-on Server List dialog box lets you add or edit lists of servers which will automate the submission of login credentials during smart tunnel setup. Auto Sign-on over a smart tunnel is available for Internet Explorer and Firefox.

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Smart Tunnels**, and make sure Smart Tunnel Auto Sign-on Server List is expanded to display.

Step 2 Click **Add**, and enter a unique name for a list of remote servers that will help you to distinguish its contents or purpose from other lists that you are likely to configure. The string can be up to 64 characters. Do not use spaces.

After you create a smart tunnel auto sign-on list, that list name appears next to the Auto Sign-on Server List attribute under Smart Tunnel in the clientless SSL VPN group policy and local user policy configurations.

Adding Servers to a Smart Tunnel Auto Sign-on Server List

The following steps describe how to add servers to the list of servers for which to provide auto sign-on in smart tunnel connections, and assign that list to a group policies or a local user.

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Smart Tunnels**, select one of the lists, and click **Edit**.

Step 2 Click the **Add** button on the Add Smart Tunnel Auto Sign-on Server List dialog to add one more more server smart tunnel servers.

Step 3 Enter the hostname or IP address of the server to auto-authenticate to:

- If you select Hostname, enter a hostname or wildcard mask to auto-authenticate to. You can use the following wildcard characters:
  - * to match any number of characters or zero characters
  - ? to match any single character
  - [] to match any single character in the range expressed inside the brackets
  - For example, enter *.example.com. Using this option protects the configuration from dynamic changes to IP addresses.
- If you select IP Address, enter an IP address.

Note Firefox does not support a host mask with wild cards, a subnet using IP addresses, or a netmask; you must use an exact host name or IP address. For example, within Firefox, if you enter *.cisco.com, auto sign-on to host email.cisco.com will fail.

Step 4 Windows Domain (Optional) - Click to add the Windows domain to the username, if authentication requires it. If you do so, be sure to specify the domain name when assigning the smart tunnel list to one or more group policies or local user policies.

Step 5 HTTP-based Auto Sign-On (Optional)

- Authentication Realm - TheRealm is associated with the protected area of the website and passed back to the browser either in the authentication prompt or in the HTTP headers during authentication. Once auto-sign is configured here, and a realm string is specified, users can configure the realm string on a web application (such as Outlook Web Access) and access web applications without signing on.

  Use the address format used in the source code of the web pages on the intranet. If you are configuring smart tunnel auto sign-on for browser access and some web pages use host names and others use IP addresses, or you do not know, specify both in different smart tunnel auto sign-on entries. Otherwise, if a link on a web page uses a different format than the one you specify, it fails when the user clicks it.

Note If administrators do not know the corresponding realm, they should perform logon once and get the string from the prompt dialog.

- Port Number - Specify a port number for the corresponding hosts. For Firefox, if no port number is specified, auto sign-on is performed on HTTP and HTTPS, accessed by default port numbers 80 and 443 respectively.

Step 6 Click **OK**.

Step 7 Following the configuration of the smart tunnel auto sign-on server list, you must assign it to a group policy or a local user policy for it to become active, as follows:

- To assign the list to a group policy:
  1. Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies,** and open a group policy,
  2. Select the Portal tab, find the Smart Tunnel area, and choose the auto sign-on server list from the drop-down list next to the Auto Sign-on Server List attribute.
- To assign the list to a local user policy:
  1. choose **Configuration > Remote Access VPN > AAA/Local Users > Local Users**, and edit the local user you want to assign an auto sign-on server list to.
  2. Navigate to VPN Policy > Clientless SSL VPN, and find the Auto Sign-on Server setting under the Smart Tunnel area
  3. Uncheck Inherit, and choose a server list from the drop-down list next to the Auto Sign-on Server List attribute.

Enabling and Disabling Smart Tunnel Access

By default, smart tunnels are disabled.

If you enable smart tunnel access, the user will have to start it manually, using the **Application Access > Start Smart Tunnels** button on the clientless SSL VPN portal page.

Configuring Smart Tunnel Log Off

This section describes how to ensure that the smart tunnel is properly logged off. Smart tunnel can be logged off when all browser windows have been closed, or you can right click the notification icon and confirm log out.

Note We strongly recommend the use of the logout button on the portal. This method pertains to clientless SSL VPNs and logs off regardless of whether smart tunnel is used or not. The notification icon should be used only when using standalone applications without the browser.

When Its Parent Process Terminates

This practice requires the closing of all browsers to signify log off. The smart tunnel lifetime is now tied to the starting process lifetime. For example, if you started a smart tunnel from Internet Explorer, the smart tunnel is turned off when no iexplore.exe is running. Smart tunnel can determine that the VPN session has ended even if the user closed all browsers without logging out.

Note In some cases, a lingering browser process is unintentional and is strictly a result of an error. Also, when a Secure Desktop is used, the browser process can run in another desktop even if the user closed all browsers within the secure desktop. Therefore, smart tunnel declares all browser instances gone when no more visible windows exist in the current desktop.

With A Notification Icon

You may also choose to disable logging off when a parent process terminates so that a session survives if you close a browser. For this practice, you use a notification icon in the system tray to log out. The icon remains until the user clicks the icon to logout. If the session has expired before the user has logged out, the icon remains until the next connection is tried. You may have to wait for the session status to update in the system tray.

Note This icon is an alternative way to log out of SSL VPN. It is not an indicator of VPN session status.

Detailed Steps

To enable the icon in the notification area, follow these steps:

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Smart Tunnels**.

Step 2 Enable the **Click on smart-tunnel logoff icon in the system tray** radio button.

Step 3 In the Smart Tunnel Networks portion of the window, check **Add** and enter both the IP address and hostname of the network which should include the icon.

Note If you right click the icon, a single menu item appears which prompts the user to log out of the SSL VPN.

Configuring Port Forwarding

The following sections describe port forwarding and how to configure it:

- Information About Port Forwarding, page 91-55
- Configuring DNS for Port Forwarding
- Adding Applications to Be Eligible for Port Forwarding
- Adding/Editing Port Forwarding Entry
- Assigning a Port Forwarding List
- Enabling and Disabling Port Forwarding

Information About Port Forwarding

Port forwarding lets users access TCP-based applications over a clientless SSL VPN connection. Such applications include the following:

- Lotus Notes
- Microsoft Outlook Express
- Perforce

- Sametime
- Secure FTP (FTP over SSH)
- SSH
- TELNET
- Windows Terminal Service

Other TCP-based applications may also work, but we have not tested them. Applications that use UDP do not work.

Port forwarding is the legacy technology for supporting TCP-based applications over a clientless SSL VPN connection. You may choose to use port forwarding because you have built earlier configurations that support this technology.

Consider the following alternatives to port forwarding:

- Smart tunnel access offers the following advantages to users:
  - Smart tunnel offers better performance than plug-ins.
  - Unlike port forwarding, smart tunnel simplifies the user experience by not requiring the user connection of the local application to the local port.
  - Unlike port forwarding, smart tunnel does not require users to have administrator privileges.

When configuring port forwarding on the ASA, you specify the port the application uses. When configuring smart tunnel access, you specify the name of the executable file or its path.

Prerequisites

- Refer to the Supported VPN Platforms, Cisco ASA 5500 Series compatibility guide for port forwarding pre-requisites.
- Browser-based users of Safari on Mac OS X 10.5.3 must identify a client certificate for use with the URL of the ASA, once with the trailing slash and once without it, because of the way Safari interprets URLs. For example,
  - https://example.com/
  - https://example.com

  For details, go to the Safari, Mac OS X 10.5.3: Changes in client certificate authentication.
- Users of Microsoft Windows Vista or later who use port forwarding or smart tunnels must add the URL of the ASA to the Trusted Site zone. To access the Trusted Site zone, they must start Internet Explorer and choose the **Tools > Internet Options > Security** tab. Vista (or later) users can also disable Protected Mode to facilitate smart tunnel access; however, we recommend against this method because it increases the computer's vulnerability to attack.

Restrictions

- Port forwarding supports only TCP applications that use static TCP ports. Applications that use dynamic ports or multiple TCP ports are not supported. For example, SecureFTP, which uses port 22, works over clientless SSL VPN port forwarding, but standard FTP, which uses ports 20 and 21, does not.
- Port forwarding does not support Microsoft Outlook Exchange (MAPI) proxy. However, you can configure smart tunnel support for Microsoft Office Outlook in conjunction with Microsoft Outlook Exchange Server.
- A stateful failover does not retain sessions established using Application Access (either port forwarding or smart tunnel access). Users must reconnect following a failover.

- The Java applet displays in its own window on the end user HTML interface. It shows the contents of the list of forwarded ports available to the user, as well as which ports are active, and amount of traffic in bytes sent and received.
- The port forwarding applet displays the local port and the remote port as the same when the local IP address 127.0.0.1 is being used and cannot be updated by the clientless SSL VPN connection from the ASA. As a result, the ASA creates new IP addresses 127.0.0.2, 127.0.0.3, and so on for local proxy IDs. Because you can modify the hosts file and use different loopbacks, the remote port is used as the local port in the applet. To connect, you can use Telnet with the host name, without specifying the port. The correct local IP addresses are available in the local hosts file.

Configuring DNS for Port Forwarding

Port Forwarding forwards the domain name of the remote server or its IP address to the ASA for resolution and connection. In other words, the port forwarding applet accepts a request from the application and forwards it to the ASA. The ASA makes the appropriate DNS queries and establishes the connection on behalf of the port forwarding applet. The port forwarding applet only makes DNS queries to the ASA. It updates the host file so that when a port forwarding application attempts a DNS query, the query redirects to a loopback address.

Step 1 Click **Configuration > Remote Access VPN > Clientless SSL VPN Access > Connection Profiles**.

The DefaultWEBVPNGroup entry is the default connection profile used for clientless connections.

Step 2 Highlight the DefaultWEBVPNGroup entry, then click **Edit** if your configuration uses it for clientless connections. Otherwise, highlight a connection profile used in your configuration for clientless connections, then click **Edit**.

The Basic window opens.

Step 3 Scan to the DNS area and select the DNS server from the drop-down list. Note the domain name, disregard the remaining steps, and go to the next section if ASDM displays the DNS server you want to use. You need to enter the same domain name when you specify the remote server while configuring an entry in the port forwarding list. Continue with the remaining steps if the DNS server is not present in the configuration.

Step 4 Click **Manage** in the DNS area.

The Configure DNS Server Groups window opens.

Step 5 Click **Configure Multiple DNS Server Groups**.

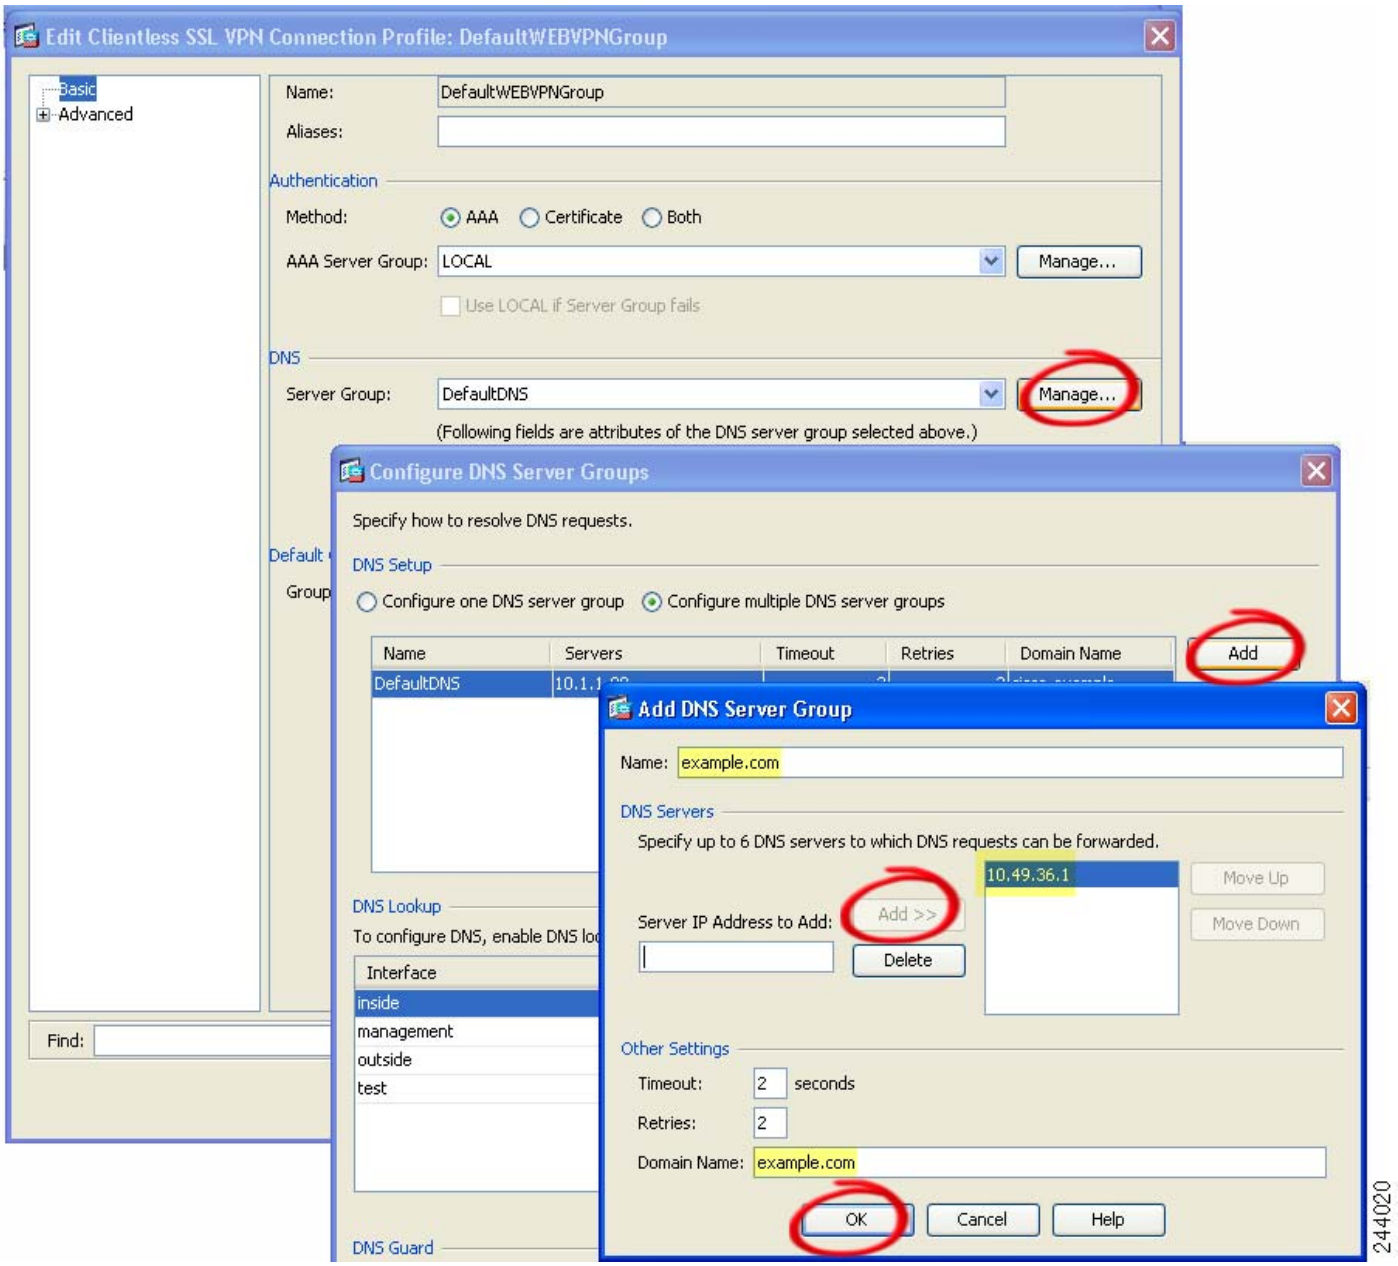
A window displays a table of DNS server entries.

Step 6 Click **Add.**

The Add DNS Server Group window opens.

Step 7 Enter a new server group name in the Name field, and enter the IP address and domain name (see Figure 91-12).

Figure 91-12 Example DNS Server Values for Port Forwarding



Note the domain name you entered. You need it when you specify the remote server later while configuring a port forwarding entry.

Step 8 Click **OK** until the Connection Profiles window becomes active again.

Step 9 Repeat Steps 2–8 for each remaining connection profile used in your configuration for clientless connections.

Step 10 Click **Apply**.

Adding Applications to Be Eligible for Port Forwarding

The clientless SSL VPN configuration of each ASA supports *port forwarding lists*, each of which specifies local and remote ports used by the applications for which you want to provide access. Because each group policy or username supports only one port forwarding list, you must group each set of applications to be supported into a list. To display the port forwarding list entries already present in the ASA configuration, enter the following commands:

Following the configuration of a port forwarding list, assign the list to group policies or usernames, as described in the next section.

Adding/Editing Port Forwarding Entry

The Add/Edit Port Forwarding Entry dialog boxes let you specify TCP applications to associate with users or group policies for access over clientless SSL VPN connections. Assign values to the attributes in these windows as follows:

Prerequisites

The DNS name assigned to the Remote Server parameter must match the Domain Name and Server Group parameters to establish the tunnel and resolve to an IP address, per the instructions in the "Assigning a Port Forwarding List" section on page 91-59. The default setting for both the Domain and Server Group parameters is DefaultDNS.

Detailed Steps

Step 1 Click **Add**.

Step 2 Type a TCP port number for the application to use. You can use a local port number only once for a listname. To avoid conflicts with local TCP services, use port numbers in the range 1024 to 65535.

Step 3 Enter either the domain name or IP address of the remote server. We recommend using a domain name so that you do not have to configure the client applications for the specific IP address.

Step 4 Type the well-known port number for the application.

Step 5 Type a description of the application. The maximum is 64 characters.

Step 6 (Optional) Highlight a port forwarding list and click **Assign** to assign the selected list to one or more group policies, dynamic access policies, or user policies.

Assigning a Port Forwarding List

You can add or edit a named list of TCP applications to associate with users or group policies for access over clientless SSL VPN connections. For each group policy and username, you can configure clientless SSL VPN to do one of the following:

- Start port forwarding access automatically upon user login.
- Enable port forwarding access upon user login, but require the user to start it manually, using the **Application Access > Start Applications** button on the clientless SSL VPN Portal Page.

Note These options are mutually exclusive for each group policy and username. Use only one.

Detailed Steps

The Add or Edit Port Forwarding List dialog box lets you add or edit the following:

Step 1 Provide an alphanumeric name for the list. The maximum is 64 characters.

Step 2 Enter which local port listens for traffic for the application. You can use a local port number only once for a listname. To avoid conflicts with local TCP services, use port numbers in the range 1024 to 65535.

Note Enter the IP address or DNS name of the remote server. We recommend using a domain name so that you do not have to configure the client applications for the specific IP address.

Step 3 Enter the remote port that listens for traffic for the application.

Step 4 Describe the TCP application. The maximum is 64 characters.

For details, go to the section that addresses the option you want to use.

Enabling and Disabling Port Forwarding

By default, port forwarding is disabled.

If you enable port forwarding, the user will have to start it manually, using the **Application Access > Start Applications** button on the clientless SSL VPN portal page.

Configuring the Use of External Proxy Servers

Use the Proxies pane to configure the ASA to use external proxy servers to handle HTTP requests and HTTPS requests. These servers act as an intermediary between users and the Internet. Requiring all Internet access via servers you control provides another opportunity for filtering to assure secure Internet access and administrative control.

Restrictions

HTTP and HTTPS proxy services do not support connections to personal digital assistants.

Detailed Steps

Step 1 Click Use an HTTP proxy server.

Step 2 Identify the HTTP proxy server by its IP address or hostname.

Step 3 Enter the hostname or IP address of the external HTTP proxy server.

Step 4 Enter the port that listens for HTTP requests. The default port is 80.

Step 5 (Optional) Enter a URL or a comma-delimited list of several URLs to exclude from those that can be sent to the HTTP proxy server. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards:

- ***** to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string.
- **?** to match any single character, including slashes and periods.
- [*x*-*y*] to match any single character in the range of *x* and *y*, where *x* represents one character and *y* represents another character in the ANSI character set.
- [**!***x*-*y*] to match any single character that is not in the range.

Step 6 (Optional) Enter this keyword to accompany each HTTP proxy request with a username to provide basic, proxy authentication.

Step 7 Enter a password to send to the proxy server with each HTTP request.

Step 8 As an alternative to specifying the IP address of the HTTP proxy server, you can choose Specify PAC file URL to specify a Proxy autoconfiguration file to download to the browser. Once downloaded, the PAC file uses a JavaScript function to identify a proxy for each URL. Enter **http://** and type the URL of the proxy autoconfiguration file into the adjacent field. If you omit the **http://** portion, the ASA ignores it.

Step 9 Choose if you want to use an HTTPS proxy server.

Step 10 Click to identify the HTTPS proxy server by its IP address or hostname.

Step 11 Enter the hostname or IP address of the external HTTPS proxy server.

Step 12 Enter the port that listens for HTTPS requests. The default port is 443.

Step 13 (Optional) Enter a URL or a comma-delimited list of several URLs to exclude from those that can be sent to the HTTPS proxy server. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards:

- ***** to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string.
- **?** to match any single character, including slashes and periods.
- [*x*-*y*] to match any single character in the range of *x* and *y*, where *x* represents one character and *y* represents another character in the ANSI character set.
- [**!***x*-*y*] to match any single character that is not in the range.

Step 14 (Optional) Enter this keyword to accompany each HTTPS proxy request with a username to provide basic, proxy authentication.

Step 15 Enter a password to send to the proxy server with each HTTPS request.

SSO Servers

The SSO Server pane lets you configure or delete single sign-on (SSO) for users of clientless SSL VPN connecting to a Computer Associates SiteMinder SSO server or to a Security Assertion Markup Language (SAML), Version 1.1, Browser Post Profile SSO server. SSO support, available only for clientless SSL VPN, lets users access different secure services on different servers without entering a username and password more than once.

You can choose from four methods when configuring SSO: Auto Signon using basic HTTP and/or NTLMv1 authentication, HTTP Form protocol, or Computer Associates eTrust SiteMinder (formerly Netegrity SiteMinder), or SAML, Version 1.1 Browser Post Profile.

Restrictions

The SAML Browser Artifact profile method of exchanging assertions is not supported.

The following sections describe the procedures for setting up SSO with both SiteMinder and SAML Browser Post Profile.

- Configuring SiteMinder and SAML Browser Post Profile, page 91-62—configures SSO with basic HTTP or NTLM authentication.
- Configuring Session Settings —configures SSO with the HTTP Form protocol.

The SSO mechanism either starts as part of the AAA process (HTTP Forms) or just after successful user authentication to either a AAA server (SiteMinder) or a SAML Browser Post Profile server. In these cases, the clientless SSL VPN server running on the ASA acts as a proxy for the user to the authenticating server. When a user logs in, the clientless SSL VPN server sends an SSO authentication request, including username and password, to the authenticating server using HTTPS.

If the authenticating server approves the authentication request, it returns an SSO authentication cookie to the clientless SSL VPN server. This cookie is kept on the ASA on behalf of the user and used to authenticate the user to secure websites within the domain protected by the SSO server.

Configuring SiteMinder and SAML Browser Post Profile

SSO authentication with SiteMinder or with SAML Browser Post Profile is separate from AAA and occurs after the AAA process completes. To set up SiteMinder SSO for a user or group, you must first configure a AAA server (RADIUS, LDAP and so forth). After the AAA server authenticates the user, the clientless SSL VPN server uses HTTPS to send an authentication request to the SiteMinder SSO server.

In addition to configuring the ASA, for SiteMinder SSO, you also must configure your CA SiteMinder Policy Server with the Cisco authentication scheme. See Adding the Cisco Authentication Scheme to SiteMinder.

For SAML Browser Post Profile you must configure a Web Agent (Protected Resource URL) for authentication.

Detailed Steps

Use the SAML server documentation provided by the server software vendor to configure the SAML server in Relying Party mode. The following fields are displayed:

- Server Name—*Display only.* Displays the names of configured SSO Servers. The minimum number of characters is 4, and the maximum is 31.
- Authentication Type—*Display only.* Displays the type of SSO server. The ASA currently supports the SiteMinder type and the SAML Browser Post Profile type.
- URL—*Display only.* Displays the SSO server URL to which the ASA makes SSO authentication requests.
- Secret Key—*Display only.* Displays the secret key used to encrypt authentication communications with the SSO server. The key can be comprised of any regular or shifted alphanumeric character. There is no minimum or maximum number of characters.
- Maximum Retries—*Display only.* Displays the number of times the ASA retries a failed SSO authentication attempt. The range is 1 to 5 retries, and the default number of retries is 3.
- Request Timeout (seconds)—*Display only.* Displays the number of seconds before a failed SSO authentication attempt times out. The range is 1 to 30 seconds, and the default number of seconds is 5.

- Add/Edit—Opens the Add/Edit SSO Server dialog box.
- Delete—Deletes the selected SSO server.
- Assign—Highlight an SSO server and click this button to assign the selected server to one or more VPN group policies or user policies.

Step 1 Configure the SAML server parameters to represent the asserting party (the ASA):

- Recipient consumer (Web Agent) URL (same as the assertion consumer URL configured on the ASA)
- Issuer ID, a string, usually the hostname of appliance
- Profile type -Browser Post Profile

Step 2 Configure certificates.

Step 3 Specify that asserting party assertions must be signed.

Step 4 Select how the SAML server identifies the user:

- Subject Name Type is DN
- Subject Name format is uid=<user>

Adding the Cisco Authentication Scheme to SiteMinder

Besides configuring the ASA for SSO with SiteMinder, you must also configure your CA SiteMinder Policy Server with the Cisco authentication scheme, provided as a Java plug-in. This section presents general tasks, not a complete procedure. Refer to the CA SiteMinder documentation for the complete procedure for adding a custom authentication scheme. To configure the Cisco authentication scheme on your SiteMinder Policy Server, perform the following steps:

Prerequisites

Configuring the SiteMinder Policy Server requires experience with SiteMinder.

Detailed Steps

Step 1 With the Siteminder Administration utility, create a custom authentication scheme being sure to use the following specific arguments:

- In the Library field, enter **smjavaapi**.
- In the Secret field, enter the same secret configured in the Secret Key field of the Add SSO Server dialog to follow.
- In the Parameter field, enter **CiscoAuthApi**.

Step 2 Using your Cisco.com login, download the file **cisco_vpn_auth.jar** from http://www.cisco.com/cisco/software/navigator.html and copy it to the default library directory for the SiteMinder server. This .jar file is also available on the Cisco ASA CD.

Adding or Editing SSO Servers

This SSO method uses CA SiteMinder and SAML Browser Post Profile. You can also set up SSO using the HTTP Form protocol, or Basic HTML and NTLM authentication. To use the HTTP Form protocol, see Configuring Session Settings. To set use basic HTML or NTLM authentication, use the **auto-signon** command at the command line interface.

Note NTLM is not the most secure choice and other better alternatives exist. NTLM does not support recent cryptographic methods such as AES or SHA-256. Cisco recommends that applications not use NTLM.

Detailed Steps

Step 1 If adding a server, enter the name of the new SSO server. If editing a server, this field is display only; it displays the name of the selected SSO server.

Step 2 *Display only.* Displays the type of SSO server. The types currently supported by the ASA are SiteMinder and SAML Browser Post Profile.

Step 3 Enter a secret key used to encrypt authentication requests to the SSO server. Key characters can be any regular or shifted alphanumeric characters. There is no minimum or maximum number of characters. The secret key is similar to a password: you create it, save it, and configure it. It is configured on the ASA, the SSO server, and the SiteMinder Policy Server using the Cisco Java plug-in authentication scheme.

Step 4 Enter the number of times the ASA retries a failed SSO authentication attempt before the authentication times-out. The range is from 1 to 5 retries inclusive, and the default is 3 retries.

Step 5 Enter the number of seconds before a failed SSO authentication attempt times out. The range is from1 to 30 seconds inclusive, and the default is 5 seconds.

Application Access User Notes

The following sections provide information about using application access:

- Closing Application Access to Prevent hosts File Errors
- Closing Application Access to Prevent hosts File Errors
- Recovering from hosts File Errors When Using Application Access

Closing Application Access to Prevent hosts File Errors

To prevent hosts file errors that can interfere with Application Access, close the Application Access window properly when you finish using Application Access. To do so, click the close icon.

Recovering from hosts File Errors When Using Application Access

The following errors can occur if you do not close the Application Access window properly:

- The next time you try to start Application Access, it might be disabled; you receive a `Backup HOSTS File Found` error message.
- The applications themselves might be disabled or might malfunction, even when you are running them locally.

These errors can result from terminating the Application Access window in any improper way. For example:

- Your browser crashes while you are using Application Access.
- A power outage or system shutdown occurs while you are using Application Access.
- You minimize the Application Access window while you are working, then shut down your computer with the window active (but minimized).

This section includes the following topics:

- Understanding the hosts File
- Stopping Application Access Improperly
- Reconfiguring a Host's File Automatically Using Clientless SSL VPN
- Reconfiguring hosts File Manually

Understanding the hosts File

The hosts file on your local system maps IP addresses to host names. When you start Application Access, clientless SSL VPN modifies the hosts file, adding clientless SSL VPN-specific entries. Stopping Application Access by properly closing the Application Access window returns the file to its original state.

Before invoking Application Access...	hosts file is in original state.
When Application Access starts....	• Clientless SSL VPN copies the hosts file to hosts.webvpn, thus creating a backup. • Clientless SSL VPN then edits the hosts file, inserting clientless SSL VPN-specific information.
When Application Access stops...	• Clientless SSL VPN copies the backup file to the `hosts` file, thus restoring the hosts file to its original state. • Clientless SSL VPN deletes hosts.webvpn.
After finishing Application Access...	hosts file is in original state.

Note Microsoft anti-spyware software blocks changes that the port forwarding Java applet makes to the hosts file. See www.microsoft.com for information on how to allow hosts file changes when using anti-spyware software.

Stopping Application Access Improperly

When Application Access terminates abnormally, the `hosts` file remains in a clientless SSL VPN-customized state. Clientless SSL VPN checks the state the next time you start Application Access by searching for a hosts.webvpn file. If it finds one, a `Backup HOSTS File Found` error message (Figure 91-13) appears, and Application Access is temporarily disabled.

Once you shut down Application Access improperly, you leave your remote access client/server applications in limbo. If you try to start these applications without using clientless SSL VPN, they might malfunction. You might find that hosts that you normally connect to are unavailable. This situation could commonly occur if you run applications remotely from home, fail to quit the Application Access window before shutting down the computer, then try to run the applications later from the office.

Reconfiguring a Host's File Automatically Using Clientless SSL VPN

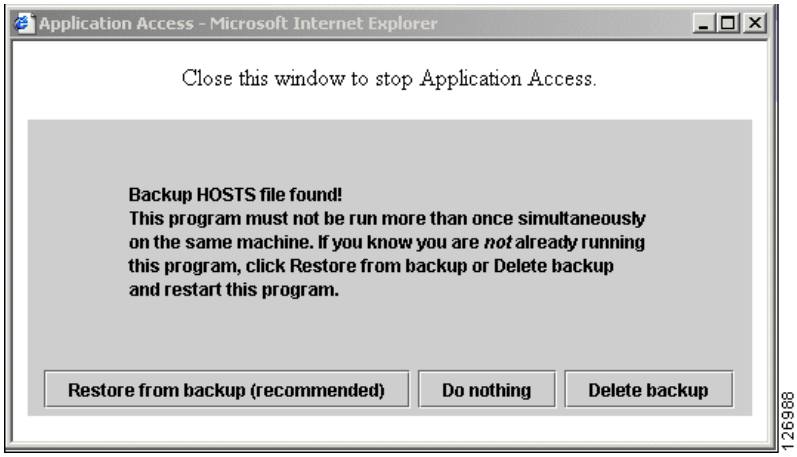
If you are able to connect to your remote access server, follow these steps to reconfigure the host's file and re-enable both Application Access and the applications.

Detailed Steps

Step 1 Start clientless SSL VPN and log in. The home page opens.

Step 2 Click the **Applications Access** then **Start Applications**, a `Backup HOSTS File Found` message appears. (See Figure 91-13.)

Figure 91-13 Backup HOSTS File Found Message



Step 3 Choose one of the following options:

- **Restore from backup**—Clientless SSL VPN forces a proper shutdown. It copies the hosts.webvpn backup file to the `hosts` file, restoring it to its original state, then deletes hosts.webvpn. You then have to restart Application Access.
- **Do nothing**—Application Access does not start. The remote access home page reappears.
- **Delete backup**—Clientless SSL VPN deletes the hosts.webvpn file, leaving the hosts file in its clientless SSL VPN-customized state. The original `hosts` file settings are lost. Application Access then starts, using the clientless SSL VPN-customized hosts file as the new original. Choose this

option only if you are unconcerned about losing hosts file settings. If you or a program you use might have edited the hosts file after Application Access has shut down improperly, choose one of the other options, or edit the hosts file manually. (See "Reconfiguring hosts File Manually.")

Reconfiguring hosts File Manually

If you are not able to connect to your remote access server from your current location, or if you have customized the hosts file and do not want to lose your edits, follow these steps to reconfigure the hosts file and reenable both Application Access and the applications.

Detailed Steps

Step 1 Locate and edit your hosts file. The most common location is c:\windows\sysem32\drivers\etc\hosts.

Step 2 Check to see if any lines contain the string: `# added by WebVpnPortForward`
If any lines contain this string, your hosts file is clientless SSL VPN-customized. If your hosts file is clientless SSL VPN-customized, it looks similar to the following example:

```
server1 # added by WebVpnPortForward
server1.example.com invalid.cisco.com # added by WebVpnPortForward
server2 # added by WebVpnPortForward
server2.example.com invalid.cisco.com # added by WebVpnPortForward
server3 # added by WebVpnPortForward
server3.example.com invalid.cisco.com # added by WebVpnPortForward

# Copyright (c) 1993-1999 Microsoft Corp.
#
# This is a sample HOSTS file used by Microsoft TCP/IP for Windows.
#
# This file contains the mappings of IP addresses to host names. Each
# entry should be kept on an individual line. The IP address should
# be placed in the first column followed by the corresponding host name.
# The IP address and the host name should be separated by at least one
# space.
#
# Additionally, comments (such as these) may be inserted on individual
# lines or following the machine name denoted by a '#' symbol.
#
# For example:
#
#      102.54.94.97     cisco.example.com          # source server
#       38.25.63.10     x.example.com              # x client host

127.0.0.1       localhost
```

Step 3 Delete the lines that contain the string: `# added by WebVpnPortForward`

Step 4 Save and close the file.

Step 5 Start clientless SSL VPN and log in.

The home page appears.

Step 6 Click the **Application Access** link.

The Application Access window appears. Application Access is now enabled.

Configuring File Access

Clientless SSL VPN serves remote users with HTTPS portal pages that interface with proxy CIFS and/or FTP clients running on the ASA. Using either CIFS or FTP, clientless SSL VPN provides users with network access to the files on the network, to the extent that the users meet user authentication requirements and the file properties do not restrict access. The CIFS and FTP clients are transparent; the portal pages delivered by clientless SSL VPN provide the appearance of direct access to the file systems.

When a user requests a list of files, clientless SSL VPN queries the server designated as the master browser for the IP address of the server containing the list. The ASA gets the list and delivers it to the remote user on a portal page.

Clientless SSL VPN lets the user invoke the following CIFS and FTP functions, depending on user authentication requirements and file properties:

- Navigate and list domains and workgroups, servers within a domain or workgroup, shares within a server, and files within a share or directory
- Create directories
- Download, upload, rename, move, and delete files

The ASA uses a master browser, WINS server, or DNS server, typically on the same network as the ASA or reachable from that network, to query the network for a list of servers when the remote user clicks **Browse Networks** in the menu of the portal page or on the toolbar displayed during the clientless SSL VPN session.

The master browser or DNS server provides the CIFS/FTP client on the ASA with a list of the resources on the network, which clientless SSL VPN serves to the remote user.

Note Before configuring file access, you must configure the shares on the servers for user access.

CIFS File Access Requirement and Limitation

To access `\\server\share\subfolder\personal folder`, the user must have a minimum of read permission for all parent folders, including the share itself.

Use **Download** or **Upload** to copy and paste files to and from CIFS directories and the local desktop. The Copy and Paste buttons are intended for remote to remote actions only, not local to remote, or remote to local.

The CIFS browse server feature does not support double-byte character share names (share names exceeding 13 characters in length). This only affects the list of folders displayed, and does not affect user access to the folder. As a workaround, you can pre-configure the bookmark(s) for the CIFS folder(s) that use double-byte share names, or the user can enter the URL or bookmark of the folder in the format cifs://server/<long-folder-name> . For example:

```
cifs://server/Do you remember?
cifs://server/Do%20you%20remember%3F
```

Adding Support for File Access

Configure file access as follows:

Note The first procedure describes how to specify the master browser and WINS servers. As an alternative, you can use ASDM to configure URL lists and entries that provide access to file shares.

Adding a share in ASDM does not require a master browser or a WINS server. However, it does not provide support for the Browse Networks link. You can use a hostname or an IP address to refer to ServerA when entering this command. If you use a hostname, the ASA requires a DNS server to resolve it to an IP address.

For a complete description of these commands, see the *Cisco Security Appliance Command Reference*.

Ensuring Clock Accuracy for SharePoint Access

The clientless SSL VPN server on the ASA uses cookies to interact with applications such as Microsoft Word on the endpoint. The cookie expiration time set by the ASA can cause Word to malfunction when accessing documents on a SharePoint server if the time on the ASA is incorrect. To prevent this malfunction, set the ASA clock properly. We recommend configuring the ASA to dynamically synchronize the time with an NTP server. For instructions, see "Setting the Date and Time."

Customizing the Clientless SSL VPN User Experience

You can customize the clientless SSL VPN user experience, including the logon, portal, and logout pages. There are two methods you can use. You can customize pre-defined page components in the Add/Edit Customization Object window. This window adds, or makes changes to, an XML file stored on the ASA (a customization object) that is used to customize the pages. Alternatively, you can export the XML file to a local computer or server, make changes to the XML tags, and re-import the file to the ASA. Either method creates a customization object that you apply to a connection profile or group policy.

Rather than customizing the pre-defined components of the logon page, you can create your own page and import it to the ASA for full customization. To do this see the "Replacing the Logon Page with your own Fully Customized Page" section on page 91-71.

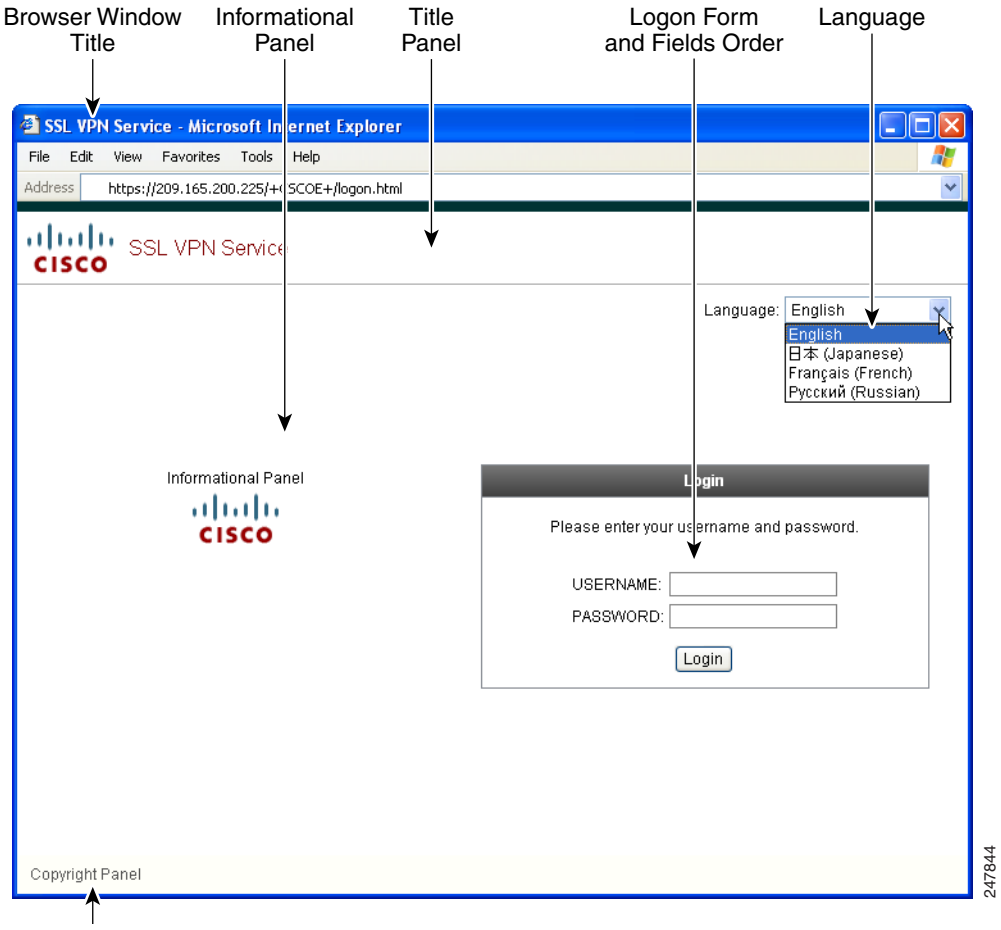
You can customize pre-defined components of the logon page, including titles, language options, and messages to users. Alternatively, you can completely replace the page with your own custom page (full customization). The following sections detail both procedures:

- Customizing the Logon Page with the Customization Editor, page 91-69
- Replacing the Logon Page with your own Fully Customized Page, page 91-71

Customizing the Logon Page with the Customization Editor

Figure 91-14 shows the logon page and the pre-defined components you can customize:

Figure 91-14 Components of Clientless Logon Page



To customize all the components of the logon page, follow this procedure. You can preview your changes for each component by clicking the Preview button:

Step 1 Specify pre-defined customization. Go to Logon Page and select **Customize pre-defined logon page components**. Specify a title for the browser window.

Step 2 Display and customize the title panel. Go to Logon Page > Title Panel and check **Display title panel**. Enter text to display as the title and specify a logo. Specify any font styles.

Step 3 Specify language options to display. Go to Logon Page > Language and check **Enable Language Selector**. Add or delete any languages to display to remote users. Languages in the list require translation tables that you configure in Configuration > Remote Access VPN > Language Localization.

Step 4 Customize the logon form. Go to Logon Page > Logon Form. Customize the text of the form and the font style in the panel. The secondary password field appears to users only if a secondary authentication server is configured in the connection profile.

Step 5 Arrange the position of the logon form fields. Go to Logon Page > Form Fields Order. Use the up and down arrow buttons to change the order that the fields are displayed.

Step 6 Add messages to users. Go to Logon Page > Informational Panel and check **Display informational panel**. Add text to display in the panel, change the position of the panel relative to the logon form, and specify a logo to display in this panel.

Step 7 Display a copyright statement. Go to Logon Page > Copyright Panel and check **Display copyright panel**. Add text to display for copyright purposes.

Step 8 Click **OK**, then apply the changes to the customization object you edited.

Replacing the Logon Page with your own Fully Customized Page

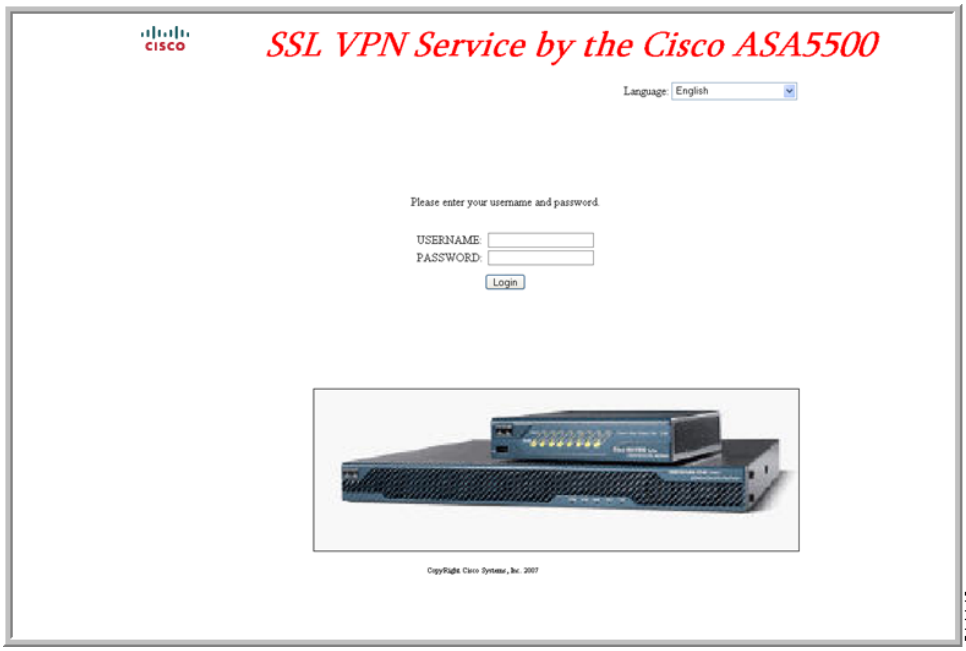
If you prefer to use your own, custom login screen, rather than changing specific components of the logon page we provide, you can perform this advanced customization using the Full Customization feature.

With Full Customization, you provide the HTML for your own login screen, and you insert Cisco HTML code that calls functions on the ASA that create the Login form and the Language Selector drop-down list.

This document describes the modifications you need to make to your HTML code and the tasks required to configure the ASA to use your code.

Figure 91-15 shows a simple example of a custom login screen enabled by the Full Customization feature.

Figure 91-15 Example of Full Customization of Logon Page



The following sections describe the tasks to customize the login screen:

- Creating the Custom Login Screen File
- Importing the File and Images
- Configuring the Security Appliance to use the Custom Login Screen

Creating the Custom Login Screen File

The following HTML code is used as an example and is the code that displays:

```
<head>
<meta http-equiv="Content-Type" content="text/html; charset=windows-1252">
<title>New Page 3</title>
<base target="_self">
</head>

<p align="center">
<img border="0" src="/+CSCOU+/cisco_logo.jpg" width="188" height="48"><font face="Snap
ITC" size="6" color="#FF00FF">
</font><font face="Snap ITC" color="#FF00FF" size="7"> </font><i><b><font
color="#FF0000" size="7" face="Sylfaen"> SSL VPN Service by the Cisco
ASA5500</font></b></i></p>

    <body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">

    <table>

    <tr><td colspan=3 height=20 align=right><div id="selector" style="width:
    300px"></div></td></tr>
    <tr><td></td><td></td><td></td></tr>
    <tr>
    <td height="379"></td>
    <td height="379"></td>
    <td align=middle valign=middle>
    <div id=lform >
    <p> </p>
    <p> </p>
    <p> </p>
    <p>Loading...</p>
    </div>
    </td>
    </tr>
    <tr>
    <td width="251"></td>
    <td width="1"></td>
    <td align=right valign=right width="800">
    <img border="1" src="/+CSCOU+/asa5500.jpg" width="660" height="220" align="middle">
    </td></tr>

    </table>
```

The indented code injects the Login form and the Language Selector on the screen. The function **csco_ShowLoginForm('lform')** injects the logon form. **csco_ShowLanguageSelector('selector')** injects the Language Selector.

Follow these steps to modify your HTML file:

Step 1 Name your file **logon.inc**. When you import the file, the ASA recognizes this filename as the logon screen.

Step 2 Modify the paths of images used by the file to include **/+CSCOU+/**.

Files that are displayed to remote users before authentication must reside in a specific area of the ASA cache memory represented by the path /+CSCOU+/. Therefore, the source for each image in the file must include this path. For example:

```
src="/+CSCOU+/asa5520.gif"
```

Step 3 Insert the special HTML code below. This code contains the Cisco functions, described earlier, that inject the login form and language selector onto the screen.

```
<body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">

<table>

<tr><td colspan=3 height=20 align=right><div id="selector" style="width:
300px"></div></td></tr>
<tr><td></td><td></td><td></td></tr>
<tr>
<td height="379"></td>
<td height="379"></td>
<td align=middle valign=middle>
<div id=lform >
<p> </p>
<p> </p>
<p> </p>
<p>Loading...</p>
</div>
</td>
</tr>
<tr>
<td width="251"></td>
<td width="1"></td>
<td align=right valign=right width="800">
<img border="1" src="/+CSCOU+/asa5500.jpg" width="660" height="220" align="middle">
</td></tr>

</table>
```

Importing the File and Images

Follow these steps to import your HTML file and any images to the ASA:

Step 1 Go to **Clientless SSL VPN Access > Portal > Web Contents**.

Step 2 Click Import. The Import Web Content window displays.

- **a.** Select the **Source** option, and enter the path the web content files.
- **b.** In the **Destination** area, select **No** for *Require Authentication to access its content* . This ensures the files are stored in the area of flash memory accessible to users before authentication.

Step 3 Click Import Now, and kee used by the file as Web Content using the same window.

Configuring the Security Appliance to use the Custom Login Screen

Follow these steps to enable the ASA to use the new login screen in a customization object:

Step 1 Select a customization object. Go to **Clientless SSL VPN Access > Portal > Customization**. Select a customization object in the table and click **Edit**. The Edit Customization Object window displays.

Step 2 In the navigation pane, select Logon Page.

Step 3 Choose Replace pre-defined logon page with a custom page.

Step 4 Click Manage to import your logon page file. The Import Web Content window displays.

Step 5 In the Destination area, select **No** to ensure your logon page is visible to users before they authenticate.

Step 6 Back in the Edit Customization Object window, click General and enable the customization object for the connection profile and/or group policies you desire.

Using Clientless SSL VPN with PDAs

You can access clientless SSL VPN from your Pocket PC or other certified personal digital assistant device. Neither the ASA administrator nor the clientless SSL VPN user need do anything special to use clientless SSL VPN with a certified PDA.

Cisco has certified the following PDA platform:

HP iPaq H4150
Pocket PC 2003
Windows CE 4.20.0, build 14053
Pocket Internet Explorer (PIE)
ROM version 1.10.03ENG
ROM Date: 7/16/2004

Some differences in the PDA version of clientless SSL VPN exist:

- A banner web page replaces the popup clientless SSL VPN window.
- An icon bar replaces the standard clientless SSL VPN floating toolbar. This bar displays the Go, Home and Logout buttons.
- The Show Toolbar icon is not included on the main clientless SSL VPN portal page.
- Upon clientless SSL VPN logout, a warning message provides instructions for closing the PIE browser properly. If you do not follow these instructions and you close the browser window in the common way, PIE does not disconnect from clientless SSL VPN or any secure website that uses HTTPS.

Restrictions

- Clientless SSL VPN supports OWA 2000 and OWA 2003 Basic Authentication. If Basic Authentication is not configured on an OWA server and a clientless SSL VPN user attempts to access that server, access is denied.
- Unsupported clientless SSL VPN features:
  - Application Access and other Java-dependent features.
  - HTTP proxy.
  - The Citrix Metaframe feature (if the PDA does not have the corresponding Citrix ICA client software).

Using E-Mail over Clientless SSL VPN

Clientless SSL VPN supports several ways to access e-mail. This section includes the following methods:

- Configuring E-mail Proxies

- Configuring Web E-mail: MS Outlook Web App

Configuring E-mail Proxies

Clientless SSL VPN supports IMAP4S, POP3S, and SMTPS e-mail proxies. The following attributes apply globally to e-mail proxy users.

Restrictions

E-mail clients such as MS Outlook, MS Outlook Express, and Eudora lack the ability to access the certificate store.

1 With the Eudora e-mail client, SMTPS works only on port 465, even though the default port for SMTPS connections is 988.

Configuring Web E-mail: MS Outlook Web App

The ASAsupports Microsoft Outlook Web App to Exchange Server 2010 and Microsoft Outlook Web Access to Exchange Server 2007, 2003, and 2000. OWA requires that users perform the following steps:

Detailed Steps

Step 1 Enter the URL of the e-mail service into the address field or click an associated bookmark in the clientless SSL VPN session.

Step 2 When prompted, enter the e-mail server username in the format *domain\username*.

Step 3 Enter the e-mail password.

Configuring Portal Access Rules

This enhancement allows customers to configure a global clientless SSL VPN access policy to permit or deny clientless SSL VPN sessions based on the data present in the HTTP header. If the ASA denies a clientless SSL VPN session, it returns an error code to the endpoint immediately.

The ASA evaluates this access policy before the endpoint authenticates to the ASA. As a result, in the case of a denial, fewer ASA processing resources are consumed by additional connection attempts from the endpoint.

Prerequisites

Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays this prompt:

```
hostname(config)#
```

Detailed Steps

Step 1 Start ASDM and select **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Portal Access Rule**.

The Portal Access Rule window opens.

Step 2 Click **Add** to create a portal access rule or select an existing rule and click **Edit.**

The Add (or Edit) Portal Access Rule dialog box opens.

Step 3 Enter a rule number from 1-65535 in the Rule Priority field.

Rules are processed in order of priority from 1-65535.

Step 4 In the User Agent field, enter the name of the user agent you want to find in the HTTP header.

- Surround the string with wildcards (*) to generalize the string; for example, *Thunderbird*. We recommend using wildcards in your search string. Without wildcards, the rule may not match any strings or it may match many fewer strings than you expect.
- If your string contains a space, ASDM automatically adds quotes to the beginning and end of the string when it saves the rule. For example, if you enter `my agent`, ASDM will save the string as `"my agent"`. ASA will then search for matches of `my agent`.

  Do not add quotes to a string with spaces yourself unless you want ASA to match the quotes you added to the string. For example, if you enter `"my agent"` ASDM will save the string as `"\"my agent\""` and try to find a match for `"my agent"` and it will not find `my agent`.
- If you want to use wildcards with a string that contains a space, start and end the entire string with wildcards, for example, `*my agent*` and ASDM will automatically surround that string with quotes when it saves the rule.

Step 5 In the Action field, select either **Deny** or **Permit**.

The ASA will deny or permit a clientless SSL VPN connection based on this setting.

Step 6 Enter an HTTP message code in the Returned HTTP Code field.

The HTTP message number 403 is pre-populated in the field and is the default value for portal access rules. The allowed range of message codes is 200-599.

Step 7 Click **OK**.

Step 8 Click **Apply**.

Using Proxy Bypass

You can configure the ASA to use proxy bypass when applications and web resources work better with the special content rewriting this feature provides. Proxy bypass is an alternative method of content rewriting that makes minimal changes to the original content. It is often useful with custom web applications.

You can configure multiple proxy bypass entries. The order in which you configure them is unimportant. The interface and path mask or interface and port uniquely identify a proxy bypass rule.

If you configure proxy bypass using ports rather than path masks, depending on your network configuration, you might need to change your firewall configuration to allow these ports access to the ASA. Use path masks to avoid this restriction. Be aware, however, that path masks can change, so you might need to use multiple pathmask statements to exhaust the possibilities.

A path is everything in a URL after the .com or .org or other types of domain name. For example, in the URL www.example.com/hrbenefits, *hrbenefits* is the path. Similarly, for the URL www.example.com/hrinsurance, *hrinsurance* is the path. If you want to use proxy bypass for all hr sites, you can avoid using the command multiple times by using the * wildcard as follows: /hr*.

Detailed Steps

You can set rules for when the ASA performs little or no content rewriting:

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Proxy Bypass**.

Step 2 Select the Interface name for proxy bypass.

Step 3 Specify either a port or a URI for proxy bypass:

- Port—(radio button) Click to use a port for proxy bypass. The valid port numbers are 20000-21000.
- Port (field)—Enter a high-numbered port for the ASA to reserve for proxy bypass.
- Path Mask—(radio button) Click to use a URL for proxy bypass.
- Path Mask—(Field) Enter a URL for proxy bypass. It can contain a regular expression.

Step 4 Define target URLs for proxy bypass:

- URL—(drop-down list) Click either http or https as the protocol.
- URL (text field)—Enter a URL to which you want to apply proxy bypass.

Step 5 Specify the content to rewrite. The choices are none or a combination of XML, links, and cookies.

- XML—Check to rewrite XML content.
- Hostname—Check to rewrite links.

Clientless SSL VPN End User Setup

This section is for the system administrator who sets up clientless SSL VPN for end users. It describes how to customize the end-user interface.

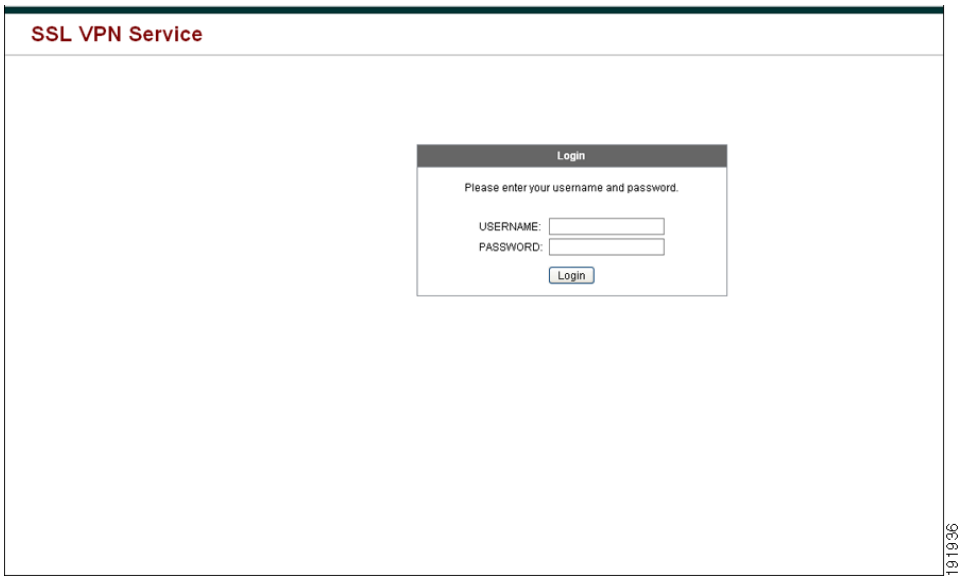
This section summarizes configuration requirements and tasks for a remote system. It specifies information to communicate to users to get them started using clientless SSL VPN. It includes the following topics:

- Defining the End User Interface
- Customizing Clientless SSL VPN Pages, page 91-80
- Customizing Help, page 91-121
- Requiring Usernames and Passwords
- Communicating Security Tips
- Configuring Remote Systems to Use Clientless SSL VPN Features

Defining the End User Interface

The clientless SSL VPN end user interface consists of a series of HTML panels. A user logs on to clientless SSL VPN by entering the IP address of an ASA interface in the format https://*address*. The first panel that displays is the login screen (Figure 91-16).

Figure 91-16 Clientless SSL VPN Login Screen



Viewing the Clientless SSL VPN Home Page

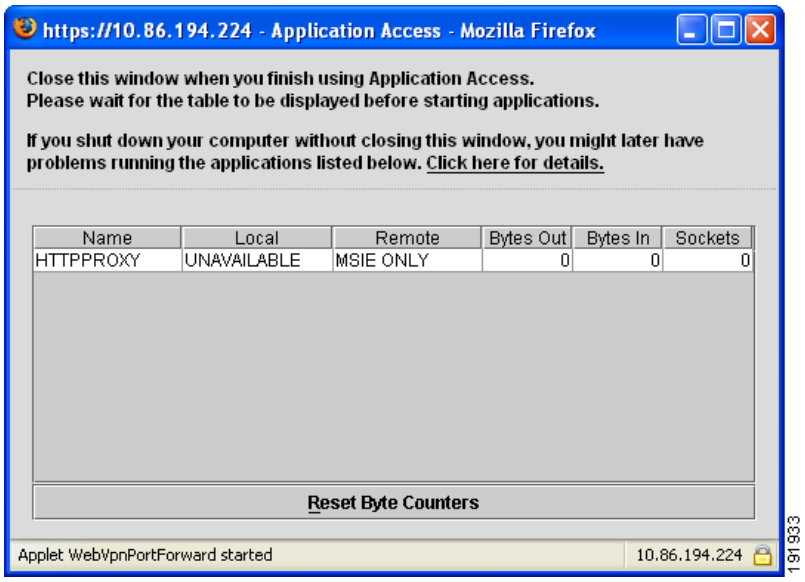
After the user logs in, the portal page opens.

The home page displays all of the clientless SSL VPN features you have configured, and its appearance reflects the logo, text, and colors you have selected. This sample home page includes all available clientless SSL VPN features with the exception of identifying specific file shares. It lets users browse the network, enter URLs, access specific websites, and use Application Access (port forwarding and smart tunnels) to access TCP applications.

Viewing the Clientless SSL VPN Application Access Panel

To start port forwarding or smart tunnels, a user clicks the **Go** button in the Application Access box. The Application Access window opens (Figure 91-17).

Figure 91-17 Clientless SSL VPN Application Access Window



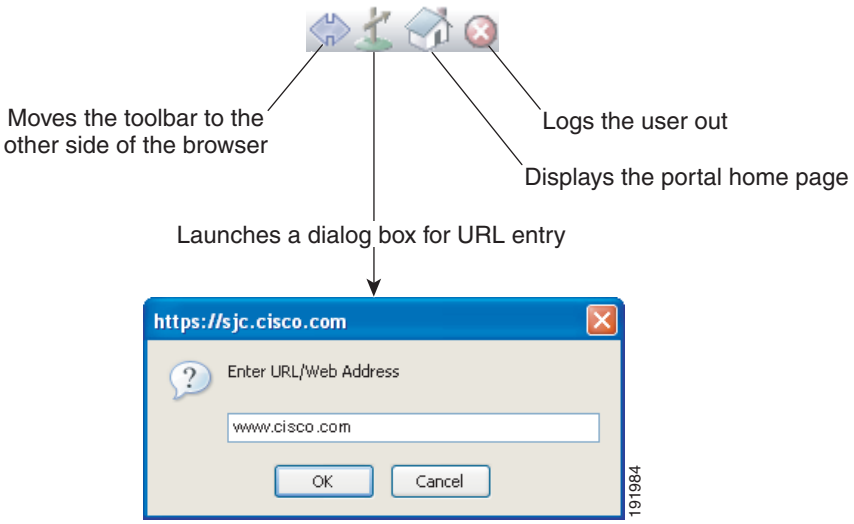
This window displays the TCP applications configured for this clientless SSL VPN connection. To use an application with this panel open, the user starts the application in the normal way.

Note A stateful failover does not retain sessions established using Application Access. Users must reconnect following a failover.

Viewing the Floating Toolbar

The floating toolbar shown in Figure 91-18 represents the current clientless SSL VPN session.

Figure 91-18 Clientless SSL VPN Floating Toolbar



Be aware of the following characteristics of the floating toolbar:

- The toolbar lets you enter URLs, browse file locations, and choose preconfigured web connections without interfering with the main browser window.
- If you configure your browser to block popups, the floating toolbar cannot display.
- If you close the toolbar, the ASA prompts you to confirm that you want to end the clientless SSL VPN session.

See Table 91-14 on page 91-123 for detailed information about using clientless SSL VPN.

Customizing Clientless SSL VPN Pages

You can change the appearance of the portal pages displayed to clientless SSL VPN users. This includes the Login page displayed to users when they connect to the security appliance, the Home page displayed to users after the security appliance authenticates them, the Application Access window displayed when users launch an application, and the Logout page displayed when users log out of clientless SSL VPN sessions.

After you customize the portal pages, you can save your customization and apply it to a specific connection profile, group policy, or user. The changes do not take effect until you reload the ASA, or you disable and then enable clientless SSL.

You can create and save many customization objects, enabling the security appliance to change the appearance of portal pages for individual users or groups of users.

This section includes the following topics:

- Information About Customization, page 91-80
- Exporting a Customization Template, page 77-84
- Editing the Customization Template, page 91-81
- Login Screen Advanced Customization, page 91-87
- Login Screen Advanced Customization, page 91-87

Information About Customization

The ASA uses customization objects to define the appearance of user screens. A customization object is compiled from an XML file which contains XML tags for all the customizable screen items displayed to remote users. The ASA software contains a customization template that you can export to a remote PC. You can edit this template and import the template back into the ASA as a new customization object.

When you export a customization object, an XML file containing XML tags is created at the URL you specify. The XML file created by the customization object named *Template* contains empty XML tags, and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory but can be exported, edited, and imported back into the ASA as a new customization object.

Customization Objects, Connection Profiles, and Group Policies

Initially, when a user first connects, the default customization object (named *DfltCustomization*) identified in the connection profile (tunnel group) determines how the logon screen appears. If the connection profile list is enabled, and the user selects a different group which has its own customization, the screen changes to reflect the customization object for that new group.

After the remote user is authenticated, the screen appearance is determined by whether a customization object that has been assigned to the group policy.

Exporting a Customization Template

When you export a customization object, an XML file is created at the URL you specify. The customization template (named *Template*) contains empty XML tags and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory but can be exported, edited, and imported back into the ASA as a new customization object.

Editing the Customization Template

This section shows the contents of the customization template and has convenient figures to help you quickly choose the correct XML tag and make changes that affect the screens.

You can use a text editor or an XML editor to edit the XML file. The following example shows the XML tags of the customization template. Some redundant tags have been removed for easier viewing:

Example:

```
<custom>
   <localization>
      <languages>en,ja,zh,ru,ua</languages>
      <default-language>en</default-language>
   </localization>
    <auth-page>
      <window>
          <title-text l10n="yes"><![CDATA[SSL VPN Service]]></title-text>

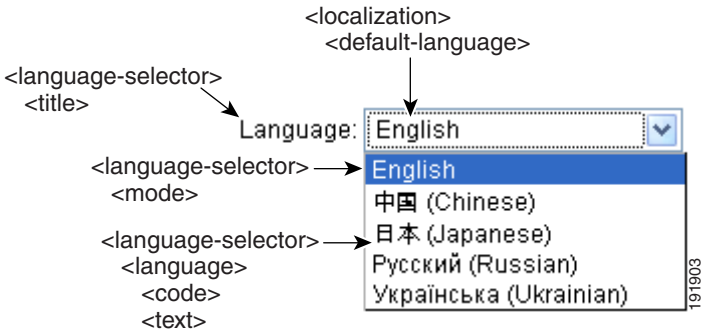

Figure 91-21 shows the Information Panel that is available on the Logon page, and the XML tags for customizing this feature. This information can appear to the left or right of the login box. These tags are nested within the higher-level <auth-page> tag.

Figure 91-21 Information Panel on Logon Screen and Associated XML Tags

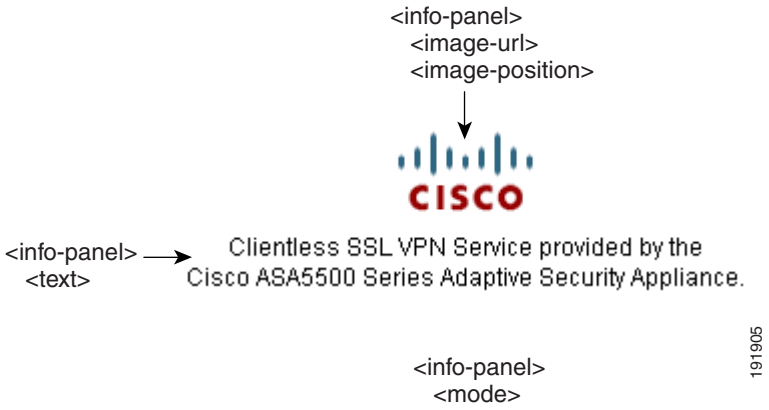

Figure 91-22 shows the Portal page and the XML tags for customizing this feature. These tags are nested within the higher-level <auth-page> tag.

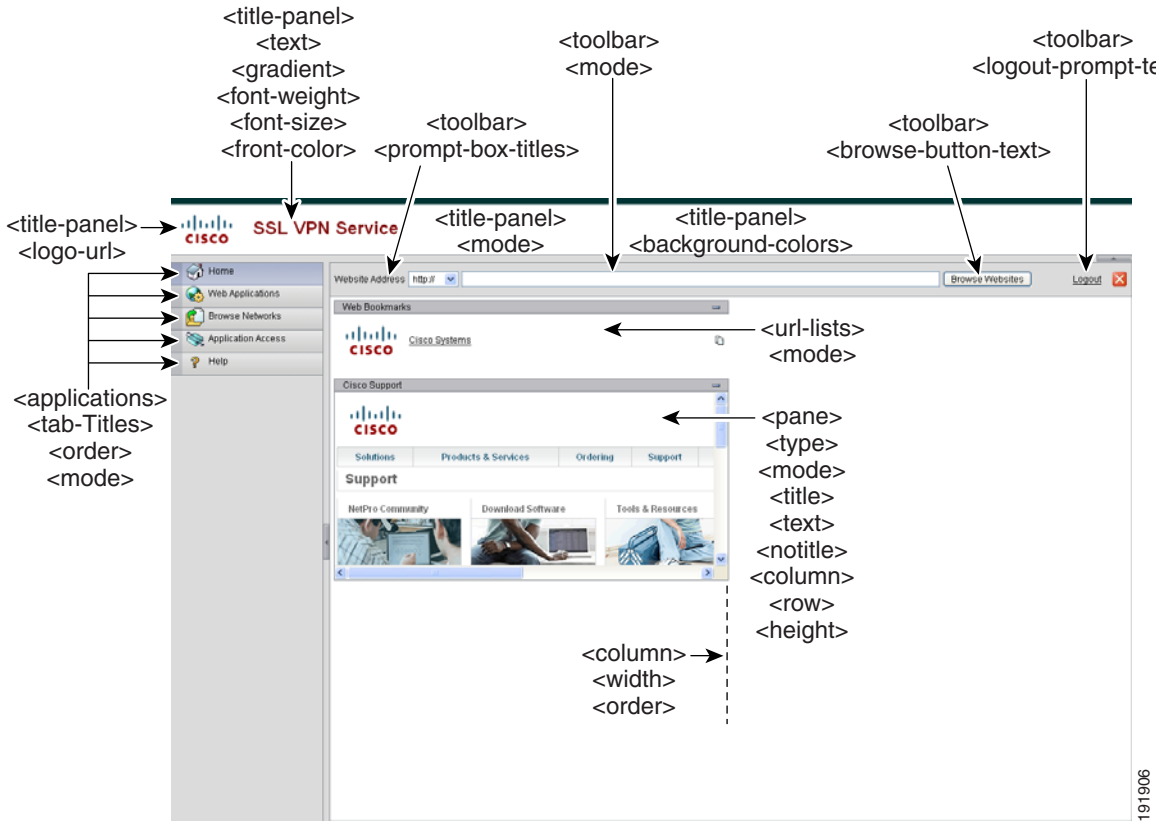
Figure 91-22 Portal Page and Associated XML Tags



Login Screen Advanced Customization

If you prefer to use your own, custom login screen, rather than changing specific screen elements of the login screen we provide, you can perform this advanced customization using the *Full Customization* feature.

With Full Customization, you provide the HTML for your own login screen, and you insert Cisco HTML code that calls functions on the ASA that create the Login form and the Language Selector drop-down list.

This section describes the modifications you need to make to your HTML code and the tasks required to configure the ASA to use your code.

Figure 91-23 shows the standard Cisco login screen that displays to clientless SSL VPN users. The Login form is displayed by a function called by the HTML code.

Figure 91-23 Standard Cisco Login Page

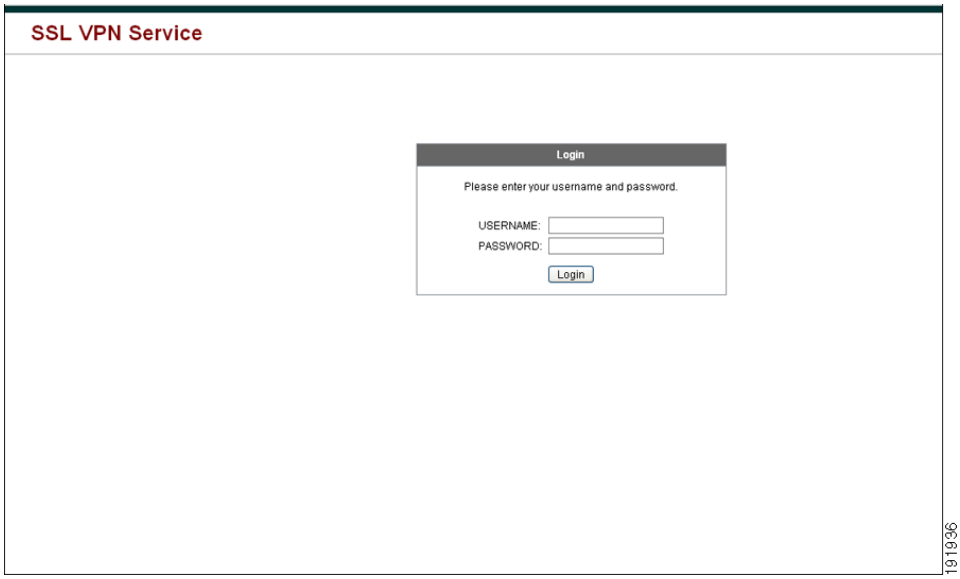


Figure 91-24 shows the Language Selector drop-down list. This feature is an option for clientless SSL VPN users and is also called by a function in the HTML code of the login screen.

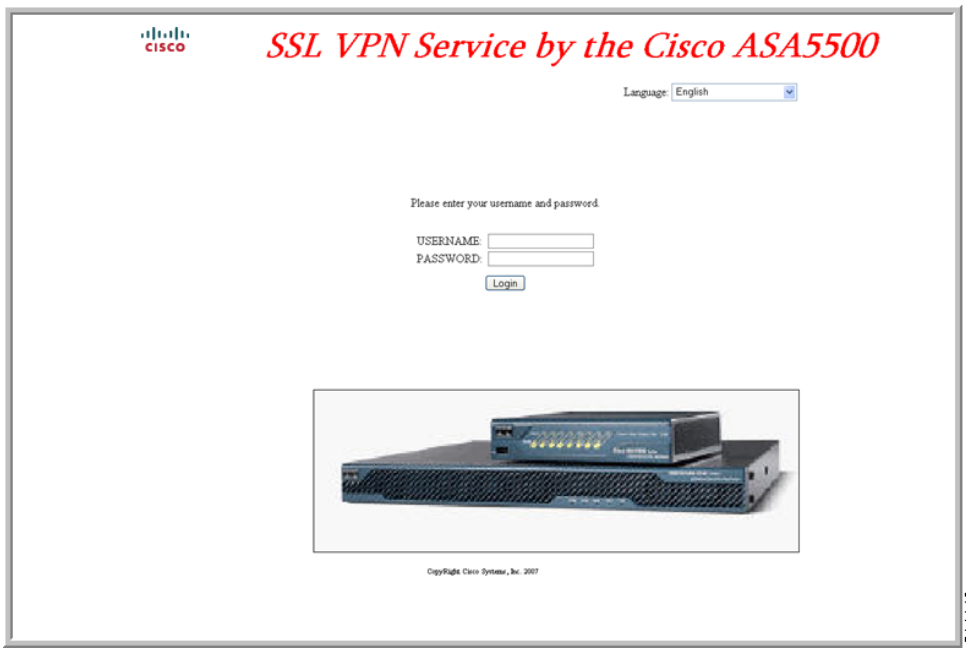
Figure 91-24 Language Selector Drop-down List

Figure 91-25 shows a simple example of a custom login screen enabled by the Full Customization feature.

Figure 91-25 Example of Full Customization of Login Screens



The following HTML code is used as an example and is the code that displays:

Example:

```
<head>
<meta http-equiv="Content-Type" content="text/html; charset=windows-1252">
<title>New Page 3</title>
<base target="_self">
</head>

<p align="center">
<img border="0" src="/+CSCOU+/cisco_logo.jpg" width="188" height="48"><font face="Snap
ITC" size="6" color="#FF00FF">
</font><font face="Snap ITC" color="#FF00FF" size="7"> </font><i><b><font
color="#FF0000" size="7" face="Sylfaen"> SSL VPN Service by the Cisco
ASA5500</font></b></i></p>

    <body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">

    <table>

    <tr><td colspan=3 height=20 align=right><div id="selector" style="width:
    300px"></div></td></tr>
    <tr><td></td><td></td><td></td></tr>
    <tr>
    <td height="379"></td>
    <td height="379"></td>
    <td align=middle valign=middle>
    <div id=lform >
    <p> </p>
```

```
<p> </p>
<p> </p>
<p>Loading...</p>
</div>
</td>
</tr>
<tr>
<td width="251"></td>
<td width="1"></td>
<td align=right valign=right width="800">
<img border="1" src="/+CSCOU+/asa5500.jpg" width="660" height="220" align="middle">
</td></tr>

</table>
```

The indented code injects the Login form and the Language Selector on the screen. The function **csco_ShowLoginForm('lform')** injects the logon form. **csco_ShowLanguageSelector('selector')** injects the Language Selector.

Modifying Your HTML File

Follow these steps to modify your HTML file:

Detailed Steps

Step 1 Name your file **logon.inc**. When you import the file, the ASA recognizes this filename as the logon screen.

Step 2 Modify the paths of images used by the file to include **/+CSCOU+/**.

Files that are displayed to remote users before authentication must reside in a specific area of the ASA cache memory represented by the path /+CSCOU+/. Therefore, the source for each image in the file must include this path. For example:

```
src="/+CSCOU+/asa5520.gif"
```

Step 3 Insert the special HTML code below. This code contains the Cisco functions, described earlier, that inject the login form and language selector onto the screen.

```
<body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">

<table>

<tr><td colspan=3 height=20 align=right><div id="selector" style="width:
300px"></div></td></tr>
<tr><td></td><td></td><td></td><td></td></tr>
<tr>
<td height="379"></td>
<td height="379"></td>
<td align=middle valign=middle>
<div id=lform >
<p> </p>
<p> </p>
<p> </p>
<p>Loading...</p>
</div>
</td>
</tr>
<tr>
<td width="251"></td>
<td width="1"></td>
```

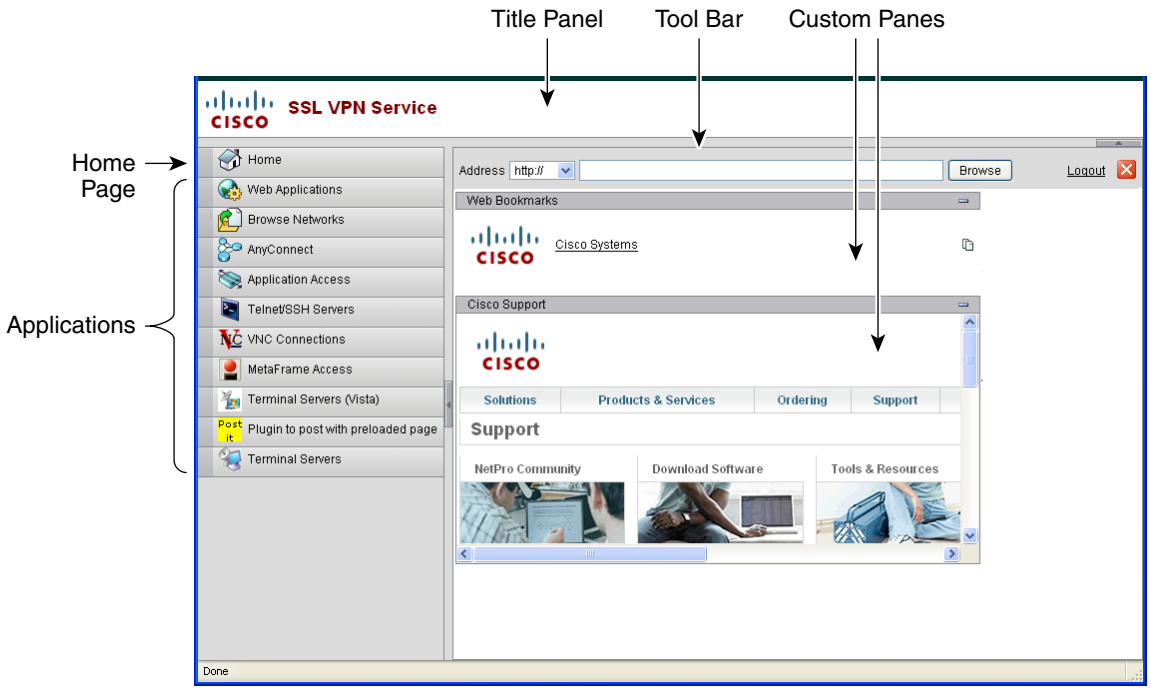
```
<td align=right valign=right width="800">
<img border="1" src="/+CSCOU+/asa5500.jpg" width="660" height="220" align="middle">
</td></tr>

</table>
```

Customizing the Portal Page

Figure 91-26 shows the portal page and the pre-defined components you can customize:

Figure 91-26 Customizable Components of the Portal Page



In addition to customizing the components of the page, you can divide the portal page into custom panes that display text, an image, an RSS feed, or HTML. In Figure 91-26, the portal page is divided into one column with two rows.

To customize the portal page, follow this procedure. You can preview your changes for each component by clicking the **Preview** button:

Step 1 Go to Portal Page and specify a title for the browser window.

Step 2 Display and customize the title panel. Go to Portal Page > Title Panel and check **Display title panel**. Enter text to display as the title and specify a logo. Specify any font styles.

Step 3 Enable and customize the toolbar. Go to Portal Page > Toolbar and check **Display toolbar**. Customize the Prompt Box, Browse button, and Logout prompt as desired.

Step 4 Customize the Applications list. Go to Portal Page > Applications and check **Show navigation panel**. The applications populated in the table are those applications you enabled in the ASA configuration, including client-server plugins and port forwarding applications.

Step 5 Create custom panes in the portal page space. Go to Portal Page > Custom Panes and divide the window into rows and columns for text, images, RSS feeds, or HTML pages, as desired.

Step 6 Specify a home page URL. Go to Portal Page > Home Page and check **Enable custom intranet web page**. Choose a bookmark mode that defines how bookmarks are organized.

Configure a timeout alert message and a tooltip. Go to Portal Page > Timeout Alerts. See Configuring Custom Portal Timeout Alerts for full instructions.

Configuring Custom Portal Timeout Alerts

So that users of the clientless SSL VPN feature can manage their time in the VPN session, the clientless SSL VPN portal page displays a countdown timer showing the total time left before the clientless VPN session expires. Sessions can timeout due to inactivity or because they have reached the end of a maximum allowed connection time that you have configured.

You can create custom messages to alert users that their session is about to end because of an idle timeout or a session timeout. Your custom message replaces the default idle timeout message. The default message is, "`Your session will expire in %s .`" The **`%s`** place holder in your message is replaced by a ticking countdown timer.

Step 1 Start ASDM and select **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Customization**.

Step 2 Click **Add** to add a new customization object or select an existing customization object and click **Edit** to add a custom idle timeout message to an existing customization object.

Step 3 In the Add / Edit Customization Object pane, expand the Portal Page node on the navigation tree and click **Timeout Alerts**.

Step 4 Check **Enable alert visual tooltip (red background for timer countdown)**. This displays the countdown timer as a tool tip on a red background. When users click the Time left area, the time area expands to display your custom timeout alert message. If you leave this box unchecked, users see the custom timeout alerts in a pop-up window.

Step 5 Enter a message in the Idle Timeout Message box and in the Session Timeout Message box. An example of a message could be, `Warning: Your session will end in %s. Please complete your work and prepare to close your applications.`

Step 6 Click **OK**.

Step 7 Click **Apply**.

Specifying a Custom Timeout Alert in a Customization Object File

If you desire, you can edit an existing customization object file outside of the ASA and import it to the ASA. For more information about Importing and Exporting Customization objects see Importing/Exporting Customization Object, page 91-94. See also, Creating XML-Based Portal Customization Objects and URL Lists, page 91-94.

The timeout messages are configured in the <timeout-alerts> XML element of your XML customization object file. The <timeout-alerts> element is a child of the <portal> element. The <portal> element is a child of the <custom> element.

The <timeout-alerts> element is placed after the <home-page> element and before any <application> elements in the order of the <portal> child elements.

You need to specify these child-elements of <timeout-alerts>:

- <alert-tooltip> – If set to “yes”, users see the countdown timer on a red background as a tool tip. Clicking the count down timer expands the tooltip to display your custom message. If set to “no” or if is undefined, users receive your custom messages in pop-up windows.
- <session-timeout-message> – Enter your custom session timeout message in this element. If set and not empty, users receive your custom message instead of the default message. The %s place holder in the message will be replaced with a ticking countdown timer.
- <idle-timeout-message> – Enter your custom idle timeout message in this element. If set and not empty, users receive your custom message instead of the default message. The %s place holder will be replaced with a ticking countdown timer.

Configuration Example for Timeout-alert Element and Child Elements

This example shows only the <timeout-alerts> elements of the <portal> element.

Note Do not cut and paste this example into an existing customization object.

```
<portal>
    <window></window>
    <title-panel></title-panel>
    <toolbar></toolbar>
    <url-lists></url-lists>
    <navigation-panel></navigation-panel>
    <home-page>
    <timeout-alerts>
        <alert-tooltip>yes</alert-tooltip>

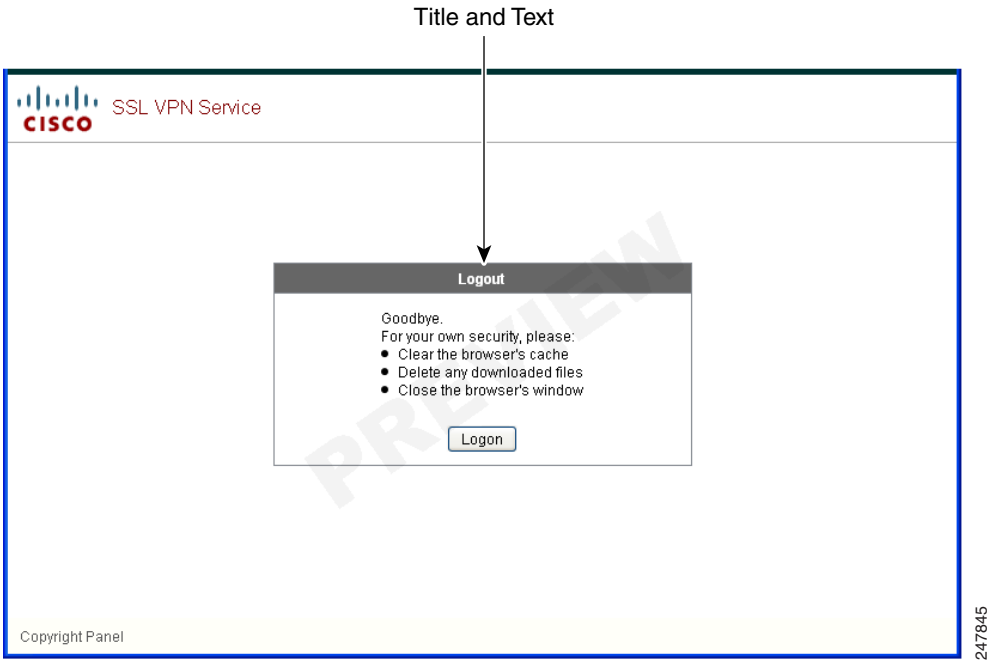
Customizing the Logout Page

Figure 91-27 shows the logout page you can customize:

Figure 91-27 Components of the Logout Page



To customize the logout page, follow this procedure. You can preview your changes for each component by clicking the **Preview** button:

Step 1 Go to Logout Page. Customize the title or text as you desire.

Step 2 For the convenience of the user, you can display the Login button on the Logout page. To do this, check **Show logon button**. Customize the button text, if desired.

Step 3 Customize the title font or background, as desired.

Step 4 Click **OK**, then apply the changes to the customization object you edited.

Customizing the External Portal Page

Adding Customization Object

To add a customization object, create a copy of and provide a unique name for the DfltCustomization object. Then you can modify or edit it to meet your requirements.

Detailed Steps

Step 1 Click **Add** and enter a name for the new customization object. Maximum 64 characters, no spaces.

Step 2 (Optional) Click **Find** to search for a customization object. Start typing in the field, and the tool searches the beginning characters of every field for a match. You can use wild cards to expand your search. For example, typing *sal* in the Find field matches a customization object named sales but not a customization object named wholesalers. If you type **sal* in the Find field, the search finds the first instance of either sales or wholesalers in the table.

Use the up and down arrows to skip up or down to the next string match. Check the **Match Case** checkbox to make your search case sensitive.

Step 3 Specify when the onscreen keyboard shows on portal pages. The choices are as follows:

- Do not show OnScreen Keyboard
- Show only for the login page
- Show for all portal pages requiring authentication

Step 4 (Optional) Highlight a customization object and click **Assign** to assign the selected object to one or more group policies, connection profiles, or LOCAL users.

Importing/Exporting Customization Object

You can import or export already-existing customization objects. Import an object that you want to apply to end users. Export a customization object already resident on the ASA for editing purposes, after which you can reimport it.

Detailed Steps

Step 1 Identify the customization object by name. Maximum 64 characters, no spaces.

Step 2 Choose the method by which you want to import or export the customization file:

- Local computer—Choose this method to import a file that resides on the local PC.
- Path—Provide the path to the file.
- Browse Local Files—Browse to the path for the file.
- Flash file system—Choose this method to export a file that resides on the ASA.
- Path—Provide the path to the file.
- Browse Flash—Browse to the path for the file.
- Remote server—Choose this option to import a customization file that resides on a remote server accessible from the ASA.
- Path—Identify the method to access the file (ftp, http, or https), and provide the path to the file.

Step 3 Click to import or export the file.

Creating XML-Based Portal Customization Objects and URL Lists

This section includes the following topics:

- Understanding the XML Customization File Structure, page 91-95

- Configuration Example for Customization, page 91-98
- Using the Customization Template, page 91-101
- Help Customization, page 91-113
- Import/Export Application Help Content, page 91-116

Understanding the XML Customization File Structure

Table 91-8 presents the file structure for an XML customization object.

Note Absence of a parameter/tag results in a default/inherited value, while presence results in setting the parameter/tag value even it is an empty string.

Table 91-8 XML-Based Customization File Structure

Tag	Type	Values	Preset value	Description
custom	**node**	—	—	**Root tag**
auth-page	**node**	—	—	**Tag-container of authentication page configuration**
window	**node**	—	—	**Browser window**
title-text	string	Arbitrary string	empty string	—
title-panel	**node**	—	—	**The page top pane with a logo and a text**
mode	text	enable|disable	disable	—
text	text	Arbitrary string	empty string	—
logo-url	text	Arbitrary URL	empty image URL	—
copyright-panel	**node**	—	—	**The page bottom pane with a copyright information**
mode	text	enable|disable	disable	—
text	text	Arbitrary URL	empty string	—
info-panel	**node**	—	—	**The pane with a custom text and image**
mode	string	enable|disable	disable	—
image-position	string	above|below	above	The image position, relative to text
image-url	string	Arbitrary URL	empty image	—
text	string	Arbitrary string	empty string	—
logon-form	**node**	—	—	**The form with username, password, group prompt**
title-text	string	Arbitrary string	Logon	—

Table 91-8 XML-Based Customization File Structure (continued)

message-text	string	Arbitrary string	empty string	—
username-prompt-text	string	Arbitrary string	Username	—
password-prompt-text	string	Arbitrary string	Password	—
internal-password-prompt-text	string	Arbitrary string	Internal Password	—
group-prompt-text	string	Arbitrary string	Group	—
submit-button-text	string	Arbitrary string	Logon	
logout-form	**node**	**—**	**—**	**The form with a logout message and the buttons to login or close the window**
title-text	string	Arbitrary string	Logout	—
message-text	string	Arbitrary string	Empty string	—
login-button-text	string	Arbitrary string	Login	
close-button-text	string	Arbitrary string	Close window	—
language-selector	**node**	**—**	**—**	**The drop-down list to select a language**
mode	string	enable|disable	disable	—
title	text	—	Language	The prompt text to select language
language	**node (multiple)**	**—**	**—**	**—**
code	string	—	—	—
text	string	—	—	—
portal	**node**	**—**	**—**	**Tag-container of the portal page configuration**
window	**node**	**—**	**—**	**see authentication page description**
title-text	string	Arbitrary string	Empty string	—
title-panel	**node**	**—**	**—**	**see authentication page description**
mode	string	enable|disable	Disable	—
text	string	Arbitrary string	Empty string	—
logo-url	string	Arbitrary URL	Empty image URL	—
navigation-panel	**node**	**—**	**—**	**The pane on the left with application tabs**
mode	string	enable|disable	enable	—

Table 91-8 XML-Based Customization File Structure (continued)

application	**node (multiple)**	—	**N/A**	**The node changes defaults for the configured (by id) application**
id	string	For stock application web-access file-access app-access net-access help For ins: Unique plug-in	N/A	—
tab-title	string	—	N/A	—
order	number	—	N/A	Value used to sort elements. The default element order values have step 1000, 2000, 3000, etc. For example, to insert an element between the first and second element, use a value 1001 – 1999.
url-list-title	string	—	N/A	If the application has bookmarks, the title for the panel with grouped bookmarks
mode	string	enableldisable	N/A	v
toolbar	**node**	—	—	—
mode	string	enableldisable	Enable	—
prompt-box-title	string	Arbitrary string	Address	Title for URL prompt list
browse-button-text	string	Arbitrary string	Browse	Browse button text
logout-prompt-text	string	Arbitrary string	Logout	—
column	**node (multiple)**	—	—	**One column will be shown by default**
width	string	—	N/A	—
order	number	—	N/A	Value used to sort elements.

Table 91-8 XML-Based Customization File Structure (continued)

url-lists	**node**	**—**	**—**	**URL lists are considered to be default elements on the portal home page, if they are not explicitly disabled**
mode	string	group | nogroup	group	Modes: group – elements grouped by application type i.e. Web Bookmarks, File Bookmarks) no-group – url-lists are shown in separate panes disable – do not show URL lists by default
panel	node (multiple)	—	—	Allows to configure extra panes
mode	string	enable|disable	—	Used to temporarily disable the panel without removing its configuration
title	string	—	—	—
type	string	—	—	Supported types: RSS IMAGE TEXT HTML
url url-mode	string string	— —	— —	URL for RSS,IMAGE or HTML type paned Modes: mangle, no-mangle
text	string	—	—	Text for TEXT type panes
column	number	—	—	—

Configuration Example for Customization

The following example illustrates the following customization options:

- Hides tab for the File access application
- Changes title and order of Web Access application

- Defines two columns on the home page
- Adds an RSS pane
- Adds three panes (text, image, and html) at the top of second pane

```
<custom name="Default">
  <auth-page>

</custom>
```

Using the Customization Template

A customization template, named *Template*, contains all currently employed tags with corresponding comments that describe how to use them. Use the **export** command to download the customization template from the ASA, as follows:

```
hostname# export webvpn customization Template tftp://webserver/default.xml
hostname#
```

You cannot change or delete the file *Template*. When you export it, as in this example, you are saving it to a new name, *default.xml*. After you make your changes to this file to create a customization object that meets the needs of your organization, import it to the ASA, either as *default.xml* or another name of your choosing. For example:

```
hostname# import webvpn customization General tftp://webserver/custom.xml
hostname#
```

where you import an XML object called *custom.xml*, and name it *General* on the ASA.

The Customization Template

The customization template, named *Template*, follows:

```
<?xml version="1.0" encoding="UTF-8" ?>
- <!--

Copyright (c) 2008,2009 by Cisco Systems, Inc.
All rights reserved.

Note: all white spaces in tag values are significant and preserved.

Tag: custom
Description: Root customization tag

Tag: custom/languages
Description: Contains list of languages, recognized by ASA
Value: string containing comma-separated language codes. Each language code is
       a set dash-separated alphanumeric characters, started with
       alpha-character (for example: en, en-us, irokese8-language-us)
Default value: en-us
Tag: custom/default-language
Description: Language code that is selected when the client and the server
             were not able to negotiate the language automatically.
             For example the set of languages configured in the browser
             is "en,ja", and the list of languages, specified by
             'custom/languages' tag is "cn,fr", the default-language will be
             used.
Value: string, containing one of the language coded, specified in
'custom/languages' tag above.
Default value: en-us

*****************************************************
```

```
Tag: custom/auth-page
Description: Contains authentication page settings

******************************************************
Tag: custom/auth-page/window
Description: Contains settings of the authentication page browser window

Tag: custom/auth-page/window/title-text
Description: The title of the browser window of the authentication page
Value: arbitrary string
Default value: Browser's default value

******************************************************

Tag: custom/auth-page/title-panel
Description: Contains settings for the title panel

Tag: custom/auth-page/title-panel/mode
Description: The title panel mode
Value: enable|disable
Default value: disable
Tag: custom/auth-page/title-panel/text
Description: The title panel text.
Value: arbitrary string
Default value: empty string

Tag: custom/auth-page/title-panel/logo-url
Description: The URL of the logo image (imported via "import webvpn webcontent")
Value: URL string
Default value: empty image URL

Tag: custom/auth-page/title-panel/background-color
Description: The background color of the title panel
Value: HTML color format, for example #FFFFFF
Default value: #FFFFFF

Tag: custom/auth-page/title-panel/font-color
Description: The background color of the title panel
Value: HTML color format, for example #FFFFFF
Default value: #000000

Tag: custom/auth-page/title-panel/font-weight
Description: The font weight
Value: CSS font size value, for example bold, bolder,lighter etc.
Default value: empty string

Tag: custom/auth-page/title-panel/font-size
Description: The font size
Value: CSS font size value, for example 10pt, 8px, x-large, smaller etc.
Default value: empty string

Tag: custom/auth-page/title-panel/gradient
Description: Specifies using the background color gradient
Value: yes|no
Default value:no

Tag: custom/auth-page/title-panel/style
Description: CSS style of the title panel
Value: CSS style string
Default value: empty string
```

```
**********************************************************

Tag: custom/auth-page/copyright-panel
Description: Contains the copyright panel settings

Tag: custom/auth-page/copyright-panel/mode
Description: The copyright panel mode
Value: enable|disable
Default value: disable

Tag: custom/auth-page/copyright-panel/text
Description: The copyright panel text
Value: arbitrary string
Default value: empty string

Tag: custom/auth-page/info-panel
Description: Contains information panel settings

Tag: custom/auth-page/info-panel/mode
Description: The information panel mode
Value: enable|disable
Default value: disable

Tag: custom/auth-page/info-panel/image-position
Description: Position of the image, above or below the informational panel text
Values: above|below
Default value: above

Tag: custom/auth-page/info-panel/image-url
Description: URL of the information panel image (imported via "import webvpn webcontent")
Value: URL string
Default value: empty image URL

Tag: custom/auth-page/info-panel/text
Description: Text of the information panel
Text: arbitrary string
Default value: empty string

**********************************************************

Tag: custom/auth-page/logon-form
Description: Contains logon form settings

Tag: custom/auth-page/logon-form/title-text
Description: The logon form title text
Value: arbitrary string
Default value: "Logon"

Tag: custom/auth-page/logon-form/message-text
Description: The message inside of the logon form
Value: arbitrary string
Default value: empty string

Tag: custom/auth-page/logon-form/username-prompt-text
Description: The username prompt text
Value: arbitrary string
Default value: "Username"

Tag: custom/auth-page/logon-form/password-prompt-text
Description: The password prompt text
Value: arbitrary string
Default value: "Password"
```

```
Tag: custom/auth-page/logon-form/internal-password-prompt-text
Description: The internal password prompt text
Value: arbitrary string
Default value: "Internal Password"

Tag: custom/auth-page/logon-form/group-prompt-text
Description: The group selector prompt text
Value: arbitrary string
Default value: "Group"

Tag: custom/auth-page/logon-form/submit-button-text
Description: The submit button text
Value: arbitrary string
Default value: "Logon"

Tag: custom/auth-page/logon-form/internal-password-first
Description: Sets internal password first in the order
Value: yes|no
Default value: no

Tag: custom/auth-page/logon-form/title-font-color
Description: The font color of the logon form title
Value: HTML color format, for example #FFFFFF
Default value: #000000

Tag: custom/auth-page/logon-form/title-background-color
Description: The background color of the logon form title
Value: HTML color format, for example #FFFFFF
Default value: #000000

Tag: custom/auth-page/logon-form/font-color
Description: The font color of the logon form
Value: HTML color format, for example #FFFFFF
Default value: #000000

Tag: custom/auth-page/logon-form/background-color
Description: The background color of the logon form
Value: HTML color format, for example #FFFFFF
Default value: #000000

Description: The font weight
Value: CSS font size value, for example bold, bolder,lighter etc.
Default value: empty string

Tag: custom/portal/title-panel/font-size
Description: The font size
Value: CSS font size value, for example 10pt, 8px, x-large, smaller etc.
Default value: empty string
Tag: custom/portal/title-panel/gradient
Description: Specifies using the background color gradient
Value: yes|no
Default value:no

Tag: custom/portal/title-panel/style
Description: CSS style for title text
Value: CSS style string
Default value: empty string

*******************************************************

Tag: custom/portal/application (multiple)
Description: Contains the application setting

Tag: custom/portal/application/mode
Description: The application mode
Value: enable|disable
Default value: enable

Tag: custom/portal/application/id
Description: The application ID. Standard application ID's are: home, web-access,
file-access, app-access, network-access, help
Value: The application ID string
Default value: empty string

Tag: custom/portal/application/tab-title
Description: The application tab text in the navigation panel
Value: arbitrary string
Default value: empty string

Tag: custom/portal/application/order
Description: The order of the application's tab in the navigation panel. Applications with
lesser order go first.
Value: arbitrary number
Default value: 1000

Tag: custom/portal/application/url-list-title
Description: The title of the application's URL list pane (in group mode)
Value: arbitrary string
Default value: Tab tite value concatenated with "Bookmarks"

*******************************************************
```

```
Tag: custom/portal/navigation-panel
Description: Contains the navigation panel settings

Tag: custom/portal/navigation-panel/mode
Description: The navigation panel mode
Value: enable|disable
Default value: enable

Tag: custom/portal/toolbar
Description: Contains the toolbar settings

Tag: custom/portal/toolbar/mode
Description: The toolbar mode
Value: enable|disable
Default value: enable

Tag: custom/portal/toolbar/prompt-box-title
Description: The universal prompt box title
Value: arbitrary string
Default value: "Address"
Tag: custom/portal/toolbar/browse-button-text
Description: The browse button text
Value: arbitrary string
Default value: "Browse"

Tag: custom/portal/toolbar/logout-prompt-text
Description: The logout prompt text
Value: arbitrary string
Default value: "Logout"

*********************************************************

Tag: custom/portal/column (multiple)
Description: Contains settings of the home page column(s)

Tag: custom/portal/column/order
Description: The order the column from left to right. Columns with lesser order values go
first
Value: arbitrary number
Default value: 0

Tag: custom/portal/column/width
Description: The home page column width
Value: percent
Default value: default value set by browser
Note: The actual width may be increased by browser to accommodate content

*********************************************************

Tag: custom/portal/url-lists
Description: Contains settings for URL lists on the home page

Tag: custom/portal/url-lists/mode
Description: Specifies how to display URL lists on the home page:
             group URL lists by application (group) or
             show individual URL lists (nogroup).
             URL lists fill out cells of the configured columns, which are not taken
             by custom panes.
             Use the attribute value "nodisplay" to not show URL lists on the home page.
```

```
Value: group|nogroup|nodisplay
Default value: group
*******************************************************

Tag: custom/portal/pane (multiple)
Description: Contains settings of the custom pane on the home page

Tag: custom/portal/pane/mode
Description: The mode of the pane
Value: enable|disable
Default value: disable

Tag: custom/portal/pane/title
Description: The title of the pane
Value: arbitrary string
Default value: empty string

Tag: custom/portal/pane/notitle
Description: Hides pane's title bar
Value: yes|no
Default value: no

Tag: custom/portal/pane/type
Description: The type of the pane. Supported types:
             TEXT - inline arbitrary text, may contain HTML tags;
             HTML - HTML content specified by URL shown in the individual iframe;
             IMAGE - image specified by URL
             RSS - RSS feed specified by URL
Value: TEXT|HTML|IMAGE|RSS
Default value: TEXT

Tag: custom/portal/pane/url
Description: The URL for panes with type  HTML,IMAGE or RSS
Value: URL string
Default value: empty string

Tag: custom/portal/pane/text
Description: The text value for panes with type TEXT
Value: arbitrary string
Default value:empty string

Tag: custom/portal/pane/column
Description: The column where the pane located.
Value: arbitrary number
Default value: 1

Tag: custom/portal/pane/row
Description: The row where the pane is located
Value: arbitrary number
Default value: 1

Tag: custom/portal/pane/height
Description: The height of the pane
Value: number of pixels
Default value: default value set by browser

*******************************************************

Tag: custom/portal/browse-network-title
Description: The title of the browse network link
Value: arbitrary string
Default value: Browse Entire Network
```

```
Tag: custom/portal/access-network-title
Description: The title of the link to start a network access session
Value: arbitrary string
Default value: Start AnyConnect

Help Customization

The ASA displays help content on the application panes during clientless sessions. Each clientless application pane displays its own help file content using a predetermined filename. For example, the help content displayed on the Application Access panel is from the file named app-access-hlp.inc. Table 91-9 shows the clientless application panels and predetermined filenames for the help content.

Table 91-9 Clientless Applications

Application Type	Panel	Filename
Standard	Application Access	app-access-hlp.inc
Standard	Browse Networks	file-access-hlp.inc

Table 91-9 Clientless Applications

Application Type	Panel	Filename
Standard	AnyConnect Client	net-access-hlp.inc
Standard	Web Access	web-access-hlp.inc
Plug-in	MetaFrame Access	ica-hlp.inc
Plug-in	Terminal Servers	rdp-hlp.inc
Plug-in	Telnet/SSH Servers[1]	ssh,telnet-hlp.inc
Plug-in	VNC Connections	vnc-hlp.inc

1. This plug-in is capable of doing both sshv1 and sshv2.

You can customize the help files provided by Cisco or create help files in other languages. Then use the Import button to copy them to the flash memory of the ASA for display during subsequent clientless sessions. You can also export previously imported help content files, customize them, and reimport them to flash memory.

The following sections describe how to customize or create help content visible on clientless sessions:

- Customizing a Help File Provided By Cisco
- Creating Help Files for Languages Not Provided by Cisco

Detailed Steps

Step 1 Click **Import** to launch the Import Application Help Content dialog, where you can import new help content to flash memory for display during clientless sessions.

Step 2 (Optional) Click **Export** to retrieve previously imported help content selected from the table.

Step 3 (Optional) Click **Delete** to delete previously imported help content selected from the table.

Step 4 The abbreviation of the language rendered by the browser is displayed. This field is *not* used for file translation; it indicates the language used in the file. To identify the name of a language associated with an abbreviation in the table, display the list of languages rendered by your browser. For example, a dialog window displays the languages and associated language codes when you use one of the following procedures:

- Open Internet Explorer and choose **Tools > Internet Options > Languages > Add**.
- Open Mozilla Firefox and choose **Tools > Options > Advanced > General**, click **Choose** next to Languages, and click **Select a language to add**.

The filename that the help content file was imported as is provided.

Customizing a Help File Provided by Cisco

To customize a help file provided by Cisco, you need to get a copy of the file from the flash memory card first. Get the copy and customize it by performing the following steps:

Step 1 Use your browser to establish a clientless session with the ASA.

Step 2 Display the help file by appending the string in "URL of Help File in Flash Memory of the Security Appliance" in Table 91-10, to the address of the ASA, substituting *language* as described below, then press **Enter**.

Table 91-10 Help Files Provided by Cisco for Clientless Applications

Application Type	Panel	URL of Help File in Flash Memory of the Security Appliance
Standard	Application Access	/+CSCOE+/help/*language*/app-access-hlp.inc
Standard	Browse Networks	/+CSCOE+/help/*language*/file-access-hlp.inc
Standard	AnyConnect Client	/+CSCOE+/help/*language*/net-access-hlp.inc
Standard	Web Access	/+CSCOE+/help/*language*/web-access-hlp.inc
Plug-in	Terminal Servers	/+CSCOE+/help/*language*/rdp-hlp.inc
Plug-in	Telnet/SSH Servers	/+CSCOE+/help/*language*/ssh,telnet-hlp.inc
Plug-in	VNC Connections	/+CSCOE+/help/*language*/vnc-hlp.inc

language is the abbreviation for the language rendered by the browser. It is *not* used for file translation; it indicates the language used in the file. For help files provided by Cisco in English, enter the abbreviation **en**.

The following example address displays the English version of the Terminal Servers help:

https://*address_of_security_appliance***/+CSCOE+/help/en/rdp-hlp.inc**

Step 3 Choose **File > Save (Page) As**.

Note Do not change the contents of the File name box.

Step 4 Change the Save as type option to **Web Page, HTML only** and click **Save**.

Step 5 Use your preferred HTML editor to customize the file.

Note You can use most HTML tags, but do *not* use tags that define the document and its structure (for example, do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Step 6 Save the file as HTML only, using the original filename and extension.

Step 7 Make sure the filename matches the one in Table 91-11, and that it does not have an extra filename extension.

Return to ASDM and choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Help Customization > Import** to import the modified help file into flash memory.

Creating Help Files for Languages Not Provided by Cisco

Use standard HTML to create help files in other languages. We recommend creating a separate folder for each language you want to support.

Note You can use most HTML tags, but do *not* use tags that define the document and its structure (for example, do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Save the file as HTML only. Use the filename in the Filename column.

Return to ASDM and choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Help Customization > Import** to import the new help file into flash memory.

Import/Export Application Help Content

Use the Import Application Help Content dialog box to import help files to flash memory for display on the portal pages during clientless sessions. Use the Export Application Help Content dialog box to retrieve previously imported help files for subsequent editing.

Detailed Steps

Step 1 The Language field specifies the language rendered by the browser but is not used for file translation. (This field is inactive in the Export Application Help Content dialog box.) Click the dots next to the Language field and double-click the row containing the language shown in the Browse Language Code dialog box. Confirm the abbreviation in the Language Code field matches the abbreviation in the row and click **OK**.

Step 2 If the language for which you want to provide help content is not present in the Browse Language Code dialog box, perform the following

1. Display the list of languages and abbreviations rendered by your browser.
2. Enter the abbreviation for the language in the Language Code field and click **OK.**

   OR

   You can also enter it into the Language text box to the left of the dots.

A dialog box displays the languages and associated language codes when you use one of the following procedures:

- Open Internet Explorer and choose **Tools > Internet Options > Languages > Add**.
- Open Mozilla Firefox and choose **Tools > Options > Advanced > General**, click **Choose** next to Languages, and click **Select a language to add**.

Step 3 If you are importing, choose the new help content file from the File Name drop-down list. If you are exporting, this field is unavailable.

Step 4 Configure the parameters for the source file (if importing) or destination file (if exporting):

- Local computer—Indicate if the source or destination file is on a local computer:
  - Path—Identify the path of the source or destination file.
  - Browse Local Files—Click to browse the local computer for the source or destination file.
- Flash file system—Indicate if the source or destination file is located in flash memory on the ASA:
  - Path—Identify the path of the source or destination file in flash memory.
  - Browse Flash—Click to browse the flash memory for the source or destination file.

- Remote server—Indicate if the source or destination file is on a remote server:
  - Path—Choose the file transfer (copy) method, either ftp, tftp, or http (for importing only), and specify the path.

Customizing a Help File Provided by Cisco

To customize a help file provided by Cisco, you need to get a copy of the file from the flash memory card first. Get the copy and customize it by performing the following steps:

Step 1 Use your browser to establish a clientless session with the ASA.

Step 2 Display the help file by appending the string in "URL of Help File in Flash Memory of the Security Appliance" in Table 91-11, to the address of the ASA, substituting *language* as described below, then press **Enter**.

Table 91-11 Help Files Provided by Cisco for Clientless Applications

Application Type	Panel	URL of Help File in Flash Memory of the Security Appliance
Standard	Application Access	/+CSCOE+/help/*language*/app-access-hlp.inc
Standard	Browse Networks	/+CSCOE+/help/*language*/file-access-hlp.inc
Standard	AnyConnect Client	/+CSCOE+/help/*language*/net-access-hlp.inc
Standard	Web Access	/+CSCOE+/help/*language*/web-access-hlp.inc
Plug-in	Terminal Servers	/+CSCOE+/help/*language*/rdp-hlp.inc
Plug-in	Telnet/SSH Servers	/+CSCOE+/help/*language*/ssh,telnet-hlp.inc
Plug-in	VNC Connections	/+CSCOE+/help/*language*/vnc-hlp.inc

language is the abbreviation for the language rendered by the browser. It is *not* used for file translation; it indicates the language used in the file. For help files provided by Cisco in English, enter the abbreviation **en**.

The following example address displays the English version of the Terminal Servers help:

https://*address_of_security_appliance***/+CSCOE+/help/en/rdp-hlp.inc**

Step 3 Choose **File > Save (Page) As**.

Note Do not change the contents of the File name box.

Step 4 Change the Save as type option to "Web Page, HTML only" and click **Save**.

Step 5 Use your preferred HTML editor to customize the file.

Note You can use most HTML tags, but do *not* use tags that define the document and its structure (for example, do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Step 6 Save the file as HTML only, using the original filename and extension.

Step 7 Make sure the filename matches the one in Table 91-11, and that it does not have an extra filename extension.

Return to ASDM and choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Help Customization > Import** to import the modified help file into flash memory.

Creating Help Files for Languages Not Provided by Cisco

Use standard HTML to create help files in other languages. We recommend creating a separate folder for each language you want to support.

Note You can use most HTML tags, but do *not* use tags that define the document and its structure (for example, do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Save the file as HTML only. Use the filename in the Filename column of Table 91-13.

Return to ASDM and choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Help Customization > Import** to import the new help file into flash memory.

Configuring Browser Access to Client-Server Plug-ins

The Client-Server Plug-in table displays the plug-ins the ASA makes available to browsers in clientless SSL VPN sessions.

To add, change, or remove a plug-in, do one of the following:

- To add a plug-in, click **Import**. The Import Plug-ins dialog box opens.

To remove a plug-in, choose it and click **Delete**.The following sections describe the integration of browser plug-ins for Clientless SSL VPN browser access:

- About Installing Browser Plug-ins
- Preparing the Security Appliance for a Plug-in
- Installing Plug-ins Redistributed By Cisco

About Installing Browser Plug-ins

A browser plug-in is a separate program that a web browser invokes to perform a dedicated function, such as connect a client to a server within the browser window. The ASA lets you import plug-ins for download to remote browsers in clientless SSL VPN sessions. Of course, Cisco tests the plug-ins it redistributes, and in some cases, tests the connectivity of plug-ins we cannot redistribute. However, we do not recommend importing plug-ins that support streaming media at this time.

The ASA does the following when you install a plug-in onto the flash device:

- (Cisco-distributed plug-ins only) Unpacks the jar file specified in the *URL*.
- Writes the file to the csco-config/97/plugin directory on the ASA file system.
- Populates the drop-down menu next to the URL attributes in ASDM.

- Enables the plug-in for all future clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down menu next to the Address field of the portal page.

  Table 91-12 shows the changes to the main menu and address field of the portal page when you add the plug-ins described in the following sections.

Table 91-12 Effects of Plug-ins on the Clientless SSL VPN Portal Page

Plug-in	Main Menu Option Added to Portal Page	Address Field Option Added to Portal Page
ica	Citrix Client	citrix://
rdp	Terminal Servers	rdp://
rdp2	Terminal Servers Vista	rdp2://
ssh,telnet	SSH	ssh://
	Telnet	telnet://
vnc	VNC Client	vnc://

Note A secondary ASA obtains the plug-ins from the primary ASA.

When the user in a clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can select the protocol displayed in the drop-down menu and enter the URL in the Address field to establish a connection.

Note Some Java plug-ins may report a status of connected or online even when a session to the destination service is not set up. The open-source plug-in reports the status, not the ASA.

Before installing the first plug-in, you must follow the instructions in the next section.

Prerequisites

- The plug-ins do not work if the security appliance configures the clientless session to use a proxy server.

Note The remote desktop protocol plug-in does not support load balancing with a session broker. Because of the way the protocol handles the redirect from the session broker, the connection fails. If a session broker is not used, the plug-in works.

- The plug-ins support single sign-on (SSO). They use the *same* credentials entered to open the clientless SSL VPN session. Because the plug-ins do not support macro substitution, you do not have the options to perform SSO on different fields such as the internal domain password or on an attribute on a RADIUS or LDAP server.
- To configure SSO support for a plug-in, you install the plug-in, add a bookmark entry to display a link to the server, and specify SSO support when adding the bookmark.
- The minimum access rights required for remote use belong to the guest privilege mode.

Requirements

- Per the GNU General Public License (GPL), Cisco redistributes plug-ins without having made any changes to them. Per the GPL, Cisco cannot directly enhance these plug-ins.

- Clientless SSL VPN must be enabled on the ASA to provide remote access to the plug-ins.
- A stateful failover does not retain sessions established using plug-ins. Users must reconnect following a failover.
- Plug-ins require that ActiveX or Oracle Java Runtime Environment (JRE) 1.4.2 (or later) is enabled on the browser. There is no ActiveX version of the RDP plug-in for 64-bit browsers.

RDP Plug-in ActiveX Debug Quick Reference

To set up and use an RDP plug-in, you must add a new environment variable. For the process of adding a new environment variable, use the following steps:

Step 1 Right-click **My Computer** to access the System Properties, and choose the **Advanced** tab.

Step 2 On the Advanced tab, choose the environment variables button.

Step 3 In the new user variable dialog box, enter the RF_DEBUG variable.

Step 4 Verify the new Environment Variable in the user variables section.

Step 5 If you used the client computer with versions of WebVPN before version 8.3, you must remove the old Cisco Portforwarder Control. Go to the C:/WINDOWS/Downloaded Program Files directory, right-click portforwarder control, and choose **Remove**.

Step 6 Clear all of the Internet Explorer browser cache.

Step 7 Launch your WebVPN session and establish an RDP session with the RDP ActiveX Plug-in.

You can now observe events in the Windows Application Event viewer.

Preparing the Security Appliance for a Plug-in

Before installing a plug-in, prepare the ASA by performing the following steps:

Step 1 Make sure clientless SSL VPN (“webvpn”) is enabled on an ASA interface.

Step 2 Install an SSL certificate onto the ASA interface to which remote users use a fully-qualified domain name (FQDN) to connect.

Note Do not specify an IP address as the common name (CN) for the SSL certificate. The remote user attempts to use the FQDN to communicate with the ASA. The remote PC must be able to use DNS or an entry in the System32\drivers\etc\hosts file to resolve the FQDN.

Customizing Help

The ASA displays help content on the application panels during VPN sessions. You can customize the help files provided by Cisco or create help files in other languages. You then import them to flash memory for display during subsequent sessions. You can also retrieve previously imported help content files, modify them, and reimport them to flash memory.

Each application panel displays its own help file content using a predetermined filename. The prospective location of each is in the /+CSCOE+/help/*language*/ URL within flash memory of the ASA. Table 91-13 shows the details about each of the help files you can maintain for VPN sessions.

Table 91-13 VPN Application Help Files

Application Type	Panel	URL of Help File in Flash Memory of the Security Appliance	Help File Provided By Cisco in English?
Standard	Application Access	/+CSCOE+/help/*language*/app-access-hlp.inc	Yes
Standard	Browse Networks	/+CSCOE+/help/*language*/file-access-hlp.inc	Yes
Standard	AnyConnect Client	/+CSCOE+/help/*language*/net-access-hlp.inc	Yes
Standard	Web Access	/+CSCOE+/help/*language*/web-access-hlp.inc	Yes
Plug-in	MetaFrame Access	/+CSCOE+/help/*language*/ica-hlp.inc	No
Plug-in	Terminal Servers	/+CSCOE+/help/*language*/rdp-hlp.inc	Yes
Plug-in	Telnet/SSH Servers	/+CSCOE+/help/*language*/ssh,telnet-hlp.inc	Yes
Plug-in	VNC Connections	/+CSCOE+/help/*language*/vnc-hlp.inc	Yes

language is the abbreviation of the language rendered by the browser. This field is *not* used for file translation; it indicates the language used in the file. To specify a particular language code, copy the language abbreviation from the list of languages rendered by your browser. For example, a dialog window displays the languages and associated language codes when you use one of the following procedures:

- Open Internet Explorer and choose **Tools > Internet Options > Languages > Add**.
- Open Mozilla Firefox and choose **Tools > Options > Advanced > General**, click **Choose** next to Languages, and click **Select a language to add**.

The following sections describe how to customize the help contents:

- Customizing a Help File Provided By Cisco, page 91-121
- Creating Help Files for Languages Not Provided by Cisco, page 91-122
- Requiring Usernames and Passwords, page 91-122

Customizing a Help File Provided By Cisco

To customize a help file provided by Cisco, you need to get a copy of the file from the flash memory card first. Get the copy and customize it as follows:

Detailed Steps

Step 1 Use your browser to establish a clientless SSL VPN session with the ASA.

Step 2 Display the help file by appending the string in "URL of Help File in Flash Memory of the Security Appliance" in Table 91-13, to the address of the ASA, then press Enter.

Note Enter **en** in place of *language* to get the help file in English.

The following example address displays the English version of the Terminal Servers help:

https://*address_of_security_appliance***/+CSCOE+/help/en/rdp-hlp.inc**

Step 3 Choose **File > Save (Page) As**.

Note Do not change the contents of the File name box.

Step 4 Change the Save as type option to **Web Page, HTML only** and click **Save**.

Step 5 Use your preferred HTML editor to modify the file.

Note You can use most HTML tags, but do *not* use tags that define the document and its structure (e.g., do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Step 6 Save the file as HTML only, using the original filename and extension.

Step 7 Make sure the filename matches the one in Table 91-13, and that it does not have an extra filename extension.

See "Requiring Usernames and Passwords" to import the modified file.

Creating Help Files for Languages Not Provided by Cisco

Use HTML to create help files in other languages.

We recommend creating a separate folder for each language you want to support.

Save the file as HTML only. Use the filename following the last slash in "URL of Help File in Flash Memory of the Security Appliance" in Table 91-13.

See the next section to import the files for display during VPN sessions.

Restrictions

You can use most HTML tags, but do *not* use tags that define the document and its structure (e.g., do not use <html>, <title>, <body>, <head>, <h1>, <h2>, etc. You can use character tags, such as the <b> tag, and the <p>, <ol>, <ul>, and <li> tags to structure content.

Requiring Usernames and Passwords

Depending on your network, during a remote session users might have to log in to any or all of the following: the computer itself, an Internet service provider, clientless SSL VPN, mail or file servers, or corporate applications. Users might have to authenticate in many different contexts, requiring different information, such as a unique username, password, or PIN.

Table 91-14 lists the type of usernames and passwords that clientless SSL VPN users might need to know.

Table 91-14 Usernames and Passwords to Give to Users of Clientless SSL VPN Sessions

Login Username/ Password Type	Purpose	Entered When
Computer	Access the computer	Starting the computer
Internet Service Provider	Access the Internet	Connecting to an Internet service provider
Clientless SSL VPN	Access remote network	Starting clientless SSL VPN
File Server	Access remote file server	Using the clientless SSL VPN file browsing feature to access a remote file server
Corporate Application Login	Access firewall-protected internal server	Using the clientless SSL VPN web browsing feature to access an internal protected website
Mail Server	Access remote mail server via clientless SSL VPN	Sending or receiving e-mail messages

Communicating Security Tips

Advise users to always click the logout icon on the toolbar to close the clientless SSL VPN session. (Closing the browser window does not close the session.)

Clientless SSL VPN ensures the security of data transmission between the remote PC or workstation and the ASA on the corporate network. Advise users that using clientless SSL VPN does not ensure that communication with every site is secure. If a user then accesses a non-HTTPS web resource (located on the Internet or on the internal network), the communication from the corporate ASA to the destination web server is not private because it is not encrypted.

"Observing Clientless SSL VPN Security Precautions" on page 5 addresses an additional tip to communicate with users, depending on the steps you follow within that section.

Configuring Remote Systems to Use Clientless SSL VPN Features

This section describes how to set up remote systems to use clientless SSL VPN and includes the following topics:

- Starting Clientless SSL VPN, page 91-124
- Using the Clientless SSL VPN Floating Toolbar, page 91-124
- Browsing the Web, page 91-125
- Browsing the Network (File Management), page 91-125
- Using Port Forwarding, page 91-127
- Using E-mail Via Port Forwarding, page 91-128

- Using E-mail Via Web Access, page 91-129
- Using E-mail Via E-mail Proxy, page 91-129
- Using Smart Tunnel, page 91-129

You may configure user accounts differently and different clientless SSL VPN features can be available to each user.

Starting Clientless SSL VPN

You can connect to the internet using any supported connection including:

- home DSL, cable, or dial-ups
- public kiosks
- hotel hook-ups
- airport wireless nodes
- internet cafes

Note See the *Cisco ASA 5500 Series VPN Compatibility Reference* for the list of web browsers supported by clientless SSL VPN.

Prerequisites

- Cookies must be enabled on the browser in order to access applications via port forwarding.
- You must have a URL for clientless SSL VPN. The URL must be an https address in the following form: https://*address*, where *address* is the IP address or DNS hostname of an interface of the ASA (or load balancing cluster) on which SSL VPN is enabled. For example, https://cisco.example.com.
- You must have a clientless SSL VPN username and password.

Restrictions

- Clientless SSL VPN supports local printing, but it does not support printing through the VPN to a printer on the corporate network.

Using the Clientless SSL VPN Floating Toolbar

A floating toolbar is available to simplify the use of clientless SSL VPN. The toolbar lets you enter URLs, browse file locations, and choose preconfigured web connections without interfering with the main browser window.

The floating toolbar represents the current clientless SSL VPN session. If you click the **Close** button, the ASA prompts you to confirm that you want to close the clientless SSL VPN session.

Tip To paste text into a text field, use Ctrl-V. (Right-clicking is disabled on the toolbar displayed during the clientless SSL VPN session.)

Restrictions

If you configure your browser to block popups, the floating toolbar cannot display.

Browsing the Web

Using clientless SSL VPN does not ensure that communication with every site is secure. See Communicating Security Tips.

The look and feel of web browsing with clientless SSL VPN might be different from what users are accustomed to. For example:

- The title bar for clientless SSL VPN appears above each web page.
- You access websites by:
  - Entering the URL in the **Enter Web Address** field on the clientless SSL VPN Home page
  - Clicking on a preconfigured website link on the clientless SSL VPN Home page
  - Clicking a link on a webpage accessed via one of the previous two methods

Also, depending on how you configured a particular account, it might be that:

- Some websites are blocked
- Only the websites that appear as links on the clientless SSL VPN Home page are available

Prerequisites

- You need the username and password for protected websites.

Restrictions

Also, depending on how you configured a particular account, it might be that:

- Some websites are blocked
- Only the websites that appear as links on the clientless SSL VPN Home page are available

Browsing the Network (File Management)

Users might not be familiar with how to locate their files through your organization network.

Note Do not interrupt the **Copy File to Server** command or navigate to a different screen while the copying is in progress. Interrupting the operation can cause an incomplete file to be saved on the server.

Prerequisites

- You must configure file permissions for shared remote access.
- You must have the server names and passwords for protected file servers.
- You must have the domain, workgroup, and server names where folders and files reside.

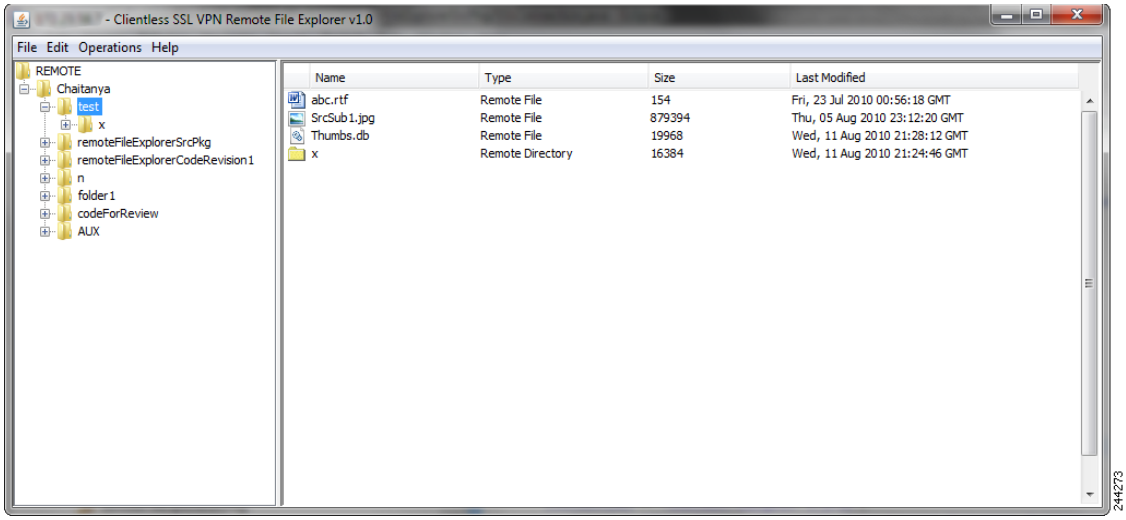
Restrictions

Only shared folders and files are accessible via clientless SSL VPN.

Using the Remote File Explorer

The Remote File Explorer provides the user with a way to browse the corporate network from their web browser. When the users clicks the Remote File System icon on the Cisco SSL VPN portal page, an applet is launched on the user's system displaying the remote file system in a tree and folder view.

Figure 91-28 Clientless SSL VPN Remote File Explorer



The browser enables the user to:

- Browse the remote file system
- Rename files
- Move or copy files within the remote file system and between the remote and local file systems.
- Perform bulk uploads and downloads of files

Note This functionality requires the Oracle Java Runtime Environment (JRE) 1.4 or later is installed on the user's machine and Java enabled in the web browser. Launching remote files requires JRE 1.6 or later.

Renaming a File or Folder

To rename a file or folder:

Step 1 Click the file or folder to be renamed.

Step 2 Select **Edit** > **Rename**.

Step 3 When prompted, enter the new name in the dialog.

Step 4 Click **OK** to rename the file or folder. Alternative, click **Cancel** to leave the name unchanged.

Moving or Copying Files or Folders on the Remote Server

To move or copy a file or folder on the remote server:

Step 1 Navigate to the source folder containing the file or folder to be moved or copied.

Step 2 Click the file or folder.

Step 3 To copy the file select **Edit** > **Copy**. Alternatively, to move the file select **Edit** > **Cut**.

Step 4 Navigate to the destination folder.

Step 5 Select **Edit** > **Paste**.

Copying Files from the Local System Drive to the Remote Folder

You can copy files between the local file system and the remote file system by dragging and dropping them between the right pane of the Remote File Browser and your local file manager application.

Uploading and Downloading Files

You can download a file by clicking it in the browser, selecting **Operations** > **Download**, and providing a location and name to save the file in the **Save** dialog.

You can upload a file by clicking the destination folder, selecting **Operations** > **Upload**, and providing the location and name of the file in the **Open** dialog,

This functionality has the following restrictions:

- The user cannot view sub-folders for which they are not permitted access.
- Files that the user is not permitted to access cannot be moved or copied, even though they are displayed in the browser.
- The maximum depth of nested folders is 32.
- The tree view does not support drag and drop copying.
- When moving files between multiple instances of the Remote File Explorer, all instances must be exploring the same server (root share).
- The Remote File Explorer can display a maximum of 1500 files and folders in a single folder. If a folder exceeds this limit the folder cannot be displayed.

Using Port Forwarding

Note Users should always close the Application Access window when they finish using applications by clicking the **Close** icon. Failure to quit the window properly can cause Application Access or the applications themselves to be disabled. See Recovering from hosts File Errors When Using Application Access for details.

Prerequisites

- On Mac OS X, only the Safari browser supports this feature.
- You must have client applications installed.
- You must have Cookies enabled on the browser.
- You must have administrator access on the PC if you use DNS names to specify servers, because modifying the hosts file requires it.
- You must have Oracle Java Runtime Environment (JRE) version 1.4.x and 1.5.x installed.

  If JRE is not installed, a pop-up window displays, directing users to a site where it is available. On rare occasions, the port forwarding applet fails with Java exception errors. If this happens, do the following:

  a. Clear the browser cache and close the browser.

b. Verify that no Java icons are in the computer task bar.

c. Close all instances of Java.

d. Establish a clientless SSL VPN session and launch the port forwarding Java applet.

- You must have JavaScript enabled on the browser. By default, it is enabled.
- If necessary, you must configure client applications.

Note The Microsoft Outlook client does not require this configuration step. All non-Windows client applications require configuration. To determine if configuration is necessary for a Windows application, check the value of the Remote Server field. If the Remote Server field contains the server hostname, you do not need to configure the client application. If the Remote Server field contains an IP address, you must configure the client application.

Restrictions

Because this feature requires installing Oracle Java Runtime Environment (JRE) and configuring the local clients, and because doing so requires administrator permissions on the local system or full control of C:\windows\System32\drivers\etc, it is unlikely that users will be able to use applications when they connect from public remote systems.

Detailed Steps

To configure the client application, use the server's locally mapped IP address and port number. To find this information:

1. Start a clientless SSL VPN session and click the **Application Access** link on the Home page. The Application Access window appears.
2. In the Name column, find the name of the server you want to use, then identify its corresponding client IP address and port number (in the Local column).
3. Use this IP address and port number to configure the client application. Configuration steps vary for each client application.

Note Clicking a URL (such as one in an -e-mail message) in an application running over a clientless SSL VPN session does not open the site over that session. To open a site over the session, paste the URL into the Enter Clientless SSL VPN (URL) Address field.

Using E-mail Via Port Forwarding

To use e-mail, start Application Access from the clientless SSL VPN home page. The mail client is then available for use.

Note If you are using an IMAP client and you lose your mail server connection or are unable to make a new connection, close the IMAP application and restart clientless SSL VPN.

Prerequisites

You must fulfill requirements for application access and other mail clients.

Restrictions

We have tested Microsoft Outlook Express versions 5.5 and 6.0.

Clientless SSL VPN should support other SMTPS, POP3S, or IMAP4S e-mail programs via port forwarding, such as Lotus Notes and Eudora, but we have not verified them.

Using E-mail Via Web Access

The following e-mail applications are supported:

- Microsoft Outlook Web App to Exchange Server 2010.

  OWA requires Internet Explorer 7 or later, or Firefox 3.01 or later.
- Microsoft Outlook Web Access to Exchange Server 2007, 2003, and 2000.

  For best results, use OWA on Internet Explorer 8.x or later, or Firefox 8.x.
- Lotus iNotes

Prerequisites

You must have the web-based e-mail product installed.

Restrictions

Other web-based e-mail applications should also work, but we have not verified them.

Using E-mail Via E-mail Proxy

The following legacy e-mail applications are supported:

- Microsoft Outlook 2000 and 2002
- Microsoft Outlook Express 5.5 and 6.0

See the instructions and examples for your mail application in Using E-Mail over Clientless SSL VPN.

Prerequisites

- You must have the SSL-enabled mail application installed.
- Do not set the ASA SSL version to TLSv1 Only. Outlook and Outlook Express do not support TLS.
- You must have your mail application properly configured.

Restrictions

- Other SSL-enabled clients should also work, but we have not verified them.

Using Smart Tunnel

Administration privileges are not required to use Smart Tunnel.

Note Java is not automatically downloaded for you as in port forwarder.

Prerequisites

- Smart tunnel requires either ActiveX or JRE (1.4x and 1.5x) on Windows and Java Web Start on Mac OS X.
- You must ensure cookies enabled on the browser.
- You must ensure JavaScript is enabled on the browser.

Restrictions

- Mac OS X does not support a front-side proxy.
- Supports only the operating systems and browsers specified in "Configuring Smart Tunnel Access" section on page 91-45.
- Only TCP socket-based applications are supported.

The ASA includes a translation table template for each domain that is part of standard functionality. The templates for plug-ins are included with the plug-ins and define their own translation domains.

You can export the template for a translation domain, which creates an XML file of the template at the URL you provide. The message fields in this file are empty. You can edit the messages and import the template to create a new translation table object that resides in flash memory.

You can also export an existing translation table. The XML file created displays the messages you edited previously. Reimporting this XML file with the same language name creates a new version of the translation table object, overwriting previous messages.

Some templates are static, but some change based on the configuration of the ASA. Because you can customize the *logon and logout pages, portal page, and URL bookmarks for clientless users,* the **ASA generates the customization** and **url-list** translation domain templates dynamically, and the template automatically reflects your changes to these functional areas.

After creating translation tables, they are available to customization objects that you create and apply to group policies or user attributes. With the exception of the AnyConnect translation domain, a translation table has no affect, and messages are not translated on user screens until you create a customization object, identify a translation table to use in that object, and specify that customization for the group policy or user. Changes to the translation table for the AnyConnect domain are immediately visible to AnyConnect client users.

Note

Step 1 Navigate to **Configuration > Remote Access VPN > Language Localization**. The Language Localization pane displays. Click **Add**. The Add Language Localization window displays.

Step 2 Choose a Language Localization Template from the drop-down box. The entries in the box correspond to functional areas that are translated.

Step 3 Specify a language for the template. The template becomes a translation table in cache memory with the name you specify. Use an abbreviation that is compatible with the language options for your browser. For example, if you are creating a table for the Chinese language, and you are using IE, use the abbreviation *zh,* that is recognized by IE.

Step 4 Edit the translation table. For each message represented by the msgid field that you want to translate, enter the translated text between the quotes of the associated msgstr field. The example below shows the message Connected, with the Spanish text in the msgstr field:

```
msgid "Connected"
msgstr "Conectado"
```

Step 5 Click **OK**. The new table appears in the list of translation tables.

Adding/Editing Localization Entry

You can add a new translation table, based on a template, or you can modify an already-imported translation table in this pane.

Step 1 Select a template to modify and use as a basis for a new translation table. The templates are organized into translation domains and affect certain areas of functionality. The following table shows the translation domains and the functional areas affected:

Translation Domain	Functional Areas Translated
AnyConnect	Messages displayed on the user interface of the Cisco AnyConnect VPN client.
CSD	Messages for the Cisco Secure Desktop (CSD).
customization	Messages on the logon and logout pages, portal page, and all the messages customizable by the user.
keepout	Message displayed to remote users when VPN access is denied.
PortForwarder	Messages displayed to Port Forwarding users.
url-list	Text that user specifies for URL bookmarks on the portal page.
webvpn	All the layer 7, AAA and portal messages that are not customizable.
plugin-ica	Messages for the Citrix plug-in.
plugin-rdp	Messages for the Remote Desktop Protocol plug-in.
plugin-telnet,ssh	Messages for the Telnet and SSH plug-in.
plugin-vnc	Messages for the VNC plug-in.

Step 2 Specify a language. Use an abbreviation that is compatible with the language options of your browser. The ASA creates the new translation table with this name.

Step 3 Use the editor to change the message translations. The message ID field (msgid) contains the default translation. The message string field (msgstr) that follows msgid provides the translation. To create a translation, enter the translated text between the quotes of the msgstr string. For example, to translate the message “Connected” with a Spanish translation, insert the Spanish text between the msgstr quotes:

```
msgid "Connected"
msgstr "Conectado"
```

After making changes, click **Apply** to import the translation table.

Customizing the AnyConnect Client

You can customize the AnyConnect VPN client to display your own corporate image to remote users, including clients running on Windows, Linux, and Mac OS X computers.

You can use one of three methods to customize the client:

- Rebrand the client by importing individual client GUI components, such as the corporate logo and icons, to the ASA which deploys them to remote computers with the installer.
- Import your own program (Windows and Linux only) that provides its own GUI or CLI and uses the AnyConnect API.
- Import a transform (Windows only) that you create for more extensive rebranding. The ASA deploys it with installer.
- Create Scripts that deploy with the client and run when the client establishes or terminates a VPN connection.

The following sections explain how to customize the AnyConnect client:

- Customizing AnyConnect by Importing Resource Files, page 91-132
- Customizing Your Own AnyConnect GUI Text and Scripts, page 91-133
- Customizing AnyConnect GUI Text and Messages, page 91-136
- Customizing the Installer Program Using Installer Transforms, page 91-137
- Localizing the Install Program using Installer Transforms, page 91-138

Restrictions

- Customization is not supported for the AnyConnect client running on a Windows Mobile device.

Customizing AnyConnect by Importing Resource Files

You can customize the AnyConnect client by importing your own custom files to the security appliance, which deploys the new files with the client. For detailed information about the original GUI icons and information about their sizes, see the *AnyConnect VPN Client Administrators Guide*. You can use this information to create your custom files.

Detailed Steps

To import and deploy your custom files with the client, follow this procedure:

Step 1 Go to **Configuration > Remote Access VPN > Network (Client) Access > AnyConnect Customization/Localization > Resources**.

Click **Import**. The Import AnyConnect Customization Object window displays.

Step 2 Enter the Name of the file to import. See the *AnyConnect VPN Client Administrators Guide* for the filenames of all the GUI components that you can replace.

Note The filenames of your custom components must match the filenames used by the AnyConnect client GUI. The filenames of the GUI components are different for each OS and are case sensitive for Mac and Linux. For example, if you want to replace the corporate logo for Windows clients, you must import your corporate logo as *company_logo.bmp*. If you import it as a different filename, the AnyConnect installer does not change the component. However, if you deploy your own executable to customize the GUI, the executable can call resource files using any filename.

Step 3 Select a platform and specify the file to import. Click **Import Now**. The file now appears in the table.

Note If you import an image as a resource file (such as company_logo.bmp), the image you import customizes the AnyConnect client until you reimport another image using the same filename. For example, if you replace company_logo.bmp with a custom image, and then delete the image, the client continues to display your image until you import a new image (or the original Cisco logo image) using the same filename.

Step 4 Clicking **Import** launches the Import AnyConnect Customization Objects dialog, where you can specify a file to import as an object.

Step 5 Clicking **Export** launches the Export AnyConnect Customization Objects dialog, where you can specify a file to export as an object.

Step 6 Clicking **Delete** removes the selected object.

The type of remote PC platform supported by the object and the object name is displayed.

Customizing Your Own AnyConnect GUI Text and Scripts

For Windows, Linux, or Mac (PPP or Intel-based) computers, you can deploy your own client that uses the AnyConnect client API. You replace the AnyConnect GUI or the AnyConnect CLI by replacing the client binary files.

You can also download and run scripts that run when the client establishes a connection (an *OnConnect* script), or when the client terminates a session (an *OnDisconnect* script). Some examples that show how you might want to use this feature include:

- Refreshing the group policy upon VPN connection.
- Mapping a network drive upon VPN connection, and un-mapping it after disconnection.
- Logging on to a service upon VPN connection, and logging off after disconnection.

For complete information about customizing the AnyConnect GUI and creating and deploying scripts, see the *AnyConnect VPN Client Administrators Guide*.

The following sections describe how to import binary executables and scripts to the ASA:

- Importing your own GUI as a Binary Executable, page 91-133
- Importing Scripts, page 91-134

Importing your own GUI as a Binary Executable

For Windows, Linux, or Mac (PPP or Intel-based) computers, you can deploy your own client that uses the AnyConnect client API. You replace the AnyConnect GUI or the AnyConnect CLI by replacing the client binary files. Table 91-15 lists the filenames of the client executable files for the different operating systems.

Table 91-15 Filenames of Client Executables

Client OS	Client GUI File	Client CLI File
Windows	vpnui.exe	vpncli.exe

Table 91-15 Filenames of Client Executables

Client OS	Client GUI File	Client CLI File
Linux	vpnui	vpn
Mac	Not supported[1]	vpn

1. Not supported by ASA deployment. However, you can deploy an executable for the Mac that replaces the client GUI using other means, such as Altiris Agent.

Your executable can call any resource files, such as logo images, that you import to the ASA (See Table 91-15). Unlike replacing the pre-defined GUI components, when you deploy your own executable, can use any filenames for your resource files.

We recommend that you sign your custom Windows client binaries (either GUI or CLI version) that you import to the ASA. A signed binary has a wider range of functionality available to it. If the binaries are not signed the following functionality is affected:

- Web-Launch—The clientless portal is available and the user can authenticate. However, the behavior surrounding tunnel establishment does not work as expected. Having an unsigned GUI on the client results in the client not starting as part of the clientless connection attempt. And once it detects this condition, it aborts the connection attempt.
- SBL—The Start Before Logon feature requires that the client GUI used to prompt for user credentials be signed. If it is not, the GUI does not start. Because SBL is not supported for the CLI program, this affects only the GUI binary file.
- Auto Upgrade—During the upgrade to a newer version of the client, the old GUI exits, and after the new GUI installs, the new GUI starts. The new GUI does not start unless it is signed. As with Web-launch, the VPN connection terminates if the GUI is not signed. However, the upgraded client remains installed.

Restrictions

The ASA does not support this feature for the AnyConnect VPN client, Versions 2.0 and 2.1. For more information on manually customizing the client, see the *AnyConnect VPN Client Administrator Guide* and the *Release Notes for Cisco AnyConnect VPN Client*.

Importing Scripts

AnyConnect lets you download and run scripts when the following events occur:

- Upon the establishment of a new AnyConnect client VPN session with the security appliance. We refer to a script triggered by this event as an *OnConnect* script because it requires this filename prefix.
- Upon the tear-down of an AnyConnect client VPN session with the security appliance. We refer to a script triggered by this event as an *OnDisconnect* script because it requires this filename prefix.

Thus, the establishment of a new AnyConnect VPN session initiated by Trusted Network Detection triggers the OnConnect script (assuming the requirements are satisfied to run the script). The reconnection of a persistent AnyConnect VPN session after a network disruption does not trigger the OnConnect script.

Prerequisites

These instructions assume you know how to write scripts and run them from the command line of the targeted endpoint to test them.

Restrictions

- The AnyConnect software download site provides some example scripts; if you examine them, please remember that they are only examples; they may not satisfy the local computer requirements for running them, and are unlikely to be usable without customizing them for your network and user needs. Cisco does not support example scripts or customer-written scripts.

For complete information about deploying scripts, and their limitations and restrictions, see the *AnyConnect VPN Client Administrators Guide*.

Writing, Testing, and Deploying Scripts

Deploy AnyConnect scripts as follows:

Restrictions

- Scripts written on Microsoft Windows computers have different line endings than scripts written on Mac OS X and Linux. Therefore, you should write and test the script on the targeted OS. If a script cannot run properly from the command line on the native OS, AnyConnect cannot run it properly either.
- Microsoft Windows Mobile does not support this option. You must deploy scripts using the manual method for this OS.

Step 1 Write and test the script using the OS type on which it will run when AnyConnect launches it.

Step 2 To import a script, go to **Network (Client) Access > AnyConnect Customization/Localization > Script.** The Customization Scripts pane displays.

Step 3 Enter a name for the script. Be sure to specify the correct extension with the name. For example, *myscript*.bat.

Step 4 Choose a script action: *Script runs when client connects* or *Script runs when client disconnects*.

AnyConnect adds the prefix *scripts_* and the prefix *OnConnect* or *OnDisconnect* to your filename to identify the file as a script on the ASA. When the client connects, the ASA downloads the script to the proper target directory on the remote computer, removing the *scripts_* prefix and leaving the remaining *OnConnect* or *OnDisconnect* prefix. For example, if you import the script *myscript.bat*, the script appears on the ASA as *scripts_OnConnect_myscript.bat*. On the remote computer, the script appears as *OnConnect_myscript.bat.*

To ensure the scripts run reliably, configure all ASAs to deploy the same scripts. If you want to modify or replace a script, use the same name as the previous version and assign the replacement script to all of the ASAs that the users might connect to. When the user connects, the new script overwrites the one with the same name.

Step 5 Select a file as the source of the script. The name does not need to be the same as the name you provided for the script. ASDM imports the file from any source file, creating the new name you specify for Name in Step 3.

Table 91-16 shows the locations of scripts on the remote computer:

Table 91-16 Required Script Locations

OS	Directory
Microsoft Windows 7 and Vista	%ALLUSERPROFILE%\Cisco\Cisco AnyConnect VPN Client\Scripts
Microsoft Windows XP	%ALLUSERPROFILE%\Application Data\Cisco\Cisco AnyConnect VPN Client\Scripts

Table 91-16 Required Script Locations

OS	Directory
Linux	/opt/cisco/vpn/scripts **Note** Assign execute permissions to the file for User, Group and Other.
Mac OS X	/opt/cisco/vpn/scripts
Windows Mobile	%PROGRAMFILES%\Cisco AnyConnect VPN Client\Scripts

Step 6 Click **Import** to launch the Import AnyConnect Customization Objects dialog, where you can specify a file to import as an object.

Step 7 Click **Export** to launch the Export AnyConnect Customization Objects dialog, where you can specify a file to export as an object.

Step 8 Click **Delete** to remove a selected object.

The type of remote PC platform supported by the object and the object name is displayed.

Customizing AnyConnect GUI Text and Messages

Change text and messages displayed on the AnyConnect client GUI displayed to remote users in this pane. This pane also shares functionality with the Language Localization pane. For more extensive language translation, go to Configuration > Remote Access VPN > Language Localization.

To change messages that appear on the AnyConnect GUI, perform the following steps:

Step 1 Click **Template** to expand the template area. Click **Export** to export the English language template to your local PC or a remote device.

Step 2 Edit the template and make changes to any messages. The text contained between the quotes of the msgid field represents the default text. *Do not* change this text. To display a different message, insert your custom text between the quotes of mgstr. The example below shows a message containing connection termination information:

```
msgid ""
"The VPN connection has been disconnected due to the system suspending. The
"reconnect capability is disabled.  A new connection requires re-"
"authentication and must be started manually.  Close all sensitive networked
"applications."
msgstr ""
```

Step 3 Click **Import** to import the file you edited as a new translation template.

Step 4 Specify a language for the template. The template becomes a translation table in cache memory with the name you specify. Use an abbreviation that is compatible with the language options for your browser. For example, if you are creating a table for the Chinese language, and you are using IE, use the abbreviation *zh,* that is recognized by IE.

Step 5 Click **Apply to make your changes to the** ASA.

Step 6 (Optional) Click **Add** to launch the Add Localization Entry dialog where you can select a localization template to add and you can edit the contents of the template.

Step 7 (Optional) Click **Edit** to launch the Edit Localization Entry dialog for the selected language in the table, and allows you to edit the previously-imported language localization table.

Step 8 (Optional) Click **Delete** to delete a selected language localization table.

Step 9 (Optional) Click **Import** to launch the Import Language Localization dialog where you can import a language localization template or table.

Step 10 (Optional) Click **Export** to launch the Export Language Localization dialog where you can export a language localization template or table to a URL where you can make changes to the table or template.

Step 11 (Optional) Specify the language of the localization table.

Customizing the Installer Program Using Installer Transforms

You can perform more extensive customizing of the AnyConnect client GUI (Windows only) by creating your own transform that deploys with the client installer program. You import the transform to the ASA, which deploys it with the installer program.

To create an MSI transform, you can download and install the free database editor from Microsoft, named Orca. With this tool, you can modify existing installations and even add new files. The Orca tool is part of the Microsoft Windows Installer Software Development Kit (SDK) which is included in the Microsoft Windows SDK. The following link leads to the bundle containing the Orca program:

http://msdn.microsoft.com/library/default.asp?url=/library/en-us/msi/setup/orca_exe.asp.

After you install the SDK, the Orca MSI is located here:

C:\Program Files\Microsoft SDK SP1\Microsoft Platform SDK\Bin\Orca.msi.

Install the Orca software, then access the Orca program from your Start > All Programs menu.

To import your transform, follow these steps:

Step 1 Go to **Configuration > Remote Access VPN > Network (Client) Access > AnyConnect Customization/Localization > Customized Installer Transforms**. Click **Import**. The Import AnyConnect Customization Objects windows displays.

Step 2 Enter the Name of the file to import. Unlike the names of other customizing objects, the name is not significant to the ASA and is for your own convenience.

Step 3 Select a platform and specify the file to import. Click **Import Now**. The file now appears in the table.

Note Windows is the only valid choice for applying a transform.

Step 4 (Optional) Click **Import** to launch the Import AnyConnect Customization Objects dialog, where you can specify a transform file to import.

Step 5 (Optional) Click **Export** to launch the Export AnyConnect Customization Objects dialog, where you can specify a transform file to export.

Step 6 (Optional) Click **Delete** to remove the selected file.

The type of remote PC platform supported by the transform and the name of the transform is displayed.

Configuration Example for Transform

While offering a tutorial on creating transforms is beyond the scope of this document, we provide the text below as representative of some entries in a transform. These entries replace *company_logo.bmp* with a local copy and install the custom profile *MyProfile.xml*.

```
DATA CHANGE - Component Component ComponentId
+ MyProfile.xml {39057042-16A2-4034-87C0-8330104D8180}

Directory_ Attributes Condition KeyPath
Profile_DIR 0 MyProfile.xml

DATA CHANGE - FeatureComponents Feature_ Component_
  + MainFeature MyProfile.xml

DATA CHANGE - File File Component_ FileName FileSize Version Language Attributes Sequence
+ MyProfile.xml MyProfile.xml MyProf~1.xml|MyProfile.xml 601 8192 35
 <> company_logo.bmp 37302{39430} 8192{0}

DATA CHANGE - Media DiskId LastSequence DiskPrompt Cabinet VolumeLabel Source
  + 2 35
```

Specify transform files for customizing the AnyConnect client installation in this pane.

Localizing the Install Program using Installer Transforms

As with the AnyConnect client GUI, you can translate messages displayed by the client installer program. The ASA uses transforms to translate the messages displayed by the installer. The transform alters the installation, but leaves the original security-signed MSI intact. These transforms only translate the installer screens and do not translate the client GUI screens.

Each language has its own transform. You can edit a transform with a transform editor such as Orca, and make changes to the message strings. Then you import the transform to the ASA. When the user downloads the client, the client detects the preferred language of the computer (the locale specified during installation of the operating system) and applies the appropriate transform.

We currently offer transforms for 30 languages. These transforms are available in the following .zip file on the AnyConnect client software download page at cisco.com:

anyconnect-win-<VERSION>-web-deploy-k9-lang.zip

In this file, `<VERSION>` is the version of AnyConnect release (e.g. 2.2.103).

The package contains the transforms (.mst files) for the available translations. If you need to provide a language to remote users that is not one of the 30 languages we provide, you can create your own transform and import it to the ASA as a new language. With Orca, the database editor from Microsoft, you can modify existing installations and new files. Orca is part of the Microsoft Windows Installer Software Development Kit (SDK) which is included in the Microsoft Windows SDK. The following link leads to the bundle containing the Orca program:

http://msdn.microsoft.com/library/default.asp?url=/library/en-us/msi/setup/orca_exe.asp.

After you install the SDK, the Orca MSI is located here:

C:\Program Files\Microsoft SDK SP1\Microsoft Platform SDK\Bin\Orca.msi.

The following procedure shows how to import a transform to the ASA using ASDM:

Step 1 Import a Transform. Go to: **Configuration > Remote Access VPN > Network (Client) Access > AnyConnect Customization/Localization > Localized Installer Transforms**. Click **Import**. The Import MST Language Localization window opens.

Step 2 Choose a language for this transform. Click the Language drop-list to display languages and their industry-recognized abbreviations. If you enter the abbreviation manually, be sure to use an abbreviation recognized by browsers and operating systems.

Step 3 Click **Import Now**. A message displays saying you successfully imported the table.

Be sure to click **Apply** to save your changes.

Step 4 (Optional) Click **Import** to launch the Import AnyConnect Customization Objects dialog, where you can specify a file to import as a transform.

Step 5 (Optional) Click **Export** to launch the Export AnyConnect Customization Objects dialog, where you can specify a file to export as a transform.

Step 6 (Optional) Click **Delete** to remove the selected transform.

The type of remote PC platform supported by the transform and the name are displayed.

Importing/Exporting Language Localization

In the Import Translation Table and Export Translation Table dialog boxes, you can import or export a translation table to the ASA to provide translation of user messages.

Translation templates are XML files that contain message fields that can be edited with translated messages. You can export a template, edit the message fields, and import the template as a new translation table, or you can export an existing translation table, edit the message fields, and re-import the table to overwrite the previous version.

Detailed Steps

Step 1 Enter a name for the language.

- When *exporting*, it is automatically filled-in with the name from the entry you selected in the table.
- When *importing*, you enter the language name in the manner that you want it to be identified. The imported translation table then appears in the list with the abbreviation you designated. To ensure that your browser recognizes the language, use language abbreviations that are compatible with the language options of the browser. For example, if you are using IE, use ***zh*** as the abbreviation for the Chinese language.

Step 2 The name of the XML file containing the message fields includes the following:

- AnyConnect—Messages displayed on the user interface of the Cisco AnyConnect VPN Client.
- CSD—Messages for the Cisco Secure Desktop (CSD).
- customization—Messages on the logon and logout pages, portal page, and all the messages customizable by the user.
- keepout—Message displayed to remote users when VPN access is denied.
- PortForwarder—Messages displayed to Port Forwarding users.
- url-list—Text that user specifies for URL bookmarks on the portal page.

- webvpn—All the layer 7, AAA and portal messages that are not customizable.
- plugin-ica—Messages for the Citrix plug-in.
- plugin-rdp—Messages for the Remote Desktop Protocol plug-in.
- plugin-telnet,ssh—Messages for the TELNET and SSH plug-in. This plug-in is capable of doing both sshv1 and sshv2.
- plugin-vnc—Messages for the VNC plug-in.

Step 3 Choose the method by which you want to import or export the file:

- Remote server—Select this option to import a customization file that resides on a remote server accessible from the ASA.
- Path—Identify the method to access the file (ftp, http, or https), and provide the file location.
- Flash file system—Choose this method to export a file that resides on the ASA.
- Path—File location.
- Browse Flash—Browse to the path for the file.
- Local computer—Choose this method to import a file that resides on the local PC.
- Path—Provide the path to the file.
- Browse Local Files—Browse to the path for the file.

Step 4 Click **Import/Export Now** to import or export the file.

Configuring Bookmarks

The Bookmarks panel lets you add, edit, delete, import, and export bookmark lists.

Use the Bookmarks panel to configure lists of servers and URLs for access over clientless SSL VPN. Following the configuration of a bookmark list, you can assign the list to one or more policies – group policies, dynamic access policies, or both. Each policy can have only one bookmark list. The list names populate a drop-down list on the URL Lists tab of each DAP.

You can now use bookmarks with macro substitutions for auto sign-on on some web pages. The former POST plug-in approach was created so that administrators could specify a POST bookmark with sign-on macros and receive a kick-off page to load prior to posting the POST request. This POST plug-in approach eliminated those requests that required the presence of cookies or other header items. Now an an administrator determines the pre-load page and URL, which specifies where you want the post login request sent. A pre-load page enables an endpoint browser to fetch certain information that is sent along to the webserver or web application rather than just using a POST request with credentials.

The existing bookmark lists are displayed. You can add, edit, delete, import, or export the bookmark list. You can configure lists of servers and URLs for access and order the items in the designated URL list.

Guidelines

Configuring bookmarks does not prevent the user from visiting fraudulent sites or sites that violate your company's acceptable use policy. In addition to assigning a bookmark list to the group policy, dynamic access policy, or both, apply a web ACL to these policies to control access to traffic flows. Disable URL Entry on these policies to prevent user confusion over what is accessible. See the "Observing Clientless SSL VPN Security Precautions" section on page 91-5 for instructions.

Detailed Steps

Step 1 Specify the name of the list to be added or select the name of the list to be modified or deleted.

The bookmark title and actual associated URL are displayed.

Step 2 (Optional) Click **Add** to configure a new server or URL. See these procedures for additional information:

- Adding a Bookmark for a URL with a GET or Post Method, page 91-141
- Adding a URL for a Predefined Application Template, page 91-142
- Adding a Bookmark for an Auto Sign-On Application, page 91-144

Step 3 (Optional) Click **Edit** to make changes to the server, URL, or display name.

Step 4 (Optional) Click **Delete** to remove the selected item from the URL list. No confirmation or undo exists.

Step 5 (Optional) Choose the location from which you want to import or export the file:

- Local computer—Click to import or export a file that resides on the local PC.
- Flash file system—Click to import or export a file that resides on the ASA.
- Remote server—Click to import a file that resides on a remote server accessible from the ASA.
- Path—Identify the method to access the file (ftp, http, or https), and provide the path to the file.
- Browse Local Files.../Browse Flash...—Browse to the path for the file.

Step 6 (Optional) Highlight a bookmark and click **Assign** to assign the selected bookmark to one or more group policies, dynamic access policies, or LOCAL users.

Step 7 (Optional) Change the position of the selected item in the URL list using the **Move Up** or **Move Down** options.

Step 8 Click OK.

Adding a Bookmark for a URL with a GET or Post Method

The Add Bookmark Entry dialog box lets you create a link or bookmark for a URL list.

Prerequisites

To access a shared folder on your network, use the format \\server\share\subfolder\<*personal folder*>. The user must have list permission for all points above <*personal folder*>.

Detailed Steps

Step 1 Navigate to **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Bookmarks**, and click the **Add** button.

Step 2 Select **URL with GET or POST method** to use for bookmark creation.

Step 3 Enter a name for thise bookmark, which will be displayed on the portal.

Step 4 Use the URL drop-down menu to select the URL type: http, https, cifs, or ftp. The URL drop-down shows standard URL types, plus types for all the plug-ins you installed.

Step 5 Enter the DNS name or IP address for this bookmark (URL). For a plug-in, enter the name of the server. Enter a forward slash and a question mark (/?) after the server name to specify optional parameters, then use an ampersand to separate parameter-value pairs, as shown in the following syntax:

server/?*Parameter*=*Value*&*Parameter*=*Value*

For example:

host/?**DesiredColor=4&DesiredHRes=1024&DesiredVRes=768**

The particular plug-in determines the optional parameter-value pairs that you can enter.

To provide single sign-on support for a plug-in, use the parameter-value pair **csco_sso=1**. For example:

host/?**csco_sso=1&DesiredColor=4&DesiredHRes=1024&DesiredVRes=768**

Step 6 (Optional) Enter a preload URL. When you enter a preload URL, you can also enter the wait time, which is the time you allow for loading of the page until you are forwarded to the actual POST URL.

Step 7 As a subtitle, provide additional user-visible text that describes the bookmark entry.

Step 8 Use the Thumbnail drop-down menu to select an icon to associate with the bookmark on the end-user portal.

Step 9 Click **Manage** to import or export images to use as thumbnails.

Step 10 Click to open the bookmark in a new window that uses the smart tunnel feature to pass data through the ASA to or from the destination server. All browser traffic passes securely over the SSL VPN tunnel. This option lets you provide smart tunnel support for a browser-based application, whereas the Smart Tunnels option, also in the Clientless SSL VPN > Portal menu, lets you add nonbrowser-based applications to a smart tunnel list for assignment to group policies and usernames.

Step 11 Check **Allow the users to bookmark the link** to let clientless SSL VPN users use the Bookmarks or Favorites options on their browsers. Uncheck to prevent access to these options. If you uncheck this option, the bookmark does not appear in the Home section of the WebVPN portal.

Step 12 (Optional) Choose **Advanced Options** to configure further bookmark characteristics.

- URL Method—Choose **Get** for simple data retrieval. Choose **Post** when processing the data might involve changes to it, for example, storing or updating data, ordering a product, or sending e-mail.
- Post Parameters—Configure the particulars of the Post URL method.
- Add/Edit—Click to add a post parameter.
- Edit—Click to edit the highlighted post parameter.
- Delete—Click to delete the highlighted post parameter.

Adding a URL for a Predefined Application Template

This option simplifies bookmark creation with users selecting a predefined ASDM template that contains the pre-filled necessary values for certain well-defined applications.

Prerequisites

Predefined application templates are currently available for the following applications only:

- Citrix XenApp
- Citrix XenDesktop
- Domino WebAccess
- Microsoft Outlook Web Access 2010

- Microsoft Sharepoint 2007
- Microsoft SharePoint 2010

Detailed Steps

Step 1 Enter a name for the bookmark to display for the user.

Step 2 As a subtitle, provide additional user-visible text that describes the bookmark entry.

Step 3 Use the **Thumbnail** drop-down menu to select an icon to associate with the bookmark on the end-user portal.

Step 4 Click **Manage** to import or export images to use as thumbnails.

Step 5 (Optional) Select the **Place this bookmark on the VPN home page** check box.

Step 6 In the **Select Auto Sign-on Application** list, click the required application. The available applications are:

- Citrix XenApp
- Citrix XenDesktop
- Domino WebAccess
- Microsoft Outlook Web Access 2010
- Microsoft Sharepoint 2007
- Microsoft SharePoint 2010

Step 7 Enter the URL of the page which is loaded before the login page. This page will require user interaction to proceed to the login screen. The URL will allow * to substitute an arbitrary number of symbols, for example http*://www.example.com/test.

Step 8 Enter the **Pre-login Page Control ID**. This is the ID of the control / tag that will get a click event on the pre-login page URL to proceed to the login page.

Step 9 Enter the **Application Parameters**. Depending on the application these may include the following:

- **Protocol**. HTTP or HTTPs.
- **Host Name**. For example `www.cisco.com`.
- **Port Number**. The port used by the application.
- **URL Path Appendix**. For example `/Citrix/XenApp`. This is normally auto-populated.
- **Domain**. The domain to connect to
- **User Name**. The SSL VPN Variable to use as a user name. Click **Select Variable** to choose a different variable.
- P**assword**. The SSL VPN Variable to use as a password. Click **Select Variable** to choose a different variable.

Step 10 (Optional) Click **Preview** to view the template output. You can click **Edit** to modify the template.

Step 11 Click **OK** to make your changes. Alternatively, click **Cancel** to abandon your changes.

Adding a Bookmark for an Auto Sign-On Application

This option lets you create a bookmark for any complex auto-sign on application.

Prerequisites

Configuring auto sign-on applications requires two steps:

1. Define the bookmark with some basic initial data and without the POST parameters. Save and assign the bookmark to use in a group or user policy.
2. Edit the bookmark again. Use the capture function to capture the SSL VPN parameters and edit them in the bookmark.

Detailed Steps

Step 1 Enter a name for the bookmark to display for the user.

Step 2 Use the URL drop-down menu to select the URL type: http, https, cifs, or ftp. The URL types of all imported plug-ins also populate this menu. Select the URL type of a plug-in if you want to display the plug-in as a link on the portal page.

Step 3 Enter the DNS name or IP address for the bookmark. For a plug-in, enter the name of the server. Enter a forward slash and a question mark (/?) after the server name to specify optional parameters, then use an ampersand to separate parameter-value pairs, as shown in the following syntax:

*server***/?***Parameter***=***Value***&***Parameter***=***Value*

For example:

*host***/?DesiredColor=4&DesiredHRes=1024&DesiredVRes=768**

The particular plug-in determines the optional parameter-value pairs that you can enter.

To provide single sign-on support for a plug-in, use the parameter-value pair **csco_sso=1**. For example:

*host***/?csco_sso=1&DesiredColor=4&DesiredHRes=1024&DesiredVRes=768**

Step 4 As a subtitle, provide additional user-visible text that describes the bookmark entry.

Step 5 Use the **Thumbnail** drop-down menu to select an icon to associate with the bookmark on the end-user portal.

Step 6 Click **Manage** to import or export images to use as thumbnails.

Step 7 (Optional) Select the **Place this bookmark on the VPN home page** check box.

Step 8 Enter the **Login Page URL**. Wildcards can be used in the URL you enter. For example, you can enter `http*://www.example.com/myurl*`.

Step 9 Enter the **Landing Page URL**. The ASA requires the Landing Page to be configured to detect a successful login to the application.

Step 10 (Optional) Enter a **Post Script**. Some Web applications, such as Microsoft Outlook Web Access, may execute a JavaScript to change the request parameters before the log-on form is submitted. The **Post Script** field enables you to enter JavaScript for such applications.

Step 11 Add the required **Form Parameters**. For each required SSL VPN Variable, click **Add**, enter a **Name**, and select a variable from the list. You can click **Edit** to change parameters and **Delete** to remove them.

Step 12 Enter the URL of the page which is loaded before the login page. This page will require user interaction to proceed to the login screen. The URL will allow * to substitute an arbitrary number of symbols, for example http*://www.example.com/test.

Step 13 Enter the **Pre-login Page Control ID**. This is the ID of the control / tag that will get a click event on the pre-login page URL to proceed to the login page.

Step 14 Click **OK** to make your changes. Alternatively, click **Cancel** to abandon your changes.

When you edit the bookmark you can use the HTML Parameter Capture function to capture the VPN auto sign-on parameters. The bookmark must have been saved and assigned first to a group policy or user.

Enter the **SSL VPN Username** then click **Start Capture**. Then use a Web browser to start the VPN session and navigate to the intranet page. To complete the process, click Stop Capture. The parameters will then be available for editing and inserted in the bookmark.

Importing/Exporting Bookmark List

You can import or export already configured bookmark lists. Import lists that are ready to use. Export lists to modify or edit them, and then reimport.

Detailed Steps

Step 1 Identify the bookmark list by name. Maximum is 64 characters, no spaces.

Step 2 Choose the method by which you want to import or export the list file:

- Local computer—Click to import a file that resides on the local PC.
- Flash file system—Click to export a file that resides on the ASA.
- Remote server—Click to import a url list file that resides on a remote server accessible from the ASA.
- Path—Identify the method to access the file (ftp, http, or https), and provide the path to the file.
- Browse Local Files/Browse Flash—Browse to the path for the file.
- Import/Export Now—Click to import or export the list file.

Importing/Exporting GUI Customization Objects (Web Contents)

This dialogue box lets you import and export web content objects. The names of the web content objects and their file types are displayed.

Web contents can range from a wholly configured home page to icons or images you want to use when you customize the end user portal. You can import or export already configured web contents. Import web contents that are ready for use. Export web contents to modify or edit them, and then reimport.

Step 1 Choose the location from which you want to import or export the file:

- Local computer—Click to import or export a file that resides on the local PC.
- Flash file system—Click to import or export a file that resides on the ASA.
- Remote server—Click to import a file that resides on a remote server accessible from the ASA.
- Path—Identify the method to access the file (ftp, http, or https), and provide the path to the file.
- Browse Local Files.../Browse Flash...—Browse to the path for the file.

Step 2 Determine whether authentication is required to access the content.

The prefix to the path changes depending on whether you require authentication. The ASA uses /+CSCOE+/ for objects that require authentication, and /+CSCOU+/ for objects that do not. The ASA displays /+CSCOE+/ objects on the portal page only, while /+CSCOU+/ objects are visible and usable in either the logon or the portal pages.

Step 3 Click to import or export the file.

Adding/Editing Post Parameter

Use this pane to configure post parameters for bookmark entries and URL lists.

Clientless SSL VPN variables allow for substitutions in URLs and forms-based HTTP post operations. These variables, also known as macros, let you configure users for access to personalized resources that contain the user ID and password or other input parameters. Examples of such resources include bookmark entries, URL lists, and file shares.

Detailed Steps

Step 1 Provide the name and value of the parameters exactly as in the corresponding HTML form, for example: <input name="*param_name*" value="*param_value*">.

You can choose one of the supplied variables from the drop-down list, or you can construct a variable. The variables you can choose from the drop-down list include the following:

Table 91-17 Clientless SSL VPN Variables

No.	Variable Substitution	Definition
1	CSCO_WEBVPN_USERNAME	SSL VPN user login ID
2	CSCO_WEBVPN_PASSWORD	SSL VPN user login password
3	CSCO_WEBVPN_INTERNAL_PASSWORD	SSL VPN user internal resource password. This is a cached credential, and not authenticated by a AAA server. If a user enters this value, it is used as the password for auto-signon, instead of the password value.
4	CSCO_WEBVPN_CONNECTION_PROFILE	SSL VPN user login group drop-down, a group alias within the connection profile
5	CSCO_WEBVPN_MACRO1	Set via RADIUS/LDAP vendor-specific attribute. I f you are mapping this from LDAP via an ldap-attribute-map, the Cisco attribute that uses this variable is WEBVPN-Macro-Substitution-Value1. Variable substitution via RADIUS is performed by VSA#223.
6	CSCO_WEBVPN_MACRO2	Set via RADIUS/LDAP vendor-specific attribute. If you are mapping this from LDAP via an ldap-attribute-map, the Cisco attribute that uses this variable is WEBVPN-Macro-Substitution-Value2. Variable substitution via RADIUS is performed by VSA#224.
7	CSCO_WEBVPN_PRIMARY_USERNAME	Primary user login ID for double authentication.

Table 91-17 Clientless SSL VPN Variables

No.	Variable Substitution	Definition
8	CSCO_WEBVPN_PRIMARY_PASSWORD	Primary user login password for double authentication.
9	CSCO_WEBVPN_SECONDARY_USERNAME	Secondary user login ID for double authentication.
10	CSCO_WEBVPN_SECONDARY_PASSWORD	Secondary user login ID for double authentication.

When the ASA recognizes one of these six variable strings in an end-user request—in a bookmark or a post form—it replaces it with the user-specific value before passing the request to a remote server.

Note You can obtain the http-post parameters for any application by performing an HTTP Sniffer trace in the clear (without the security appliance involved). Here is a link to a free browser capture tool, also called an HTTP Analyzer: http://www.ieinspector.com/httpanalyzer/downloadV2/IEHttpAnalyzerV2.exe.

Using Variables 1 - 4

The ASA obtains values for the first four substitutions from the SSL VPN Login page, which includes fields for username, password, internal password (optional), and group. It recognizes these strings in user requests and replaces them with the value specific to the user before it passes the request on to a remote server.

For example, if a URL list contains the link, http://someserver/homepage/CSCO_WEBVPN_USERNAME.html, the ASA translates it to the following unique links:

- For USER1 the link becomes http://someserver/homepage/USER1.html
- For USER2 the link is http://someserver/homepage/USER2.html

In the following case, cifs://server/users/CSCO_WEBVPN_USERNAME, lets the ASA map a file drive to specific users:

- For USER1 the link becomes cifs://server/users/USER1
- For USER1 the link is cifs://server/users/USER2

Using Variables 5 and 6

Values for macros 5 and 6 are RADIUS or LDAP vendor-specific attributes (VSAs). These substitutions let you set substitutions configured on either a RADIUS or an LDAP server.

Using Variables 7 - 10

Each time the ASA recognizes one of these four strings in an end-user request (a bookmark or a post form), it replaces it with the user-specific value before passing the request to a remote server.

Example 1: Setting a Homepage

The following example sets a URL for the homepage:

- WebVPN-Macro-Value1 (ID=223), type string, is returned as *wwwin-portal.example.com*
- WebVPN-Macro-Value2 (ID=224), type string, is returned as *401k.com*

To set a home page value, you would configure the variable substitution as

https://CSCO_WEBVPN_MACRO1, which would translate to https://wwwin-portal.example.com.

The best way to do this is to configure the Homepage URL parameter in ASDM. Without writing a script or uploading anything, an administrator can specify which homepage in the group policy to connect with via smart tunnel.

Go to the Add/Edit Group Policy pane, from either the Network Client SSL VPN or Clientless SSL VPN Access section of ASDM. The paths are as follows:

- Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit Group Policy > Advanced > SSL VPN Client > Customization > Homepage URL attribute.
- Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policies > Add/Edit Group Policy > More Options > Customization > Homepage URL attribute.

Configuration Example for Setting a Bookmark or URL Entry

You can use an HTTP Post to log in to an OWA resource using an RSA one-time password (OTP) for SSL VPN authentication, and then the static, internal password for OWA e-mail access. The best way to do this is to add or edit a bookmark entry in ASDM.

There are several paths to the Add Bookmark Entry pane, including the following:

- Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Bookmarks > Add/Edit Bookmark Lists > Add/Edit Bookmark Entry > Advanced Options area > Add/Edit Post Parameters (available after you click **Post** in the URL Method attribute).

  or

  (Available after you click **Post** in the URL Method attribute):

- Network (Client) Access > Dynamic Access Policies > Add/Edit Dynamic Access Policy > URL Lists tab > Manage button > Configured GUI Customization Objects > Add/Edit button > Add/Edit Bookmark List > Add/Edit Bookmark Entry > Advanced Options area > Add/Edit Post Parameters.

Configuration Example for Configuring File Share (CIFS) URL Substitutions

You can allow a more flexible bookmark configuration by using variable substitution for CIFS URLs.

If you configure the URL cifs://server/CSCO_WEBVPN_USERNAME, the ASA automatically maps it to the user's file share home directory. This method also allows for password and internal password substitution. The following are example URL substitutions:

cifs://CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_PASSWORD@server

cifs://CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_INTERNAL_PASSWORD@server

cifs://domain;CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_PASSWORD@server

cifs://domain;CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_INTERNAL_PASSWORD@server

cifs://domain;CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_PASSWORD@server/CSCO_WEBVPN_USERNAME

cifs://domain;CSCO_WEBVPN_USERNAME:CSCO_WEBVPN_INTERNAL_PASSWORD@server/CSCO_WEBVPN_USERNAME

Configuration Example for Customizing External Ports

You can use the external portal feature to create your own portal instead of using the pre-configured one. If you set up your own portal, you can bypass the clientless portal and send a POST request to retrieve your portal.

Detailed Steps

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Customization**. Highlight the desired customization and choose **Edit**.

Step 2 Check the Enable External Portal check box.

Step 3 In the URL field, enter the desired external portal so that POST requests are allowed.

Sending an Administrator's Alert to Clientless SSL VPN Users

To send an alert message to clientless SSL VPN users (for example, about connection status), perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Administrator's Alert Message to Clientless SSL VPN Users**.

The Administrator's Alert Message to Clientless SSL VPN Users dialog box appears.

Step 2 Enter the new or edited alert content that you want to send, and then click **Post Alert**.

Step 3 To remove current alert content and enter new alert content, click **Cancel Alert**.

E-Mail Proxy

E-mail proxies extend remote e-mail capability to users of Clientless SSL VPN. When users attempt an e-mail session via e-mail proxy, the e-mail client establishes a tunnel using the SSL protocol.

The e-mail proxy protocols are as follows:

POP3S

POP3S is one of the e-mail proxies Clientless SSL VPN supports. By default the Security Appliance listens to port 995, and connections are automatically allowed to port 995 or to the configured port. The POP3 proxy allows only SSL connections on that port. After the SSL tunnel establishes, the POP3 protocol starts, and then authentication occurs. POP3S is for receiving e-mail.

IMAP4S

IMAP4S is one of the e-mail proxies Clientless SSL VPN supports. By default the Security Appliance listens to port 993, and connections are automatically allowed to port 993 or to the configured port. The IMAP4 proxy allows only SSL connections on that port. After the SSL tunnel establishes, the IMAP4 protocol starts, and then authentication occurs. IMAP4S is for receiving e-mail.

SMTPS

SMTPS is one of the e-mail proxies Clientless SSL VPN supports. By default, the Security Appliance listens to port 988, and connections automatically are allowed to port 988 or to the configured port. The SMTPS proxy allows only SSL connections on that port. After the SSL tunnel establishes, the SMTPS protocol starts, and then authentication occurs. SMTPS is for sending e-mail.

Configuring E-Mail Proxy

Configuring e-mail proxy on the consists of the following tasks:

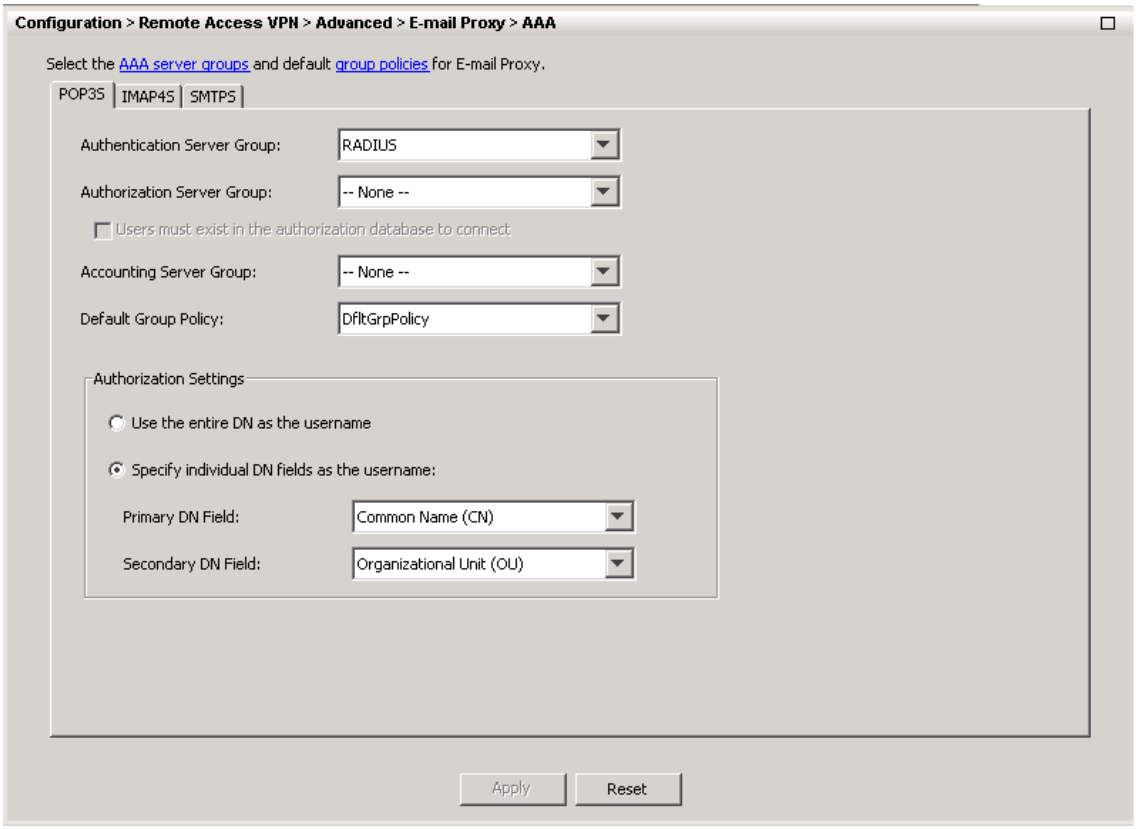
- Enabling e-Mail proxy on interfaces.
- Configuring e-mail proxy default servers.
- Setting AAA server groups and a default group policy.
- Configuring delimiters.

Configuring E-mail proxy also has these requirements:

- Users who access e-mail from both local and remote locations via e-mail proxy require separate e-mail accounts on their e-mail program for local and remote access.
- E-mail proxy sessions require that the user authenticate.

AAA

Configuration > Features > VPN > E-mail Proxy > AAA



This panel has three tabs:

- POP3S Tab
- IMAP4S Tab
- SMTPS Tab

POP3S Tab

Configuration > Features > VPN > E-mail Proxy > AAA > POP3S Tab

The POP3S AAA panel associates AAA server groups and configures the default group policy for POP3S sessions.

Fields

- AAA server groups—Click to go to the AAA Server Groups panel (Configuration > Features > Properties > AAA Setup > AAA Server Groups), where you can add or edit AAA server groups.
- group policies—Click to go to the Group Policy panel (Configuration > Features > VPN > General > Group Policy), where you can add or edit group policies.

- Authentication Server Group—Select the authentication server group for POP3S user authentication. The default is to have no authentication servers configured. If you have set AAA as the authentication method for POP3S (Configuration > Features AAA > VPN > E-Mail Proxy > Authentication panel), you must configure an AAA server and select it here, or authentication always fails.
- Authorization Server Group—Select the authorization server group for POP3S user authorization. The default is to have no authorization servers configured.
- Accounting Server Group—Select the accounting server group for POP3S user accounting. The default is to have no accounting servers configured.
- Default Group Policy—Select the group policy to apply to POP3S users when AAA does not return a CLASSID attribute. The length must be between 4 and 15 alphanumeric characters. If you do not specify a default group policy, and there is no CLASSID, the ASA can not establish the session.
- Authorization Settings—Lets you set values for usernames that the ASA recognizes for POP3S authorization. This applies to POP3S users that authenticate with digital certificates and require LDAP or RADIUS authorization.
  - User the entire DN as the username—Select to use the Distinguished Name for POP3S authorization.
  - Specify individual DN fields as the username—Select to specify specific DN fields for user authorization.

    You can choose two DN fields, primary and secondary. For example, if you choose EA, users authenticate according to their e-mail address. Then a user with the Common Name (CN) John Doe and an e-mail address of johndoe@cisco.com cannot authenticate as John Doe or as johndoe. He must authenticate as johndoe@cisco.com. If you choose EA and O, John Does must authenticate as johndoe@cisco.com and Cisco Systems, Inc.
  - Primary DN Field—Select the primary DN field you want to configure for POP3S authorization. The default is CN. Options include the following:

DN Field	Definition
Country (C)	The two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
Common Name (CN)	The name of a person, system, or other entity. This is the lowest (most specific) level in the identification hierarchy.
DN Qualifier (DNQ)	A specific DN attribute.
E-mail Address (EA)	The e-mail address of the person, system or entity that owns the certificate.
Generational Qualifier (GENQ)	A generational qualifier such as Jr., Sr., or III.
Given Name (GN)	The first name of the certificate owner.
Initials (I)	The first letters of each part of the certificate owner's name.
Locality (L)	The city or town where the organization is located.
Name (N)	The name of the certificate owner.
Organization (O)	The name of the company, institution, agency, association, or other entity.
Organizational Unit (OU)	The subgroup within the organization.
Serial Number (SER)	The serial number of the certificate.
Surname (SN)	The family name or last name of the certificate owner.

DN Field	Definition
State/Province (S/P)	The state or province where the organization is located.
Title (T)	The title of the certificate owner, such as Dr.
User ID (UID)	The identification number of the certificate owner.

  - Secondary DN Field—(Optional) Select the secondary DN field you want to configure for POP3S authorization. The default is OU. Options include all of those in the preceding table, with the addition of **None**, which you select if you do not want to include a secondary field.

IMAP4S Tab

Configuration > Features > VPN > E-mail Proxy > AAA > IMAP4S Tab

The IMAP4S AAA panel associates AAA server groups and configures the default group policy for IMAP4S sessions.

Fields

- AAA server groups—Click to go to the AAA Server Groups panel (Configuration > Features > Properties > AAA Setup > AAA Server Groups), where you can add or edit AAA server groups.
- group policy—Click to go to the Group Policy panel (Configuration > Features > VPN > General > Group Policy), where you can add or edit group policies.
- Authentication Server Group—Select the authentication server group for IMAP4S user authentication. The default is to have no authentication servers configured. If you have set AAA as the authentication method for IMAP4S (Configuration > Features AAA > VPN > E-Mail Proxy > Authentication panel), you must configure an AAA server and select it here, or authentication always fails.
- Authorization Server Group—Select the authorization server group for IMAP4S user authorization. The default is to have no authorization servers configured.
- Accounting Server Group—Select the accounting server group for IMAP4S user accounting. The default is to have no accounting servers configured.
- Default Group Policy—Select the group policy to apply to IMAP4S users when AAA does not return a CLASSID attribute. If you do not specify a default group policy, and there is no CLASSID, the ASA can not establish the session.
- Authorization Settings—Lets you set values for usernames that the ASA recognizes for IMAP4S authorization. This applies to IMAP4S users that authenticate with digital certificates and require LDAP or RADIUS authorization.
  - User the entire DN as the username—Select to use the fully qualified domain name for IMAP4S authorization.
  - Specify individual DN fields as the username—Select to specify specific DN fields for user authorization.

    You can choose two DN fields, primary and secondary. For example, if you choose EA, users authenticate according to their e-mail address. Then a user with the Common Name (CN) John Doe and an e-mail address of johndoe@cisco.com cannot authenticate as John Doe or as johndoe. He must authenticate as johndoe@cisco.com. If you choose EA and O, John Does must authenticate as johndoe@cisco.com *and* Cisco. Systems, Inc.

– **Primary DN Field**—Select the primary DN field you want to configure for IMAP4S authorization. The default is CN. Options include the following:

DN Field	Definition
Country (C)	The two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
Common Name (CN)	The name of a person, system, or other entity. This is the lowest (most specific) level in the identification hierarchy.
DN Qualifier (DNQ)	A specific DN attribute.
E-mail Address (EA)	The e-mail address of the person, system or entity that owns the certificate.
Generational Qualifier (GENQ)	A generational qualifier such as Jr., Sr., or III.
Given Name (GN)	The first name of the certificate owner.
Initials (I)	The first letters of each part of the certificate owner's name.
Locality (L)	The city or town where the organization is located.
Name (N)	The name of the certificate owner.
Organization (O)	The name of the company, institution, agency, association, or other entity.
Organizational Unit (OU)	The subgroup within the organization.
Serial Number (SER)	The serial number of the certificate.
Surname (SN)	The family name or last name of the certificate owner.
State/Province (S/P)	The state or province where the organization is located.
Title (T)	The title of the certificate owner, such as Dr.
User ID (UID)	The identification number of the certificate owner.

– Secondary DN Field—(Optional) Select the secondary DN field you want to configure for IMAP4S authorization. The default is OU. Options include all of those in the preceding table, with the addition of None, which you select if you do not want to include a secondary field.

SMTPS Tab

Configuration > Features > VPN > E-mail Proxy > AAA > SMTPS Tab

The SMTPS AAA panel associates AAA server groups and configures the default group policy for SMTPS sessions.

Fields

- AAA server groups—Click to go to the AAA Server Groups panel (Configuration > Features > Properties > AAA Setup > AAA Server Groups), where you can add or edit AAA server groups.
- group policy—Click to go to the Group Policy panel (Configuration > Features > VPN > General > Group Policy), where you can add or edit group policies.

- Authentication Server Group—Select the authentication server group for SMTPS user authentication. The default is to have no authentication servers configured. If you have set AAA as the authentication method for SMTPS (Configuration > Features AAA > VPN > E-Mail Proxy > Authentication panel), you must configure an AAA server and select it here, or authentication always fails.
- Authorization Server Group—Select the authorization server group for SMTPS user authorization. The default is to have no authorization servers configured.
- Accounting Server Group—Select the accounting server group for SMTPS user accounting. The default is to have no accounting servers configured.
- Default Group Policy—Select the group policy to apply to SMTPS users when AAA does not return a CLASSID attribute. If you do not specify a default group policy, and there is no CLASSID, the ASA can not establish the session.
- Authorization Settings—Lets you set values for usernames that the ASA recognizes for SMTPS authorization. This applies to SMTPS users that authenticate with digital certificates and require LDAP or RADIUS authorization.
  - User the entire DN as the username—Select to use the fully qualified domain name for SMTPS authorization.
  - Specify individual DN fields as the username—Select to specify specific DN fields for user authorization.

    You can choose two DN fields, primary and secondary. For example, if you choose EA, users authenticate according to their e-mail address. Then a user with the Common Name (CN) John Doe and an e-mail address of johndoe@cisco.com cannot authenticate as John Doe or as johndoe. He must authenticate as johndoe@cisco.com. If you choose EA and O, John Does must authenticate as johndoe@cisco.com *and* Cisco. Systems, Inc.
  - Primary DN Field—Select the primary DN field you want to configure for SMTPS authorization. The default is CN. Options include the following:

DN Field	Definition
Country (C)	The two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
Common Name (CN)	The name of a person, system, or other entity. This is the lowest (most specific) level in the identification hierarchy.
DN Qualifier (DNQ)	A specific DN attribute.
E-mail Address (EA)	The e-mail address of the person, system or entity that owns the certificate.
Generational Qualifier (GENQ)	A generational qualifier such as Jr., Sr., or III.
Given Name (GN)	The first name of the certificate owner.
Initials (I)	The first letters of each part of the certificate owner's name.
Locality (L)	The city or town where the organization is located.
Name (N)	The name of the certificate owner.
Organization (O)	The name of the company, institution, agency, association, or other entity.
Organizational Unit (OU)	The subgroup within the organization.
Serial Number (SER)	The serial number of the certificate.
Surname (SN)	The family name or last name of the certificate owner.

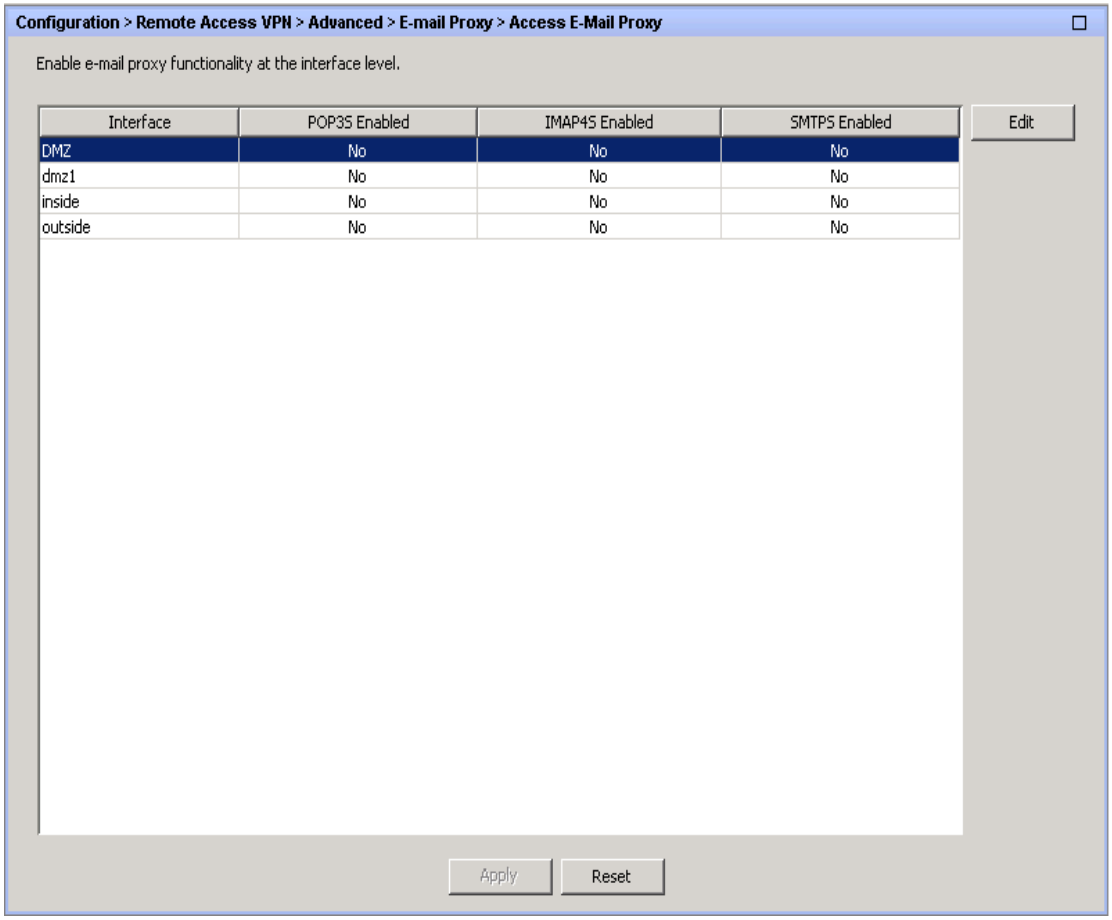
DN Field	Definition
State/Province (S/P)	The state or province where the organization is located.
Title (T)	The title of the certificate owner, such as Dr.
User ID (UID)	The identification number of the certificate owner.

– **Secondary DN Field**—(Optional) Select the secondary DN field you want to configure for SMTPS authorization. The default is OU. Options include all of those in the preceding table, with the addition of None, which you select if you do not want to include a secondary field.

Access

Configuration > VPN > E-Mail Proxy > Access

The E-mail Proxy Access screen lets you identify interfaces on which to configure e-mail proxy. You can configure and edit e-mail proxies on individual interfaces, and you can configure and edit e-mail proxies for one interface and then apply your settings to all interfaces. You cannot configure e-mail proxies for management-only interfaces, or for subinterfaces.



Fields

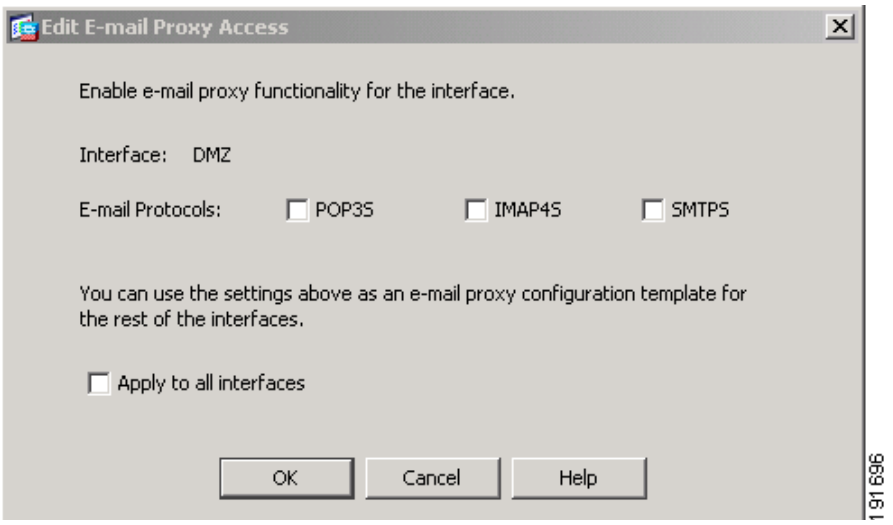
- Interface—Displays the names of all configured interfaces.

- POP3S Enabled—Shows whether POP3S is enabled for the interface.
- IMAP4s Enabled—Shows whether IMAP4S is enabled for the interface.
- SMTPS Enabled—Shows whether SMTPS is enabled for the interface.
- Edit—Click to edit the e-mail proxy settings for the highlighted interface.

Edit E-Mail Proxy Access

Configuration > VPN > E-Mail Proxy > Access > Edit E-Mail Proxy Access

The E-mail Proxy Access screen lets you identify interfaces on which to configure e-mail proxy. You can configure e-mail proxies on individual interfaces, and you can configure e-mail proxies for one interface and then apply your settings to all interfaces.



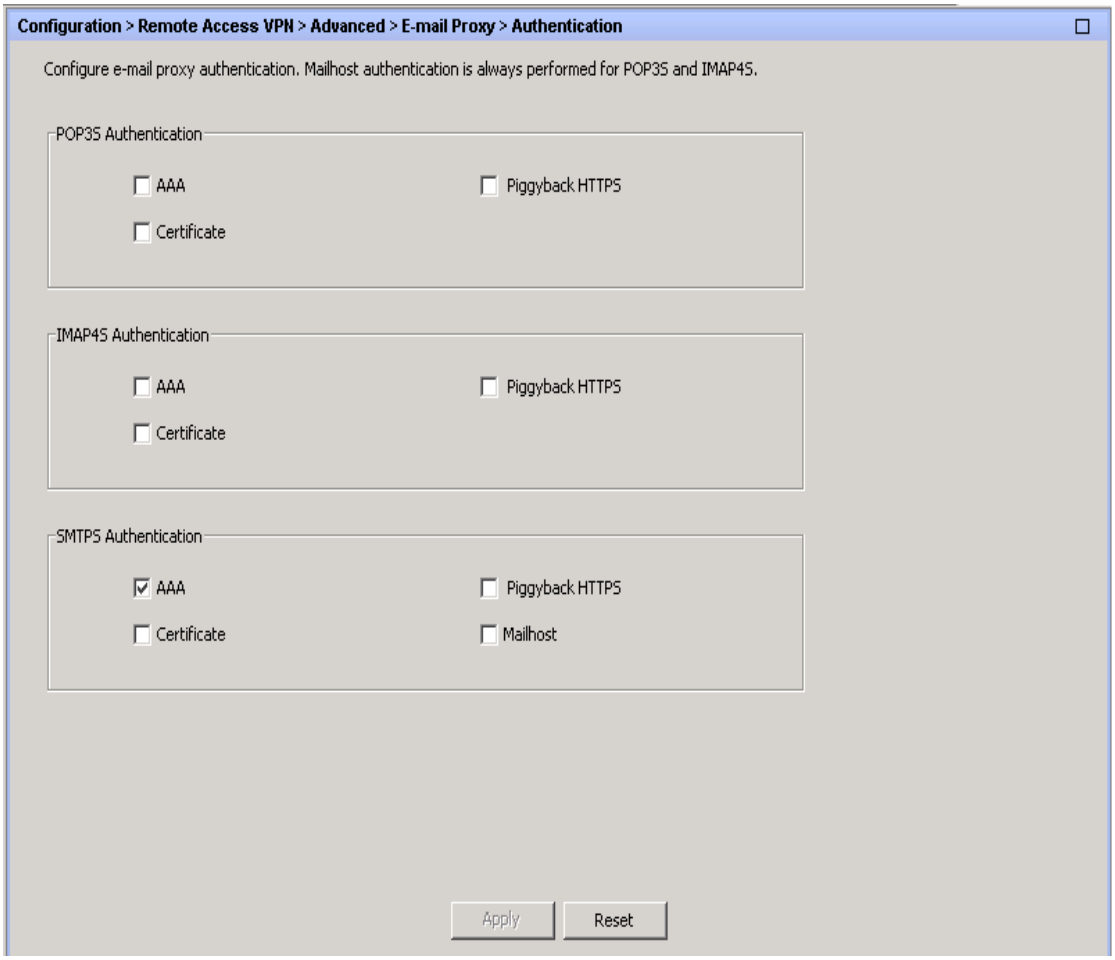
Fields

- Interface—Displays the name of the selected interface.
- POP3S Enabled—Select to enable POP3S for the interface.
- IMAP4S Enabled—elect to enable IMAP4S for the interface.
- SMTPS Enabled—Select to enable SMTPS for the interface.
- Apply to all interface—Select to apply the settings for the current interface to all configured interfaces.

Authentication

Configuration > Features > VPN >E-mail Proxy > Authentication

This panel lets you configure authentication methods for e-mail proxy sessions.



Fields

POP3S/IMAP4S/SMTPS Authentication—Let you configure authentication methods for each of the e-mail proxy types. You can select multiple methods of authentication.

- AAA—Select to require AAA authentication. This option requires a configured AAA server. The user presents a username, server and password. Users must present both the VPN username and the e-mail username, separated by the VPN Name Delimiter, only if the usernames are different from each other.
- Certificate—Certificate authentication does not work for e-mail proxies in the current ASA software release.
- Piggyback HTTPS—Select to require piggyback authentication.

  This authentication scheme requires a user to have already established a Clientless SSL VPN session. The user presents an e-mail username only. No password is required. Users must present both the VPN username and the e-mail username, separated by the VPN Name Delimiter, only if the usernames are different from each other.

  SMTPS e-mail most often uses piggyback authentication because most SMTP servers do not allow users to log in.

Note IMAP generates a number of sessions that are not limited by the simultaneous user count but do count against the number of simultaneous logins allowed for a username. If the number of IMAP sessions exceeds this maximum and the Clientless SSL VPN connection expires, a user cannot subsequently establish a new connection. There are several solutions:

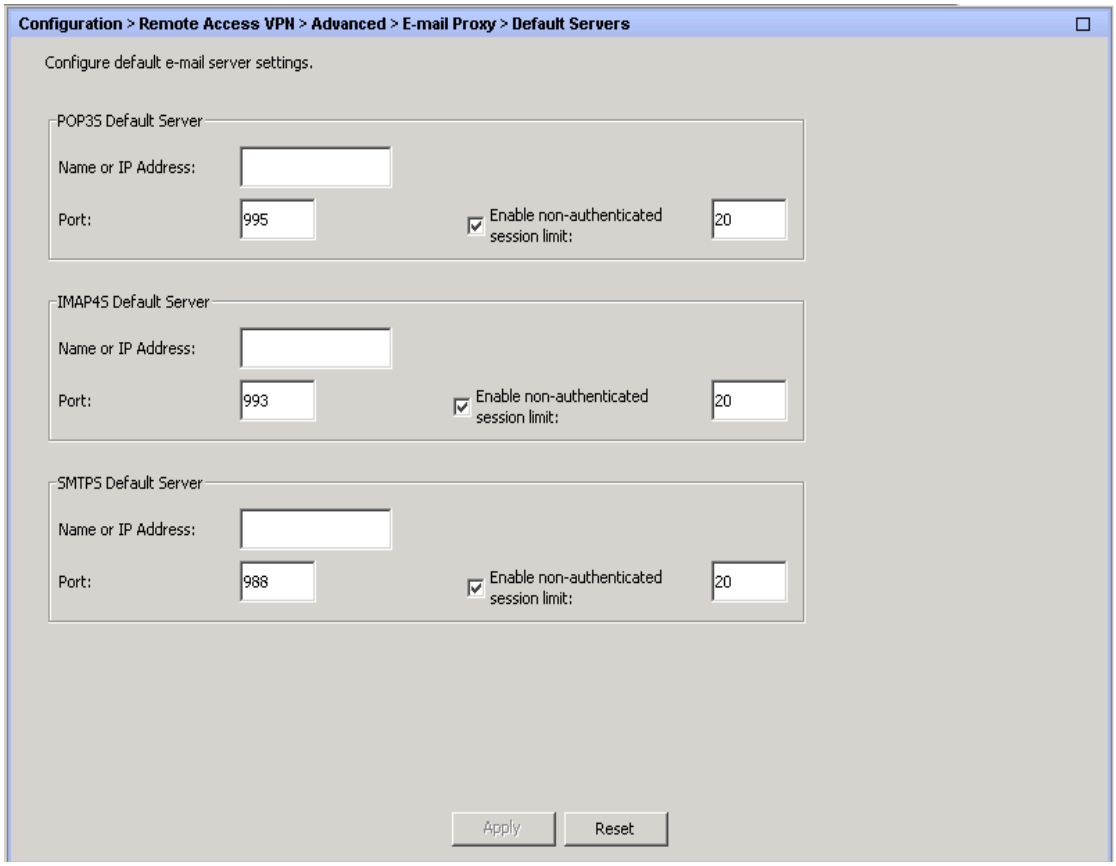
- The user can close the IMAP application to clear the sessions with the ASA, and then establish a new Clientless SSL VPN connection.
- The administrator can increase the simultaneous logins for IMAP users (Configuration > Features > VPN > General > Group Policy > Edit Group Policy > General).
- Disable HTTPS/Piggyback authentication for e-mail proxy.

- Mailhost—(SMTPS only) Select to require mailhost authentication. This option appears for SMTPS only because POP3S and IMAP4S always perform mailhost authentication. It requires the user's e-mail username, server and password.

Default Servers

Configuration > Features > VPN > E-mail Proxy > Default Servers

This panel lets you identify proxy servers to the ASA. Enter the IP address and port of the appropriate proxy server.



Fields

- POP3S/IMAP4S/SMTPS Default Server—Let you configure a default server, port and non-authenticated session limit for e-mail proxies.
- Name or IP Address—Type the DNS name or IP address for the default e-mail proxy server.
- Port—Type the port number on which the ASA listens for e-mail proxy traffic. Connections are automatically allowed to the configured port. The e-mail proxy allows only SSL connections on this port. After the SSL tunnel establishes, the e-mail proxy starts, and then authentication occurs.

  For POP3s the default port is 995, for IMAP4S it is 993, and for SMTPS it is 988.
- Enable non-authenticated session limit—Select to restrict the number of non-authenticated e-mail proxy sessions.

  E-mail proxy connections have three states:

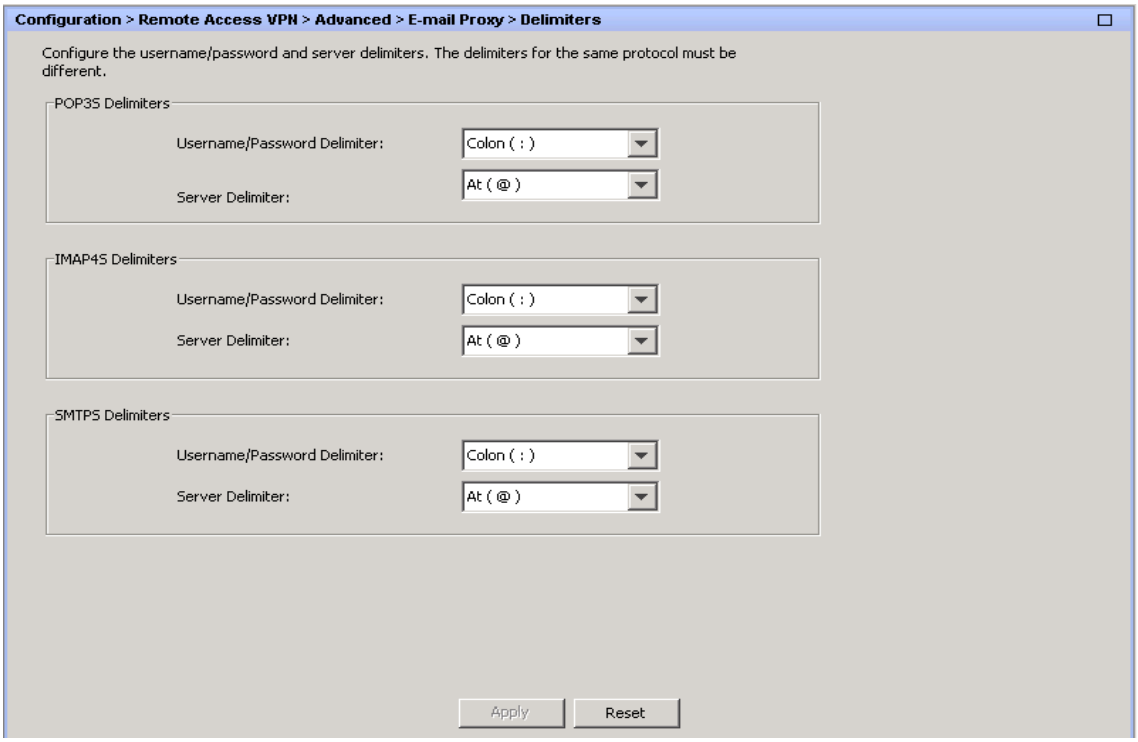
  1. A new e-mail connection enters the “unauthenticated” state.
  2. When the connection presents a username, it enters the “authenticating” state.
  3. When the ASA authenticates the connection, it enters the “authenticated” state.

  This feature lets you set a limit for sessions in the process of authenticating, thereby preventing DOS attacks. When a new session exceeds the set limit, the ASA terminates the oldest non-authenticating connection. If there are no non-authenticating connections, the oldest authenticating connection is terminated. The does not terminate authenticated sessions.

Delimiters

Configuration > Features > VPN > E-mail Proxy > Delimiters

This panel lets you configure username/password delimiters and server delimiters for e-mail proxy authentication.



Fields

- POP3S/IMAP4S/SMTPS Delimiters—Let you configure username/password and server delimiters for each of the e-mail proxies.
  - Username/Password Delimiter—Select a delimiter to separate the VPN username from the e-mail username. Users need both usernames when using AAA authentication for e-mail proxy and the VPN username and e-mail username are different. Users enter both usernames, separated by the delimiter you configure here, and also the e-mail server name, when they log in to an e-mail proxy session.

Note Passwords for Clientless SSL VPN e-mail proxy users cannot contain characters that are used as delimiters.

  - Server Delimiter—Select a delimiter to separate the username from the name of the e-mail server. It must be different from the VPN Name Delimiter. Users enter both their username and server in the username field when they log in to an e-mail proxy session.

    For example, using : as the VPN Name Delimiter and @ as the Server Delimiter, when logging in to an e-mail program via e-mail proxy, the user would enter their username in the following format: vpn_username:e-mail_username@server.

Monitoring VPN

This chapter describes how to use VPN monitoring parameters and statistics for the following:

- VPN statistics for specific Network (Client) Remote Access, Site-to-Site VPN, Clientless SSL VPN, and E-mail Proxy sessions
- Encryption statistics for tunnel groups
- Protocol statistics for tunnel groups
- Global IPsec and IKE statistics
- Crypto statistics for IPsec, IKE, SSL, and other protocols
- Statistics for cluster VPN server loads

VPN Connection Graphs

Displays VPN connection data in graphical or tabular form for the ASA.

IPsec Tunnels

Monitoring > VPN > VPN Connection Graphs > IPSec Tunnels

Use this pane to specify graphs and tables of the IPsec tunnel types you want to view, or prepare to export or print.

Fields

- Graph Window Title—Displays the default title that appears in the pane when you click Show Graphs. This attribute is particularly useful when you want to clarify data in that pane before printing or exporting it. To change the title, choose an alternative from the drop-down list or type the title.
- Available Graphs—Shows the types of active tunnels you can view. For each type you want to view collectively in a single pane, choose the entry and click **Add**.
- Selected Graphs—Shows the types of tunnels selected.

  If you click Show Graphs, ASDM shows the active tunnels types listed in a single pane.

  A highlighted entry indicates the type of tunnel to be removed from the list if you click **Remove**.
- Add—Moves the selected tunnel type from the Available Graphs column to the Selected Graphs column.

- Remove—Moves the selected tunnel type from the Selected Graphs column to the Available Graphs column.
- Show Graphs—Displays a pane consisting of graphs of the tunnel types displayed in the Selected Graphs column. Each type in the pane displayed has a Graph tab and a Table tab you can click to alternate the representation of active tunnel data.

Sessions

Monitoring > VPN > VPN Connection Graphs > Sessions

Use this pane to specify graphs and tables of the VPN session types you want to view, or prepare to export or print.

Fields

- Graph Window Title—Displays the default title that appears in the pane when you click Show Graphs. This attribute is particularly useful when you want to clarify data in that pane before printing or exporting it. To change the title, select an alternative from the drop-down list or type the title.
- Available Graphs—Shows the types of active sessions you can view. For each type you want to view collectively in a single pane, click the entry in this box and click Add.
- Selected Graphs—Shows the types of active sessions selected.

  If you click Show Graphs, ASDM shows all of the active session types listed in this box in a single pane.

  A highlighted entry indicates the type of session to be removed from the list if you click Remove.
- Add—Moves the selected session type from the Available Graphs box to the Selected Graphs box.
- Remove—Moves the selected session type from the Selected Graphs box to the Available Graphs box.
- Show Graphs—Displays a pane consisting of graphs of the session types displayed in the Selected Graphs box. Each type in the pane displayed has a Graph tab and a Table tab you can click to alternate the representation of active session data.

VPN Statistics

These panes show detailed parameters and statistics for a specific remote-access, LAN-to-LAN, Clientless SSL VPN, or E-mail Proxy session. The parameters and statistics differ depending on the session protocol. The contents of the statistical tables depend on the type of connection you choose. The detail tables show all the relevant parameters for each session.

Sessions Window

Monitoring > VPN > VPN Statistics > Sessions

Use this pane to view VPN session statistics for the adaptive security appliance.

Fields

- Session types (unlabeled)—Lists the number of currently active sessions of each type, the total limit, and the total cumulative session count.
  - All Remote Access—Shows the number of remote access sessions.
  - Site-to-Site—Shows the number of LAN-to-LAN sessions.
  - Clientless SSL VPN—Shows the number of clientless browser-based VPN sessions.
  - AnyConnect Client—Shows the number of client-based SSL VPN sessions. With ASA version 8.x and above, this represents the AnyConnect SSL VPN client 2.x and above.
  - SSL VPN–Inactive—Shows the number of SSL VPN sessions that are inactive on the remote computer.

    Note An administrator can keep track of the number of users in the inactive state and can look at the statistics. The sessions that have been inactive for the longest time are marked as idle (and are automatically logged off) so that license capacity is not reached and new users can log in. You can also access these statistics using the **show vpn-sessiondb** CLI command (refer to the *Cisco Security Appliance Command Reference Guide)*.

  - SSL VPN–Total—Shows the number of client-based and clientless SSL VPN sessions.
  - E-mail Proxy—Shows the number of E-mail proxy sessions.
  - VPN Load Balancing—Shows the number of load-balanced VPN sessions
  - Total—Shows the total number of active concurrent sessions.
  - Total Cumulative—Shows the cumulative number of sessions since the last time the ASA was rebooted or reset.
- Filter By—Specifies the type of sessions that the statistics in the following table represent.
  - Session type (unlabeled)—Designates the session type that you want to monitor. You can filter by any of these sessions: IPsec Site-to-Site, All Remote Access, AnyConnect Client, Clientless SSL VPN, IPsec (IKEv1) Remote Access, OSPFv3 IPsec, or Email Proxy.

    The column headings in the results table change depending on the Session type you choose.
  - Filter name (unlabeled)—Specifies the name of the filter to apply. If you specify --All Sessions-- as the session filter list, this field is not available. For all other session filter selections, this field cannot be blank.

    If you choose a Session type filter of IPsec Site-to-Site, AnyConnect Client, Clientless SSL VPN, or OSPFv3 IPsec then you would be able to filter by Assigned IP Address Type or Public IP Address Type.
  - Filter value—Enter the value that corresponds to the filter you are using.

    If you are filtering by Assigned IP Address Type or Public IP Address type, specify the IP address type in this field, either IPv4 or IPv6.
  - Filter—Executes the filtering operation.

The contents of the second table, also unlabeled, in this pane depend on the selection in the Filter By list. In the following list, the first-level bullets show the Filter By selection, and the second-level bullets show the column headings for this table.

- All Remote Access—Indicates that the values in this table relate to remote access (IPsec software and hardware clients) traffic.

  - Username/Connection Profile—Shows the username or login name and the connection profile (tunnel group) for the session. If the client is using a digital certificate for authentication, the field shows the Subject CN or Subject OU from the certificate.
  - Group Policy Connection Profile—Displays the tunnel group policy connection profile for the session.
  - Assigned IP Address/Public IP Address—Shows the private ("assigned") IP address assigned to the remote client for this session. This is also known as the "inner" or "virtual" IP address, and it lets the client appear to be a host on the private network. Also shows the Public IP address of the client for this remote-access session. This is also known as the "outer" IP address. It is typically assigned to the client by the ISP, and it lets the client function as a host on the public network.

Note The Assigned IP Address field does not apply to Clientless SSL VPN sessions, as the ASA (proxy) is the source of all traffic. For a hardware client session in Network Extension mode, the Assigned IP address is the subnet of the hardware client's private/inside network interface.

  - Protocol/Encryption—Shows the protocol and the data encryption algorithm this session is using, if any.
  - Login Time/Duration—Shows the date and time (MMM DD HH:MM:SS) that the session logged in. and the length of the session. Time is displayed in 24-hour notation.
  - Client (Peer) Type/Version—Shows the type and software version number (for example, rel. 7.0_int 50) for connected clients, sorted by username.
  - Bytes Tx/Bytes Rx—Shows the total number of bytes transmitted to/received from the remote peer or client by the ASA.

- IPsec Site-to-Site—Indicates that the values in this table relate to LAN-to-LAN traffic.
  - Connection Profile/IP Address—Shows the name of the tunnel group and the IP address of the peer.
  - Protocol/Encryption—Shows the protocol and the data encryption algorithm this session is using, if any.
  - Login Time/Duration—Shows the date and time (MMM DD HH:MM:SS) that the session logged in. and the length of the session. Time is displayed in 24-hour notation.
  - Bytes Tx/Bytes Rx—Shows the total number of bytes transmitted to/received from the remote peer or client by the ASA.
- Clientless SSL VPN—Indicates that the values in this table relate to Clientless SSL VPN traffic.
  - Username/IP Address—Shows the username or login name for the session and the IP address of the client.
  - Group Policy Connection Profile—Displays the connection profile of the tunnel group policy.
  - Protocol/Encryption—Shows the protocol and the data encryption algorithm this session is using, if any.
  - Login Time/Duration—Shows the date and time (MMM DD HH:MM:SS) that the session logged in. and the length of the session. Time is displayed in 24-hour notation.
  - Bytes Tx/Bytes Rx—Shows the total number of bytes transmitted to/received from the remote peer or client by the ASA.
- SSL VPN Client—Indicates that the values in this table relate to traffic for SSL VPN Client sessions.

  - Username/IP Address—Shows the username or login name for the session and the IP address of the client.
  - Group Policy Connection Profile—Displays the connection profile of the tunnel group policy.
  - Protocol/Encryption—Shows the protocol and the data encryption algorithm this session is using, if any.
  - Login Time/Duration—Shows the date and time (MMM DD HH:MM:SS) that the session logged in. and the length of the session. Time is displayed in 24-hour notation.
  - Bytes Tx/Bytes Rx—Shows the total number of bytes transmitted to/received from the remote peer or client by the ASA.
- E-Mail Proxy—Indicates that the values in this table relate to traffic for Clientless SSL VPN sessions.
  - Username/IP Address—Shows the username or login name for the session and the IP address of the client.
  - Protocol/Encryption—Shows the protocol and the data encryption algorithm this session is using, if any.
  - Login Time/Duration—Shows the date and time (MMM DD HH:MM:SS) that the session logged in. and the length of the session. Time is displayed in 24-hour notation.
  - Bytes Tx/Bytes Rx—Shows the total number of bytes transmitted to/received from the remote peer or client by the ASA.

The remainder of this section describes the buttons and fields beside and below the table.

- Details—Displays the details for the selected session. The parameters and values differ, depending on the type of session.
- Logout—Ends the selected session.
- Ping—Sends an ICMP `ping` (Packet Internet Groper) packet to test network connectivity. Specifically, the ASA sends an ICMP Echo Request message to a selected host. If the host is reachable, it returns an Echo Reply message, and the ASA displays a Success message with the name of the tested host, as well as the elapsed time between when the request was sent and the response received. If the system is unreachable for any reason, (for example: host down, ICMP not running on host, route not configured, intermediate router down, or network down or congested), the ASA displays an Error screen with the name of the tested host.
- Logout By—Chooses a criterion to use to filter the sessions to be logged out. If you choose any but --All Sessions--, the box to the right of the Logout By list becomes active. If you choose the value Protocol for Logout By, the box becomes a list, from which you can choose a protocol type to use as the logout filter. The default value of this list is IPsec. For all choices other than Protocol, you must supply an appropriate value in this column.
- Logout Sessions—Ends all sessions that meet the specified Logout By criteria.
- Refresh—Updates the screen and its data. The date and time indicate when the screen was last updated.

Viewing Active AnyConnect Sessions

Step 1 Select **Monitoring > VPN > VPN Statistics > Sessions**.

Step 2 In the Filter By field, select **AnyConnect Client**.

Step 3 In the Session Filter field (unlabeled), next to the Filter By field, select the session type you want to use to further refine your filter. Then, enter a value in the Session Value field (unlabeled) to the right of the Session Filter field. These are the available session filters and session values:

Session Filter	Session Value
Username	Then enter the username you want to sort by.
Assigned IP Address	The assigned IP address is the IP address assigned by the ASA to the AnyConnect Client connection. Enter the IPv4 or IPv6 address you want to sort by.
Assigned IP Address Type	Choose IP version 4 or IP version 6.
Public Address	The public IP address is the IP address assigned by your enterprise to the endpoint. Enter the IPv4 or IPv6 address you want to sort by.
Public Address Type	Choose IP version 4 or IP version 6.
Encryption	Select the encryption type for the session.
Connection Status	Select Active or Inactive.

Step 4 Cick **Filter**.

Viewing VPN Sessions Details

Monitoring > VPN > VPN Statistics > Sessions >Details

The Session Details pane displays configuration settings, statistics, and state information about the selected session.

The Remote Detailed table at the top of the Session Details pane displays the following columns:

- Username—Shows the username or login name associated with the session. If the remote peer is using a digital certificate for authentication, the field shows the Subject CN or Subject OU from the certificate.
- Group Policy and Tunnel Group—Group policy assigned to the session and the name of the tunnel group upon which the session is established.
- Assigned IP Address and Public IP Address—Private IP address assigned to the remote peer for this session. Also called the inner or virtual IP address, the assigned IP address lets the remote peer appear to be on the private network. The second field shows the public IP address of the remote computer for this session. Also called the outer IP address, the public IP address is typically assigned to the remote computer by the ISP. It lets the remote computer function as a host on the public network.
- Protocol/Encryption—Protocol and the data encryption algorithm this session is using, if any.
- Login Time and Duration—Time and date of the session initialization, and the length of the session. The session initialization time is in 24-hour notation.
- Client Type and Version—Type and software version number (for example, rel. 7.0_int 50) of the client on the remote computer.

- Bytes Tx and Bytes Rx—Shows the total number of bytes transmitted to and received from the remote peer by the ASA.
- NAC Result and Posture Token—The ASDM displays values in this column only if you configured Network Admission Control on the ASA.

  The NAC Result shows one of the following values:

  - Accepted—The ACS successfully validated the posture of the remote host.
  - Rejected—The ACS could not successfully validate the posture of the remote host.
  - Exempted—The remote host is exempt from posture validation according to the Posture Validation Exception list configured on the ASA.
  - Non-Responsive—The remote host did not respond to the EAPoUDP Hello message.
  - Hold-off—The ASA lost EAPoUDP communication with the remote host after successful posture validation.
  - N/A—NAC is disabled for the remote host according to the VPN NAC group policy.
  - Unknown—Posture validation is in progress.

  The posture token is an informational text string which is configurable on the Access Control Server. The ACS downloads the posture token to the ASA for informational purposes to aid in system monitoring, reporting, debugging, and logging. The typical posture token that follows the NAC result is as follows: Healthy, Checkup, Quarantine, Infected, or Unknown.

The Details tab in the Session Details pane displays the following columns:

- ID—Unique ID dynamically assigned to the session. The ID serves as the ASA index to the session. It uses this index to maintain and display information about the session.
- Type—Type of session: IKE, IPsec, or NAC.
- Local Addr., Subnet Mask, Protocol, Port, Remote Addr., Subnet Mask, Protocol, and Port—Addresses and ports assigned to both the actual (Local) peer and those assigned to this peer for the purpose of external routing.
- Encryption—Data encryption algorithm this session is using, if any.
- Assigned IP Address and Public IP Address—Shows the private IP address assigned to the remote peer for this session. Also called the inner or virtual IP address, the assigned IP address lets the remote peer appear to be on the private network. The second field shows the public IP address of the remote computer for this session. Also called the outer IP address, the public IP address is typically assigned to the remote computer by the ISP. It lets the remote computer function as a host on the public network.
- Other—Miscellaneous attributes associated with the session.

  The following attributes apply to an IKE session:

  The following attributes apply to an IPsec session:

  The following attributes apply to a NAC session:

  - Revalidation Time Interval— Interval in seconds required between each successful posture validation.
  - Time Until Next Revalidation—0 if the last posture validation attempt was unsuccessful. Otherwise, the difference between the Revalidation Time Interval and the number of seconds since the last successful posture validation.

- Status Query Time Interval—Time in seconds allowed between each successful posture validation or status query response and the next status query response. A status query is a request made by the ASA to the remote host to indicate whether the host has experienced any changes in posture since the last posture validation.
- EAPoUDP Session Age—Number of seconds since the last successful posture validation.
- Hold-Off Time Remaining—0 seconds if the last posture validation was successful. Otherwise, the number of seconds remaining before the next posture validation attempt.
- Posture Token—Informational text string configurable on the Access Control Server. The ACS downloads the posture token to the ASA for informational purposes to aid in system monitoring, reporting, debugging, and logging. A typical posture token is Healthy, Checkup, Quarantine, Infected, or Unknown.
- Redirect URL—Following posture validation or clientless authentication, the ACS downloads the access policy for the session to the ASA. The Redirect URL is an optional part of the access policy payload. The ASA redirects all HTTP (port 80) and HTTPS (port 443) requests for the remote host to the Redirect URL if it is present. If the access policy does not contain a Redirect URL, the ASA does not redirect HTTP and HTTPS requests from the remote host.

  Redirect URLs remain in force until either the IPsec session ends or until posture revalidation, for which the ACS downloads a new access policy that can contain a different redirect URL or no redirect URL.

  More—Press this button to revalidate or initialize the session or tunnel group.

The ACL tab displays the ACL containing the ACEs that matched the session.

Cluster Loads

Monitoring > VPN > VPN Statistics > Cluster Loads

Use this pane to view the current traffic load distribution among the servers in a VPN load-balancing cluster. If the server is not part of a cluster, you receive an information message saying that this server does not participate in a VPN load-balancing cluster.

Fields

- VPN Cluster Loads—Displays the current load distribution in the VPN load-balancing cluster. Clicking a column heading sorts the table, using the selected column as the sort key.
  - Public IP Address—Displays the externally visible IP address for the server.
  - Role—Indicates whether this server is a master or backup device in the cluster.
  - Priority—Shows the priority assigned to this server in the cluster. The priority must be an integer in the range of 1 (lowest) to 10 (highest). The priority is used in the master-election process as one way to determine which of the devices in a VPN load-balancing cluster becomes the master or primary device for the cluster.
  - Model—Indicates the ASA model name and number for this server.
  - IPsec Load%—Indicates what percentage of a server's total capacity is in use, based upon the capacity of that server.
  - SSL Load%—Indicates what percentage of a SSL server's total capacity is in use, based upon the capacity of that server.
  - IPsec Sessions—Shows the number of currently active sessions.
  - SSL Sessions—Shows the number of currently active sessions.

- Refresh—Loads the table with updated statistics.

Crypto Statistics

Monitoring > VPN > VPN Statistics > Crypto Statistics

This pane displays the crypto statistics for currently active user and administrator sessions on the ASA. Each row in the table represents one crypto statistic.

Fields

- Show Statistics For—Selects a specific protocol, IKE Protocol (the default), IPsec Protocol, SSL Protocol, or other protocols.
- Statistics—Shows the statistics for all the protocols in use by currently active sessions.
  - Statistic—Lists the name of the statistical variable. The contents of this column vary, depending upon the value you select for the Show Statistics For parameter.
  - Value—The numerical value for the statistic in this row.
- Refresh—Updates the statistics shown in the Crypto Statistics table.

Compression Statistics

Monitoring > VPN > VPN Statistics > Compression Statistics

This pane displays the compression statistics for currently active user and administrator sessions on the ASA. Each row in the table represents one compression statistic.

Fields

- Show Statistics For—Lets you select compression statistics for clientless SSL VPN or SSL VPN Client sessions.
- Statistics—Shows all the statistics for the selected VPN type.
  - Statistic—Lists the name of the statistical variable. The contents of this column vary, depending upon the value you select for the Show Statistics For parameter.
  - Value—The numerical value for the statistic in this row.
- Refresh—Updates the statistics shown in the Compression Statistics table.

Encryption Statistics

Monitoring > VPN > VPN Statistics > Encryption Statistics

This pane shows the data encryption algorithms used by currently active user and administrator sessions on the ASA. Each row in the table represents one encryption algorithm type.

Fields

- Show Statistics For—Selects a specific server or group or all tunnel groups.
- Encryption Statistics—Shows the statistics for all the data encryption algorithms in use by currently active sessions.
  - Encryption Algorithm—Lists the encryption algorithm to which the statistics in this row apply.

  - Sessions—Lists the number of sessions using this algorithm.
  - Percentage—Indicates the percentage of sessions using this algorithm relative to the total active sessions, as a number. The sum of this column equals 100 percent (rounded).
- Total Active Sessions—Shows the number of currently active sessions.
- Cumulative Sessions—Shows the total number of sessions since the ASA was last booted or reset.
- Refresh—Updates the statistics shown in the Encryption Statistics table.

Global IKE/IPsec Statistics

Monitoring > VPN > VPN Statistics > Global IKE/IPSec Statistics

This pane displays the global IKE/IPsec statistics for currently active user and administrator sessions on the ASA. Each row in the table represents one global statistic.

Fields

- Show Statistics For—Selects a specific protocol, IKE Protocol (the default) or IPsec Protocol.
- Statistics—Shows the statistics for all the protocols in use by currently active sessions.
  - Statistic—Lists the name of the statistical variable. The contents of this column vary, depending upon the value you select for the Show Statistics For parameter.
  - Value—The numerical value for the statistic in this row.
- Refresh—Updates the statistics shown in the Global IKE/IPsec Statistics table.

NAC Session Summary

The NAC Session Summary pane lets you view the active and cumulative Network Admission Control sessions.

Fields

- Active NAC Sessions—General statistics about remote peers that are subject to posture validation.
- Cumulative NAC Sessions—General statistics about remote peers that are or have been subject to posture validation.
- Accepted—Number of peers that passed posture validation and have been granted an access policy by an Access Control Server.
- Rejected—Number of peers that failed posture validation or were not granted an access policy by an Access Control Server.
- Exempted—Number of peers that are not subject to posture validation because they match an entry in the Posture Validation Exception list configured on the ASA.
- Non-responsive—Number of peers not responsive to Extensible Authentication Protocol (EAP) over UDP requests for posture validation. Peers on which no CTA is running do not respond to these requests. If the ASA configuration supports clientless hosts, the Access Control Server downloads the access policy associated with clientless hosts to the ASA for these peers. Otherwise, the ASA assigns the NAC default policy.
- Hold-off—Number of peers for which the ASA lost EAPoUDP communications after a successful posture validation. The NAC Hold Timer attribute (Configuration > VPN > NAC) determines the delay between this type of event and the next posture validation attempt.

- N/A—Number of peers for which NAC is disabled according to the VPN NAC group policy.
- Revalidate All—Click if the posture of the peers or the assigned access policies (that is, the downloaded ACLs), have changed. Clicking this button initiates new, unconditional posture validations of all NAC sessions managed by the ASA. The posture validation and assigned access policy that were in effect for each session before you clicked this button remain in effect until the new posture validation succeeds or fails. Clicking this button does not affect sessions that are exempt from posture validation.
- Initialize All—Click if the posture of the peers or the assigned access policies (that is, the downloaded ACLs) have changed, and you want to clear the resources assigned to the sessions. Clicking this button purges the EAPoUDP associations and assigned access policies used for posture validations of all NAC sessions managed by the ASA, and initiates new, unconditional posture validations. The NAC default ACL is effective during the revalidations, so the session initializations can disrupt user traffic. Clicking this button does not affect sessions that are exempt from posture validation.

Protocol Statistics

Monitoring > VPN > VPN Statistics > Protocol Statistics

This pane displays the protocols used by currently active user and administrator sessions on the ASA. Each row in the table represents one protocol type.

Fields

- Show Statistics For—Selects a specific server or group or all tunnel groups.
- Protocol Statistics—Shows the statistics for all the protocols in use by currently active sessions.
  - Protocol—Lists the protocol to which the statistics in this row apply.
  - Sessions—Lists the number of sessions using this protocol.
  - Percentage—Indicates the percentage of sessions using this protocol relative to the total active sessions, as a number. The sum of this column equals 100 percent (rounded).
- Total Active Tunnel—Shows the number of currently active sessions.
- Cumulative Tunnels—Shows the total number of sessions since the ASA was last booted or reset.
- Refresh—Updates the statistics shown in the Protocol Statistics table.

VLAN Mapping Sessions

This pane displays the number of sessions assigned to an egress VLAN, as determined by the value of the Restrict Access to VLAN parameter of each group policy in use. The ASA forwards all traffic to the specified VLAN.

Field

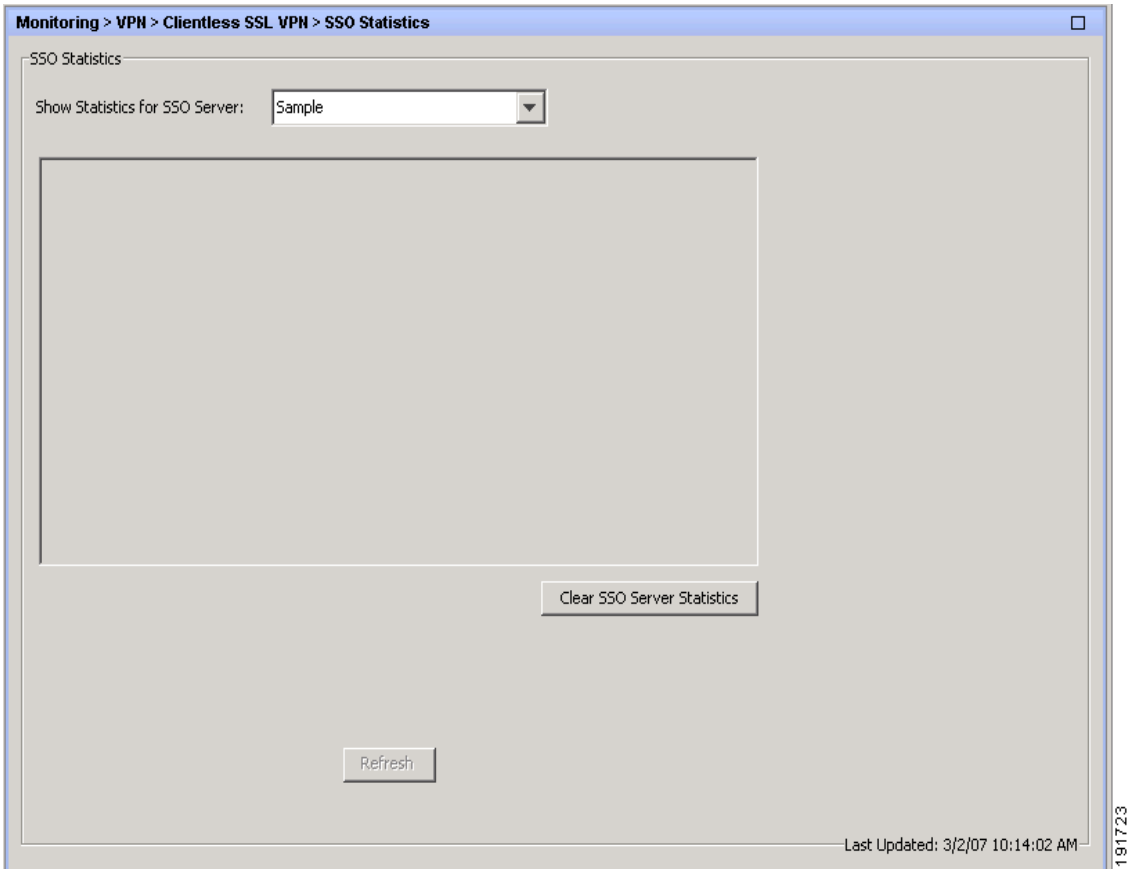
- Active VLAN Mapping Sessions—Number of VPN sessions assigned to an egress VLAN.

SSO Statistics for Clientless SSL VPN Session

Monitoring > VPN > WebVPN > SSO Statistics

This pane displays the single sign-on statistics for currently active SSO servers configured for the ASA.

Note These statistics are for SSO with SiteMinder and SAML Browser Post Profile servers only.



Fields

- Show Statistics For SSO Server—Selects an SSO server.
- SSO Statistics—Shows the statistics for all the currently active sessions on the selected SSO server. SSO statistics that display include:
  - Name of SSO server
  - Type of SSO server
  - Authentication Scheme Version (SiteMinder servers)
  - Web Agent URL (SiteMinder servers)
  - Assertion Consumer URL (SAML POST servers)
  - Issuer (SAML POST servers)
  - Number of pending requests
  - Number of authorization requests
  - Number of retransmissions

  - Number of accepts
  - Number of rejects
  - Number of timeouts
  - Number of unrecognized responses
- Refresh—Updates the statistics shown in the SSO Statistics table
- Clear SSO Server Statistics—Resets statistics for the displayed server.

VPN Connection Status for the Easy VPN Client

Use this pane to view the status of the ASA configured as an Easy VPN client. This features applies to the ASA 5505 only.

Fields

VPN Client Detail—Displays configuration information for the ASA5505 configured as an Easy VPN Client.

Connect—Establishes a client connection

Refresh—Refreshes the information displayed in the VPN Client Detail panel.

Configuring SSL Settings

SSL

Configuration > Properties > SSL

The ASA uses the Secure Sockets Layer (SSL) protocol and its successor, Transport Layer Security (TLS) to achieve secure message transmission for both ASDM and Clientless, browser-based sessions. The SSL window lets you configure SSL versions for clients and servers and encryption algorithms. It also lets you apply previously configured trustpoints to specific interfaces, and to configure a fallback trustpoint for interfaces that do not have an associated trustpoint.

Fields

- **Server SSL Version**—Choose to specify the SSL/TLS protocol version the ASA uses to negotiate as a server. You can make only one selection.

Options for Server SSL versions include the following:

Any	The ASA accepts SSL version 2 client hellos, and negotiates either SSL version 3 or TLS version 1.
Negotiate SSL V3	The ASA accepts SSL version 2 client hellos, and negotiates to SSL version 3.
Negotiate TLS V1	The ASA accepts SSL version 2 client hellos, and negotiates to TLS version 1.
SSL V3 Only	The security appliance accepts only SSL version 3 client hellos, and uses only SSL version 3.
TLS V1 Only	The security appliance accepts only TLSv1 client hellos, and uses only TLS version 1.

Note To use port forwarding for Clientless SSL VPN, you must select Any or Negotiate SSL V3. The issue is that JAVA only negotiates SSLv3 in the client Hello packet when you launch the Port Forwarding application.

- **Client SSL Version—**Choose to specify the SSL/TLS protocol version the ASA uses to negotiate as a client. You can make only one selection.

Options for Client SSL versions include the following:

any	The ASA sends SSL version3 hellos, and negotiates either SSL version 3 or TLS version 1.
sslv3-only	The security appliance sends SSL version 3 hellos, and accepts only SSL version 3.
tlsv1-only	The security appliance sends TLSv1 client hellos, and accepts only TLS version 1.

- **Encryption**—Lets you set SSL encryption algorithms.
  - **Available Algorithms**—Lists the encryption algorithms the ASA supports that are not in use for SSL connections. To use, or make active, an available algorithm, highlight the algorithm and click **Add**.
  - **Active Algorithms**—Lists the encryption algorithms the security appliance supports and is currently using for SSL connections. To discontinue using, or change an active algorithm to available status, highlight the algorithm and click **Remove**.
  - **Add/Remove**—Click to change the status of encryption algorithms in either the Available or Active Algorithms columns.
  - **Move Up/Move Down**—Highlight an algorithm and click these buttons to change its priority. The ASA attempts to use an algorithm
- **Certificates—**Lets you select a fallback certificate, and displays configured interfaces and the configured certificates associated with them.
  - **Fallback Certificate**—Click to select a certificate to use for interfaces that have no certificate associated with them. If you select **None**, the ASA uses the default RSA key-pair and certificate.
  - **Interface** and **ID Certificate** columns—Display configured interfaces and the certificate, if any, for the interface.
  - **Edit**—Click to change the trustpoint for the highlighted interface.
- **Apply—**Click to apply your changes.
- **Reset**—Click to remove changes you have made and reset SSL parameters to the values that they held when you opened the window.

Edit SSL Certificate

Configuration > Properties > SSL > Edit SSL Trustpoint

Fields

- **Interface**—Displays the name of the interface you are editing.
- **Certificate**—Click to select a previously enrolled certificate to associate with the named interface.

SSL Certificates

In this pane, you can require that device management sessions require user certificates for SSL authentication.

Configuration > Properties > SSL > Edit SSL Trustpoint

Fields

- **Interface**—Displays the name of the interface you are editing.
- **User Certificate Required**—Click to select a previously enrolled certificate to associate with the named interface.

PART 16

Configuring Logging, SNMP, and Smart Call Home

Configuring Logging

This chapter describes how to configure and manage logs for the ASA and ASASM and includes the following sections:

- Information About Logging, page 96-1
- Licensing Requirements for Logging, page 96-5
- Prerequisites for Logging, page 96-6
- Guidelines and Limitations, page 96-6
- Configuring Logging, page 96-6
- Monitoring the Logs, page 96-24
- Feature History for Logging, page 96-28

Information About Logging

System logging is a method of collecting messages from devices to a server running a syslog daemon. Logging to a central syslog server helps in aggregation of logs and alerts. Cisco devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and stores them in files, or prints them according to a simple configuration file. This form of logging provides protected long-term storage for logs. Logs are useful both in routine troubleshooting and in incident handling.

The ASA system logs provide you with information for monitoring and troubleshooting the ASA. With the logging feature, you can do the following:

- Specify which syslog messages should be logged.
- Disable or change the severity level of a syslog message.
- Specify one or more locations where syslog messages should be sent, including an internal buffer, one or more syslog servers, ASDM, an SNMP management station, specified e-mail addresses, or to Telnet and SSH sessions.
- Configure and manage syslog messages in groups, such as by severity level or class of message.
- Specify whether or not a rate-limit is applied to syslog generation.
- Specify what happens to the contents of the internal log buffer when it becomes full: overwrite the buffer, send the buffer contents to an FTP server, or save the contents to internal flash memory.
- Filter syslog messages by locations, severity level, class, or a custom message list.

This section includes the following topics:

- Logging in Multiple Context Mode, page 96-2
- Analyzing Syslog Messages, page 96-2
- Syslog Message Format, page 96-3
- Severity Levels, page 96-3
- Message Classes and Range of Syslog IDs, page 96-4
- Filtering Syslog Messages, page 96-4
- Sorting in the Log Viewers, page 96-4
- Using Custom Message Lists, page 96-5
- Using Clustering, page 96-5

Logging in Multiple Context Mode

Each security context includes its own logging configuration and generates its own messages. If you log in to the system or admin context, and then change to another context, messages you view in your session are only those messages that are related to the current context.

Syslog messages that are generated in the system execution space, including failover messages, are viewed in the admin context along with messages generated in the admin context. You cannot configure logging or view any logging information in the system execution space.

You can configure the ASA and ASASM to include the context name with each message, which helps you differentiate context messages that are sent to a single syslog server. This feature also helps you to determine which messages are from the admin context and which are from the system; messages that originate in the system execution space use a device ID of **system**, and messages that originate in the admin context use the name of the admin context as the device ID.

Analyzing Syslog Messages

The following are some examples of the type of information you can obtain from a review of various syslog messages:

- Connections that are allowed by ASA and ASASM security policies. These messages help you spot holes that remain open in your security policies.
- Connections that are denied by ASA and ASASM security policies. These messages show what types of activity are being directed toward your secured inside network.
- Using the ACE deny rate logging feature shows attacks that are occurring on your ASA or ASA Services Module.
- IDS activity messages can show attacks that have occurred.
- User authentication and command usage provide an audit trail of security policy changes.
- Bandwidth usage messages show each connection that was built and torn down as well as the duration and traffic volume used.
- Protocol usage messages show the protocols and port numbers used for each connection.
- Address translation audit trail messages record NAT or PAT connections being built or torn down, which are useful if you receive a report of malicious activity coming from inside your network to the outside world.

Syslog Message Format

Syslog messages begin with a percent sign (%) and are structured as follows:

```
%ASA Level Message_number: Message_text
```

Field descriptions are as follows:

ASA	The syslog message facility code for messages that are generated by the ASA and ASASM. This value is always ASA.
Level	1 through 7. The level reflects the severity of the condition described by the syslog message—the lower the number, the more severe the condition. See Table 96-1 for more information.
Message_number	A unique six-digit number that identifies the syslog message.
Message_text	A text string that describes the condition. This portion of the syslog message sometimes includes IP addresses, port numbers, or usernames.

Severity Levels

Table 96-1 lists the syslog message severity levels. You can assign custom colors to each of the severity levels to make it easier to distinguish them in the ASDM log viewers. To configure syslog message color settings, either choose the **Tools > Preferences > Syslog** tab or, in the log viewer itself, click **Color Settings** on the toolbar.

Table 96-1 Syslog Message Severity Levels

Level Number	Severity Level	Description
0	**emergencies**	System is unusable.
1	**alert**	Immediate action is needed.
2	**critical**	Critical conditions.
3	**error**	Error conditions.
4	**warning**	Warning conditions.
5	**notification**	Normal but significant conditions.
6	**informational**	Informational messages only.
7	**debugging**	Debugging messages only.

Note The ASA and ASASM do not generate syslog messages with a severity level of zero (emergencies). This level is provided in the **logging** command for compatibility with the UNIX syslog feature but is not used by the ASA.

Message Classes and Range of Syslog IDs

For a list of syslog message classes and the ranges of syslog message IDs that are associated with each class, see the syslog messages guide.

Filtering Syslog Messages

You can filter generated syslog messages so that only certain syslog messages are sent to a particular output destination. For example, you could configure the ASA and ASASM to send all syslog messages to one output destination and to send a subset of those syslog messages to a different output destination.

Specifically, you can configure the ASA and ASASM so that syslog messages are directed to an output destination according to the following criteria:

- Syslog message ID number
- Syslog message severity level
- Syslog message class (equivalent to a functional area of the ASA and ASASM)

You customize these criteria by creating a message list that you can specify when you set the output destination. Alternatively, you can configure the ASA or ASASM to send a particular message class to each type of output destination independently of the message list.

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages using the **logging class** command.
- Create a message list that specifies the message class using the **logging list** command.

The syslog message class provides a method of categorizing syslog messages by type, equivalent to a feature or function of the ASA and ASASM. For example, the vpnc class denotes the VPN client.

All syslog messages in a particular class share the same initial three digits in their syslog message ID numbers. For example, all syslog message IDs that begin with the digits 611 are associated with the vpnc (VPN client) class. Syslog messages associated with the VPN client feature range from 611101 to 611323.

In addition, most of the ISAKMP syslog messages have a common set of prepended objects to help identify the tunnel. These objects precede the descriptive text of a syslog message when available. If the object is not known at the time that the syslog message is generated, the specific *heading = value* combination does not appear.

The objects are prefixed as follows:

Group = *groupname*, Username = *user*, IP = *IP_address*

Where the group is the tunnel-group, the username is the username from the local database or AAA server, and the IP address is the public IP address of the remote access client or L2L peer.

Sorting in the Log Viewers

You can sort messages in all ASDM log viewers (that is, the Real-Time Log Viewer, the Log Buffer Viewer, and the Latest ASDM Syslog Events Viewer). To sort tables by multiple columns, click the header of the first column that you want to sort by, then press and hold down the **Ctrl** key and at the same

time, click the headers of the other column(s) that you want to include in the sort order. To sort messages chronologically, select both the date and time columns; otherwise, the messages are sorted only by date (regardless of the time) or only by time (regardless of the date).

When you sort messages in the Real-Time Log Viewer and in the Latest ASDM Syslog Events Viewer, the new messages that come in appear in the sorted order, instead of at the top, as they normally would be. That is, they are mixed in with the rest of the messages.

Using Custom Message Lists

Creating a custom message list is a flexible way to exercise control over which syslog messages are sent to which output destination. In a custom syslog message list, you specify groups of syslog messages using any or all of the following criteria: severity level, message IDs, ranges of syslog message IDs, or message class.

For example, you can use message lists to do the following:

- Select syslog messages with the severity levels of 1 and 2 and send them to one or more e-mail addresses.
- Select all syslog messages associated with a message class (such as ha) and save them to the internal buffer.

A message list can include multiple criteria for selecting messages. However, you must add each message selection criterion with a new command entry. It is possible to create a message list that includes overlapping message selection criteria. If two criteria in a message list select the same message, the message is logged only once.

Using Clustering

Syslog messages are an invaluable tool for accounting, monitoring, and troubleshooting in a clustering environment. Each ASA unit in the cluster (up to eight units are allowed) generates syslog messages independently; certain **logging** commands then enable you to control header fields, which include a timestamp and device ID. The syslog server uses the device ID to identify the syslog generator. You can use the **logging device-id** command to generate syslog messages with identical or different device IDs to make messages appear to come from the same or different units in the cluster.

Note To monitor syslog messages from units in a cluster, you must open an ASDM session to each of the units that you want to monitor.

Licensing Requirements for Logging

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Prerequisites for Logging

Logging has the following prerequisites:

- The syslog server must run a server program called syslogd. Windows (except for Windows 95 and Windows 98) provides a syslog server as part of its operating system. For Windows 95 and Windows 98, you must obtain a syslogd server from another vendor.
- To view logs generated by the ASA or ASASM, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the ASA and ASASM generate messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately. For example, to designate more than one syslog server as an output destination, specify separate entries in the Syslog Server pane for each syslog server.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context modes.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

- Sending syslogs over TCP is not supported on a standby ASA.
- The ASA supports the configuration of 16 syslog servers with the **logging host** command in single context mode. In multiple context mode, the limitation is 4 servers per context.

Configuring Logging

This section describes how to configure logging and includes the following topics:

- Enabling Logging, page 96-7
- Configuring an Output Destination, page 96-7

Note The minimum configuration depends on what you want to do and what your requirements are for handling syslog messages in the ASA and ASASM.

Enabling Logging

To enable logging, perform the following steps:

Path	Purpose
Choose one of the following: • **Home > Latest ASDM Syslog Messages > Enable Logging** • **Configuration > Device Management > Logging > Logging Setup** • **Monitoring > Real-Time Log Viewer > Enable Logging** • **Monitoring > Log Buffer > Enable Logging**	Enables logging.

What to Do Next

See the "Configuring an Output Destination" section on page 96-7.

Configuring an Output Destination

To optimize syslog message usage for troubleshooting and performance monitoring, we recommend that you specify one or more locations where syslog messages should be sent, including an internal log buffer, one or more external syslog servers, ASDM, an SNMP management station, the console port, specified e-mail addresses, or Telnet and SSH sessions.

This section includes the following topics:

- Sending Syslog Messages to an External Syslog Server, page 96-8
- Configuring FTP Settings, page 96-9
- Configuring Logging Flash Usage, page 96-9
- Configuring Syslog Messaging, page 96-10
- Editing Syslog ID Settings, page 96-10
- Including a Device ID in Non-EMBLEM Formatted Syslog Messages, page 96-11
- Sending Syslog Messages to the Internal Log Buffer, page 96-12
- Saving an Internal Log Buffer to Flash, page 96-13
- Viewing and Copying Logged Entries with the ASDM Java Console, page 96-13
- Sending Syslog Messages to an E-mail Address, page 96-13
- Adding or Editing E-Mail Recipients, page 96-14
- Configuring the Remote SMTP Server, page 96-14
- Viewing Syslog Messages in ASDM, page 96-15
- Applying Message Filters to a Logging Destination, page 96-15
- Applying Logging Filters, page 96-15

- Adding or Editing a Message Class and Severity Filter, page 96-16
- Adding or Editing a Syslog Message ID Filter, page 96-17
- Sending Syslog Messages to the Console Port, page 96-17
- Sending Syslog Messages to a Telnet or SSH Session, page 96-17
- Creating a Custom Event List, page 96-17
- Generating Syslog Messages in EMBLEM Format to a Syslog Server, page 96-18
- Adding or Editing Syslog Server Settings, page 96-19
- Generating Syslog Messages in EMBLEM Format to Other Output Destinations, page 96-19
- Changing the Amount of Internal Flash Memory Available for Logs, page 96-20
- Configuring the Logging Queue, page 96-20
- Sending All Syslog Messages in a Class to a Specified Output Destination, page 96-21
- Enabling Secure Logging, page 96-21
- Including the Device ID in Non-EMBLEM Format Syslog Messages, page 96-21
- Including the Date and Time in Syslog Messages, page 96-22
- Disabling a Syslog Message, page 96-22
- Changing the Severity Level of a Syslog Message, page 96-22
- Limiting the Rate of Syslog Message Generation, page 96-22
- Assigning or Changing Rate Limits for Individual Syslog Messages, page 96-23
- Adding or Editing the Rate Limit for a Syslog Message, page 96-23
- Editing the Rate Limit for a Syslog Severity Level, page 96-24

Sending Syslog Messages to an External Syslog Server

You can archive messages according to the available disk space on the external syslog server, and manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

To send syslog messages to an external syslog server, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Logging Setup**.

Step 2 Check the **Enable logging** check box to turn on logging for the main ASA.

Step 3 Check the **Enable logging on the failover standby unit** check box to turn on logging for the standby ASA, if available.

Step 4 Check the **Send debug messages as syslogs** check box to redirect all debugging trace output to system logs. The syslog message does not appear on the console if this option is enabled. Therefore, to view debugging messages, you must have logging enabled at the console and have it configured as the destination for the debugging syslog message number and severity level. The syslog message number to use is **711001**. The default severity level for this syslog message is debugging.

Step 5 Check the **Send syslogs in EMBLEM format** check box to enable EMBLEM format so that it is used for all logging destinations, except syslog servers.

Step 6 In the Buffer Size field, specify the size of the internal log buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, messages are overwritten unless you save the logs to an FTP server or to internal flash memory. The default buffer size is 4096 bytes. The range is 4096 to 1048576.

Step 7 To save the buffer content to the FTP server before it is overwritten, check the **Save Buffer To FTP Server** check box. To allow overwriting of the buffer content, uncheck this check box.

Step 8 Click **Configure FTP Settings** to identify the FTP server and configure the FTP parameters used to save the buffer content. For more information, see the "Configuring FTP Settings" section on page 96-9.

Step 9 To save the buffer content to internal flash memory before it is overwritten, check the **Save Buffer To Flash** check box.

Note This option is only available in routed or transparent single mode.

Step 10 Click **Configure Flash Usage** to specify the maximum space to be used in internal flash memory for logging and the minimum free space to be preserved (in KB). Enabling this option creates a directory called "syslog" on the device disk on which messages are stored. For more information, see the "Configuring Logging Flash Usage" section on page 96-9.

Note This option is only available in single routed or transparent mode.

Step 11 In the Queue Size field, specify the queue size for system logs that are to be viewed in the ASA or ASASM.

Configuring FTP Settings

To specify the configuration for the FTP server that is used to save the log buffer content, perform the following steps:

Step 1 Check the **Enable FTP client** check box to enable configuration of the FTP client.

Step 2 In the Server IP Address field, specify the IP address of the FTP server.

Step 3 In the Path field, specify the directory path on the FTP server to store the saved log buffer content.

Step 4 In the Username field, specify the username to log in to the FTP server.

Step 5 In the Password field, specify the password associated with the username to log in to the FTP server.

Step 6 In the Confirm Password field, reenter the password, and click **OK**.

Configuring Logging Flash Usage

To specify the limits for saving the log buffer content to internal flash memory, perform the following steps:

Step 1 In the Maximum Flash to Be Used by Logging field, specify the maximum amount of internal flash memory that can be used for logging (in KB).

Step 2 In the Minimum Free Space to Be Preserved field, specify the amount of internal flash memory that is preserved (in KB). When the internal flash memory approaches that limit, new logs are no longer saved.

Step 3 Click **OK** to close this dialog box.

Configuring Syslog Messaging

To configure syslog messaging, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Syslog Setup**.

Step 2 From the Facility code to include in syslogs drop-down list, choose a system log facility for syslog servers to use as a basis to file messages. The default is LOCAL(4)20, which is what most UNIX systems expect. However, because your network devices share eight available facilities, you might need to change this value for system logs.

Step 3 To add the date and time in each syslog message sent, check the **Include timestamp in syslogs** check box.

Step 4 From the Show drop-down list, choose the information to be displayed in the Syslog ID table. Available options are as follows:

- To specify that the Syslog ID table should display the entire list of syslog message IDs, choose **Show all syslog IDs**.
- To specify that the Syslog ID table should display only those syslog message IDs that have been explicitly disabled, choose **Show disabled syslog IDs**.
- To specify that the Syslog ID table should display only those syslog message IDs with severity levels that have changed from their default values, choose **Show syslog IDs with changed logging**.
- To specify that the Syslog ID table should display only those syslog message IDs with severity levels that have been modified and the IDs of syslog messages that have been explicitly disabled, choose **Show syslog IDs that are disabled or with a changed logging level**.

Step 5 The Syslog ID Setup Table displays the list of syslog messages based on the setting in the Syslog ID Setup Table. Choose individual messages or ranges of message IDs that you want to modify. You can either disable the selected message IDs or modify their severity levels. To select more than one message ID in the list, click the first ID in the range and Shift-click the last ID in the range.

Step 6 To configure syslog messages to include a device ID, click **Advanced**. For more information, see the "Editing Syslog ID Settings" section on page 96-10 and the "Including a Device ID in Non-EMBLEM Formatted Syslog Messages" section on page 96-11.

Editing Syslog ID Settings

To change syslog message settings, perform the following steps:

Note The Syslog ID(s) field is display-only. The values that appear in this area are determined by the entries you chose in the Syslog ID table, located in the Syslog Setup pane.

Step 1 Check the **Disable Message(s)** check box to disable messages for the syslog message ID(s) displayed in the Syslog ID(s) list.

Step 2 From the Logging Level drop-down list, choose the severity level of messages to be sent for the syslog message ID(s) displayed in the Syslog ID(s) list. Severity levels are defined as follows:

- Emergency (level 0, system is unusable)

  Note Using a severity level of zero is not recommended.

- Alert (level 1, immediate action is needed)
- Critical (level 2, critical conditions)
- Error (level 3, error conditions)
- Warning (level 4, warning conditions)
- Notification (level 5, normal but significant conditions)
- Informational (level 6, informational messages only)
- Debugging (level 7, debugging messages only)

Step 3 Click **OK** to close this dialog box.

Including a Device ID in Non-EMBLEM Formatted Syslog Messages

To include a device ID in non-EMBLEM formatted syslog messages, perform the following steps:

Step 1 Check the **Enable syslog device ID** check box to specify that a device ID should be included in all non-EMBLEM formatted syslog messages.

Step 2 To specify which to use as the device ID, choose one of the following options:

- Hostname of the ASA
- Interface IP address

  Choose the interface name that corresponds to the selected IP address from the drop-down list.

  If you are using clustering, check the **In an ASA cluster, always use master's IP address for the selected interface** check box.

- String

  In the User-Defined ID field, specify an alphanumeric, user-defined string.

- ASA cluster name

Step 3 Click **OK** to close this dialog box.

Sending Syslog Messages to the Internal Log Buffer

To send syslog messages to the internal log buffer, perform the following steps:

	Path	Purpose
Step 1	Choose one of the following: • **Home > Latest ASDM Syslog Messages > Configure ASDM Syslog Filters** • **Configuration > Device Management > Logging > Logging Filters**	Specifies which syslog messages should be sent to the internal log buffer, which serves as a temporary storage location. New messages are appended to the end of the list. When the buffer is full, that is, when the buffer wraps, old messages are overwritten as new messages are generated, unless you configure the ASA and ASASM to save the full buffer to another location. To empty the internal log buffer, choose **Monitoring > Logging > Log Buffer > View**. Then in the Log Buffer pane, choose **File > Clear Internal Log Buffer**.
Step 2	**Configuration > Device Management > Logging > Logging Setup**	Changes the size of the internal log buffer. The buffer size is 4 KB.
Step 3	Choose one of the following options:	
	Configuration > Device Management > Logging > Logging Setup > Configure Flash Usage	When saving the buffer content to another location, the ASA and ASASM create log files with names that use the following time-stamp format: `LOG-YYYY-MM-DD-HHMMSS.TXT` where *YYYY* is the year, *MM* is the month, *DD* is the day of the month, and *HHMMSS* is the time in hours, minutes, and seconds. The ASA and ASASM continue to save new messages to the internal log buffer and saves the full log buffer content to the internal flash memory.
	Configuration > Device Management > Logging > Logging Setup > Configure FTP Settings	When saving the buffer content to another location, the ASA and ASASM create log files with names that use the following time-stamp format: `LOG-YYYY-MM-DD-HHMMSS.TXT` where *YYYY* is the year, *MM* is the month, *DD* is the day of the month, and *HHMMSS* is the time in hours, minutes, and seconds. The ASA and ASASM continue saving new messages to the internal log buffer and saves the full log buffer content to an FTP server.
	Configuration > Device Management > Logging > Logging Setup > Configure FTP Settings	Identifies the FTP server on which you want to store log buffer content.
	Configuration > Device Management > Logging > Logging Setup > Configure FTP Settings	Saves the current log buffer content to the internal flash memory.

Saving an Internal Log Buffer to Flash

To save the internal log buffer to flash memory, perform the following steps:

Step 1 In the main ASDM application window, choose **File > Save Internal Log Buffer to Flash**.

The Enter Log File Name dialog box appears.

Step 2 Choose the first option to save the log buffer with the default filename, LOG-YYYY-MM-DD-hhmmss.txt.

Step 3 Choose the second option to specify a filename for the log buffer.

Step 4 Enter the filename for the log buffer, and then click **OK**.

Viewing and Copying Logged Entries with the ASDM Java Console

You can use the ASDM Java console to view and copy logged entries in a text format, which can help you troubleshoot ASDM errors.

To access the ASDM Java Console, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > ASDM Java Console**.

Step 2 To show the virtual machine memory statistics, enter **m** in the console.

Step 3 To perform garbage collection, enter **g** in the console.

Step 4 To monitor memory usage, open the Windows Task Manager and double-click the **asdm_launcher.exe** file.

Note The maximum memory allocation allowed is 256 MB.

Step 5 To continue, see the "Monitoring Performance" section on page 73-8.

Sending Syslog Messages to an E-mail Address

To send syslog messages to an e-mail address, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > E-Mail Setup**.

Step 2 In the Source E-Mail Address field, specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

Step 3 Click **Add** to enter a new e-mail address recipient of the specified syslog messages. For more information, see the "Adding or Editing E-Mail Recipients" section on page 96-14.

Step 4 Choose the severity level of the syslog messages that are sent to the recipient from the drop-down list. The syslog message severity filter used for the destination e-mail address causes messages of the specified severity level and higher to be sent. The global filter specified in the Logging Filters pane is also applied to each e-mail recipient. For more information, see the "Applying Logging Filters" section on page 96-15.

Step 5 Click **Edit** to modify an existing severity level of the syslog messages that are sent to this recipient. For more information, see the "Adding or Editing E-Mail Recipients" section on page 96-14.

Step 6 Click **OK** to close this dialog box.

Step 7 To continue, see the "Configuring the Remote SMTP Server" section on page 96-14.

Adding or Editing E-Mail Recipients

To add or edit e-mail recipients and severity levels, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > E-mail Setup**.

Step 2 Click **Add** or **Edit** to display the Add/Edit E-Mail Recipient dialog box.

Step 3 Enter the destination e-mail address, and choose the syslog severity level from the drop-down list. Severity levels are defined as follows:

- Emergency (level 0, system is unusable)

Note Using a severity level of zero is not recommended.

- Alert (level 1, immediate action is needed)
- Critical (level 2, critical conditions)
- Error (level 3, error conditions)
- Warning (level 4, warning conditions)
- Notification (level 5, normal but significant conditions)
- Informational (level 6, informational messages only)
- Debugging (level 7, debugging messages only)

Note The severity level used to filter messages for the destination e-mail address is the higher of the severity level specified in the Add/Edit E-Mail Recipient dialog box and the global filter set for all e-mail recipients in the Logging Filters pane.

Step 4 Click **OK** to close this dialog box.

The added or revised entry appears in the E-mail Recipients pane.

Step 5 Click **Apply** to save your changes to the running configuration.

Configuring the Remote SMTP Server

To configure the remote SMTP server to which e-mail alerts and notifications are sent in response to specific events, perform the following steps:

Step 1 Choose **Configuration > Device Setup > Logging > SMTP**.

Step 2 Enter the IP address of the primary SMTP server.

Step 3 (Optional) Enter the IP address of the standby SMTP server, then click **Apply** to save your changes to the running configuration.

Viewing Syslog Messages in ASDM

To view the latest syslog messages that have been sent to ASDM, choose **Home > Latest ASDM Syslog Messages**. The ASA or ASASM sets aside a buffer area for syslog messages waiting to be sent to ASDM and saves messages in the buffer as they occur. The ASDM log buffer is a different buffer than the internal log buffer. When the ASDM log buffer is full, the ASA or ASASM deletes the oldest syslog message to make room in the buffer for new ones. Deleting the oldest syslog message to make room for new ones is the default setting in ASDM.

Applying Message Filters to a Logging Destination

To apply message filters to a logging destination, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Logging Filters**.

Step 2 Choose the name of the logging destination to which you want to apply a filter. Available logging destinations are as follows:

- ASDM
- Console port
- E-Mail
- Internal buffer
- SNMP server
- Syslog server
- Telnet or SSH session

  Included in this selection are the second column, Syslogs From All Event Classes, and the third column, Syslogs From Specific Event Classes. The second column lists the severity or the event class to use to filter messages for the logging destination, or whether logging is disabled for all event classes. The third column lists the event class to use to filter messages for that logging destination. For more information, see the "Adding or Editing a Message Class and Severity Filter" section on page 96-16 and the "Adding or Editing a Syslog Message ID Filter" section on page 96-17.

Step 3 Click **Edit** to display the Edit Logging Filters dialog box. To apply, edit, or disable filters, see the "Applying Logging Filters" section on page 96-15.

Applying Logging Filters

To apply filters, perform the following steps:

Step 1 Choose the **Filter on severity** option to filter syslog messages according to their severity level.

Step 2 Choose the **Use event list** option to filter syslog messages according to an event list.

Step 3 Choose the **Disable logging from all event classes** option to disable all logging to the selected destination.

Step 4 Click **New** to add a new event list. To add a new event list, see the "Creating a Custom Event List" section on page 96-17.

Step 5 Choose the event class from the drop-down list. Available event classes change according to the device mode that you are using.

Step 6 Choose the level of logging messages from the drop-down list. Severity levels include the following:

- Emergency (level 0, system is unusable)

  Note Using a severity level of zero is not recommended.

- Alert (level 1, immediate action is needed)
- Critical (level 2, critical conditions)
- Error (level 3, error conditions)
- Warning (level 4, warning conditions)
- Notification (level 5, normal but significant conditions)
- Informational (level 6, informational messages only)
- Debugging (level 7, debugging messages only)

Step 7 Click **Add** to add the event class and severity level, and then click **OK**.

The selected logging destination for a filter appears at the top.

Adding or Editing a Message Class and Severity Filter

To add or edit a message class and severity level for filtering messages, perform the following steps:

Step 1 Choose the event class from the drop-down list. Available event classes change according to the device mode that you are using.

Step 2 Choose the level of logging messages from the drop-down list. Severity levels include the following:

- Emergency (level 0, system is unusable)

  Note Using a severity level of zero is not recommended.

- Alert (level 1, immediate action is needed)
- Critical (level 2, critical conditions)
- Error (level 3, error conditions)
- Warning (level 4, warning conditions)
- Notification (level 5, normal but significant conditions)
- Informational (level 6, informational messages only)
- Debugging (level 7, debugging messages only)

Step 3 Click **OK** when you are done making selections.

Adding or Editing a Syslog Message ID Filter

To add or edit a syslog message ID filter, see the "Editing Syslog ID Settings" section on page 96-10.

Sending Syslog Messages to the Console Port

To send syslog messages to the console port, enter the following command:

Path	Purpose
Choose one of the following: • **Home > Latest ASDM Syslog Messages > Configure ASDM Syslog Filters** • **Configuration > Device Management > Logging > Logging Filters**	Specifies which syslog messages should be sent to the console port.

Sending Syslog Messages to a Telnet or SSH Session

To send syslog messages to a Telnet or SSH session, perform the following steps:

	Path	Purpose
Step 1	Choose one of the following: • **Home > Latest ASDM Syslog Messages > Configure ASDM Syslog Filters** • **Configuration > Device Management > Logging > Logging Filters**	Specifies which syslog messages should be sent to a Telnet or SSH session.
Step 2	**Configuration > Device Management > Logging > Logging Setup**	Enables logging to the current session only.

Creating a Custom Event List

You use the following three criteria to define an event list:

- Event Class
- Severity
- Message ID

To create a custom list of events to send to a specific logging destination (for example, an SNMP server), perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Event Lists**.

Step 2 Click **Add** to display the Add Event List dialog box.

Step 3 In the Name field, enter the name of the event list. No spaces are allowed.

Step 4 In the Event Class/Severity area, click **Add** to display the Add Class and Severity Filter dialog box.

Step 5 Choose the event class from the drop-down list. Available event classes change according to the device mode that you are using.

Step 6 Choose the severity level from the drop-down list. Severity levels include the following:

- Emergency (level 0, system is unusable)

  Note Using a severity level of zero is not recommended.

- Alert (level 1, immediate action is needed)
- Critical (level 2, critical conditions)
- Error (level 3, error conditions)
- Warning (level 4, warning conditions)
- Notification (level 5, normal but significant conditions)
- Informational (level 6, informational messages only)
- Debugging (level 7, debugging messages only)

Step 7 Click **OK** to close this dialog box.

Step 8 In the Message ID Filters area, click **Add** to display the Add Syslog Message ID Filter dialog box.

Step 9 In the Message IDs field, enter a syslog message ID or range of IDs (for example, 101001-199012) to include in the filter.

Step 10 Click **OK** to close this dialog box.

The event of interest appears in the list. To change this entry, click **Edit**.

Generating Syslog Messages in EMBLEM Format to a Syslog Server

To generate syslog messages in EMBLEM format to a syslog server, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Syslog Server**.

Step 2 To add a new syslog server, click **Add** to display the Add Syslog Server dialog box. To change an existing syslog server settings, click **Edit** to display the Edit Syslog Server dialog box.

Note You can set up a maximum of four syslog servers per security context (up to a total of 16).

Step 3 Specify the number of messages that are allowed to be queued on the ASA or ASASM when a syslog server is busy. A zero value means an unlimited number of messages may be queued.

Step 4 Check the **Allow user traffic to pass when TCP syslog server is down** check box to specify whether or not to restrict all traffic if any syslog server is down.

Step 5 To continue, see the "Adding or Editing Syslog Server Settings" section on page 96-19.

Adding or Editing Syslog Server Settings

To add or edit syslog server settings, perform the following steps:

Step 1 Choose the interface used to communicate with the syslog server from the drop-down list.

Step 2 Enter the IP address that is used to communicate with the syslog server.

Step 3 Choose the protocol (either TCP or UDP) that is used by the syslog server to communicate with the ASA or ASASM.

Step 4 Enter the port number used by the syslog server to communicate with the ASA or ASASM.

Step 5 Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

Step 6 Check the **Enable secure logging using SSL/TLS (TCP only)** check box to specify that the connection to the syslog server is secure through the use of SSL/TLS over TCP, and that the syslog message content is encrypted.

Step 7 Click **OK** to complete the configuration.

Generating Syslog Messages in EMBLEM Format to Other Output Destinations

To generate syslog messages in EMBLEM format to other output destinations, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Logging Setup	Sends syslog messages in EMBLEM format to output destinations other than a syslog server, such as Telnet or SSH sessions.

Changing the Amount of Internal Flash Memory Available for Logs

To change the amount of internal flash memory available for logs, perform the following steps:

	Path	Purpose
Step 1	**Configuration > Device Management > Logging > Logging Setup**	Specifies the maximum amount of internal flash memory available for saving log files. By default, the ASA can use up to 1 MB of internal flash memory for log data. The minimum amount of internal flash memory that must be free for the ASA and ASASM to save log data is 3 MB. If a log file being saved to internal flash memory would cause the amount of free internal flash memory to fall below the configured minimum limit, the ASA or ASASM deletes the oldest log files to ensure that the minimum amount of memory remains free after saving the new log file. If there are no files to delete or if, after all old files have been deleted, free memory is still below the limit, the ASA or ASASM fails to save the new log file.
Step 2	**Configuration > Device Management > Logging > Logging Setup**	Specifies the minimum amount of internal flash memory that must be free for the ASA or ASASM to save a log file.

Configuring the Logging Queue

To configure the logging queue, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Logging Setup	Specifies the number of syslog messages that the ASA and ASASM can hold in its queue before sending them to the configured output destination. The ASA and ASASM have a fixed number of blocks in memory that can be allocated for buffering syslog messages while they are waiting to be sent to the configured output destination. The number of blocks required depends on the length of the syslog message queue and the number of syslog servers specified. The default queue size is 512 syslog messages. The queue size is limited only by block memory availability. Valid values are from 0 to 8192 messages, depending on the platform. If the logging queue is set to zero, the queue is the maximum configurable size (8192 messages), depending on the platform. The maximum queue size by platform is as follows: • ASA-5505—1024 • ASA-5510—2048 • On all other platforms—8192

Sending All Syslog Messages in a Class to a Specified Output Destination

To send all syslog messages in a class to a specified output destination, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Logging Filters	Overrides the configuration in the specified output destination command. For example, if you specify that messages at severity level 7 should go to the internal log buffer and that ha class messages at severity level 3 should go to the internal log buffer, then the latter configuration takes precedence. To specify that a class should go to more than one destination, choose a different filtering option for each output destination.

Enabling Secure Logging

To enable secure logging, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Syslog Server	Enables secure logging.

Including the Device ID in Non-EMBLEM Format Syslog Messages

To include the device ID in non-EMBLEM format syslog messages, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Syslog Setup > Advanced > Advanced Syslog Configuration	Configures the ASA or ASASMto include a device ID in non-EMBLEM-format syslog messages. You can specify only one type of device ID for syslog messages. If you enable the logging device ID for the admin context in multiple context mode, messages that originate in the system execution space use a device ID of **system**, and messages that originate in the admin context use the name of the admin context as the device ID. **Note** In an ASA cluster, always use the master unit IP address for the selected interface. **Note** If enabled, the device ID does not appear in EMBLEM-formatted syslog messages nor in SNMP traps.

Including the Date and Time in Syslog Messages

To include the date and time in syslog messages, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Syslog Setup	Specifies that syslog messages should include the date and time that they were generated.

Disabling a Syslog Message

To disable a specified syslog message, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Syslog Setup	Prevents the ASA or ASASMfrom generating a particular syslog message.

Changing the Severity Level of a Syslog Message

To change the severity level of a syslog message, enter the following command:

Path	Purpose
Configuration > Device Management > Logging > Syslog Setup	Specifies the severity level of a syslog message.

Limiting the Rate of Syslog Message Generation

To limit the rate of syslog message generation, perform the following steps:

Step 1 Choose **Configuration > Device Management > Logging > Rate Limit**.

Step 2 Choose the logging level (message severity level) to which you want to assign rate limits. Severity levels are defined as follows:

Description	Severity Level
Emergency	0—System is unusable
Alert	1—Immediate action is needed
Critical	2—Critical conditions
Error	3—Error conditions
Warning	4—Warning conditions
Notification	5—Normal but significant conditions

Description	Severity Level
Informational	6—Informational messages only
Debugging	7—Debugging messages only

Step 3 The No of Messages field displays the number of messages sent. The Interval (Seconds) field displays the interval, in seconds, that is used to limit how many messages at this logging level can be sent. Choose a logging level from the table and click **Edit** to display the Edit Rate Limit for Syslog Logging Level dialog box.

Step 4 To continue, see the "Assigning or Changing Rate Limits for Individual Syslog Messages" section on page 96-23.

Assigning or Changing Rate Limits for Individual Syslog Messages

To assign or change rate limits to individual syslog messages, perform the following steps:

Step 1 To assign the rate limit of a specific syslog message, click **Add** to display the Add Rate Limit for Syslog Message dialog box.

Step 2 To continue, see the "Adding or Editing the Rate Limit for a Syslog Message" section on page 96-23.

Step 3 To change the rate limit of a specific syslog message, click **Edit** to display the Edit Rate Limit for Syslog Message dialog box.

Step 4 To continue, see the "Editing the Rate Limit for a Syslog Severity Level" section on page 96-24.

Adding or Editing the Rate Limit for a Syslog Message

To add or change the rate limit for a specific syslog message, perform the following steps:

Step 1 To add a rate limit to a specific syslog message, click **Add** to display the Add Rate Limit for Syslog Message dialog box. To change a rate limit for a syslog message, click **Edit** to display the Edit Rate Limit for Syslog Message dialog box.

Step 2 Enter the message ID of the syslog message that you want to limit.

Step 3 Enter the maximum number of messages that can be sent in the specified time interval.

Step 4 Enter the amount of time, in seconds, that is used to limit the rate of the specified message, and click **OK**.

Note To allow an unlimited number of messages, leave both the Number of Messages and Time Interval fields blank.

Editing the Rate Limit for a Syslog Severity Level

To change the rate limit of a specified syslog severity level, perform the following steps:

Step 1 Enter the maximum number of messages at this severity level that can be sent.

Step 2 Enter the amount of time, in seconds, that is used to limit the rate of messages at this severity level, and click **OK**.

The selected message severity level appears.

Note To allow an unlimited number of messages, leave both the Number of Messages and Time Interval fields blank.

Monitoring the Logs

This section includes the following topics:

- Filtering Syslog Messages Through the Log Viewers, page 96-25
- Editing Filtering Settings, page 96-27
- Executing Certain Commands Using the Log Viewers, page 96-27

To monitor the logs in the log buffer or in real-time and assist in monitoring the system performance, choose one of the following:

Path	Purpose
Choose one of the following: • **Monitoring > Logging > Log Buffer > View** • **Monitoring > Logging > Real-Time Log Viewer > View**	Shows syslog messages, including the severity level. **Note** The maximum number of syslog messages that are available to view is 1000, which is the default setting. The maximum number of syslog messages that are available to view is 2000. Displays the message explanations, additional details, and recommended actions to take, if necessary, to resolve an error in a separate window. Provides text search within messages and message filtering. Allows creation of a reverse access control rule that performs the opposite action of the access control rule that originally generated the syslog message. Reverse access control rules can be applied *only* to syslog messages 106100, 106023, 338001 through 338004, 338201, and 338202. Provides the ability to use the following options in the log viewers from the Tools menu: Ping, Traceroute, Whois, and DNS Lookup. Provides sorting of messages in each column shown. Allows detailed message filtering based on the syslog ID, date and time, severity level, source and destination IP addresses, source and destination ports, and description listed. Displays popup help in the Build Filter dialog box.

Filtering Syslog Messages Through the Log Viewers

You can filter syslog messages based on one or multiple values that correspond to any column of the Real-Time Log Viewer and the Log Buffer Viewer.

To filter syslog messages through one of the log viewers, perform the following steps:

Step 1 Choose one of the following:

- **Monitoring > Logging > Real-Time Log Viewer > View**
- **Monitoring > Logging > Log Buffer > View**

Step 2 In either the Real-Time Log Viewer or the Log Buffer Viewer dialog box, click **Build Filter** on the toolbar.

Step 3 In the Build Filter dialog box, specify the filtering criteria to apply to syslog messages:

a. In the Date and Time area, choose one of the following three options: real-time, a specific time, or a time range. If you chose a specific time, indicate the time by entering the number and choosing hours or minutes from the drop-down list. If you chose a time range, in the Start Time field, click the drop-down arrow to display a calendar. Choose a start date and a start time from the drop-down list, then click **OK**. In the End Time field, click the drop-down arrow to display a calendar. Choose an end date and an end time from the drop-down list, then click **OK**.

b. Enter a valid severity level in the Severity field. Alternatively, click the **Edit** icon on the right of the Severity field. In the Severity dialog box, click the severity levels in the list on which you want to filter. To include severity levels 1-7, click **All**. Click **OK** to display these settings in the Build Filter dialog box. For additional information about the correct input format to use, click the **Info** icon on the right of the Severity field.

c. Enter a valid syslog ID in the Syslog ID field. Alternatively, click the **Edit** icon on the right of the Syslog ID field. In the Syslog ID dialog box, choose a condition on which to filter from the drop-down list, then click **Add**. Click **OK** to display these settings in the Build Filter dialog box. Click **Delete** to remove these settings and enter new ones. For additional information about the correct input format to use, click the **Info** icon on the right of the Syslog ID field.

d. Enter a valid source IP address in the Source IP Address field, or click the **Edit** icon on the right of the Source IP Address field. In the Source IP Address dialog box, choose a single IP address or a specified range of IP addresses, then click **Add**. To exclude a specific IP address or range of IP addresses, check the **Do not include (exclude) this address or range** check box. Click **OK** to display these settings in the Build Filter dialog box. Click **Delete** to remove these settings and enter new ones. For additional information about the correct input format to use, click the **Info** icon on the right of the Source IP Address field.

e. Enter a valid source port in the Source Port field, or click the **Edit** icon on the right of the Source Port field. In the Source Port dialog box, choose a condition on which to filter from the drop-down list, then click **Add**. Click **OK** to display these settings in the Build Filter dialog box. Click **Delete** to remove these settings and enter new ones. For additional information about the correct input format to use, click the **Info** icon on the right of the Source Port field.

f. Enter a valid destination IP address in the Destination IP Address field, or click the **Edit** icon on the right of the Destination IP Address field. In the Destination IP Address dialog box, choose a single IP address or a specified range of IP addresses, then click **Add**. To exclude a specific IP address or range of IP addresses, check the **Do not include (exclude) this address or range** check box. Click **OK** to display these settings in the Build Filter dialog box. Click **Delete** to remove these settings and enter new ones. For additional information about the correct input format to use, click the **Info** icon on the right of the Destination IP Address field.

g. Enter a valid destination port in the Destination Port field, or click the **Edit** icon on the right of the Destination Port field. In the Destination Port dialog box, choose a condition on which to filter from the drop-down list, then click **Add**. Click **OK** to display these settings in the Build Filter dialog box. Click **Delete** to remove these settings and enter new ones. For additional information about the correct input format to use, click the **Info** icon on the right of the Destination Port field.

h. Enter filtering text for the Description field. The text may be any string of one or more characters, including a regular expression. However, semicolons are not valid characters, and this setting is case-sensitive. Multiple entries must be separated by commas.

i. Click **OK** to add the filter settings you have just specified to the Filter By drop-down list in the log viewers. The filter strings follow a specific format. The prefix FILTER: designates all custom filters that appear in the Filter By drop-down list. You may still type random text into this field.

   The following table shows examples of the format used.

Build Filter Example	Filter String Format
Source IP = 192.168.1.1 or 0.0.0.0 Source Port = 67	FILTER: srcIP=192.168.1.1,0.0.0.0;srcPort=67;
Severity = Informational Destination IP = 1.1.1.1 through 1.1.1.10	FILTER: sev=6;dstIP=1.1.1.1-1.1.1.10;

Syslog ID not in the range 725001 through 725003	FILTER: sysID=!725001-725003;
Source IP = 1.1.1.1 Description = Built outbound	FILTER: srcIP=1.1.1.1;descr=Built outbound

Step 4 To filter syslog messages, choose one of the settings in the Filter By drop-down list, then click **Filter** on the toolbar. This setting also applies to all future syslog messages. To clear all filters, click **Show All** on the toolbar.

Note You cannot save filters that you have specified with the Build Filter dialog box. These filters are valid only for the ASDM session during which they were created.

Editing Filtering Settings

To edit filtering settings that you created using the Build Filter dialog box, perform the following steps:

Choose one of the following:

- Revise a filter directly by entering the changes in the Filter By drop-down list.
- Choose a filter in the Filter By drop-down list, then click **Build Filter** to display the Build Filter dialog box. To remove the current filter settings and enter new ones, click **Clear Filter**. Otherwise, change the settings that appear, and click **OK**.

  Note These filter settings apply only to those defined in the Build Filter dialog box.

- To stop filtering and show all syslog messages, click **Show All** on the toolbar.

Executing Certain Commands Using the Log Viewers

You can execute the following commands using either of the log viewers: **ping**, **traceroute**, **whois**, and **dns lookup**.

To execute any of these commands, perform the following steps:

Step 1 Choose one of the following:

- **Monitoring > Logging > Real-Time Log Viewer > View**
- **Monitoring Logging > Log Buffer > View**

Step 2 From the Real-Time Log Viewer or Log Buffer pane, click **Tools**, then choose the command that you want to execute. Alternatively, you can right-click a specific syslog message that is listed to display a context menu, then choose the command that you want to execute.

The Entering command dialog box appears, with the command that you selected automatically showing in the drop-down list.

Step 3 Enter either the source or destination IP address of the selected syslog message in the Address field, then click **Go**.

The command output appears in the area provided.

Step 4 Click **Clear** to remove the output, and choose another command to execute from the drop-down list. Repeat Step 3, if necessary. Click **Close** when you are done.

Feature History for Logging

Table 96-2 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 96-2 Feature History for Logging

Feature Name	Platform Releases	Feature Information
Logging	7.0(1)	Provides ASA network logging information through various output destinations, and includes the option to view and save log files. We introduced the following screen: Configuration > Device Management > Logging > Logging Setup.
Rate limit	7.0(4)	Limits the rate at which syslog messages are generated. We modified the following screen: Configuration > Device Management > Logging > Rate Limit.
Logging list	7.2(1)	Creates a logging list to use in other commands to specify messages by various criteria (logging level, event class, and message IDs). We modified the following screen: Configuration > Device Management > Logging > Event Lists.
Secure logging	8.0(2)	Specifies that the connection to the remote logging host should use SSL/TLS. This option is valid only if the protocol selected is TCP. We modified the following screen: Configuration > Device Management > Logging > Syslog Server.
Logging class	8.0(4), 8.1(1)	Added support for the ipaa event class of logging messages. We modified the following screen: Configuration > Device Management > Logging > Logging Filters.
Logging class and saved logging buffers	8.2(1)	Added support for the dap event class of logging messages. Added support to clear the saved logging buffers (ASDM, internal, FTP, and flash). We modified the following screen: Configuration > Device Management > Logging > Logging Setup.
Password encryption	8.3(1)	Added support for password encryption.
Log viewers	8.3(1)	The source and destination IP addresses were added to the log viewers.

Table 96-2 Feature History for Logging (continued)

Feature Name	Platform Releases	Feature Information
Enhanced logging and connection blocking	8.3(2)	When you configure a syslog server to use TCP, and the syslog server is unavailable, the ASA blocks new connections that generate syslog messages until the server becomes available again (for example, VPN, firewall, and cut-through-proxy connections). This feature has been enhanced to also block new connections when the logging queue on the ASA is full; connections resume when the logging queue is cleared. This feature was added for compliance with Common Criteria EAL4+. Unless required, we recommended allowing connections when syslog messages cannot be sent or received. To allow connections, continue to check the **Allow user traffic to pass when TCP syslog server is down** check box on the Configuration > Device Management > Logging > Syslog Servers pane. We introduced the following syslog messages: 414005, 414006, 414007, and 414008. We did not modify any ASDM screens.
Syslog message filtering and sorting	8.4(1)	Support has been added for the following: • Syslog message filtering based on multiple text strings that correspond to various columns • Creation of custom filters • Column sorting of messages. For detailed information, see the ASDM configuration guide. We modified the following screens: Monitoring > Logging > Real-Time Log Viewer > View. Monitoring > Logging > Log Buffer Viewer > View. This feature interoperates with all ASA versions.
Clustering	9.0(1)	Added support for syslog message generation in a clustering environment on the ASA 5580 and 5585-X. We modified the following screen: Configuration > Logging > Syslog Setup > Advanced > Advanced Syslog Configuration.

Configuring NetFlow Secure Event Logging (NSEL)

This chapter describes how to configure NSEL, a security logging mechanism that is built on NetFlow Version 9 technology, and how to handle events and syslog messages through NSEL.

This chapter includes the following sections:

- Information About NSEL, page 97-1
- Licensing Requirements for NSEL, page 97-4
- Prerequisites for NSEL, page 97-4
- Guidelines and Limitations, page 97-4
- Configuring NSEL, page 97-5
- Monitoring NSEL, page 97-7
- Where to Go Next, page 97-7
- Additional References, page 97-7
- Feature History for NSEL, page 97-8

Information About NSEL

This section includes the following topics:

- Using NSEL and Syslog Messages, page 97-2
- Using NSEL in Clustering, page 97-3

The ASA and ASASM support NetFlow Version 9 services. For more information about NetFlow services, see the "RFCs" section on page 97-8.

The ASA and ASASM implementations of NSEL provide a stateful, IP flow tracking method that exports only those records that indicate significant events in a flow. In stateful flow tracking, tracked flows go through a series of state changes. NSEL events are used to export data about flow status and are triggered by the event that caused the state change.

The significant events that are tracked include flow-create, flow-teardown, flow-denied (excluding those flows that are denied by EtherType ACLs), and flow-update. In addition, the ASA and ASASM implementation of NSEL generates periodic NSEL events and flow-update events to provide periodic byte counters over the duration of the flow. These events are usually time-driven, which makes them more in line with traditional Netflow; however, these events may also be triggered by state changes in the flow.

Note The flow-update event feature is available only in Version 8.4(5). It is not available in Version 9.0(1) or later.

Each NSEL record has an event ID and an extended event ID field, which describes the flow event.

The ASA and ASASM implementations of NSEL provide the following major functions:

- Tracks flow-create, flow-teardown, and flow-denied events, and generates appropriate NSEL data records.
- Defines and exports templates that describe the progression of a flow. Templates describe the format of the data records that are exported through NetFlow. Each event has several record formats or templates associated with it.
- Tracks configured NSEL collectors and delivers templates and data records to these configured NSEL collectors through NetFlow over UDP only.
- Sends template information periodically to NSEL collectors. Collectors receive template definitions, normally before receiving flow records.
- Filters NSEL events based on the traffic and event type through Modular Policy Framework, then sends records to different collectors. Traffic is matched based on the order in which classes are configured. After a match is found, no other classes are checked. The supported event types are flow-create, flow-denied, flow-teardown, and all. Records can be sent to different collectors. For example, with two collectors, you can do the following:
  - Log all flow-denied events that match access list 1 to collector 1.
  - Log all flow-create events to collector 1.
  - Log all flow-teardown events to collector 2.
- Delays the export of flow-create events.

Using NSEL and Syslog Messages

Table 97-1 lists the syslog messages that have an equivalent NSEL event, event ID, and extended event ID. The extended event ID provides more detail about the event (for example, which ACL—ingress or egress—has denied a flow).

Note Enabling NetFlow to export flow information makes the syslog messages that are listed in Table 97-1 redundant. In the interest of performance, we recommend that you disable redundant syslog messages, because the same information is exported through NetFlow.

Table 97-1 Syslog Messages and Equivalent NSEL Events

Syslog Message	Description	NSEL Event ID	NSEL Extended Event ID
106100	Generated whenever an ACL is encountered.	1—Flow was created (if the ACL allowed the flow). 3—Flow was denied (if the ACL denied the flow).	0—If the ACL allowed the flow. 1001—Flow was denied by the ingress ACL. 1002—Flow was denied by the egress ACL.
106015	A TCP flow was denied because the first packet was not a SYN packet.	3—Flow was denied.	1004—Flow was denied because the first packet was not a TCP SYN packet.
106023	When a flow was denied by an ACL attached to an interface through the **access-group** command.	3—Flow was denied.	1001—Flow was denied by the ingress ACL. 1002—Flow was denied by the egress ACL.
302013, 302015, 302017, 302020	TCP, UDP, GRE, and ICMP connection creation.	1—Flow was created.	0—Ignore.
302014, 302016, 302018, 302021	TCP, UDP, GRE, and ICMP connection teardown.	2—Flow was deleted.	0—Ignore. > 2000—Flow was torn down.
313001	An ICMP packet to the device was denied.	3—Flow was denied.	1003—To-the-box flow was denied because of configuration.
313008	An ICMP v6 packet to the device was denied.	3—Flow was denied.	1003—To-the-box flow was denied because of configuration.
710003	An attempt to connect to the device interface was denied.	3—Flow was denied.	1003—To-the-box flow was denied because of configuration.

Note When NSEL and syslog messages are both enabled, there is no guarantee of chronological ordering between the two logging types.

Using NSEL in Clustering

Each ASA establishes its own connection to the collector(s) using its unit local IP address. The fields in the header of the export packet include the system up time, UNIX time (synchronized across the cluster), and sequence number. These fields are all local to an individual ASA. The NSEL collector uses the combination of the source port of the packet to separate different exporters.

Each ASA manages and advertises its template independently. Because the ASA supports in-cluster upgrades, different units may run different image versions at a certain point in time. As a result, the template that each ASA supports may be different.

Note Clustering is available on the ASA 5580 and 5585-X only. For more information about clustering, see Chapter 10, “Configuring a Cluster of ASAs.”

Licensing Requirements for NSEL

Model	License Requirement
All models	Base License.

Prerequisites for NSEL

NSEL has the following prerequisites:

- IP address and hostname assignments must be unique throughout the NetFlow configuration.
- You must have at least one configured collector before you can use NSEL.
- You must configure NSEL collectors before you can configure filters via Modular Policy Framework.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6 for the **class-map**, **match access-list**, and **match any** commands.

Additional Guidelines and Limitations

- If you have previously configured flow-export actions using the **flow-export enable** command, and you upgrade to a later version, then your configuration is automatically converted to the new Modular Policy Framework **flow-export event-type** command, which is described under the **policy-map** command.
- Flow-export actions are not supported in interface-based policies. You can configure flow-export actions in a class-map only with the **match access-list**, **match any**, or **class-default** commands. You can only apply flow-export actions in a global service policy.
- To view bandwidth usage for NetFlow records (not available in real-time), you must use the threat detection feature.
- Only the ASA 5580 and 5585-X support clustering.
- NetFlow records are sent only for connections whose source and destination addresses are both IPv4 or both IPv6. NetFlow records are not sent for connections with mixed traffic, such as NAT64 or NAT46.

Configuring NSEL

This section describes how to configure NSEL and includes the following topics:

- Using NetFlow, page 97-5
- Matching NetFlow Events to Configured Collectors, page 97-6

Using NetFlow

The NetFlow pane lets you enable the transmission of data about a flow of packets. To access this pane, choose **Configuration > Device Management > Logging > NetFlow**.

Note IP address and hostname assignments should be unique throughout the NetFlow configuration.

To use NetFlow, perform the following steps:

Step 1 Enter the template timeout rate, which is the interval (in minutes) at which template records are sent to all configured collectors. The default value is 30 minutes.

Step 2 To delay the export of flow-creation events and process a single flow-teardown event instead of a flow-creation event and a flow-teardown event, check the **Delay export of flow creation events for short-lived flows** check box, then enter the number of seconds for the delay in the Delay By field.

Step 3 Specify the collector(s) to which NetFlow packets will be sent. You can configure a maximum of five collectors. To configure a collector, click **Add** to display the Add NetFlow Collector dialog box, and perform the following steps:

a. Choose the interface to which NetFlow packets will be sent from the drop-down list.

b. Enter the IP address or hostname and the UDP port number in the associated fields.

c. Click **OK**.

Step 4 To configure more collectors, repeat Step 2 for each additional collector.

Step 5 To change collector configuration details, select a collector and click **Edit**. To remove a configured collector, select it and click **Delete**.

Step 6 When NetFlow is enabled, certain syslog messages become redundant. To maintain system performance, we recommend that you disable all redundant syslog messages, because the same information is exported through NetFlow. To disable all redundant syslog messages, check the **Disable redundant syslog messages** check box. To display the redundant syslog messages and their status, click **Show Redundant Syslog Messages**.

The Redundant Syslog Messages dialog box appears. The Syslog ID field displays the redundant syslog message numbers. The Disabled field indicates whether or not the specified syslog message is disabled. Click **OK** to close this dialog box.

To disable individual redundant syslog messages, choose **Configuration > Device Management > Logging > Syslog Setup**.

Step 7 Click **Apply** to save your changes. Click **Reset** to enter new settings.

What to Do Next

See the "Matching NetFlow Events to Configured Collectors" section on page 97-6.

Matching NetFlow Events to Configured Collectors

After you configure NetFlow collectors, you can match a NetFlow event with any of these configured collectors.

To specify which NetFlow events should be sent to which collector, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Firewall > Service Policy Rules**.

Step 2 To add a service policy rule, perform the following steps:

a. Click **Add** to display the Add Service Policy Rule Wizard. For more information about service policy rules, see the "Adding a Service Policy Rule for Through Traffic" section on page 44-8.

b. Click the **Global - applies to all interfaces** radio button to apply the rule to the global policy. Click **Next**.

c. Check the **Source and Destination IP Address (uses ACL)** check box or the **Any traffic** check box as traffic match criteria, or click the **Use class-default as traffic class** radio button. Click **Next** to continue to the Rule Actions screen.

Note NetFlow actions are available only for global service policy rules and are applicable only to the class-default traffic class and to traffic classes with traffic match criteria of "Source and Destination IP Address (uses ACL)" or "Any traffic."

Step 3 In the Rule Actions screen, click the **NetFlow** tab.

Step 4 To specify flow events, click **Add** to display the Add Flow Event dialog box, then perform the following steps:

a. Choose the flow event type from the drop-down list. Available events are created, torn down, denied, updated, or all.

Note The flow-update event is available in Version 8.4(5) only. It is not available in Version 9.0(1) or later.

b. Choose collectors to which you want events sent by checking the corresponding check boxes in the Send column.

c. To add, edit or delete collectors, or to configure other NetFlow settings (for example, syslog messages), click **Manage** to display the Manage NetFlow Collectors dialog box. Click **OK** to close the Manage NetFlow Collectors dialog box and return to the Add Flow Event dialog box. For more information about configuring collectors, see Step 3 of the "Using NetFlow" section on page 97-5.

Step 5 Click **OK** to close the Add Flow Event dialog box and return to the NetFlow tab.

Step 6 To change flow event entries, select an entry from the list, and click **Edit**. To remove flow event entries, select an entry from the list, and click **Delete**.

Step 7 Click **Finish** to exit the wizard.

Step 8 To edit a NetFlow service policy rule, perform the following steps:

a. Select it in the Service Policy Rules table, and click **Edit**.

b. Click the **Rule Actions** tab, then click the **NetFlow** tab.

What to Do Next

See the "Monitoring NSEL" section on page 97-7.

Monitoring NSEL

You can use syslog messages to help troubleshoot errors or monitor system usage and performance.You can view real-time syslog messages that have been saved in the log buffer in a separate window, which include an explanation of the message, details about the message, and recommended actions to take, if necessary, to resolve an error. For more information, see the "Using NSEL and Syslog Messages" section on page 97-2.

To monitor NSEL, see the following pane:

Path	Purpose
Tools > Command Line Interface Enter the **show flow-export counters** command, then click **Send**.	Shows runtime counters, including statistical data and error data, for NSEL.
Tools > Command Line Interface Enter the **show running-config flow-export** command, then click **Send**.	Shows the currently configured NetFlow commands.
Tools > Command Line Interface Enter the **show logging flow-export-syslogs** command, then click **Send**.	Lists all syslog messages that are captured by NSEL events.
Tools > Command Line Interface Enter the **show running-config logging** command, then click **Send**.	Shows disabled syslog messages, which are redundant syslog messages, because they export the same information through NetFlow.

Where to Go Next

To configure the syslog server, see Chapter 96, "Configuring Logging."

Additional References

For additional information related to implementing NSEL, see the following sections:

- Related Documents, page 97-8
- RFCs, page 97-8

RFCs

RFC	Title
3954	Cisco Systems NetFlow Services Export Version 9

Feature History for NSEL

Table 97-2 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 97-2 Feature History for NSEL

Feature Name	Platform Releases	Feature Information
NetFlow	8.1(1)	The NetFlow feature enhances the ASA logging capabilities by logging flow-based events through the NetFlow protocol. NetFlow Version 9 services are used to export information about the progression of a flow from start to finish. The NetFlow implementation exports records that indicate significant events in the life of a flow. This implementation is different from traditional NetFlow, which exports data about flows at regular intervals. The NetFlow module also exports records about flows that are denied by access lists. You can configure an ASA 5580 to send the following events using NetFlow: flow create, flow teardown, and flow denied (only flows denied by ACLs are reported). We introduced the following screen: Configuration > Device Management > Logging > NetFlow.
NetFlow Filtering	8.1(2)	You can filter NetFlow events based on traffic and event type, then send records to different collectors. For example, you can log all flow-create events to one collector, and log flow-denied events to a different collector. For short-lived flows, NetFlow collectors benefit from processing a single event instead of two events: flow create and flow teardown. You can configure a delay before sending the flow-create event. If the flow is torn down before the timer expires, only the flow teardown event is sent. The teardown event includes all information regarding the flow; no loss of information occurs. We modified the following screen: Configuration > Firewall > Service Policy Rules.

Table 97-2 Feature History for NSEL (continued)

Feature Name	Platform Releases	Feature Information
NSEL	8.2(1)	The NetFlow feature has been ported to all available models of ASAs.
Clustering	9.0(1)	The NetFlow feature supports clustering.
NSEL		A new NetFlow error counter, source port allocation failure, has been added. Flow-update events have been introduced to provide periodic byte counters for flow traffic. You can change the time interval at which flow-update events are sent to the NetFlow collector. You can filter to which collectors flow-update records will be sent. We modified the following screens: Configuration > Firewall > Service Policy Rules > Add Service Policy Rule Wizard - Rule Actions > NetFlow > Add Flow Event Configuration > Device Management > Logging > NetFlow **Note** The flow-update event feature is available in Version 8.4(5) only; it is not available in Version 9.0(1) or later.

Configuring SNMP

This chapter describes how to configure SNMP to monitor the ASA and ASASM and includes the following sections:

- Information About SNMP, page 98-1
- Licensing Requirements for SNMP, page 98-4
- Prerequisites for SNMP, page 98-4
- Guidelines and Limitations, page 98-4
- Configuring SNMP, page 98-6
- Monitoring SNMP, page 98-9
- Where to Go Next, page 98-11
- Additional References, page 98-11
- Feature History for SNMP, page 98-13

Information About SNMP

SNMP is an application-layer protocol that facilitates the exchange of management information between network devices and is part of the TCP/IP protocol suite. This section describes SNMP and includes the following topics:

- Information About SNMP Terminology, page 98-2
- SNMP Version 3, page 98-2

The ASA and ASASM provide support for network monitoring using SNMP Versions 1, 2c, and 3, and supports the use of all three versions simultaneously. The SNMP agent running on the ASA interface lets you monitor the ASA and ASASM through network management systems (NMSs), such as HP OpenView. The ASA and ASASM support SNMP read-only access through issuance of a GET request. SNMP write access is not allowed, so you cannot make changes with SNMP. In addition, the SNMP SET request is not supported.

You can configure the ASA and ASASM to send traps, which are unsolicited messages from the managed device to the management station for certain events (event notifications) to an NMS, or you can use the NMS to browse the MIBs on the ASA. MIBs are a collection of definitions, and the ASA and ASASM maintain a database of values for each definition. Browsing a MIB means issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the NMS to determine values.

The ASA and ASASM have an SNMP agent that notifies designated management stations if events occur that are predefined to require a notification, for example, when a link in the network goes up or down. The notification it sends includes an SNMP OID, which identifies itself to the management stations. The ASA or ASASM SNMP agent also replies when a management station asks for information.

Information About SNMP Terminology

Table 98-1 lists the terms that are commonly used when working with SNMP:

Table 98-1 SNMP Terminology

Term	Description
Agent	The SNMP server running on the ASA. The SNMP agent has the following features: • Responds to requests for information and actions from the network management station. • Controls access to its Management Information Base, the collection of objects that the SNMP manager can view or change. • Does not allow set operations.
Browsing	Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.
Management Information Bases (MIBs)	Standardized data structures for collecting information about packets, connections, buffers, failovers, and so on. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.
Network management stations (NMSs)	The PCs or workstations set up to monitor SNMP events and manage devices, such as the ASA and ASASM.
Object identifier (OID)	The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.
Trap	Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as linkup, linkdown, coldstart, warmstart, authentication, or syslog messages.

SNMP Version 3

This section describes SNMP Version 3 and includes the following topics:

- SNMP Version 3 Overview, page 98-3
- Security Models, page 98-3
- SNMP Groups, page 98-3
- SNMP Users, page 98-3
- SNMP Hosts, page 98-3
- Implementation Differences Between the ASA, ASA Services Module, and the Cisco IOS Software, page 98-4

SNMP Version 3 Overview

SNMP Version 3 provides security enhancements that are not available in SNMP Version 1 or SNMP Version 2c. SNMP Versions 1 and 2c transmit data between the SNMP server and SNMP agent in clear text. SNMP Version 3 adds authentication and privacy options to secure protocol operations. In addition, this version controls access to the SNMP agent and MIB objects through the User-based Security Model (USM) and View-based Access Control Model (VACM). The ASA and ASASM also support the creation of SNMP groups and users, as well as hosts, which is required to enable transport authentication and encryption for secure SNMP communications.

Security Models

For configuration purposes, the authentication and privacy options are grouped together into security models. Security models apply to users and groups, which are divided into the following three types:

- NoAuthPriv—No Authentication and No Privacy, which means that no security is applied to messages.
- AuthNoPriv—Authentication but No Privacy, which means that messages are authenticated.
- AuthPriv—Authentication and Privacy, which means that messages are authenticated and encrypted.

SNMP Groups

An SNMP group is an access control policy to which users can be added. Each SNMP group is configured with a security model, and is associated with an SNMP view. A user within an SNMP group must match the security model of the SNMP group. These parameters specify what type of authentication and privacy a user within an SNMP group uses. Each SNMP group name and security model pair must be unique.

SNMP Users

SNMP users have a specified username, a group to which the user belongs, authentication password, encryption password, and authentication and encryption algorithms to use. The authentication algorithm options are MD5 and SHA. The encryption algorithm options are DES, 3DES, and AES (which is available in 128, 192, and 256 versions). When you create a user, you must associate it with an SNMP group. The user then inherits the security model of the group.

SNMP Hosts

An SNMP host is an IP address to which SNMP notifications and traps are sent. To configure SNMP Version 3 hosts, along with the target IP address, you must configure a username, because traps are only sent to a configured user. SNMP target IP addresses and target parameter names must be unique on the

ASA and ASA Services Module. Each SNMP host can have only one username associated with it. To receive SNMP traps, configure the SNMP NMS, and make sure that you configure the user credentials on the NMS to match the credentials for the ASA and ASASM.

Implementation Differences Between the ASA, ASA Services Module, and the Cisco IOS Software

The SNMP Version 3 implementation in the ASA and ASASM differs from the SNMP Version 3 implementation in the Cisco IOS software in the following ways:

- The local-engine and remote-engine IDs are not configurable. The local engine ID is generated when the ASA or ASASM starts or when a context is created.
- No support exists for view-based access control, which results in unrestricted MIB browsing.
- Support is restricted to the following MIBs: USM, VACM, FRAMEWORK, and TARGET.
- You must create users and groups with the correct security model.
- You must remove users, groups, and hosts in the correct sequence.
- Use of the **snmp-server host** command creates an ASA or ASASM rule to allow incoming SNMP traffic.

Licensing Requirements for SNMP

The following table shows the licensing requirements for this feature:

License Requirement
Base License: Base (DES).
Optional license: Strong (3DES, AES)

Prerequisites for SNMP

SNMP has the following prerequisite:

You must have Cisco Works for Windows or another SNMP MIB-II compliant browser to receive SNMP traps or browse a MIB.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Failover Guidelines

- Supported in SNMP Version 3.
- The SNMP client in each ASA or ASASM shares engine data with its peer. Engine data includes the engineID, engineBoots, and engineTime objects of the SNMP-FRAMEWORK-MIB. Engine data is written as a binary file to flash:/snmp/*contextname*.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

- Does not support view-based access control, but the VACM MIB is available for browsing to determine default view settings.
- The ENTITY-MIB is not available in the non-admin context. Use the IF-MIB instead to perform queries in the non-admin context.
- Does not support SNMP Version 3 for the AIP SSM or AIP SSC.
- Does not support SNMP debugging.
- Does not support retireval of ARP information.
- Does not support SNMP SET commands.
- When using NET-SNMP Version 5.4.2.1, only supports the encryption algorithm version of AES128. Does not support the encryption algorithm versions of AES256 or AES192.
- Changes to the existing configuration are rejected if the result places the SNMP feature in an inconsistent state.
- For SNMP Version 3, configuration must occur in the following order: group, user, host.
- Before a group is deleted, you must ensure that all users associated with that group are deleted.
- Before a user is deleted, you must ensure that no hosts are configured that are associated with that username.
- If users have been configured to belong to a particular group with a certain security model, and if the security level of that group is changed, you must do the following in this sequence:
  - Remove the users from that group.
  - Change the group security level.
  - Add users that belong to the new group.
- The creation of custom views to restrict user access to a subset of MIB objects is not supported.
- All requests and traps are available in the default Read/Notify View only.
- The connection-limit-reached trap is generated in the admin context. To generate this trap. you must have at least one snmp-server host configured in the user context in which the connection limit has been reached.
- You cannot query for the chassis temperature for the ASA 5585 SSP-40 (NPE).
- If the NMS cannot successfully request objects or is not correctly handling incoming traps from the ASA, performing a packet capture is the most useful method for determining the problem. Choose **Wizards > Packet Capture Wizard**, and follow the on-screen instructions.

Configuring SNMP

This section describes how to configure SNMP and includes the following topics:

- Enabling SNMP, page 98-6
- Configuring an SNMP Management Station, page 98-6
- Configuring SNMP Traps, page 98-7
- Using SNMP Version 1 or 2c, page 98-8
- Using SNMP Version 3, page 98-8

Enabling SNMP

The SNMP agent that runs on the ASA performs two functions:

- Replies to SNMP requests from NMSs.
- Sends traps (event notifications) to NMSs.

To enable the SNMP agent and identify an NMS that can connect to the SNMP server, see the following pane:

Path	Purpose
Configuration > Device Management > Management Access > SNMP	Ensures that the SNMP server on the ASA or ASASM is enabled. By default, the SNMP server is enabled.

What to Do Next

See the "Configuring an SNMP Management Station" section on page 98-6.

Configuring an SNMP Management Station

To receive requests from the ASA. you must configure an SNMP management station in ASDM.

To configure an SNMP management station, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > SNMP**.

Step 2 In the SNMP Management Stations pane, click **Add**.

The Add SNMP Host Access Entry dialog box appears.

Step 3 From the Interface Name drop-down list, choose the interface on which the SNMP host resides.

Step 4 In the IP Address field, enter the SNMP host IP address.

Step 5 In the UDP Port field, enter the SNMP host UDP port, or keep the default, port 162.

Step 6 In the Community String field, add the SNMP host community string. If no community string is specified for a management station, the value set in the Community String (default) field on the SNMP Management Stations pane is used.

Step 7 From the SNMP Version drop-down list, choose the SNMP version used by the SNMP host.

Step 8 If you have selected SNMP Version 3 in the previous step, from the Username drop-down list, choose the name of a configured user.

Step 9 To specify the method for communicating with this NMS, check either the **Poll** or **Trap** check box.

Step 10 Click **OK**.

The Add SNMP Host Access Entry dialog box closes.

Step 11 Click **Apply**.

The NMS is configured and changes are saved to the running configuration. For more information about SNMP Version 3 NMS tools, see the following URL:

http://www.cisco.com/en/US/docs/security/asa/asa82/snmp/snmpv3_tools.html

What to Do Next

See the "Configuring SNMP Traps" section on page 98-7.

Configuring SNMP Traps

To designate which traps that the SNMP agent generates and how they are collected and sent to NMSs, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > SNMP**.

Step 2 Click **Configure Traps**.

The SNMP Trap Configuration dialog box appears.

Step 3 The traps are divided into the following categories: standard, IKEv2, entity MIB, IPsec, remote access, resource, NAT, syslog, CPU utilization, CPU utilization and monitoring interval, and SNMP interface threshold. Check the applicable check boxes for the SNMP events to notify through SNMP traps. The default configuration has all SNMP standard traps enabled. If you do not specify a trap type, the default is the syslog trap. The default SNMP traps continue to be enabled with the syslog trap. All other traps are disabled by default. To disable a trap, uncheck the applicable check box. To configure the syslog trap severity level, choose **Configuration > Device Management > Logging > Logging Filters**.

Step 4 Click **OK**.

The SNMP Trap Configuration dialog box closes.

Step 5 Click **Apply**.

The SNMP traps are configured and the changes are saved to the running configuration.

What to Do Next

Choose one of the following:

- See the "Using SNMP Version 1 or 2c" section on page 98-8.
- See the "Using SNMP Version 3" section on page 98-8.

Using SNMP Version 1 or 2c

To configure parameters for SNMP Version 1 or 2c, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > SNMP.**

Step 2 (Optional) Enter a default community string in the Community String (default) field.

Enter the password used by the SNMP NMSs when sending requests to the ASA. The SNMP community string is a shared secret among the SNMP NMSs and the network nodes being managed. The ASA uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive value up to 32 alphanumeric characters. Spaces are not permitted. The default is public. SNMP Version 2c allows separate community strings to be set for each NMS. If no community string is configured for any NMS, the value set here is used by default.

Step 3 In the Contact field, enter the name of the ASA system administrator. The text is case-sensitive and can be up to 127 alphabetic characters. Spaces are accepted, but multiple spaces are shortened to a single space.

Step 4 In the ASA Location field, enter the location of the ASA being managed by SNMP. The text is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.

Step 5 In the Listening Port field, enter the number of the ASA port that listens for SNMP requests from NMSs; or keep the default, port number 161.

Step 6 Click **Apply**.

SNMP parameters for Versions 1 and 2c are configured and the changes are saved to the running configuration.

What to Do Next

See the "Monitoring SNMP" section on page 98-9.

Using SNMP Version 3

To configure parameters for SNMP Version 3, perform the following steps:

Step 1 Choose **Configuration > Device Management > Management Access > SNMP.**

Step 2 In the SNMPv3 Users pane, to add a configured user or a new user to a group, click **Add**. To change user parameters, click **Edit**. To remove a configured user from a group, click **Delete**. When you remove the last user in a group, ASDM deletes the group.

Note After a user has been created, you cannot change the group to which the user belongs.

The Add SNMP User Entry dialog box appears.

Step 3 From the Group Name drop-down list, choose the group to which the SNMP user belongs. The available groups are as follows:

- Auth&Encryption, in which users have authentication and encryption configured

- Authentication_Only, in which users have only authentication configured
- No_Authentication, in which users have neither authentication nor encryption configured

Step 4 In the Username field, enter the name of a configured user or a new user. The username must be unique for the SNMP server group selected.

Step 5 Indicate the type of password you want to use by clicking one of the two radio buttons: **Encrypted** or **Clear Text**.

Step 6 Indicate the type of authentication you want to use by clicking one of the two radio buttons: **MD5** or **SHA**.

Step 7 In the Authentication Password field, type the password to use for authentication.

Step 8 Indicate the type of encryption you want to use by clicking one of these three radio buttons: **DES**, **3DES**, or **AES**.

Step 9 If you chose AES encryption, then from the AES Size drop-down list, choose the level of AES encryption to use: **128**, **192**, or **256**.

Step 10 In the Encryption Password field, type the password to use for encryption. The maximum number of alphanumeric characters allowed for this password is 64.

Step 11 Click **OK** to create a group (if this is the first user in that group), display this group in the Group Name drop-down list, and create a user for that group.

The Add SNMP User Entry dialog box closes.

The SNMPv3 Users pane lists the following information: SNMP Version 3 server group name, name of the user that belongs to the specified group, encrypted password setting, authentication setting, encryption algorithm setting, and the AES size setting.

Step 12 Click **Apply**.

SNMP parameters for Version 3 are configured, and the changes are saved to the running configuration.

What to Do Next

See the "Monitoring SNMP" section on page 98-9.

Monitoring SNMP

NMSs are the PCs or workstations that you set up to monitor SNMP events and manage devices, such as the ASA.You can monitor the health of a device from an NMS by polling required information from the SNMP agent that has been set up on the device. Predefined events from the SNMP agent to the NMS generate syslog messages. This section includes the following topics:

- SNMP Syslog Messaging, page 98-10
- SNMP Monitoring, page 98-10

SNMP Syslog Messaging

SNMP generates detailed syslog messages that are numbered 212*nnn*. Syslog messages indicate the status of SNMP requests, SNMP traps, SNMP channels, and SNMP responses from the ASA or ASASM to a specified host on a specified interface.

For detailed information about syslog messages, see the syslog messages guide.

Note SNMP polling fails if SNMP syslog messages exceed a high rate (approximately 4000 per second).

SNMP Monitoring

To monitor SNMP, perform the following steps:

Path	Purpose
Tools > Command Line Interface Enter the **show running-config snmp-server** command, then click **Send**.	Shows all SNMP server configuration information.
Tools > Command Line Interface Enter the **show running-config snmp-server group** command, then click **Send**.	Shows SNMP group configuration settings.
Tools > Command Line Interface Enter the **show running-config snmp-server host** command, then click **Send**.	Shows configuration settings used by SNMP to control messages and notifications sent to remote hosts.
Tools > Command Line Interface Enter the **show running-config snmp-server user** command, then click **Send**.	Shows SNMP user-based configuration settings.
Tools > Command Line Interface Type **show snmp-server engineid** command, then click **Send**.	Shows the ID of the SNMP engine configured.
Tools > Command Line Interface Enter the **show snmp-server group** command, then click **Send**.	Shows the names of configured SNMP groups. **Note** If the community string has already been configured, two extra groups appear by default in the output. This behavior is normal.
Tools > Command Line Interface Enter the **show snmp-server statistics** command, then click **Send**.	Shows the configured characteristics of the SNMP server.
Tools > Command Line Interface Enter the **show snmp-server user** command, then click **Send**.	Shows the configured characteristics of users.

Where to Go Next

To configure the syslog server, see Chapter 96, "Configuring Logging."

Additional References

For additional information related to implementing SNMP, see the following sections:

MIBs

For a list of supported MIBs and traps for the ASA and ASASM by release, see the following URL:

http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml

Not all OIDs in MIBs are supported. To obtain a list of the supported SNMP MIBs and OIDs for a specific ASA or ASASM, choose **Tools > Command Line Interface**, the following command, then click **Send**:

```
hostname(config)# show snmp-server oidlist
```

Note Although the **oidlist** keyword does not appear in the options list for the **show snmp-server** command help, it is available. However, this command is for Cisco TAC use only. Contact the Cisco TAC before using this command.

The following is sample output from the **show snmp-server oidlist** command:

```
hostname(config)# show snmp-server oidlist
[0]     1.3.6.1.2.1.1.1.        sysDescr

Application Services and Third-Party Tools

For information about SNMP support, see the following URL:

http://www.cisco.com/en/US/tech/tk648/tk362/tk605/tsd_technology_support_sub-protocol_home.html

For information about using third-party tools to walk SNMP Version 3 MIBs, see the following URL:

http://www.cisco.com/en/US/docs/security/asa/asa83/snmp/snmpv3_tools.html

Feature History for SNMP

Table 98-2 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 98-2 Feature History for SNMP

Feature Name	Platform Releases	Feature Information
SNMP Versions 1 and 2c	7.0(1)	Provides ASA and ASASM network monitoring and event information by transmitting data between the SNMP server and SNMP agent through the clear text community string. We modified the following screen: Configuration > Device Management > Management Access > SNMP.
SNMP Version 3	8.2(1)	Provides 3DES or AES encryption and support for SNMP Version 3, the most secure form of the supported security models. This version allows you to configure users, groups, and hosts, as well as authentication characteristics by using the USM. In addition, this version allows access control to the agent and MIB objects and includes additional MIB support. We modified the following screen: Configuration > Device Management > Management Access > SNMP.
Password encryption	8.3(1)	Supports password encryption.

Table 98-2 Feature History for SNMP (continued)

Feature Name	Platform Releases	Feature Information
SNMP traps and MIBs	8.4(1)	Supports the following additional keywords: **connection-limit-reached**, **cpu threshold rising**, **entity cpu-temperature**, **entity fan-failure**, **entity power-supply**, **ikev2 stop | start**, **interface-threshold**, **memory-threshold**, **nat packet-discard**, **warmstart**. The entPhysicalTable reports entries for sensors, fans, power supplies, and related components. Supports the following additional MIBs: CISCO-ENTITY-SENSOR-EXT-MIB, CISCO-ENTITY-FRU-CONTROL-MIB, CISCO-PROCESS-MIB, CISCO-ENHANCED-MEMPOOL-MIB, CISCO-L4L7MODULE-RESOURCE-LIMIT-MIB, DISMAN-EVENT-MIB, DISMAN-EXPRESSION-MIB, ENTITY-SENSOR-MIB, NAT-MIB. Supports the following additional traps: ceSensorExtThresholdNotification, clrResourceLimitReached, cpmCPURisingThreshold, mteTriggerFired, natPacketDiscard, warmStart. We modified the following screen: Configuration > Device Management > Management Access > SNMP.
IF-MIB ifAlias OID support	8.2(5)/8.4(2)	The ASA now supports the ifAlias OID. When you browse the IF-MIB, the ifAlias OID will be set to the value that has been set for the interface description.
ASA Services Module (ASASM)	8.5(1)	The ASASM supports all MIBs and traps that are present in 8.4(1), except for the following: Unsupported MIBs in 8.5(1): • CISCO-ENTITY-SENSOR-EXT-MIB (Only objects under the entPhySensorTable group are supported). • ENTITY-SENSOR-MIB (Only objects in the entPhySensorTable group are supported). • DISMAN-EXPRESSION-MIB (Only objects in the expExpressionTable, expObjectTable, and expValueTable groups are supported). Unsupported traps in 8.5(1): • ceSensorExtThresholdNotification (CISCO-ENTITY-SENSOR-EXT-MIB). This trap is only used for power supply failure, fan failure, and high CPU temperature events. • InterfacesBandwidthUtilization.
SNMP traps	8.6(1)	Supports the following additional keywords for the ASA 5512-X, 5515-X, 5525-X, 5545-X, and 5555-X: **entity power-supply-presence**, **entity power-supply-failure**, **entity chassis-temperature**, **entity chassis-fan-failure, entity power-supply-temperature**. We modified the following command: **snmp-server enable traps**.

Table 98-2 Feature History for SNMP (continued)

Feature Name	Platform Releases	Feature Information
VPN-related MIBs	9.0(1)	An updated version of the CISCO-IPSEC-FLOW-MONITOR-MIB.my MIB has been implemented to support the next generation encryption feature. The following MIBs have been enabled for the ASASM: • ALTIGA-GLOBAL-REG.my • ALTIGA-LBSSF-STATS-MIB.my • ALTIGA-MIB.my • ALTIGA-SSL-STATS-MIB.my • CISCO-IPSEC-FLOW-MONITOR-MIB.my • CISCO-REMOTE-ACCESS-MONITOR-MIB.my
Cisco TrustSec MIB	9.0(1)	Support for the following MIB was added: CISCO-TRUSTSEC-SXP-MIB.

Configuring Anonymous Reporting and Smart Call Home

The Smart Call Home feature provides personalized, e-mail-based and web-based notification to customers about critical events involving their individual systems, often before customers know that a critical event has occurred.

The Anonymous Reporting feature is a subfeature of the Smart Call Home feature and allows Cisco to anonymously receive minimal error and health information from the device.

Note You might have received a popup dialog that invites you to do the following:

- Enable Anonymous Reporting to help improve the ASA platform.
- Register for Smart Home Notifications to receive personalized, proactive assistance from Cisco.

For information about the dialog, see the "Anonymous Reporting and Smart Call Home Prompt" section on page 99-3.

This chapter describes how to use and configure Anonymous Reporting and Smart Call Home, and it includes the following sections:

- Information About Anonymous Reporting and Smart Call Home, page 99-1
- Licensing Requirements for Anonymous Reporting and Smart Call Home, page 99-4
- Prerequisites for Smart Call Home and Anonymous Reporting, page 99-5
- Guidelines and Limitations, page 99-5
- Configuring Anonymous Reporting and Smart Call Home, page 99-6
- Monitoring Anonymous Reporting and Smart Call Home, page 99-10
- Feature History for Anonymous Reporting and Smart Call Home, page 99-11

Information About Anonymous Reporting and Smart Call Home

This section includes the following topics:

- Information About Anonymous Reporting, page 99-2
- Information About Smart Call Home, page 99-4

Information About Anonymous Reporting

Customers can help to improve the ASA platform by enabling Anonymous Reporting, which allows Cisco to securely receive minimal error and health information from the device. If you enable the feature, your customer identity will remain anonymous, and no identifying information will be sent.

Enabling Anonymous Reporting creates a trust point and installs a certificate. A CA certificate is required for your ASA to validate the server certificate present on the Smart Call Home web server and to form the HTTPS session so that your ASA can send messages securely. Cisco imports a certificate that is predefined in the software. If you decide to enable Anonymous Reporting, a certificate is installed on the ASA with a hardcoded trust point name: _SmartCallHome_ServerCA. When you enable Anonymous Reporting, this trust point is created, the appropriate certificate is installed, and you receive a message about this action. The certificate then appears in your configuration.

If the appropriate certificate already exists in your configuration when you enable Anonymous Reporting, no trust point is created, and no certificate is installed.

Note When you enable Anonymous Reporting, you acknowledge your consent to transfer the specified data to Cisco or to vendors operating on Cisco's behalf (including countries outside of the U.S.). Cisco maintains the privacy of all customers. For information about Cisco's treatment of personal information, see the Cisco Privacy Statement at the following URL: http://www.cisco.com/web/siteassets/legal/privacy.html

What is Sent to Cisco?

Messages are sent to Cisco once a month and whenever the ASA reloads. These messages are categorized by alert groups, which are predefined subsets of Smart Call Home alerts that are supported on the ASA: configuration alerts, inventory alerts, and crash information alerts.

Inventory alerts consist of output from the following commands:

- **show version**—Displays the ASA software version, hardware configuration, license key, and related uptime data for the device.
- **show environment**—Shows system environment information for ASA system components, such as hardware operational status for the chassis, drivers, fans, and power supplies, as well as temperature status, voltage, and CPU usage.
- **show inventory—**Retrieves and displays inventory information about each Cisco product that is installed in the networking device. Each product is identified by unique device information, called the UDI, which is a combination of three separate data elements: the product identifier (PID), the version identifier (VID), and the serial number (SN).
- **show failover state**—Displays the failover state of both units in a failover pair. The information displayed includes the primary or secondary status of the unit, the Active/Standby status of the unit, and the last reported reason for failover.
- **show module**—Shows information about any modules installed on the ASAs, for example, information about an AIP SSC installed on the ASA 5505 or information about an SSP installed on the ASA 5585-X, and information about an IPS SSP installed on an ASA 5585-X.

Configuration alerts consist of output from the following commands:

- **show context**—Shows allocated interfaces and the configuration file URL, the number of contexts configured, or, if you enable Anonymous Reporting in the system execution space, from a list of all contexts.

- **show call-home registered-module status**—Displays the registered module status. If you use system configuration mode, the command displays system module status based on the entire device, not per context.

Upon a system crash, modified information from the following command is sent:

- **show crashinfo** (truncated)—Upon an unexpected software reload, the device sends a modified crash information file with only the traceback section of the file included, so only function calls, register values, and stack dumps are reported to Cisco.

For more information about ASA commands, see the command reference.

DNS Requirement

A DNS server must be configured properly for your ASA to reach the Cisco Smart Call Home server and send messages to Cisco. Because it is possible that your ASA resides in a private network and does not have access to the public network, Cisco verifies your DNS configuration and then configures it for you, if necessary, by doing the following:

1. Performing a DNS lookup for all DNS servers configured.
2. Getting the DNS server from the DHCP server by sending DHCPINFORM messages on the highest security-level interface.
3. Using the Cisco DNS servers for lookup.
4. Randomly using a static IP addresses for tools.cisco.com.

These tasks are performed without changing the current configuration. (For example, the DNS server learned from DHCP will not be added to the configuration.)

If there is no DNS server configured, and your ASA cannot reach the Cisco Smart Call Home Server, Cisco generates a syslog message with the warning severity level for every Smart Call Home message sent to remind you to configure DNS correctly.

For information about syslog messages, see the syslog messages guide.

Anonymous Reporting and Smart Call Home Prompt

When you enter configuration mode you receive a prompt that invites you to enable the Anonymous Reporting and Smart Call Home features if the following criteria are met:

At the prompt, you may choose [Y]es, [N]o, [A]sk later. If you choose [A]sk later, then you are reminded again in seven days or when the ASA reloads. If you continue to choose [A]sk later, the ASA prompts two more times at seven-day intervals before it assumes a [N]o response and does not ask again.

At the ASDM prompt, you can select from the following options:

- Anonymous—Enables Anonymous Reporting.
- Registered (enter an e-mail address)—Enables Smart Call Home and registers your ASA with Cisco TAC.
- Do not enable Smart Call Home—Does not enable Smart Call Home and does not ask again.
- Remind Me Later—Defers the decision. You are reminded again in seven days or whenever the ASA reloads. The ASA prompts two more times at seven-day intervals before it assumes a “Do not enable Smart Call Home response” and does not ask again.

If you did not receive the prompt, you may enable Anonymous Reporting or Smart Call Home by performing the steps in the “Configuring Anonymous Reporting” section on page 99-6 or the “Configuring Smart Call Home” section on page 99-6.

Information About Smart Call Home

When fully configured, Smart Call Home detects issues at your site and reports them back to Cisco or through other user-defined channels (such as e-mail or directly to you), often before you know that these issues exist. Depending upon the seriousness of these problems, Cisco responds to customers regarding their system configuration issues, product end-of-life announcements, security advisory issues, and so on.

In this manner, Smart Call Home offers proactive diagnostics and real-time alerts on the ASA and provides high network availability and increased operational efficiency through proactive and quick issue resolution by doing the following:

- Identifying issues quickly with continuous monitoring, real-time proactive alerts, and detailed diagnostics.
- Making you aware of potential problems through Smart Call Home notifications, in which a service request has been opened, with all diagnostic data attached.
- Resolving critical problems faster with direct, automatic access to experts in Cisco TAC.

Smart Call Home offers increased operational efficiency by providing you with the ability to do the following:

- Use staff resources more efficiently by reducing troubleshooting time.
- Generate service requests to Cisco TAC automatically (if you have a service contract), routed to the appropriate support team, which provides detailed diagnostic information that speeds problem resolution.

The Smart Call Home Portal offers quick, web-based access to required information that provides you with the ability to do the following:

- Review all Smart Call Home messages, diagnostics, and recommendations in one place.
- Check service request status quickly.
- View the most up-to-date inventory and configuration information for all Smart Call Home-enabled devices.

Licensing Requirements for Anonymous Reporting and Smart Call Home

The following table shows the licensing requirements for Anonymous Reporting and Smart Call Home:

Model	License Requirement
All models	Base License.

Prerequisites for Smart Call Home and Anonymous Reporting

Smart Call Home and Anonymous Reporting have the following prerequisites:

- DNS must be configured. See the "DNS Requirement" section on page 99-3 and the "Configuring the DNS Server" section on page 21-8.

Guidelines and Limitations

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

Context Mode Guidelines

Supported in single mode and multiple context mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines for Anonymous Reporting

- If an Anonymous Reporting message cannot be sent on the first try, the ASA retries two more times before dropping the message.
- Anonymous Reporting can coexist with other Smart Call Home configurations without changing the existing configuration. For example, if Smart Call Home is off before enabling Anonymous Reporting, it remains off, even after enabling Anonymous Reporting.
- If Anonymous Reporting is enabled, you cannot remove the trust point, and when Anonymous Reporting is disabled, the trust point remains. If Anonymous Reporting is disabled, users can remove the trust point, but disabling Anonymous Reporting will not cause the trust point to be removed.

Additional Guidelines for Smart Call Home

- In multiple context mode, the **subscribe-to-alert-group snaphots periodic** command is divided into two commands: one to obtain information from the system configuration and one to obtain information from the user context.
- The Smart Call Home back-end server can accept messages in XML format only.

Configuring Anonymous Reporting and Smart Call Home

While Anonymous Reporting is a subfeature of the Smart Call Home feature and allows Cisco to anonymously receive minimal error and health information from the device, the Smart Call Home feature provides customized support of your system health, enabling Cisco TAC to monitor your devices and open a case when there is an issue, often before you know the issue has occurred.

Generally speaking, you can have both features configured on your system at the same time, yet configuring the Smart Call Home feature provides the same functionality as Anonymous reporting, plus customized services.

This section includes the following topics:

- Configuring Anonymous Reporting, page 99-6
- Configuring Smart Call Home, page 99-6

Configuring Anonymous Reporting

To configure Anonymous Reporting and securely provide minimal error and health information to Cisco, perform the following steps:

Step 1 Choose **Configuration > Device Management > Smart Call Home**.

Step 2 Check the **Enable Anonymous Reporting** check box.

Step 3 Click **Test Connection** to ensure that your system is able to send messages.

ASDM returns a success or error message to notify you of test results.

Step 4 Click **Apply** to save the configuration and enable Anonymous Reporting.

At any time you may also choose to enable the full Smart Call Home feature so that you may receive notification from Cisco about critical events involving your system. You can enable Smart Call Home from the same pane in which you enable Anonymous Reporting. (See the "Monitoring Anonymous Reporting and Smart Call Home" section on page 99-10.)

Configuring Smart Call Home

This section describes how to configure the Smart Call Home feature.

Configuring the Smart Call Home service on your ASA includes the following tasks:

- Enabling the Smart Call Home service.
- Configuring the mail server through which Smart Call Home messages are delivered to subscribers.
- Setting up contact information for the Smart Call Home messages.
- Defining alert processing parameters, such as the maximum rate of events that can be handled.
- Setting up alert subscription profiles. Each alert subscription profile identifies the following:
  - The subscribers to whom the Smart Call Home messages are sent, such as a Smart Call Home server at Cisco or a list of e-mail recipients.
  - Information categories for which you want to receive alerts, such as configuration or inventory information.

Detailed Steps

To configure the Smart Call Home service, system setup, and alert subscription profiles, perform the following steps. To configure Anonymous Reporting, see the "Configuring Anonymous Reporting" section on page 99-6.

Step 1 Choose **Configuration> Device Management> Smart Call Home**.

Step 2 Check the **Enable Smart Call Home** check box to enable the feature.

Step 3 Double-click **System Setup**. The System Setup consists of three panes. Each pane can be expanded or collapsed by double-clicking the title row.

a. In the Mail Servers pane you can set up mail servers through which Smart Call Home messages are delivered to e-mail subscribers.

b. In the Contact Information pane you can enter the information of the person to contact for the ASA that appears in Smart Call Home messages. This pane includes the following information:

- The name of the contact person.
- The contact phone number.
- The postal address of the contact person.
- The e-mail address of the contact.
- The "from" e-mail address in Smart Call Home e-mail.
- The "reply-to" e-mail address in Smart Call Home e-mail.
- The customer ID.
- The site ID.
- The contract ID.

c. In the Alert Control pane, administrators can adjust alert control parameters. This pane includes the Alert group status pane, which lists the status (enabled or disabled) of the following alert groups:

- The diagnostics alert group.
- The configuration alert group.
- The environmental alert group.
- The inventory alert group.
- The snapshot alert group.
- The syslog alert group.
- The telemetry alert group.
- The threat alert group.
- The maximum number of Smart Call Home messages processed per minute.
- The "from" e-mail address in Smart Call Home e-mail.

Step 4 Double-click **Alert Subscription Profiles**. Each named subscription profile identifies subscribers and alert groups of interest.

a. Click **Add** or **Edit** to display the Subscription Profile Editor, in which you can create a new subscription profile or edit an existing subscription profile.

b. Click **Delete** to remove the selected profile.

c. Check the **Active** check box to send a Smart Call Home message of the selected subscription profile to subscribers.

Step 5 When you click **Add** or **Edit**, the Add or Edit Alert Subscription Profile dialog box appears.

a. The Name field is read-only and cannot be edited.

b. Check the **Enable this subscription profile** check box to enable or disable this particular profile.

c. Click either the **HTTP** or **Email** radio button in the Alert Delivery Method area.

d. In the Subscribers field, specify the alert delivery method: e-mail address or web address.

e. The Alert Dispatch area lets the administrator specify which type of Smart Call Home information to send to subscribers and under what conditions. There are two types of alerts, time-based and event-based, chosen according to how the alert is triggered. The following alert groups are time-based: Configuration, Inventory, Snapshot, and Telemetry. The following alert groups are event-based: Diagnostic, Environmental, Syslog, and Threat.

f. The Message Parameters area lets you adjust parameters that control messages sent to the subscriber, including the preferred message format and the maximum message size.

Step 6 For time-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Add or Edit Configuration Alert Dispatch Condition dialog box.

a. In the Alert Dispatch Frequency area, specify the frequency in which to send the information to subscribers:

- For a monthly subscription, specify the day of the month, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.
- For a weekly subscription, specify the day of the week, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.
- For a daily subscription, specify the time of the day to send the information. If it is not specified, the ASA chooses an appropriate value for it.
- For an hourly subscription, specify the minute of the hour to send the information. If it is not specified, the ASA chooses an appropriate value for it. Hourly subscriptions are applicable to the snapshot and telemetry alert groups only.

b. Click the **Basic** or **Detailed** radio button to provide the desired level of information to subscribers.

c. Click **OK** to save the configuration.

Step 7 For diagnostic, environment, and threat event-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Create or Edit Diagnostic Alert Dispatch Condition dialog box.

Step 8 Specify the event severity that triggers dispatch of the alert to subscribers in the Event Severity drop-down list, and then click **OK**.

Step 9 For inventory time-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Create or Edit Inventory Alert Dispatch Condition dialog box.

Step 10 Specify how often to dispatch alerts to subscribers in the Alert Dispatch Frequency drop-down list, and then click **OK**.

Step 11 For snapshot time-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Create or Edit Snapshot Alert Dispatch Condition dialog box.

a. In the Alert Dispatch Frequency area, specify the frequency in which to send the information to subscribers:

- For a monthly subscription, specify the day of the month, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.

- For a weekly subscription, specify the day of the week, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.
- For a daily subscription, specify the time of the day to send the information. If it is not specified, the ASA chooses an appropriate value for it.
- For an hourly subscription, specify the minute of the hour to send the information. If it is not specified, the ASA chooses an appropriate value for it. Hourly subscriptions are applicable to the snapshot and telemetry alert groups only.
- For an interval subscription, specify how often, in minutes, the formation is sent to the subscribers. This requirement is applicable to the snapshot alert group only.

b. Click **OK** to save the configuration.

Step 12 For syslog event-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Create or Edit Syslog Alert Dispatch Condition dialog box.

a. Check the **Specify the event severity which triggers the dispatch of alert to subscribers check box**, and choose the event severity from the drop-down list.

b. Check the **Specify the message IDs of syslogs which trigger the dispatch of alert to subscribers** check box.

c. Specify the syslog message IDs that trigger dispatch of the alert to subscribers according to the on-screen instructions.

d. Click **OK** to save the configuration.

Step 13 For telemetry event-based alerts, in the Alert Dispatch area, click **Add** or **Edit** to display the Create or Edit Telemetry Alert Dispatch Condition dialog box.

a. In the Alert Dispatch Frequency area, specify the frequency in which to send the information to subscribers:

- For a monthly subscription, specify the day of the month, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.
- For a weekly subscription, specify the day of the week, as well as the time of the day to send the information. If they are not specified, the ASA chooses appropriate values for them.
- For a daily subscription, specify the time of the day to send the information. If it is not specified, the ASA chooses an appropriate value for it.
- For an hourly subscription, specify the minute of the hour to send the information. If it is not specified, the ASA chooses an appropriate value for it. Hourly subscriptions are applicable to the snapshot and telemetry alert groups only.

b. Click **OK** to save the configuration.

Monitoring Anonymous Reporting and Smart Call Home

To monitor the Anonymous Reporting and Smart Call Home features, navigate to the specified path and enter the specified command:

Path	Purpose
Tools > Command Line Interface Enter the **show call- home detail** command, and click **Send**.	Shows the current Smart Call Home detail configuration.
Tools > Command Line Interface Enter the **show call-home mail-server status** command, and click **Send**.	Shows the current mail server status.
Tools > Command Line Interface Enter the **show smart-call- home profile {***profile name* **| all** command, and click **Send**.	Shows the configuration of Smart Call Home profiles.
Tools > Command Line Interface Enter the **show call-home registered-module all** command, and click **Send**.	Shows the registered module status.
Tools > Command Line Interface Enter the **show smart-call statistics** command, and click **Send**.	Shows call-home detail status.
Tools > Command Line Interface Enter the **show call-home** command, and click **Send**.	Shows the current Smart Call Home configuration.
Tools > Command Line Interface Enter the **show running-config call-home** command, and click **Send**.	Shows the current Smart Call Home running configuration.
Tools > Command Line Interface Enter the **show smart-call-home alert-group** command, and click **Send**.	Shows the current status of Smart Call Home alert groups.
Tools > Command Line Interface Enter the **show running-config all** command, and click **Send**.	Shows details about the Anonymous Reporting user profile.

Feature History for Anonymous Reporting and Smart Call Home

Table 99-1 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 99-1 Feature History for Anonymous Reporting and Smart Call Home

Feature Name	Platform Releases	Feature Information
Smart Call Home	8.2(2)	The Smart Call Home feature offers proactive diagnostics and real-time alerts on the ASA, and provides higher network availability and increased operational efficiency. We introduced the following screen: Configuration> Device Management> Smart Call Home.
Anonymous Reporting	8.2(5)/8.4(2)	Customers can help to improve the ASA platform by enabling Anonymous Reporting, which allows Cisco to securely receive minimal error and health information from a device. We modified the following screen: Configuration> Device Management> Smart Call Home.

PART 17

System Administration

Managing Software and Configurations

This chapter describes how to manage the ASA software and configurations and includes the following sections:

- Upgrading the Software, page 101-1
- Managing Files, page 101-14
- Configuring the Images and Startup Configuration to Use, page 101-19
- Backing Up and Restoring Configurations or Other Files, page 101-20
- Saving the Running Configuration to a TFTP Server, page 101-27
- Scheduling a System Restart, page 101-27
- Downgrading Your Software, page 101-28
- Configuring Auto Update, page 101-30

Upgrading the Software

Note You can upgrade from any previous release (if available for your model) directly to the latest release. When upgrading to Version 9.0, because of configuration migration, you cannot perform a downgrade; be sure to back up your configuration file in case you want to downgrade.

If you are upgrading to Version 9.0, see the migration section in the release notes for configuration migration information.

If you are upgrading from a pre-8.3 release, see also the *Cisco ASA 5500 Migration Guide to Version 8.3 and Later* for important information about migrating your configuration.

This section describes how to upgrade to the latest version and includes the following topics:

- Viewing Your Current Version, page 101-2
- Downloading the Software from Cisco.com, page 101-2
- Upgrading a Standalone Unit, page 101-2
- Upgrading a Failover Pair or ASA Cluster, page 101-7

Note For CLI procedures, see the ASA documentation.

Viewing Your Current Version

The software version appears on the ASDM home page; view the home page to verify the software version of your ASA.

Downloading the Software from Cisco.com

If you are using the ASDM Upgrade Wizard, you do not have to pre-download the software. If you are manually upgrading, for example for a failover upgrade, download the images to your local computer.

If you have a Cisco.com login, you can obtain the OS and ASDM images from the following website:

http://www.cisco.com/cisco/software/navigator.html?mdfid=279513386

Upgrading a Standalone Unit

Note This section describes how to install the ASDM and operating system (OS) imagesIf the ASA is running Version 8.0 or later, then you can upgrade to the latest version of ASDM (and disconnect and reconnect to start running it) before upgrading the OS. The exception is for ASA versions that are not supported by the latest ASDM version; for example, ASA 8.5. In that case, follow the instructions for pre-8.0 versions (ASDM 5.2 and earlier).

If the ASA is running a version earlier than 8.0, then use the already installed version of ASDM to upgrade both the OS and ASDM to the latest versions, and then reload.

- Upgrading from Your Local Computer (ASDM 6.0 or Later), page 101-2
- Upgrading Using the Cisco.com Wizard (ASDM 6.3 or Later), page 101-4
- Upgrading Using the Cisco.com Wizard (ASDM 6.0 Through ASDM 6.2), page 101-5
- Upgrading from Your Local Computer (ASDM 5.2 or Earlier), page 101-6

Upgrading from Your Local Computer (ASDM 6.0 or Later)

The Upgrade Software from Local Computer tool lets you upload an image file from your computer to the flash file system to upgrade the ASA.

To upgrade software from your computer, perform the following steps:

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 2 In the main ASDM application window, choose **Tools > Upgrade Software from Local Computer**.

The Upgrade Software dialog box appears.

Step 3 From the Image to Upload drop-down list, choose **ASDM**.

Step 4 In the Local File Path field, enter the local path to the file on your computer or click **Browse Local Files** to find the file on your PC.

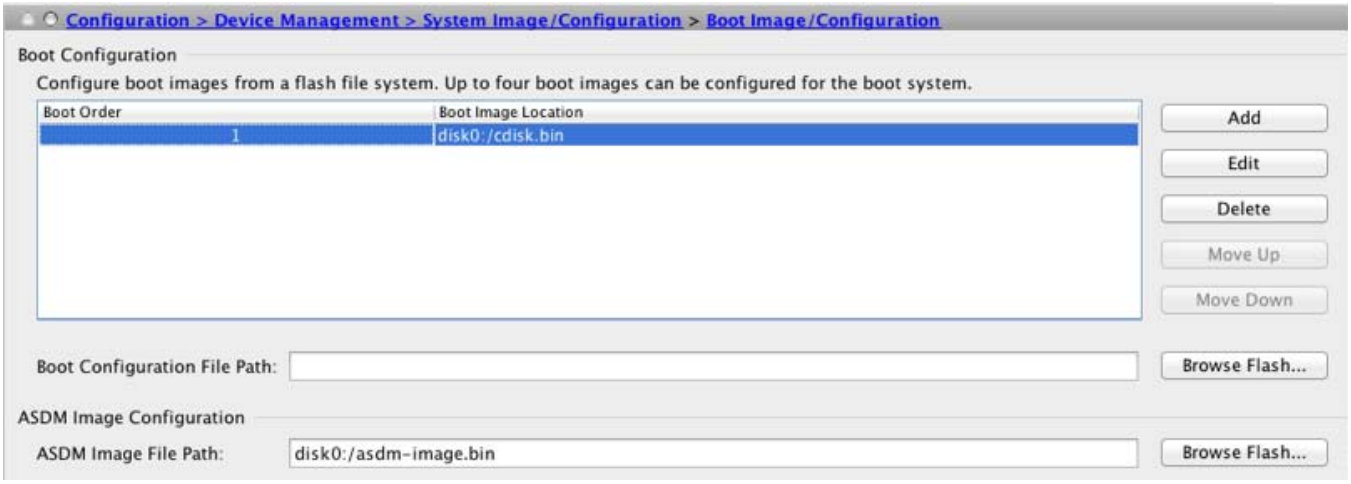
Step 5 In the Flash File System Path field, enter the path to the flash file system or click **Browse Flash** to find the directory or file in the flash file system.

Step 6 Click **Upload Image**. The uploading process might take a few minutes.

Step 7 Repeat Step 2 through Step 6, choosing **ASA** from the Image to Upload drop-down list. You can also use this procedure to upload other file types.

Step 8 Configure the ASA to use the new images.

a. Choose **Configuration > Device Management > System/Image Configuration > Boot Image/Configuration**.



b. In the Boot Configuration table, click **Add** to add the new image (if you have fewer than four images listed); or you can choose an existing image and click **Edit** to change it to the new one.

If you do not specify an image, the ASA searches the internal flash memory for the first valid image to boot; we recommend booting from a specific image.

c. Click **Browse Flash**, choose the OS image, and click **OK**.

d. Click **OK** to return to the Boot Image/Configuration pane.

e. Make sure the new image is the first image in the table by using the **Move Up** button as needed.

f. In the ASDM Image Configuration area, click **Browse Flash**, choose the ASDM image, and click **OK**.

g. Click **Apply**.

Step 9 Choose **File > Save Running Configuration to Flash** to save your configuration changes.

Step 10 Choose **Tools > System Reload** to reload the ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

Step 11 After the ASA reloads, restart ASDM.

Upgrading Using the Cisco.com Wizard (ASDM 6.3 or Later)

The Upgrade Software from Cisco.com Wizard lets you automatically upgrade the ASDM and ASA to more current versions.

In this wizard, you can do the following:

- Choose an ASA image file and/or ASDM image file to upgrade.

  Note ASDM downloads the latest image version, which includes the build number. For example, if you are downloading 8.4(2), the dowload might be 8.4(2.8). This behavior is expected, so you may proceed with the planned upgrade.

- Review the upgrade changes that you have made.
- Download the image or images and install them.
- Review the status of the installation.
- If the installation completed successfully, restart the ASA to save the configuration and complete the upgrade.

Detailed Steps

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 2 Choose **Tools > Check for ASA/ASDM Updates**.

In multiple context mode, access this menu from the System.

The Cisco.com Authentication dialog box appears.

Step 3 Enter your assigned Cisco.com username and the Cisco.com password, and then click **Login**.

The Cisco.com Upgrade Wizard appears.

Note If there are no upgrade available, a dialog box appears. Click **OK** to exit the wizard.

Step 4 Click **Next** to display the Select Software screen.

The current ASA version and ASDM version appear.

Step 5 To upgrade the ASA version and ASDM version, perform the following steps:

a. In the ASA area, check the **Upgrade to** check box, and then choose an ASA version to which you want to upgrade from the drop-down list.

b. In the ASDM area, check the **Upgrade to** check box, and then choose an ASDM version to which you want to upgrade from the drop-down list.

Step 6 Click **Next** to display the Review Changes screen.

Step 7 Verify the following items:

- The ASA image file and/or ASDM image file that you have downloaded are the correct ones.
- The ASA image file and/or ASDM image file that you want to upload are the correct ones.
- The correct ASA boot image has been selected.

Step 8 Click **Next** to start the upgrade installation.

You can then view the status of the upgrade installation as it progresses.

The Results screen appears, which provides additional details, such as the upgrade installation status (success or failure).

During the upgrade process from Version 8.2(1) to Version 8.3(1), the following files are automatically saved to flash memory:

- The startup configuration
- The per-context configuration
- The bootup error log, which includes any migration messages

If there is insufficient memory to save the configuration files, an error message appears on the console of the ASA and is saved in the bootup error log file. All previously saved configuration files are also removed.

Step 9 If the upgrade installation succeeded, for the upgrade versions to take effect, check the **Save configuration and reload device now** check box to restart the ASA, and restart ASDM.

Step 10 Click **Finish** to exit the wizard and save the configuration changes that you have made.

Note To upgrade to the next higher version, if any, you must restart the wizard.

Upgrading Using the Cisco.com Wizard (ASDM 6.0 Through ASDM 6.2)

Detailed Steps

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 2 From the Tools menu, choose **Tools > Upgrade Software from Cisco.com**.

In multiple context mode, access this menu from the System.

The Upgrade Software from Cisco.com Wizard appears.

Step 3 Click **Next**.

The Authentication screen appears.

Step 4 Enter your Cisco.com username and password, and click **Next**.

The Image Selection screen appears.

Step 5 Check the **Upgrade the ASA version** check box and the **Upgrade the ASDM version** check box to specify the most current images to which you want to upgrade, and click **Next**.

The Selected Images screen appears.

Step 6 Verify that the image file you have selected is the correct one, and then click **Next** to start the upgrade.

The wizard indicates that the upgrade will take a few minutes. You can then view the status of the upgrade as it progresses.

The Results screen appears. This screen provides additional details, such as whether the upgrade failed or whether you want to save the configuration and reload the ASA.

If you upgraded the ASA version and the upgrade succeeded, an option to save the configuration and reload the ASA appears.

Step 7 Click **Yes**.

For the upgrade versions to take effect, you must save the configuration, reload the ASA, and restart ASDM.

Step 8 Click **Finish** to exit the wizard when the upgrade is finished.

Step 9 After the ASA reloads, restart ASDM.

Upgrading from Your Local Computer (ASDM 5.2 or Earlier)

Detailed Steps

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration. For example, choose **File > Show Running Configuration in New Window** to open the configuration as an HTML page. You can also use one of the File > Save Running Configuration options.

Step 2 Choose **Tools > Upgrade Software**.

Step 3 From the Image to Upload drop-down list, choose **ASDM**.

Step 4 Click **Browse Local Files**, and browse to the ASDM image you downloaded from Cisco.com.

Step 5 Click **Browse Flash** to determine where to install the new ASDM image.

The Browse Flash dialog box appears. Choose the new location, and click **OK**. If you do not have room for both the current image and the new image, you can install over the current image.

Step 6 Click **Upload Image**.

Wait for the image to upload. An information window appears that indicates a successful upload.

Step 7 Repeat Step 2 through Step 6, choosing **ASA** from the Image to Upload drop-down list.

Step 8 Click **Close** to exit the Upgrade Software dialog box.

Step 9 Configure the ASA to use the new images.

a. Choose **Configuration > Properties > Device Administration > Boot Image/Configuration**.

b. In the Boot Configuration table, click **Add** to add the new image (if you have fewer than four images listed); or you can choose an existing image and click **Edit** to change it to the new one.

   If you do not specify an image, the ASA searches the internal flash memory for the first valid image to boot; we recommend booting from a specific image.

c. Click **Browse Flash**, choose the OS image, and click **OK**.

d. Click **OK** to return to the Boot Image/Configuration pane.

e. Make sure the new image is the first image in the table by using the **Move Up** button as needed.

f. In the ASDM Image Configuration area, click **Browse Flash**, choose the ASDM image, and click **OK**.

g. Click **Apply**.

Step 10 Choose **File > Save Running Configuration to Flash** to save your configuration changes.

Step 11 Choose **Tools > System Reload** to reload the ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

Step 12 After the ASA reloads, restart ASDM.

Upgrading a Failover Pair or ASA Cluster

- Software Version Requirements for Zero Downtime Upgrading, page 101-8
- Upgrading an Active/Standby Failover Pair, page 101-8
- Upgrading an ASA Cluster, page 101-12

Software Version Requirements for Zero Downtime Upgrading

The units in a failover configuration or ASA cluster should have the same major (first number) and minor (second number) software version. However, you do not need to maintain version parity on the units during the upgrade process; you can have different versions on the software running on each unit and still maintain failover support. To ensure long-term compatibility and stability, we recommend upgrading all units to the same version as soon as possible.

Table 101-1 shows the supported scenarios for performing zero-downtime upgrades.

Table 101-1 Zero-Downtime Upgrade Support

Type of Upgrade	Support
Maintenance Release	You can upgrade from any maintenance release to any other maintenance release within a minor release. For example, you can upgrade from 7.0(1) to 7.0(4) without first installing the maintenance releases in between.
Minor Release	You can upgrade from a minor release to the next minor release. You cannot skip a minor release. For example, you can upgrade from 7.0(1) to 7.1(1). Upgrading from 7.0(1) directly to 7.2(1) is not supported for zero-downtime upgrades; you must first upgrade to 7.1(1). For models that are not supported on a minor release, you can skip the minor release; for example, for the ASA 5585, you can upgrade from 8.2 to 8.4 (the model is not supported on 8.3).
Major Release	You can upgrade from the last minor release of the previous version to the next major release. For example, you can upgrade from 7.2(1) to 8.0(1), assuming that 7.2(1) is the last minor version in the 7.X release series. **Note** Zero downtime upgrades are possible, even when feature configuration is migrated, for example, from 8.2(X) to 8.3(X).

Upgrading an Active/Standby Failover Pair

To upgrade the Active/Standby failover pair, perform the following steps.

Detailed Steps

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 2 On the active unit, in the main ASDM application window, choose **Tools > Upgrade Software from Local Computer**.

The Upgrade Software dialog box appears.

Step 3 From the Image to Upload drop-down list, choose **ASDM**.

Step 4 In the Local File Path field, enter the local path to the file on your computer or click **Browse Local Files** to find the file on your PC.

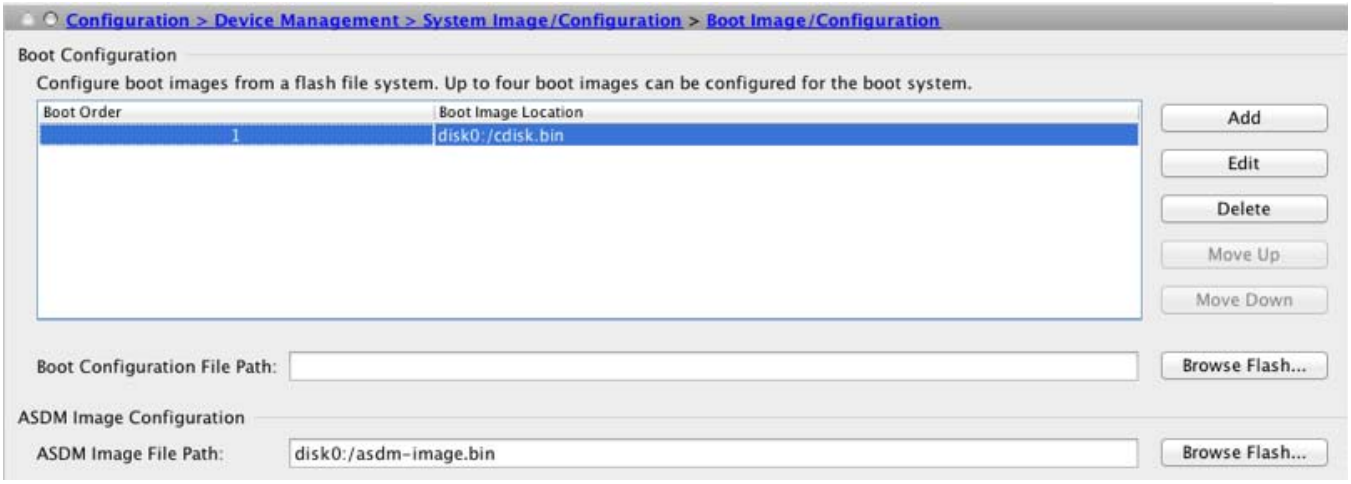
Step 5 In the Flash File System Path field, enter the path to the flash file system or click **Browse Flash** to find the directory or file in the flash file system.

Step 6 Click **Upload Image**. The uploading process might take a few minutes.

Step 7 Repeat Step 2 through Step 6, choosing **ASA** from the Image to Upload drop-down list.

Step 8 Configure the ASA to use the new images.

a. Choose **Configuration > Device Management > System/Image Configuration > Boot Image/Configuration**.



b. In the Boot Configuration table, click **Add** to add the new image (if you have fewer than four images listed); or you can choose an existing image and click **Edit** to change it to the new one.

If you do not specify an image, the ASA searches the internal flash memory for the first valid image to boot; we recommend booting from a specific image.

c. Click **Browse Flash**, choose the OS image, and click **OK**.

d. Click **OK** to return to the Boot Image/Configuration pane.

e. Make sure the new image is the first image in the table by using the **Move Up** button as needed.

f. In the ASDM Image Configuration area, click **Browse Flash**, choose the ASDM image, and click **OK**.

g. Click **Apply**.

Step 9 Choose **File > Save Running Configuration to Flash** to save your configuration changes.

Step 10 Connect ASDM to the *standby* unit, and upload the ASA and ASDM software according to Step 2 through Step 7, using the same file locations you used on the active unit.

Step 11 Choose **Tools > System Reload** to reload the standby ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

Step 12 After the standby ASA reloads, restart ASDM and connect to the standby unit to make sure it is running.

Step 13 Connect ASDM to the *active* unit again.

Step 14 Force the active unit to fail over to the standby unit by choosing **Monitoring > Properties > Failover > Status**, and clicking **Make Standby**.

Step 15 Choose **Tools > System Reload** to reload the (formerly) active ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

After the ASA comes up, it will now be the standby unit.

Upgrading an Active/Active Failover Pair

To upgrade two units in an Active/Active failover configuration, perform the following steps.

Requirements

Perform these steps in the system execution space.

Detailed Steps

Step 1 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 2 On the primary unit, in the main ASDM application window, choose **Tools > Upgrade Software from Local Computer**.

The Upgrade Software dialog box appears.

Step 3 From the Image to Upload drop-down list, choose **ASDM**.

Step 4 In the Local File Path field, enter the local path to the file on your computer or click **Browse Local Files** to find the file on your PC.

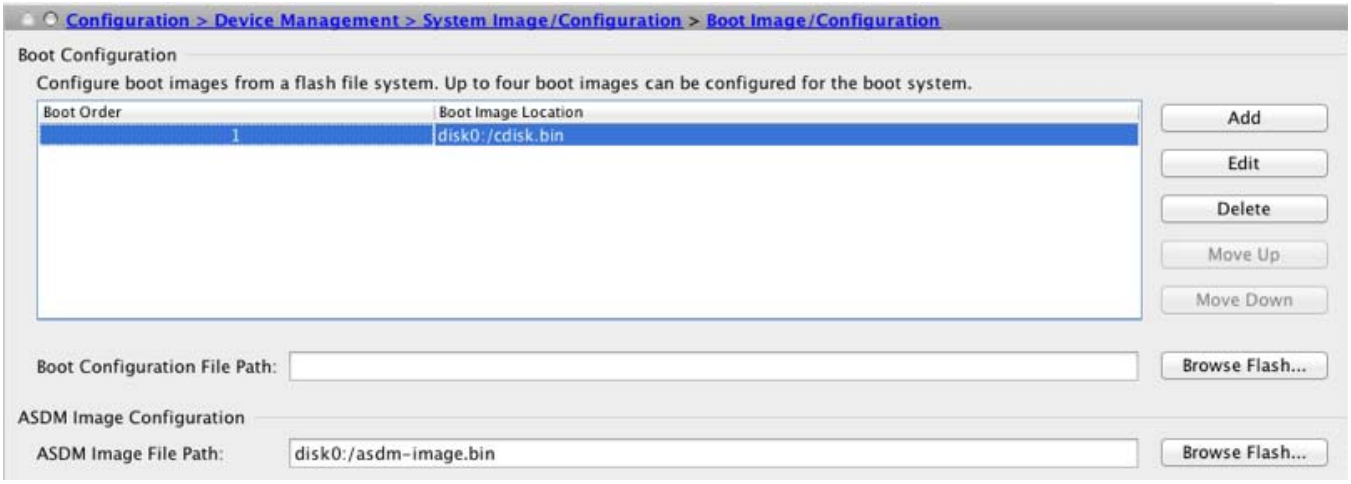
Step 5 In the Flash File System Path field, enter the path to the flash file system or click **Browse Flash** to find the directory or file in the flash file system.

Step 6 Click **Upload Image**. The uploading process might take a few minutes.

Step 7 Repeat Step 2 through Step 6, choosing **ASA** from the Image to Upload drop-down list.

Step 8 Configure the ASA to use the new images.

a. Choose **Configuration > Device Management > System/Image Configuration > Boot Image/Configuration**.



b. In the Boot Configuration table, click **Add** to add the new image (if you have fewer than four images listed); or you can choose an existing image and click **Edit** to change it to the new one.

If you do not specify an image, the ASA searches the internal flash memory for the first valid image to boot; we recommend booting from a specific image.

c. Click **Browse Flash**, choose the OS image, and click **OK**.

d. Click **OK** to return to the Boot Image/Configuration pane.

e. Make sure the new image is the first image in the table by using the **Move Up** button as needed.

f. In the ASDM Image Configuration area, click **Browse Flash**, choose the ASDM image, and click **OK**.

g. Click **Apply**.

Step 9 Choose **File > Save Running Configuration to Flash** to save your configuration changes.

Step 10 Make both failover groups active on the primary unit by choosing **Monitoring > Failover > Failover Group #**, where **#** is the number of the failover group you want to move to the primary unit, and clicking **Make Active**.

Step 11 Connect ASDM to the *secondary* unit, and upload the ASA and ASDM software according to Step 2 through Step 7, using the same file locations you used on the active unit.

Step 12 Choose **Tools > System Reload** to reload the secondary ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

Step 13 Connect ASDM to the *primary* unit, and check when the secondary unit reloads by choosing **Monitoring > Failover > System**.

Step 14 After the secondary unit comes up, force the primary unit to fail over to the secondary unit by choosing **Monitoring > Properties > Failover > System**, and clicking **Make Standby**.

Step 15 Choose **Tools > System Reload** to reload the (formerly) active ASA.

A new window appears that asks you to verify the details of the reload. Click the **Save the running configuration at the time of reload** radio button, choose a time to reload (for example, **Now**), and click **Schedule Reload**.

Once the reload is in progress, a Reload Status window appears that indicates that a reload is being performed. An option to exit ASDM is also provided.

If the failover groups are configured with Preempt Enabled, they automatically become active on their designated unit after the preempt delay has passed. If the failover groups are not configured with Preempt Enabled, you can return them to active status on their designated units using the **Monitoring > Failover > Failover Group #** pane.

Upgrading an ASA Cluster

To upgrade all units in an ASA cluster, perform the following steps on the master unit. For multiple context mode, perform these steps in the system execution space.

Detailed Steps

Step 1 Launch ASDM on the master unit.

Step 2 (If there is a configuration migration) In ASDM, back up your existing configuration using the **Tools > Backup Configurations** tool.

Step 3 In the main ASDM application window, choose **Tools > Upgrade Software from Local Computer**.

The Upgrade Software from Local Computer dialog box appears.

Step 4 Click the **All devices in the cluster** radio button.

Step 5 From the Image to Upload drop-down list, choose the new image file.

Step 6 In the Local File Path field, enter the local path to the file on your computer or click **Browse Local Files** to find the file on your PC.

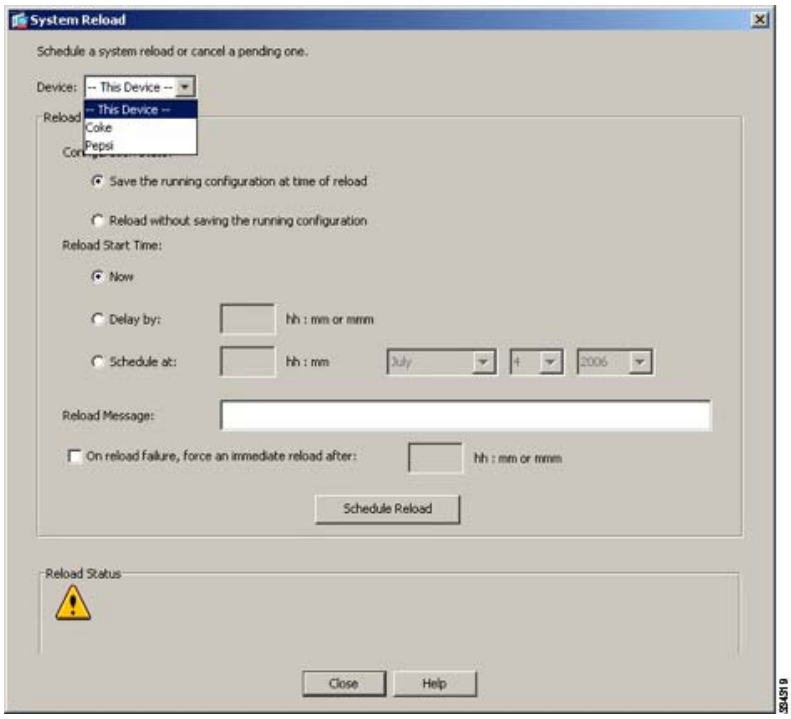
Step 7 In the Flash File System Path field, enter the path to the flash file system or click **Browse Flash** to find the directory or file in the flash file system.

Step 8 Click **Upload Image**. The uploading process might take a few minutes; make sure you wait until it is finished.

Step 9 Choose **Tools > System Reload**.

The System Reload dialog box appears.

Step 10 Reload each slave unit one at a time by choosing a slave unit name in the Device drop-down list, and then clicking **Schedule Reload** to reload the unit now.



To avoid connection loss, wait for each unit to come back up before reloading the next unit. To view when a unit rejoins the cluster, see the Monitoring > ASA Cluster > Cluster Summary pane.

Step 11 After all slave units have reloaded, reload the master unit from the System Reload dialog box by choosing **--This Device--** from the Device drop-down list.

A new election takes place for a new master unit. When the former master unit rejoins the cluster, it will be a slave.

Step 12 Quit and restart ASDM; you will reconnect to the new master unit.

Managing Files

ASDM provides a set of file management tools to help you perform basic file management tasks. The File Management tool lets you view, move, copy, and delete files stored in flash memory, transfer files, and to manage files on remote storage devices (mount points).

Note In multiple context mode, this tool is only available in the system security context.

- Accessing the File Management Tool, page 101-14
- Managing Mount Points, page 101-15
- Transferring Files, page 101-17

Accessing the File Management Tool

To use the file management tools, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > File Management**.

The File Management dialog box appears.

- The Folders pane displays the available folders on disk.
- Flash Space shows the total amount of flash memory and how much memory is available.
- The Files area displays the following information about files in the selected folder:
  - Path
  - Filename
  - Size (bytes)
  - Time Modified
  - Status, which indicates whether a selected file is designated as a boot configuration file, boot image file, ASDM image file, SVC image file, CSD image file, or APCF image file.

Step 2 Click **View** to display the selected file in your browser.

Step 3 Click **Cut** to cut the selected file for pasting to another directory.

Step 4 Click **Copy** to copy the selected file for pasting to another directory.

Step 5 Click **Paste** to paste the copied file to the selected destination.

Step 6 Click **Delete** to remove the selected file from flash memory.

Step 7 Click **Rename** to rename a file.

Step 8 Click **New Directory** to create a new directory for storing files.

Step 9 Click **File Transfer** to open the File Transfer dialog box. See the "Transferring Files" section on page 101-17 for more information.

Step 10 Click **Mount Points** to open the Manage Mount Points dialog box. See the "Managing Mount Points" section on page 101-15 for more information.

Managing Mount Points

This feature lets you configure remote storage (mount points) for network file systems using a CIFS or FTP connection. The dialog box lists the mount-point name, connection type, server name or IP address, and the enabled setting (yes or no). You can add, edit, or delete mount points. See the "Adding or Editing a CIFS/FTP Mount Point" section on page 101-15 for more information. You can access a CIFS mount point after it has been created. For more information, see Accessing a CIFS Mount Point, page 101-16.

This section includes the following topics:

- Adding or Editing a CIFS/FTP Mount Point, page 101-15
- Accessing a CIFS Mount Point, page 101-16

Adding or Editing a CIFS/FTP Mount Point

To add a CIFS mount point, perform the following steps:

Step 1 Click **Add**, and then choose **CIFS Mount Point**.

The Add CIFS Mount Point dialog box appears.

The Enable mount point check box is automatically checked, which is the default setting.

Step 2 Enter the mount-point name, server name or IP address, and share name in the applicable fields.

Step 3 In the Authentication section, enter the NT domain, username and password, and then confirm the password.

Step 4 Click **OK**.

To add an FTP mount point, perform the following steps:

Step 1 Click **Add**, and then choose **FTP Mount Point**.

The Add FTP Mount Point dialog box appears.

The Enable mount point check box is automatically checked, which is the default setting.

Step 2 Enter the mount-point name and the server name or IP address in the applicable fields.

Step 3 In the FTP Mount Options area, click the **Active Mode** or **Passive Mode** option.

Step 4 Enter the path to mount the remote storage.

Step 5 In the Authentication area, enter the NT domain, username and password, and then confirm the password.

Step 6 Click **OK**.

To edit a CIFS mount point, perform the following steps:

Step 1 Choose the CIFS mount-point you want to modify, and click **Edit**.

The Edit CIFS Mount Point dialog box appears.

Note You cannot change the CIFS mount-point name.

Step 2 Make the changes to the remaining settings, and click **OK** when you are done.

To edit an FTP mount point, perform the following steps:

Step 1 Choose the FTP mount-point you want to modify, and click **Edit**.

The Edit FTP Mount Point dialog box appears.

Note You cannot change the FTP mount-point name.

Step 2 Make the changes to the remaining settings, and click **OK** when you are done.

Accessing a CIFS Mount Point

To access a CIFS mount point after it has been created, perform the following steps:

Step 1 Start the ASA CLI.

Step 2 Create the mount by entering the **mount** *name of mount* **type cifs** command.

Step 3 Enter the **show run mount** command.

The following output appears:

Note In this example, win2003 is the name of the mount.

```
server kmmwin2003
share sharefolder
username webvpnuser2
password ********
status enable
```

Step 4 Enter the **dir** command to list all enabled mounts as subdirectories, which is similar to mounting a drive on the Windows PC. For example, in the following output, FTP2003:, FTPLINUX:, and win2K: are configured mounts.

The following is sample output from the **dir** command:

```
FTP2003: Directory or file name
FTPLINUX: Directory or file name
WIN2003: Directory or file name
all-filesystems List files on all filesystems
disk0: Directory or file name
disk1: Directory or file name
flash: Directory or file name
system: Directory or file name
win2K: Directory or file name
```

Step 5 Enter the **dir** command for that mount (for example, **dir WIN2003**), and copy files to and from flash (disk0:) to any of the listed mounts.

The following is sample output from the **dir WIN2003** command.

```
Directory of WIN2003:/

Transferring Files

The File Transfer tool lets you transfer files from either a local or remote location. You can transfer a local file on your computer or a flash file system to and from the ASA. You can transfer a remote file to and from the ASA using HTTP, HTTPS, TFTP, FTP, or SMB.

Note For the IPS SSP software module, before you download the IPS software to disk0, make sure at least 50% of the flash memory is free. When you install IPS, IPS reserves 50% of the internal flash memory for its file system.

- Transferring Files Between Local PC and Flash, page 101-18
- Transferring Files Between Remote Server and Flash, page 101-18

Transferring Files Between Local PC and Flash

To transfer files between your local computer and a flash file system, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > File Management**.

The File Management dialog box appears.

Step 2 Click the down arrow next to **File Transfer**, and then click **Between Local PC and Flash**.

The File Transfer dialog box appears.

Step 3 Select and *drag* the file(s) from either your local computer or the flash file system that you want to upload or download to the desired location. Alternatively, select the file(s) from either your local computer or the flash file system that you want to upload or download, and click the right arrow or left arrow to transfer the file(s) to the desired location.

Step 4 Click **Close** when you are done.

Transferring Files Between Remote Server and Flash

To transfer files between a remote server and a flash file system, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > File Management**.

The File Management dialog box appears.

Step 2 Click the down arrow from the File Transfer drop-down list, and then click **Between Remote Server and Flash**.

The File Transfer dialog box appears.

Step 3 To transfer a file from a remote server, click the **Remote server** option.

Step 4 Define the source file to be transferred.

a. Choose the path to the location of the file, including the IP address of the server.

Note File transfer supports IPv4 and IPv6 addresses.

b. Enter the type (if the path is FTP) or the port number (if the path is HTTP or HTTPS) of the remote server. Valid FTP types are the following:

- ap—ASCII files in passive mode
- an—ASCII files in non-passive mode
- ip—Binary image files in passive mode
- in—Binary image files in non-passive mode

Step 5 To transfer the file from the flash file system, click the **Flash file system** option.

Step 6 Enter the path to the location of the file or click **Browse Flash** to find the file location.

Step 7 In addition, you can copy a file from your startup configuration, running configuration, or an SMB file system through the CLI. For instructions about using the **copy** command, see the CLI configuration guide.

Step 8 Define the destination of the file to be transferred.

a. To transfer the file to the flash file system, choose the **Flash file system** option.

b. Enter the path to the location of the file or click **Browse Flash** to find the file location.

Step 9 To transfer a file to a remote server, choose the **Remote server** option.

a. Enter the path to the location of the file.

b. For FTP transfers, enter the type. Valid types are the following:

- ap—ASCII files in passive mode
- an—ASCII files in non-passive mode
- ip—Binary image files in passive mode
- in—Binary image files in non-passive mode

Step 10 Click **Transfer** to start the file transfer.

The Enter Username and Password dialog box appears.

Step 11 Enter the username, password, and domain (if required) for the remote server.

Step 12 Click **OK** to continue the file transfer.

The file transfer process might take a few minutes; make sure that you wait until it is finished.

Step 13 Click **Close** when the file transfer is finished.

Configuring the Images and Startup Configuration to Use

By default, the ASA boots the first application image that it finds in internal flash memory. It also boots the first ASDM image it finds in internal flash memory, or if one does not exist in this location, then in external flash memory. If you have more than one image, you should specify the image that you want to boot. For the ASDM image, if you do not specify the image to boot, even if you have only one image installed, then the ASA defines the image in the running configuration. To avoid problems with Auto Update (if configured), and to avoid the image search at each startup, you should specify the ASDM image that you want to boot in the startup configuration.

Choose **Configuration > Device Management > System Image/Configuration > Boot Image/Configuration**.

You can specify up to four local binary image files for use as the startup image, and one image located on a TFTP server for the device to boot from. If you specify an image located on a TFTP server, it must be first in the list. If the device cannot reach the TFTP server to load the image, it tries to load the next image file in the list located in flash.

If you do not specify any boot variable, the first valid image on internal flash will be chosen to boot the system. The Boot Image/Configuration pane includes the following fields:

- Boot Order—Displays the order in which binary image files will be used to boot.
- Boot Image Location—Displays the physical location and path of the boot file.
- Boot Configuration File Path—Displays the location of the configuration file.
- Add—Lets you add a flash or TFTP boot image entry to be used in the boot process. For more information, see the "Adding a Boot Image" section on page 101-20.
- Edit—Lets you edit a flash or TFTP boot image entry.

- Delete—Deletes the selected flash or TFTP boot image entry.
- Move Up—Moves the selected flash or TFTP boot image entry up in the boot order.
- Move Down—Moves the selected flash or TFTP boot image entry down in the boot order.
- Browse Flash—Lets you specify the location of a boot image or configuration file.
- ASDM Image File Path—Displays the location of the configuration file to use at startup.

Adding a Boot Image

To add a boot image entry to the boot order list, click **Add** in the Boot Image/Configuration pane.

You can select a flash or TFTP image to add a boot image to the boot order list.

Either type the path of the image, or click **Browse Flash** to specify the image location. You must type the path of the image location if you are using TFTP.

- Flash Image—Select to add a boot image located in the flash file system.
  - Path—Specify the path of the boot image in the flash file system.
- TFTP Image—Select to add a boot image located on a TFTP server.
  - [Path]—Enter the path of the boot image file on the TFTP server, including the IP address of the server.
- OK—Accepts changes and returns to the previous pane.
- Cancel—Discards changes and returns to the previous pane.
- Help—Provides more information.

Backing Up and Restoring Configurations or Other Files

The Backup and Restore features options on the Tools menu let you back up and restore the ASA running configuration, startup configuration, installed add-on images, and SSL VPN Client images and profiles.

The Backup Configurations screen on the ASDM lets you choose the file types to back up, compresses them into a single zip file, then transfer the zip file to the directory that you choose on your computer. Similarly, to restore files, you choose the source zip file on your computer and then choose the file types to be restored.

Note These tools are only available for single context mode.

- Backing Up Configurations, page 101-21
- Backing Up the Local CA Server, page 101-24
- Restoring Configurations, page 101-25
- Saving the Running Configuration to a TFTP Server, page 101-27

Backing Up Configurations

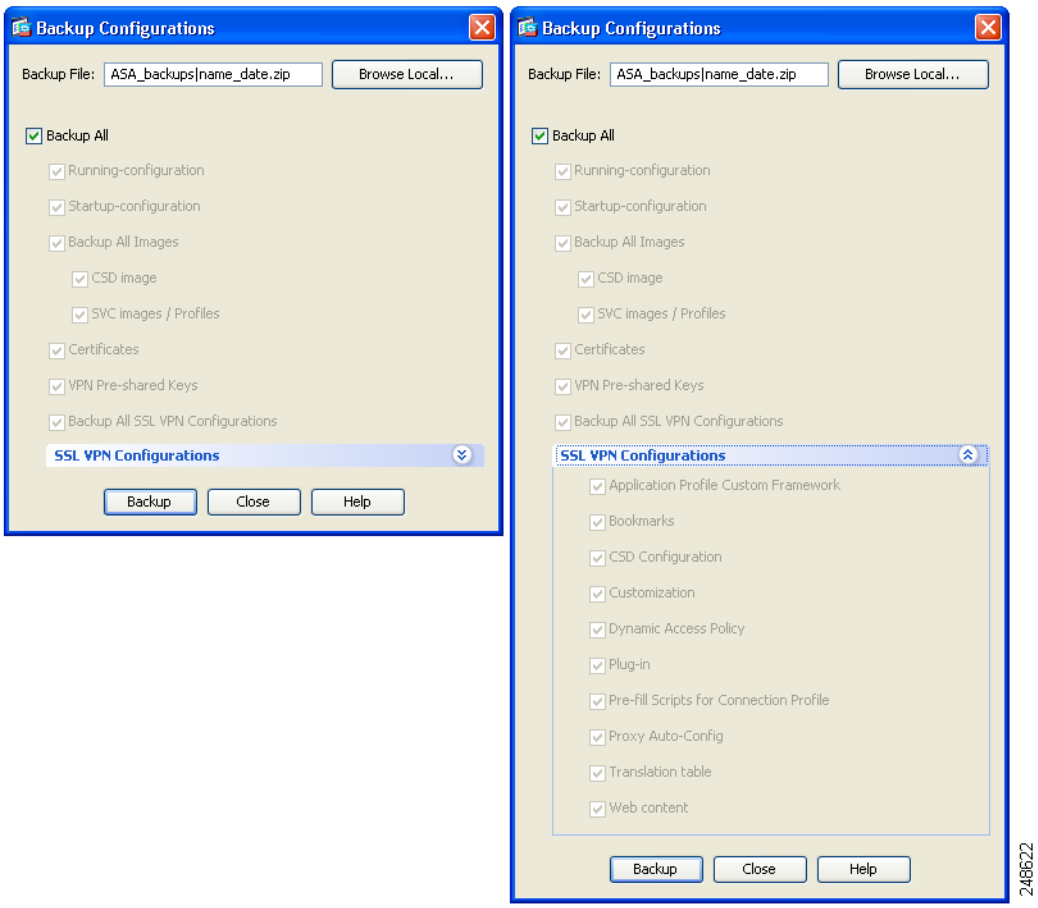
This procedure explains how to back up configurations and images to a .zip file and transfer it to your local computer.

Caution If you have set a master passphrase for the ASA, then you will need that master passphrase to restore the backup configuration that you create with this procedure. If you do not know the master passphrase for the ASA, see the "Configuring the Master Passphrase" section on page 21-4 to learn how to reset it before continuing with the backup.

Step 1 Create a folder on your computer to store backup files so they will be easy to find in case you need to restore them later.

Step 2 Choose **Tools > Backup Configurations**.

The Backup Configurations dialog box appears. Click the down arrow in the **SSL VPN Configuration** area to view the backup options for SSL VPN configurations. By default, all configuration files are checked and will be backed up if they are available. If you want to back up all of the files in the list, go to Step 5.



Step 3 Uncheck the **Backup All** check box if you want to select the configurations to back up.

Step 4 Check the check box next to the option that you want to back up.

Step 5 Click **Browse Local to specify a directory and file name for the backup .zip file.**

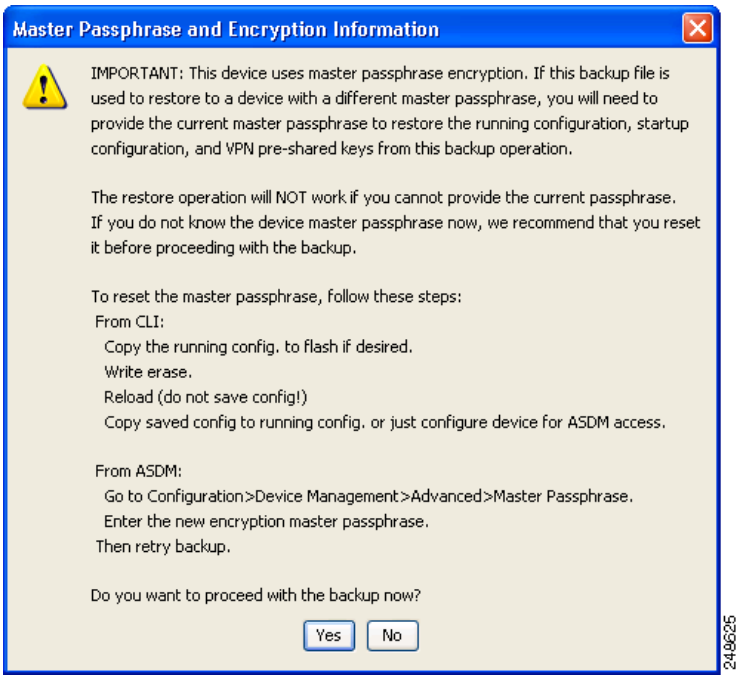
Step 6 In the Select dialog box, choose the directory in which you want to store the backup file.

Step 7 Click **Select**. The path appears in the Backup File field.

Step 8 Enter the name of the destination backup file after the directory path. The backup file name must be between 3 and 232 characters long.

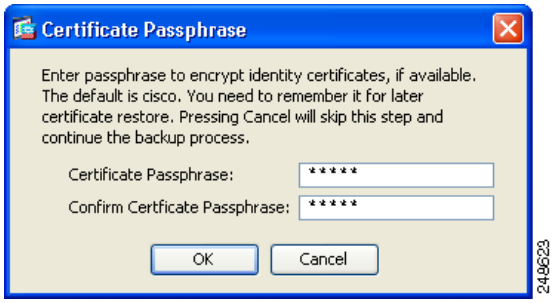
Step 9 Click **Backup**. The backup proceeds immediately unless you are backing up certificates or the ASA is using a master passphrase.

Step 10 If you have configured and enabled a master passphrase on your ASA, you receive a warning message with a suggestion to change the master passphrase, if you do not know it, before proceeding with the backup. Click **Yes** to proceed with the backup if you know the master passphrase. The backup proceeds immediately unless you are backing up identity certificates.



Step 11 If you are backing up an identity certificate, you are asked to enter a separate passphrase to be used for encoding the certificates in PKCS12 format. You can enter a passphrase or skip this step.

Note Identify certificates are backed up by this process; however, certificate authority certificates are not backed up. For instructions on backing up CA certificates, see "Backing Up the Local CA Server" section on page 101-24.

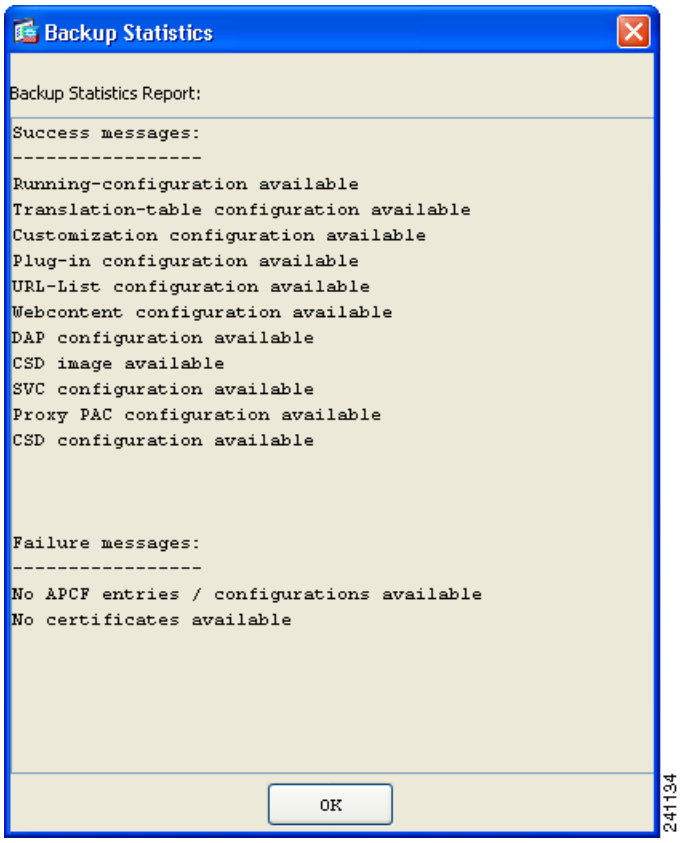


- To encrypt certificates, enter and confirm your certificate passphrase in the Certificate Passphrase dialog box and click **OK**. You will need to remember the password you enter in this dialog box when restoring the certificates.
- Clicking **Cancel** skips the step and does not back up certificates.

After clicking OK or cancel, the backup begins immediately.

Step 12 After the backup is complete, the status window closes and the Backup Statistics dialog box appears to provide success and failure messages.

Note Backup "failure messages" are most likely caused by the lack of an existing configuration for the types indicated.



Step 13 Click **OK** to close the Backup Statistics dialog box.

Backing Up the Local CA Server

When you do a ASDM backup, it does not include the local CA server database, so you are not backing up the CA certificates stored on the server. If you want to back up the local CA server, use this manual process with the ASA CLI:

Step 1 Enter the **show run crypto ca server** command.

```
crypto ca server
 keysize server 2048
 subject-name-default OU=aa,O=Cisco,ST=ca,
 issuer-name CN=xxx,OU=yyy,O=Cisco,L=Bxb,St=Mass
 smtp from-address abcd@cisco.com
 publish-crl inside 80
 publish-crl outside 80
```

Step 2 Use the **crypto ca import** command to import the local CA PKCS12 file to create the LOCAL-CA-SERVER trustpoint and to restore the keypair.

```
crypto ca import LOCAL-CA-SERVER pkcs12 <passphrase> (paste the pkcs12
base64 data here)
```

Note Be sure to use the exact name “LOCAL-CA-SERVER” for this step.

Step 3 If the LOCAL-CA-SERVER directory does not exist, you need to create it by entering **mkdir LOCAL-CA-SERVER**.

Step 4 Copy the local CA files into the LOCAL-CA-SERVER directory.

```
copy ftp://10.10.1.1/CA-backup/LOCAL-CA-SERVER.ser
disk0:/LOCAL-CA-SERVER/

copy ftp://10.10.1.1/CA-backup/LOCAL-CA-SERVER.cdb
disk0:/LOCAL-CA-SERVER/

copy ftp://10.10.1.1/CA-backup/LOCAL-CA-SERVER.udb
disk0:/LOCAL-CA-SERVER/

copy ftp://10.10.1.1/CA-backup/LOCAL-CA-SERVER.crl
disk0:/LOCAL-CA-SERVER/

copy ftp://10.10.1.1/CA-backup/LOCAL-CA-SERVER.p12
disk0:/LOCAL-CA-SERVER/
```

Step 5 Enter the **crypto ca server** command to enable the local CA server

```
crypto ca server
 no shutdown
```

Step 6 Enter the **show crypto ca server** command to check that the local CA server is up and running.

Step 7 Save the configuration.

Restoring Configurations

You can specify configurations and images to restore from a zip file on your local computer.

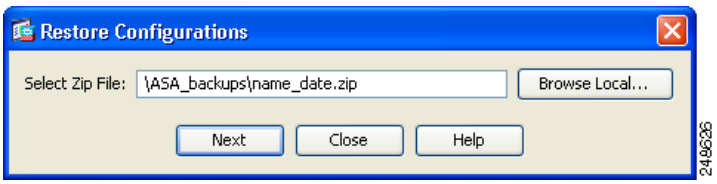
Before proceeding, note these other restrictions:

- The zip file that you restore must be created by choosing the Tools > Backup Configurations option.
- If you performed the backup with the master passphrase enabled, then you will need that master passphrase in order to restore the running configuration, start-up configuration, and VPN pre-shared keys from the backup you created. If you do not know the master passphrase for the ASA, those items will not be restored during the restore process. See the "Configuring the Master Passphrase" section on page 21-4 for more information on master passphrases.
- If you specified a certificate passphrase during the backup, you will be asked to provide that passphrase in order to restore the certificates. The default passphrase is `cisco`.
- The DAP configuration may depend on a specific running configuration, URL list, and CSD configuration.
- The CSD configuration may depend on the version of the CSD image.
- You can restore components, images, and configurations using backups made from the same ASA type. You must start with a basic configuration that allows ASDM access.

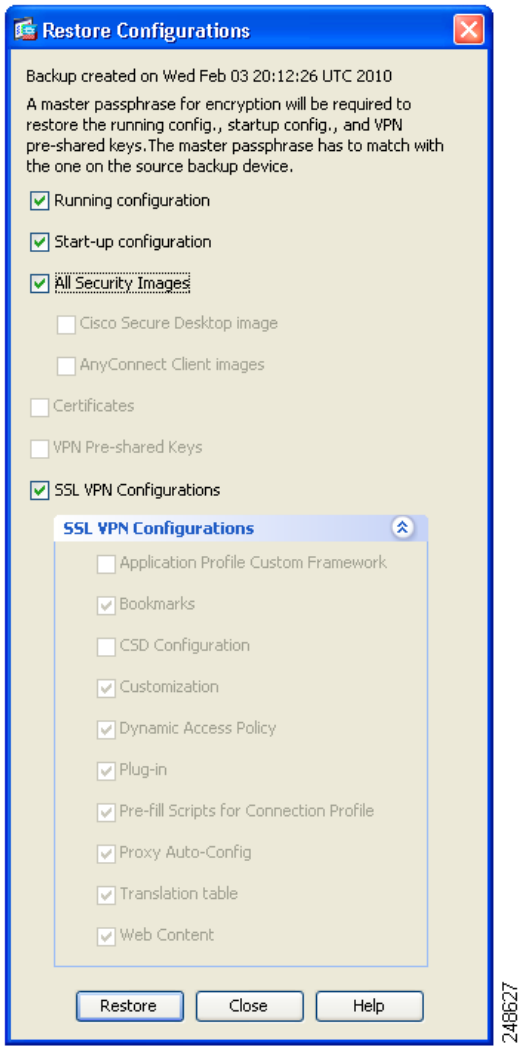
To restore selected elements of the ASA configuration, Cisco Secure Desktop image, or SSL VPN Client images and profiles, perform the following steps:

Step 1 Choose **Tools > Restore Configurations**.

Step 2 In the Restore Configurations dialog box, click **Browse Local Directory**, choose the zip file on your local computer that contains the configuration to restore, then click **Select**. The path and the zip filename appear in the Local File field.



Step 3 Click **Next**. The second Restore Configuration dialog box appears. Check the check boxes next to the configurations that you want to restore. All available SSL VPN configurations are selected by default.



Step 4 Click **Restore**.

Step 5 If you specified a certificate passphrase with which to encrypt the certificates when you created the backup file, ASDM prompts you to enter the passphrase.

Step 6 If you chose to restore the running configuration, you are asked if you want to merge the running configuration, replace the running configuration, or skip this part of the restoration process.

- Merging configurations combines the current running configuration and the backed-up running configuration.

- Replacing the running configuration uses the backed-up running configuration only.
- Skipping the step does not restore the backed-up running configuration.

ASDM displays a status dialog box until the restore operation is finished.

Step 7 If you replaced or merged the running configuration, close ASDM and restart it. If you did not restore the running configuration or the running configuration, refresh the ASDM session for the changes to take effect.

Saving the Running Configuration to a TFTP Server

This feature stores a copy of the current running configuration file on a TFTP server.

To save the running configuration to a TFTP server, perform the following steps:

Step 1 In the main ASDM application window, choose **File > Save Running Configuration to TFTP Server**.

The Save Running Configuration to TFTP Server dialog box appears.

Step 2 Enter the TFTP server IP address and file path on the TFTP server in which the configuration file will be saved, and then click **Save Configuration**.

Note To configure default TFTP settings, choose **Configuration > Device Management > Management Access > File Access > TFTP Client**. After you have configured this setting, the TFTP server IP address and file path on the TFTP server appear automatically in this dialog box.

Scheduling a System Restart

The System Reload tool lets you schedule a system restart or cancel a pending restart.

To schedule a system restart, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > System Reload**.

Step 2 In the Reload Scheduling area, define the following settings:

a. For the Configuration State, choose either to save or discard the running configuration at restart time.

b. For the Reload Start Time, choose from the following options:

- Click **Now** to perform an immediate restart.
- Click **Delay by** to delay the restart by a specified amount of time. Enter the time before the restart begins in hours and minutes or only minutes.
- Click **Schedule at** to schedule the restart to occur at a specific time and date. Enter the time of day the restart is to occur, and select the date of the scheduled restart.

c. In the Reload Message field, enter a message to send to open instances of ASDM at restart time.

d. Check the **On reload failure force immediate reload after** check box to show the amount of time elapsed in hours and minutes or only minutes before a restart is attempted again.

e. Click **Schedule Reload** to schedule the restart as configured.

The Reload Status area displays the status of the restart.

Step 3 Choose one of the following:

- Click **Cancel Reload** to stop a scheduled restart.
- Click **Refresh** to refresh the Reload Status display after a scheduled restart is finished.
- Click **Details** to display the results of a scheduled restart.

Downgrading Your Software

When you upgrade to Version 8.3, your configuration is migrated. The old configuration is automatically stored in flash memory. For example, when you upgrade from Version 8.2(1) to 8.3(1), the old 8.2(1) configuration is stored in flash memory in a file called 8_2_1_0_startup_cfg.sav.

Note You must manually restore the old configuration before downgrading.

This section describes how to downgrade and includes the following topics:

- Information About Activation Key Compatibility, page 101-28
- Performing the Downgrade, page 101-29

Information About Activation Key Compatibility

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier versions—After you upgrade, if you activate additional feature licenses that were introduced *before 8.2*, the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in Version 8.2 or later versions, the activation key is not backwards compatible. If you have an incompatible license key, see the following guidelines:
  - If you previously entered an activation key in an earlier version, the ASA uses that key (without any of the new licenses you activated in Version 8.2 or later versions).
  - If you have a new system and do not have an earlier activation key, you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier versions—Version 8.3 introduced more robust time-based key usage as well as failover license changes:
  - If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive.
  - If you have mismatched licenses on a failover pair, downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.

Performing the Downgrade

See the "The Backup and Restore features options on the Tools menu let you back up and restore the ASA running configuration, startup configuration, installed add-on images, and SSL VPN Client images and profiles." section on page 101-20 for more information about configuration migration.

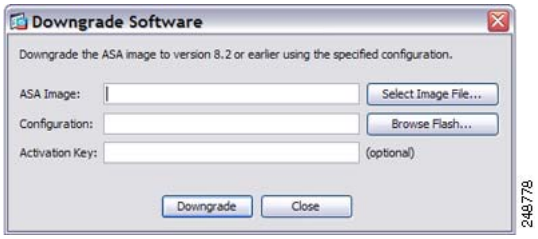
To downgrade from Version 8.3, perform the following steps:

Detailed Steps

Step 1 Choose **Tools > Downgrade Software**.

The Downgrade Software dialog box appears.

Figure 101-1 Downgrade Software



Step 2 For the ASA Image, click **Select Image File**.

The Browse File Locations dialog box appears.

Step 3 Click one of the following radio buttons:

- **Remote Server**—Choose **ftp**, **smb**, or **http** from the drop-down list, and type the path to the old image file.
- **Flash File System**—Click **Browse Flash** to choose the old image file on the local flash file system.

Step 4 For the Configuration, click **Browse Flash** to choose the pre-migration configuration file. (By default this was saved on disk0).

Step 5 (Optional) In the Activation Key field, enter the old activation key if you need to revert to a pre-8.3 activation key.

See the "Information About Activation Key Compatibility" section on page 101-28 for more information.

Step 6 Click **Downgrade**.

This tool is a shortcut for completing the following functions:

1. Clearing the boot image configuration (**clear configure boot**).
2. Setting the boot image to be the old image (**boot system**).
3. (Optional) Entering a new activation key (**activation-key**).
4. Saving the running configuration to startup (**write memory**). This sets the BOOT environment variable to the old image, so when you reload, the old image is loaded.
5. Copying the old configuration to the startup configuration (**copy** *old_config_url* **startup-config**).
6. Reloading (**reload**).

Configuring Auto Update

This section includes the following topics:

- Information About Auto Update, page 101-30
- Configuring Communication with an Auto Update Server, page 101-31

Information About Auto Update

Auto Update is a protocol specification that allows an Auto Update Server to download configurations and software images to many ASAs and can provide basic monitoring of the ASAs from a central location.

The ASA can be configured as either a client or a server. As an Auto Update client, it periodically polls the Auto Update Server for updates to software images and configuration files. As an Auto Update Server, it issues updates for ASAs configured as Auto Update clients.

Auto Update is useful in solving many issues facing administrators for ASA management, such as:

- Overcoming dynamic addressing and NAT challenges.
- Committing configuration changes in one action.
- Providing a reliable method for updating software.
- Leveraging well-understood methods for high availability (failover).
- Providing flexibility with an open interface.
- Simplifying security solutions for Service Provider environments.

The Auto Update specification provides the infrastructure necessary for remote management applications to download ASA configurations, software images, and to perform basic monitoring from a centralized location or multiple locations.

The Auto Update specification allows the Auto Update server to either push configuration information and send requests for information to the ASA, or to pull configuration information by having the ASA periodically poll the Auto Update server. The Auto Update server can also send a command to the ASA to send an immediate polling request at any time. Communication between the Auto Update server and the ASA requires a communications path and local CLI configuration on each ASA.

Guidelines and Limitations

- If the ASA configuration is updated from an Auto Update server, ASDM is not notified. You must choose **Refresh** or **File > Refresh ASDM with the Running Configuration on the Device** to obtain the latest configuration, and any changes to the configuration made in ASDM will be lost.
- If HTTPS is chosen as the protocol to communicate with the Auto Update server, the ASA uses SSL, which requires the ASA to have a DES or 3DES license.
- Auto Update is supported in single context mode only.

Configuring Communication with an Auto Update Server

Detailed Steps

To configure the Auto Update feature, choose **Configuration > Device Management > System Image/Configuration > Auto Update**. The Auto Update pane consists of an Auto Update Servers table and two areas: the Timeout area and the Polling area.

The Auto Update Servers table lets you view the parameters of previously configured Auto Update servers. The ASA polls the server listed at the top of the table first. To change the order of the servers in the table, click **Move Up** or **Move Down**. The Auto Update Servers table includes the following columns:

- Server—The name or IP address of the Auto Update server.
- User Name—The user name used to access the Auto Update server.
- Interface—The interface used when sending requests to the Auto Update server.
- Verify Certificate—Indicates whether the ASA checks the certificate returned by the Auto Update server with the CA root certificates. The Auto Update server and the ASA must use the same CA.

Double-clicking any of the rows in the Auto Update Server table opens the Edit Auto Update Server dialog box, in which you can modify the Auto Update server parameters. These changes are immediately reflected in the table, but you must click **Apply** to save them to the configuration.

The Timeout area lets you set the amount of time the ASA waits for the Auto Update server to time out. The Timeout area includes the following fields:

- Enable Timeout Period—Check to enable the ASA to time out if no response is received from the Auto Update server.
- Timeout Period (Minutes)—Enter the number of minutes the ASA will wait to time out if no response is received from the Auto Update server.

The Polling area lets you configure how often the ASA will poll for information from the Auto Update server. The Polling area includes the following fields:

- Polling Period (minutes)—The number of minutes the ASA will wait to poll the Auto Update server for new information.
- Poll on Specified Days—Allows you to specify a polling schedule.
- Set Polling Schedule—Displays the Set Polling Schedule dialog box where you can configure the days and time-of-day to poll the Auto Update server.
- Retry Period (minutes)—The number of minutes the ASA will wait to poll the Auto Update server for new information if the attempt to poll the server fails.
- Retry Count—The number of times the ASA will attempt to retry to poll the Auto Update server for new information.

Adding or Editing an Auto Update Server

The Add/Edit Auto Update Server dialog box includes the following fields:

- URL—The protocol that the Auto Update server uses to communicate with the ASA, either HTTP or HTTPS, and the path to the Auto Update server.
- Interface—The interface to use when sending requests to the Auto Update server.
- Verify Certificate—Click to enable the ASA to verify the certificate returned by the Auto Update server with the CA root certificates. The Auto Update server and the ASA must use the same CA.

The User area includes the following fields:

- User Name (Optional)—Enter the user name needed to access the Auto Update server.
- Password—Enter the user password for the Auto Update server.
- Confirm Password—Reenter the user password for the Auto Update server.
- Use Device ID to uniquely identify the ASA—Enables authentication using a device ID. The device ID is used to uniquely identify the ASA to the Auto Update server.
- Device ID—Type of device ID to use.
  - Hostname—The name of the host.
  - Serial Number—The device serial number.
  - IP Address on interface—The IP address of the selected interface, used to uniquely identify the ASA to the Auto Update server.
  - MAC Address on interface—The MAC address of the selected interface, used to uniquely identify the ASA to the Auto Update server.
  - User-defined value—A unique user ID.

Setting the Polling Schedule

The Set Polling Schedule dialog box lets you configure specific days and the time-of-day for the ASA to poll the Auto Update server.

The Set Polling Schedule dialog box includes the following fields:

Days of the Week—Check the days of the week that you want the ASA to poll the Auto Update server.

The Daily Update pane group lets you configure the time of day when you want the ASA to poll the Auto Update server, and includes the following fields:

- Start Time—Enter the hour and minute to begin the Auto Update poll.
- Enable randomization—Check to enable the ASA to randomly choose a time to poll the Auto Update server.

Troubleshooting

This chapter describes how to troubleshoot the ASA and includes the following sections:

- Configuring and Running Captures with the Packet Capture Wizard, page 102-1

Configuring and Running Captures with the Packet Capture Wizard

You can use the Packet Capture Wizard to configure and run captures for troubleshooting errors. The captures can use access lists to limit the type of traffic captured, the source and destination addresses and ports, and one or more interfaces. The wizard runs one capture on each of the ingress and egress interfaces. You can save the captures on your PC to examine them in a packet analyzer.

Note This tool does not support clientless SSL VPN capture.

To configure and run captures, perform the following steps:

Step 1 In the main ASDM application window, choose **Wizards > Packet Capture Wizard**.

The Overview of Packet Capture screen appears, with a list of the tasks through which the wizard will guide you to complete. Those tasks include the following:

- Selecting an ingress interface.
- Selecting an egress interface.
- Setting the buffer parameters.
- Running the captures.
- Saving the captures to your PC (optional).

Step 2 Click **Next**.

In a clustering environment, the Cluster Option screen appears. Go to Step 3.

Note For more information about clustering, see Chapter 10, “Configuring a Cluster of ASAs.”

In a non-clustering environment, the Ingress Traffic Selector screen appears. Go to Step 4.

Step 3 In the Cluster Option screen, choose one of the following options for running a capture: **This device only** or **The whole cluster**, then click **Next**.

Step 4 Choose the ingress interface from the drop-down list.

Step 5 In the Packet Match Criteria area, do one of the following:

- To specify the access list to use for matching packets, click the **Specify access-list** radio button, and then choose the access list from the Select access list drop-down list. To add a previously configured access list to the current drop-down list, click **Manage** to display the ACL Manager pane. Choose an access list, and click **OK**.
- To specify packets parameters, click the **Specify Packet Parameters** radio button.

Step 6 Click **Next** to display the Ingress Traffic Selector screen. For more information, see the "Ingress Traffic Selector" section on page 102-3.

Step 7 Enter the source host IP address and choose the network IP address from the drop-down list.

Step 8 Enter the destination host IP address and choose the network IP address from the drop-down list.

Step 9 Choose the protocol type to capture from the drop-down list. Available protocol types to capture are ah, eigrp, esp, gre, icmp, icmp6, igmp, igrp, ip, ipinip, nos, ospf, pcp, pim, snp, tcp, or udp.

Step 10 Click **Next** to display the Egress Traffic Selector screen. For more information, see the "Egress Traffic Selector" section on page 102-4.

Step 11 Choose the egress interface from the drop-down list.

Step 12 Enter the source host IP address and choose the network IP address from the drop-down list.

Step 13 Enter the destination host IP address and choose the network IP address from the drop-down list.

Note The source port services, destination port services, and ICMP type are read-only and are based on the choices that you made in the Ingress Traffic Selector screen.

Step 14 Click **Next** to display the Buffers & Captures screen. For more information, see the "Buffers" section on page 102-4.

Step 15 In the Capture Parameters area, to obtain the latest capture every 10 seconds automatically, check the **Get capture every 10 seconds** check box. By default, this capture uses the circular buffer.

Step 16 In the Buffer Parameters area, you specify the buffer size and packet size. The buffer size is the maximum amount of memory that the capture can use to store packets. The packet size is the longest packet that the capture can hold. We recommend that you use the longest packet size to capture as much information as possible.

a. Enter the packet size. The valid size ranges from 14 - 1522 bytes.

b. Enter the buffer size. The valid size ranges from 1534 - 33554432 bytes.

c. Check the **Use circular buffer** check box to store captured packets.

Note When you choose this setting, if all the buffer storage is used, the capture starts overwriting the oldest packets.

Step 17 Click **Next** to display the Summary screen, which shows the cluster options for all units in the cluster (if you are using clustering), traffic selectors, and buffer parameters that you have entered. For more information, see the "Summary" section on page 102-4.

Step 18 Click **Next** to display the Run Captures screen, and then click **Start** to begin capturing packets. Click **Stop** to end the capture. For more information, see the "Run Captures" section on page 102-4. If you are using clustering, go to Step 20.

Step 19 Click **Get Capture Buffer** to determine how much buffer space you have remaining. Click **Clear Buffer on Device** to remove the current content and allow room in the buffer to capture more packets.

Step 20 In a clustering environment, on the Run Captures screen, perform one or more of the following steps:

- Click **Get Cluster Capture Summary** to view a summary of packet capture information for all units in the cluster, followed by packet capture information for each unit.
- Click **Get Capture Buffer** to determine how much buffer space you have remaining in each unit of the cluster. The Capture Buffer from Device dialog box appears.
- Click **Clear Buffer on Device** to remove the current content for one or all of the units in a cluster and allow room in the buffer to capture more packets.

Step 21 Click **Save captures** to display the Save Capture dialog box. You have the option of saving either the ingress capture, the egress capture, or both. For more information, see the "Save Captures" section on page 102-5.

Step 22 To save the ingress packet capture, click **Save Ingress Capture** to display the Save capture file dialog box. Specify the storage location on your PC, and click **Save**.

Step 23 Click **Launch Network Sniffer Application** to start the packet analysis application specified in Tools > Preferences for analyzing the ingress capture.

Step 24 To save the egress packet capture, click **Save Egress Capture** to display the Save capture file dialog box. Specify the storage location on your PC, and click **Save**.

Step 25 Click **Launch Network Sniffer Application** to start the packet analysis application specified in Tools > Preferences for analyzing the egress capture.

Step 26 Click **Close,** then click **Finish** to exit the wizard.

Ingress Traffic Selector

To configure the ingress interface, source and destination hosts or networks, and the protocol for packet capture, perform the following steps:

Step 1 Enter the ingress interface name.

Step 2 Enter the ingress source host and network.

Step 3 Enter the ingress destination host and network.

Step 4 Enter the protocol type to capture. Available protocols are ah, eigrp, esp, gre, icmp, icmp6, igmp, igrp, ip, ipinip, nos, ospf, pcp, pim, snp, tcp, or udp.

a. Enter the ICMP type for ICMP only. Available types include all, alternate address, conversion-error, echo, echo-reply, information-reply, information-request, mask-reply, mask-request, mobile-redirect, parameter-problem, redirect, router-advertisement, router-solicitation, source-quench, time-exceeded, timestamp-reply, timestamp-request, traceroute, or unreachable.

b. Specify the source and destination port services for the TCP and UDP protocols only. Available options include the following:

– To include all services, choose All Services.

- To include a service group, choose Service Groups.
- To include a specific service, choose one of the following: aol, bgp, chargen, cifx, citrix-ica, ctiqbe, daytime, discard, domain, echo, exec, finger, ftp, ftp-data, gopher, h323, hostname, http, https, ident, imap4, irc, kerberos, klogin, kshell, ldap, ldaps, login, lotusnotes, lpd, netbios-ssn, nntp, pcanywhere-data, pim-auto-rp, pop2, pop3, pptp, rsh, rtsp, sip, smtp, sqlnet, ssh, sunrpc, tacacs, talk, telnet, uucp, or whois.

Egress Traffic Selector

To configure the egress interface, source and destination hosts/networks, and source and destination port services for packet capture, perform the following steps:

Step 1 Enter the egress interface name.

Step 2 Enter the egress source host and network.

Step 3 Enter the egress destination host and network.

The protocol type selected during the ingress configuration is already listed.

Buffers

To configure the packet size, buffer size, and use of the circular buffer for packet capture, perform the following steps.

Step 1 Enter the longest packet that the capture can hold. Use the longest size available to capture as much information as possible.

Step 2 Enter the maximum amount of memory that the capture can use to store packets.

Step 3 Use the circular buffer to store packets. When the circular buffer has used all of the buffer storage, the capture will overwrite the oldest packets first.

Summary

The Summary screen shows the cluster options (if you are using clustering), traffic selectors, and the buffer parameters for the packet capture selected in the previous wizard screens.

Run Captures

To start and stop the capture session, view the capture buffer, launch a network analyzer application, save packet captures, and clear the buffer, perform the following steps:

Step 1 To begin the packet capture session on a selected interface, click **Start**.

Step 2 To stop the packet capture session on a selected interface, click **Stop**.

Step 3 To obtain a snapshot of the captured packets on the interface, click **Get Capture Buffer**.

Step 4 To show the capture buffer on the ingress interface, click **Ingress**.

Step 5 To show the capture buffer on the egress interface, click **Egress**.

Step 6 To clear the buffer on the device, click **Clear Buffer on Device**.

Step 7 To start the packet analysis application for analyzing the ingress capture or the egress capture specified in Tools > Preferences, click **Launch Network Sniffer Application**.

Step 8 To save the ingress and egress captures in either ASCII or PCAP format, click **Save Captures**.

Save Captures

To save the ingress and egress packet captures to ASCII or PCAP file format for further packet analysis, perform the following steps:

Step 1 To save the capture buffer in ASCII format, click **ASCII**.

Step 2 To save the capture buffer in PCAP format, click **PCAP**.

Step 3 To specify a file in which to save the ingress packet capture, click **Save ingress capture**.

Step 4 To specify a file in which to save the egress packet capture, click **Save egress capture**.

PART 18

Reference

Addresses, Protocols, and Ports

This appendix provides a quick reference for IP addresses, protocols, and applications. This appendix includes the following sections:

- IPv4 Addresses and Subnet Masks, page A-1
- IPv6 Addresses, page A-5
- Protocols and Applications, page A-11
- TCP and UDP Ports, page A-11
- Local Ports and Protocols, page A-14
- ICMP Types, page A-15

IPv4 Addresses and Subnet Masks

This section describes how to use IPv4 addresses in the ASA. An IPv4 address is a 32-bit number written in dotted-decimal notation: four 8-bit fields (octets) converted from binary to decimal numbers, separated by dots. The first part of an IP address identifies the network on which the host resides, while the second part identifies the particular host on the given network. The network number field is called the network prefix. All hosts on a given network share the same network prefix but must have a unique host number. In classful IP, the class of the address determines the boundary between the network prefix and the host number.

This section includes the following topics:

- Classes, page A-1
- Private Networks, page A-2
- Subnet Masks, page A-2

Classes

IP host addresses are divided into three different address classes: Class A, Class B, and Class C. Each class fixes the boundary between the network prefix and the host number at a different point within the 32-bit address. Class D addresses are reserved for multicast IP.

- Class A addresses (1.xxx.xxx.xxx through 126.xxx.xxx.xxx) use only the first octet as the network prefix.

- Class B addresses (128.0.xxx.xxx through 191.255.xxx.xxx) use the first two octets as the network prefix.
- Class C addresses (192.0.0.xxx through 223.255.255.xxx) use the first three octets as the network prefix.

Because Class A addresses have 16,777,214 host addresses, and Class B addresses 65,534 hosts, you can use subnet masking to break these huge networks into smaller subnets.

Private Networks

If you need large numbers of addresses on your network, and they do not need to be routed on the Internet, you can use private IP addresses that the Internet Assigned Numbers Authority (IANA) recommends (see RFC 1918). The following address ranges are designated as private networks that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

Subnet Masks

A subnet mask lets you convert a single Class A, B, or C network into multiple networks. With a subnet mask, you can create an extended network prefix that adds bits from the host number to the network prefix. For example, a Class C network prefix always consists of the first three octets of the IP address. But a Class C extended network prefix uses part of the fourth octet as well.

Subnet masking is easy to understand if you use binary notation instead of dotted decimal. The bits in the subnet mask have a one-to-one correspondence with the Internet address:

- The bits are set to 1 if the corresponding bit in the IP address is part of the extended network prefix.
- The bits are set to 0 if the bit is part of the host number.

Example 1: If you have the Class B address 129.10.0.0 and you want to use the entire third octet as part of the extended network prefix instead of the host number, then you must specify a subnet mask of 11111111.11111111.11111111.00000000. This subnet mask converts the Class B address into the equivalent of a Class C address, where the host number consists of the last octet only.

Example 2: If you want to use only part of the third octet for the extended network prefix, then you must specify a subnet mask like 11111111.11111111.11111000.00000000, which uses only 5 bits of the third octet for the extended network prefix.

You can write a subnet mask as a dotted-decimal mask or as a */bits* (“slash *bits*”) mask. In Example 1, for a dotted-decimal mask, you convert each binary octet into a decimal number: 255.255.255.0. For a */bits* mask, you add the number of 1s: /24. In Example 2, the decimal number is 255.255.248.0 and the /bits is /21.

You can also supernet multiple Class C networks into a larger network by using part of the third octet for the extended network prefix. For example, 192.168.0.0/20.

This section includes the following topics:

- Determining the Subnet Mask, page A-3
- Determining the Address to Use with the Subnet Mask, page A-3

Determining the Subnet Mask

To determine the subnet mask based on how many hosts you want, see Table A-1.

Table A-1 Hosts, Bits, and Dotted-Decimal Masks

Hosts[1]	/Bits Mask	Dotted-Decimal Mask
16,777,216	/8	255.0.0.0 Class A Network
65,536	/16	255.255.0.0 Class B Network
32,768	/17	255.255.128.0
16,384	/18	255.255.192.0
8192	/19	255.255.224.0
4096	/20	255.255.240.0
2048	/21	255.255.248.0
1024	/22	255.255.252.0
512	/23	255.255.254.0
256	/24	255.255.255.0 Class C Network
128	/25	255.255.255.128
64	/26	255.255.255.192
32	/27	255.255.255.224
16	/28	255.255.255.240
8	/29	255.255.255.248
4	/30	255.255.255.252
Do not use	/31	255.255.255.254
1	/32	255.255.255.255 Single Host Address

1. The first and last number of a subnet are reserved, except for /32, which identifies a single host.

Determining the Address to Use with the Subnet Mask

The following sections describe how to determine the network address to use with a subnet mask for a Class C-size and a Class B-size network. This section includes the following topics:

- Class C-Size Network Address, page A-3
- Class B-Size Network Address, page A-4

Class C-Size Network Address

For a network between 2 and 254 hosts, the fourth octet falls on a multiple of the number of host addresses, starting with 0. For example, Table A-2 shows the 8-host subnets (/29) of 192.168.0.x.

Table A-2 Class C-Size Network Address

Subnet with Mask /29 (255.255.255.248)	Address Range[1]
192.168.0.0	192.168.0.0 to 192.168.0.7
192.168.0.8	192.168.0.8 to 192.168.0.15

Table A-2 Class C-Size Network Address (continued)

Subnet with Mask /29 (255.255.255.248)	Address Range[1]
192.168.0.16	192.168.0.16 to 192.168.0.31
—	—
192.168.0.248	192.168.0.248 to 192.168.0.255

1. The first and last address of a subnet are reserved. In the first subnet example, you cannot use 192.168.0.0 or 192.168.0.7.

Class B-Size Network Address

To determine the network address to use with the subnet mask for a network with between 254 and 65,534 hosts, you need to determine the value of the third octet for each possible extended network prefix. For example, you might want to subnet an address like 10.1.*x*.0, where the first two octets are fixed because they are used in the extended network prefix, and the fourth octet is 0 because all bits are used for the host number.

To determine the value of the third octet, follow these steps:

Step 1 Calculate how many subnets you can make from the network by dividing 65,536 (the total number of addresses using the third and fourth octet) by the number of host addresses you want.

For example, 65,536 divided by 4096 hosts equals 16.

Therefore, there are 16 subnets of 4096 addresses each in a Class B-size network.

Step 2 Determine the multiple of the third octet value by dividing 256 (the number of values for the third octet) by the number of subnets:

In this example, 256/16 = 16.

The third octet falls on a multiple of 16, starting with 0.

Therefore, Table A-3 shows the 16 subnets of the network 10.1.

Table A-3 Subnets of Network

Subnet with Mask /20 (255.255.240.0)	Address Range[1]
10.1.0.0	10.1.0.0 to 10.1.15.255
10.1.16.0	10.1.16.0 to 10.1.31.255
10.1.32.0	10.1.32.0 to 10.1.47.255
—	—
10.1.240.0	10.1.240.0 to 10.1.255.255

1. The first and last address of a subnet are reserved. In the first subnet example, you cannot use 10.1.0.0 or 10.1.15.255.

IPv6 Addresses

IPv6 is the next generation of the Internet Protocol after IPv4. It provides an expanded address space, a simplified header format, improved support for extensions and options, flow labeling capability, and authentication and privacy capabilities. IPv6 is described in RFC 2460. The IPv6 addressing architecture is described in RFC 3513.

This section describes the IPv6 address format and architecture and includes the following topics:

- IPv6 Address Format, page A-5
- IPv6 Address Types, page A-6
- IPv6 Address Prefixes, page A-10

Note This section describes the IPv6 address format, the types, and prefixes. For information about configuring the ASA to use IPv6, see the "Configuring IPv6 Addressing" section on page 17-15

IPv6 Address Format

IPv6 addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons (:) in the format: x:x:x:x:x:x:x:x. The following are two examples of IPv6 addresses:

- 2001:0DB8:7654:3210:FEDC:BA98:7654:3210
- 2001:0DB8:0000:0000:0008:0800:200C:417A

Note The hexadecimal letters in IPv6 addresses are not case-sensitive.

You do not need to include the leading zeros in an individual field of the address, but each field must contain at least one digit. So the example address 2001:0DB8:0000:0000:0008:0800:200C:417A can be shortened to 2001:0DB8:0:0:8:800:200C:417A by removing the leading zeros from the third through sixth fields from the left. The fields that contained all zeros (the third and fourth fields from the left) were shortened to a single zero. The fifth field from the left had the three leading zeros removed, leaving a single 8 in that field, and the sixth field from the left had the one leading zero removed, leaving 800 in that field.

It is common for IPv6 addresses to contain several consecutive hexadecimal fields of zeros. You can use two colons (::) to compress consecutive fields of zeros at the beginning, middle, or end of an IPv6 address (the colons represent the successive hexadecimal fields of zeros). Table A-4 shows several examples of address compression for different types of IPv6 address.

Table A-4 IPv6 Address Compression Examples

Address Type	Standard Form	Compressed Form
Unicast	2001:0DB8:0:0:0:BA98:0:3210	2001:0DB8::BA98:0:3210
Multicast	FF01:0:0:0:0:0:0:101	FF01::101
Loopback	0:0:0:0:0:0:0:1	::1
Unspecified	0:0:0:0:0:0:0:0	::

Note Two colons (::) can be used only once in an IPv6 address to represent successive fields of zeros.

An alternative form of the IPv6 format is often used when dealing with an environment that contains both IPv4 and IPv6 addresses. This alternative has the format x:x:x:x:x:x:y.y.y.y, where x represent the hexadecimal values for the six high-order parts of the IPv6 address and y represent decimal values for the 32-bit IPv4 part of the address (which takes the place of the remaining two 16-bit parts of the IPv6 address). For example, the IPv4 address 192.168.1.1 could be represented as the IPv6 address 0:0:0:0:0:0:FFFF:192.168.1.1 or ::FFFF:192.168.1.1.

IPv6 Address Types

The following are the three main types of IPv6 addresses:

- **Unicast**—A unicast address is an identifier for a single interface. A packet sent to a unicast address is delivered to the interface identified by that address. An interface may have more than one unicast address assigned to it.
- **Multicast**—A multicast address is an identifier for a set of interfaces. A packet sent to a multicast address is delivered to all addresses identified by that address.
- **Anycast**—An anycast address is an identifier for a set of interfaces. Unlike a multicast address, a packet sent to an anycast address is only delivered to the "nearest" interface, as determined by the measure of distances for the routing protocol.

Note There are no broadcast addresses in IPv6. Multicast addresses provide the broadcast functionality.

This section includes the following topics:

- Unicast Addresses, page A-6
- Multicast Address, page A-8
- Anycast Address, page A-9
- Required Addresses, page A-10

Unicast Addresses

This section describes IPv6 unicast addresses. Unicast addresses identify an interface on a network node.

This section includes the following topics:

- Global Address, page A-7
- Site-Local Address, page A-7
- Link-Local Address, page A-7
- IPv4-Compatible IPv6 Addresses, page A-7
- Unspecified Address, page A-8
- Loopback Address, page A-8
- Interface Identifiers, page A-8

Global Address

The general format of an IPv6 global unicast address is a global routing prefix followed by a subnet ID followed by an interface ID. The global routing prefix can be any prefix not reserved by another IPv6 address type (see the "IPv6 Address Prefixes" section on page A-10, for information about the IPv6 address type prefixes).

All global unicast addresses, other than those that start with binary 000, have a 64-bit interface ID in the Modified EUI-64 format. See the "Interface Identifiers" section on page A-8, for more information about the Modified EUI-64 format for interface identifiers.

Global unicast address that start with the binary 000 do not have any constraints on the size or structure of the interface ID portion of the address. One example of this type of address is an IPv6 address with an embedded IPv4 address (see the "IPv4-Compatible IPv6 Addresses" section on page A-7).

Site-Local Address

Site-local addresses are used for addressing within a site. They can be used to address an entire site without using a globally unique prefix. Site-local addresses have the prefix FEC0::/10, followed by a 54-bit subnet ID, and end with a 64-bit interface ID in the modified EUI-64 format.

Site-local routers do not forward any packets that have a site-local address for a source or destination outside of the site. Therefore, site-local addresses can be considered private addresses.

Link-Local Address

All interfaces are required to have at least one link-local address. You can configure multiple IPv6 addresses per interfaces, but only one link-local address.

A link-local address is an IPv6 unicast address that can be automatically configured on any interface using the link-local prefix FE80::/10 and the interface identifier in modified EUI-64 format. Link-local addresses are used in the neighbor discovery protocol and the stateless autoconfiguration process. Nodes with a link-local address can communicate; they do not need a site-local or globally unique address to communicate.

Routers do not forward any packets that have a link-local address for a source or destination. Therefore, link-local addresses can be considered private addresses.

IPv4-Compatible IPv6 Addresses

There are two types of IPv6 addresses that can contain IPv4 addresses.

The first type is the IPv4-compatibly IPv6 address. The IPv6 transition mechanisms include a technique for hosts and routers to dynamically tunnel IPv6 packets over IPv4 routing infrastructure. IPv6 nodes that use this technique are assigned special IPv6 unicast addresses that carry a global IPv4 address in the low-order 32 bits. This type of address is termed an IPv4-compatible IPv6 address and has the format ::y.y.y.y, where y.y.y.y is an IPv4 unicast address.

Note The IPv4 address used in the IPv4-compatible IPv6 address must be a globally unique IPv4 unicast address.

The second type of IPv6 address, which holds an embedded IPv4 address, is called the IPv4-mapped IPv6 address. This address type is used to represent the addresses of IPv4 nodes as IPv6 addresses. This type of address has the format ::FFFF:y.y.y.y, where y.y.y.y is an IPv4 unicast address.

Unspecified Address

The unspecified address, 0:0:0:0:0:0:0:0, indicates the absence of an IPv6 address. For example, a newly initialized node on an IPv6 network may use the unspecified address as the source address in its packets until it receives its IPv6 address.

Note The IPv6 unspecified address cannot be assigned to an interface. The unspecified IPv6 addresses must not be used as destination addresses in IPv6 packets or the IPv6 routing header.

Loopback Address

The loopback address, 0:0:0:0:0:0:0:1, may be used by a node to send an IPv6 packet to itself. The loopback address in IPv6 functions the same as the loopback address in IPv4 (127.0.0.1).

Note The IPv6 loopback address cannot be assigned to a physical interface. A packet that has the IPv6 loopback address as its source or destination address must remain within the node that created the packet. IPv6 routers do not forward packets that have the IPv6 loopback address as their source or destination address.

Interface Identifiers

Interface identifiers in IPv6 unicast addresses are used to identify the interfaces on a link. They need to be unique within a subnet prefix. In many cases, the interface identifier is derived from the interface link-layer address. The same interface identifier may be used on multiple interfaces of a single node, as long as those interfaces are attached to different subnets.

For all unicast addresses, except those that start with the binary 000, the interface identifier is required to be 64 bits long and to be constructed in the Modified EUI-64 format. The Modified EUI-64 format is created from the 48-bit MAC address by inverting the universal/local bit in the address and by inserting the hexadecimal number FFFE between the upper three bytes and lower three bytes of the of the MAC address.

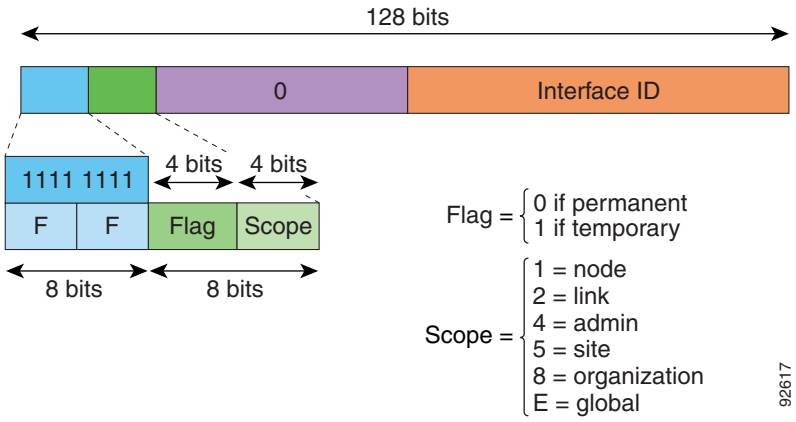
For example, and interface with the MAC address of 00E0.b601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.

Multicast Address

An IPv6 multicast address is an identifier for a group of interfaces, typically on different nodes. A packet sent to a multicast address is delivered to all interfaces identified by the multicast address. An interface may belong to any number of multicast groups.

An IPv6 multicast address has a prefix of FF00::/8 (1111 1111). The octet following the prefix defines the type and scope of the multicast address. A permanently assigned (well known) multicast address has a flag parameter equal to 0; a temporary (transient) multicast address has a flag parameter equal to 1. A multicast address that has the scope of a node, link, site, or organization, or a global scope has a scope parameter of 1, 2, 5, 8, or E, respectively. For example, a multicast address with the prefix FF02::/16 is a permanent multicast address with a link scope. Figure A-1 shows the format of the IPv6 multicast address.

Figure A-1 IPv6 Multicast Address Format



IPv6 nodes (hosts and routers) are required to join the following multicast groups:

- The All Nodes multicast addresses:
  - FF01:: (interface-local)
  - FF02:: (link-local)
- The Solicited-Node Address for each IPv6 unicast and anycast address on the node: FF02:0:0:0:0:1:FFXX:XXXX/104, where XX:XXXX is the low-order 24-bits of the unicast or anycast address.

Note Solicited-Node addresses are used in Neighbor Solicitation messages.

IPv6 routers are required to join the following multicast groups:

- FF01::2 (interface-local)
- FF02::2 (link-local)
- FF05::2 (site-local)

Multicast address should not be used as source addresses in IPv6 packets.

Note There are no broadcast addresses in IPv6. IPv6 multicast addresses are used instead of broadcast addresses.

Anycast Address

The IPv6 anycast address is a unicast address that is assigned to more than one interface (typically belonging to different nodes). A packet that is routed to an anycast address is routed to the nearest interface having that address, the nearness being determined by the routing protocol in effect.

Anycast addresses are allocated from the unicast address space. An anycast address is simply a unicast address that has been assigned to more than one interface, and the interfaces must be configured to recognize the address as an anycast address.

The following restrictions apply to anycast addresses:

- An anycast address cannot be used as the source address for an IPv6 packet.

- An anycast address cannot be assigned to an IPv6 host; it can only be assigned to an IPv6 router.

Note Anycast addresses are not supported on the ASA.

Required Addresses

IPv6 hosts must, at a minimum, be configured with the following addresses (either automatically or manually):

- A link-local address for each interface
- The loopback address
- The All-Nodes multicast addresses
- A Solicited-Node multicast address for each unicast or anycast address

IPv6 routers must, at a minimum, be configured with the following addresses (either automatically or manually):

- The required host addresses
- The Subnet-Router anycast addresses for all interfaces for which it is configured to act as a router
- The All-Routers multicast addresses

IPv6 Address Prefixes

An IPv6 address prefix, in the format ipv6-prefix/prefix-length, can be used to represent bit-wise contiguous blocks of the entire address space. The IPv6-prefix must be in the form documented in RFC 2373 where the address is specified in hexadecimal using 16-bit values between colons. The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). For example, 2001:0DB8:8086:6502::/32 is a valid IPv6 prefix.

The IPv6 prefix identifies the type of IPv6 address. Table A-5 shows the prefixes for each IPv6 address type.

Table A-5 IPv6 Address Type Prefixes

Address Type	Binary Prefix	IPv6 Notation
Unspecified	000...0 (128 bits)	::/128
Loopback	000...1 (128 bits)	::1/128
Multicast	11111111	FF00::/8
Link-Local (unicast)	1111111010	FE80::/10
Site-Local (unicast)	1111111111	FEC0::/10
Global (unicast)	All other addresses.	
Anycast	Taken from the unicast address space.	

Protocols and Applications

Table A-6 lists the protocol literal values and port numbers; either can be entered in ASA commands.

Table A-6 Protocol Literal Values

Literal	Value	Description
ah	51	Authentication Header for IPv6, RFC 1826.
eigrp	88	Enhanced Interior Gateway Routing Protocol.
esp	50	Encapsulated Security Payload for IPv6, RFC 1827.
gre	47	Generic Routing Encapsulation.
icmp	1	Internet Control Message Protocol, RFC 792.
icmp6	58	Internet Control Message Protocol for IPv6, RFC 2463.
igmp	2	Internet Group Management Protocol, RFC 1112.
igrp	9	Interior Gateway Routing Protocol.
ip	0	Internet Protocol.
ipinip	4	IP-in-IP encapsulation.
ipsec	50	IP Security. Entering the ipsec protocol literal is equivalent to entering the esp protocol literal.
nos	94	Network Operating System (Novell's NetWare).
ospf	89	Open Shortest Path First routing protocol, RFC 1247.
pcp	108	Payload Compression Protocol.
pim	103	Protocol Independent Multicast.
pptp	47	Point-to-Point Tunneling Protocol. Entering the pptp protocol literal is equivalent to entering the gre protocol literal.
snp	109	Sitara Networks Protocol.
tcp	6	Transmission Control Protocol, RFC 793.
udp	17	User Datagram Protocol, RFC 768.

Protocol numbers can be viewed online at the IANA website:

http://www.iana.org/assignments/protocol-numbers

TCP and UDP Ports

Table A-7 lists the literal values and port numbers; either can be entered in ASA commands. See the following caveats:

- The ASA uses port 1521 for SQL*Net. This is the default port used by Oracle for SQL*Net. This value, however, does not agree with IANA port assignments.
- The ASA listens for RADIUS on ports 1645 and 1646. If your RADIUS server uses the standard ports 1812 and 1813, you can configure the ASA to listen to those ports using the **authentication-port** and **accounting-port** commands.

- To assign a port for DNS access, use the **domain** literal value, not **dns**. If you use **dns**, the ASA assumes you meant to use the **dnsix** literal value.

Port numbers can be viewed online at the IANA website:

http://www.iana.org/assignments/port-numbers

Table A-7 Port Literal Values

Literal	TCP or UDP?	Value	Description
aol	TCP	5190	America Online
bgp	TCP	179	Border Gateway Protocol, RFC 1163
biff	UDP	512	Used by mail system to notify users that new mail is received
bootpc	UDP	68	Bootstrap Protocol Client
bootps	UDP	67	Bootstrap Protocol Server
chargen	TCP	19	Character Generator
citrix-ica	TCP	1494	Citrix Independent Computing Architecture (ICA) protocol
cmd	TCP	514	Similar to **exec** except that **cmd** has automatic authentication
ctiqbe	TCP	2748	Computer Telephony Interface Quick Buffer Encoding
daytime	TCP	13	Day time, RFC 867
discard	TCP, UDP	9	Discard
domain	TCP, UDP	53	DNS
dnsix	UDP	195	DNSIX Session Management Module Audit Redirector
echo	TCP, UDP	7	Echo
exec	TCP	512	Remote process execution
finger	TCP	79	Finger
ftp	TCP	21	File Transfer Protocol (control port)
ftp-data	TCP	20	File Transfer Protocol (data port)
gopher	TCP	70	Gopher
https	TCP	443	HTTP over SSL
h323	TCP	1720	H.323 call signalling
hostname	TCP	101	NIC Host Name Server
ident	TCP	113	Ident authentication service
imap4	TCP	143	Internet Message Access Protocol, version 4
irc	TCP	194	Internet Relay Chat protocol
isakmp	UDP	500	Internet Security Association and Key Management Protocol
kerberos	TCP, UDP	750	Kerberos

Table A-7 Port Literal Values (continued)

Literal	TCP or UDP?	Value	Description
klogin	TCP	543	KLOGIN
kshell	TCP	544	Korn Shell
ldap	TCP	389	Lightweight Directory Access Protocol
ldaps	TCP	636	Lightweight Directory Access Protocol (SSL)
lpd	TCP	515	Line Printer Daemon - printer spooler
login	TCP	513	Remote login
lotusnotes	TCP	1352	IBM Lotus Notes
mobile-ip	UDP	434	MobileIP-Agent
nameserver	UDP	42	Host Name Server
netbios-ns	UDP	137	NetBIOS Name Service
netbios-dgm	UDP	138	NetBIOS Datagram Service
netbios-ssn	TCP	139	NetBIOS Session Service
nntp	TCP	119	Network News Transfer Protocol
ntp	UDP	123	Network Time Protocol
pcanywhere-status	UDP	5632	pcAnywhere status
pcanywhere-data	TCP	5631	pcAnywhere data
pim-auto-rp	TCP, UDP	496	Protocol Independent Multicast, reverse path flooding, dense mode
pop2	TCP	109	Post Office Protocol - Version 2
pop3	TCP	110	Post Office Protocol - Version 3
pptp	TCP	1723	Point-to-Point Tunneling Protocol
radius	UDP	1645	Remote Authentication Dial-In User Service
radius-acct	UDP	1646	Remote Authentication Dial-In User Service (accounting)
rip	UDP	520	Routing Information Protocol
secureid-udp	UDP	5510	SecureID over UDP
smtp	TCP	25	Simple Mail Transport Protocol
snmp	UDP	161	Simple Network Management Protocol
snmptrap	UDP	162	Simple Network Management Protocol - Trap
sqlnet	TCP	1521	Structured Query Language Network
ssh	TCP	22	Secure Shell
sunrpc (rpc)	TCP, UDP	111	Sun Remote Procedure Call
syslog	UDP	514	System Log
tacacs	TCP, UDP	49	Terminal Access Controller Access Control System Plus
talk	TCP, UDP	517	Talk
telnet	TCP	23	RFC 854 Telnet

Table A-7 Port Literal Values (continued)

Literal	TCP or UDP?	Value	Description
tftp	UDP	69	Trivial File Transfer Protocol
time	UDP	37	Time
uucp	TCP	540	UNIX-to-UNIX Copy Program
who	UDP	513	Who
whois	TCP	43	Who Is
www	TCP	80	World Wide Web
xdmcp	UDP	177	X Display Manager Control Protocol

Local Ports and Protocols

Table A-8 lists the protocols, TCP ports, and UDP ports that the ASA may open to process traffic destined to the ASA. Unless you enable the features and services listed in Table A-8, the ASA does *not* open any local protocols or any TCP or UDP ports. You must configure a feature or service for the ASA to open the default listening protocol or port. In many cases you can configure ports other than the default port when you enable a feature or service.

Table A-8 Protocols and Ports Opened by Features and Services

Feature or Service	Protocol	Port Number	Comments
DHCP	UDP	67,68	—
Failover Control	105	N/A	—
HTTP	TCP	80	—
HTTPS	TCP	443	—
ICMP	1	N/A	—
IGMP	2	N/A	Protocol only open on destination IP address 224.0.0.1
ISAKMP/IKE	UDP	500	Configurable.
IPsec (ESP)	50	N/A	—
IPsec over UDP (NAT-T)	UDP	4500	—
IPsec over UDP (Cisco VPN 3000 Series compatible)	UDP	10000	Configurable.
IPsec over TCP (CTCP)	TCP	—	No default port is used. You must specify the port number when configuring IPsec over TCP.
NTP	UDP	123	—
OSPF	89	N/A	Protocol only open on destination IP address 224.0.0.5 and 224.0.0.6

Table A-8 Protocols and Ports Opened by Features and Services (continued)

Feature or Service	Protocol	Port Number	Comments
PIM	103	N/A	Protocol only open on destination IP address 224.0.0.13
RIP	UDP	520	—
RIPv2	UDP	520	Port only open on destination IP address 224.0.0.9
SNMP	UDP	161	Configurable.
SSH	TCP	22	—
Stateful Update	8 (non-secure) 9 (secure)	N/A	—
Telnet	TCP	23	—
VPN Load Balancing	UDP	9023	Configurable.
VPN Individual User Authentication Proxy	UDP	1645, 1646	Port accessible only over VPN tunnel.

ICMP Types

Table A-9 lists the ICMP type numbers and names that you can enter in ASA commands.

Table A-9 ICMP Types

ICMP Number	ICMP Name
0	echo-reply
3	unreachable
4	source-quench
5	redirect
6	alternate-address
8	echo
9	router-advertisement
10	router-solicitation
11	time-exceeded
12	parameter-problem
13	timestamp-request
14	timestamp-reply
15	information-request
16	information-reply
17	mask-request
18	mask-reply

Table A-9 ICMP Types (continued)

ICMP Number	ICMP Name
31	conversion-error
32	mobile-redirect

Configuring an External Server for Authorization and Authentication

This appendix describes how to configure an external LDAP, RADIUS, or TACACS+ server to support AAA on the ASA. Before you configure the ASA to use an external server, you must configure the server with the correct ASA authorization attributes and, from a subset of these attributes, assign specific permissions to individual users.

This appendix includes the following sections:

- Understanding Policy Enforcement of Permissions and Attributes, page B-1
- Configuring an External LDAP Server, page B-2
- Configuring an External RADIUS Server, page B-25
- Configuring an External TACACS+ Server, page B-37

Understanding Policy Enforcement of Permissions and Attributes

The ASA supports several methods of applying user authorization attributes (also called user entitlements or permissions) to VPN connections. You can configure the ASA to obtain user attributes from a Dynamic Access Policy (DAP) on the ASA, from an external authentication and/or authorization AAA server (RADIUS or LDAP), from a group policy on the ASA, or from all three.

If the ASA receives attributes from all sources, the attributes are evaluated, merged, and applied to the user policy. If there are conflicts between attributes coming from the DAP, the AAA server, or the group policy, those attributes obtained from the DAP always take precedence.

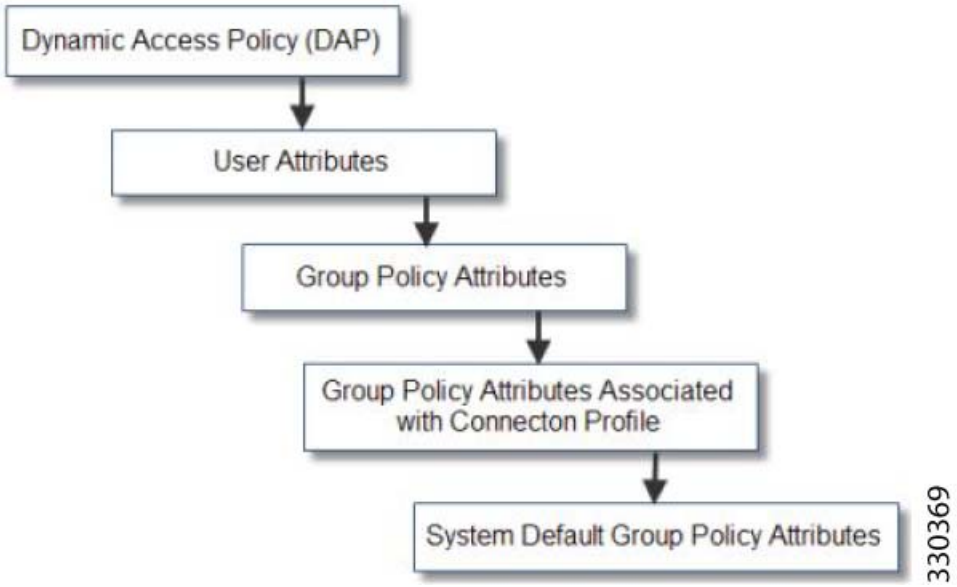
The ASA applies attributes in the following order (see Figure B-1).

1. DAP attributes on the ASA—Introduced in Version 8.0(2), these attributes take precedence over all others. If you set a bookmark or URL list in DAP, it overrides a bookmark or URL list set in the group policy.
2. User attributes on the AAA server—The server returns these attributes after successful user authentication and/or authorization. Do not confuse these with attributes that are set for individual users in the local AAA database on the ASA (User Accounts in ASDM).
3. Group policy configured on the ASA—If a RADIUS server returns the value of the RADIUS CLASS attribute IETF-Class-25 (OU=*group-policy*) for the user, the ASA places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

For LDAP servers, any attribute name can be used to set the group policy for the session. The LDAP attribute map that you configure on the ASA maps the LDAP attribute to the Cisco attribute IETF-Radius-Class.

4. Group policy assigned by the Connection Profile (called tunnel-group in the CLI)—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication. All users connecting to the ASA initially belong to this group, which provides any attributes that are missing from the DAP, user attributes returned by the server, or the group policy assigned to the user.
5. Default group policy assigned by the ASA (DfltGrpPolicy)—System default attributes provide any values that are missing from the DAP, user attributes, group policy, or connection profile.

Figure B-1 Policy Enforcement Flow



Configuring an External LDAP Server

The VPN 3000 concentrator and the ASA/PIX 7.0 software required a Cisco LDAP schema for authorization operations. Beginning with Version 7.1.x, the ASA performs authentication and authorization using the native LDAP schema, and the Cisco schema is no longer needed.

You configure authorization (permission policy) using an LDAP attribute map. For examples, see the "Active Directory/LDAP VPN Remote Access Authorization Examples" section on page B-15.

This section describes the structure, schema, and attributes of an LDAP server and includes the following topics:

- Organizing the ASA for LDAP Operations, page B-3
- Defining the ASA LDAP Configuration, page B-5
- Active Directory/LDAP VPN Remote Access Authorization Examples, page B-15

The specific steps of these processes vary, depending on which type of LDAP server that you are using.

Note For more information about the LDAP protocol, see RFCs 1777, 2251, and 2849.

Organizing the ASA for LDAP Operations

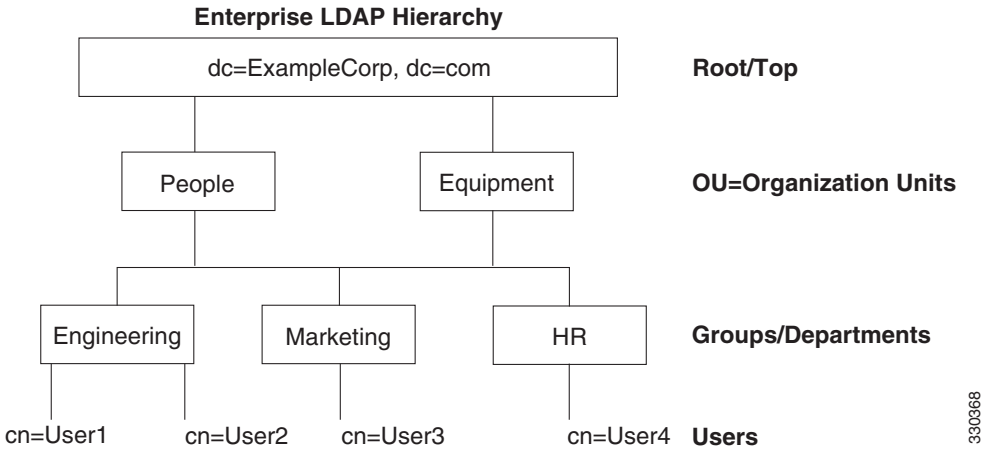
This section describes how to search within the LDAP hierarchy and perform authenticated binding to the LDAP server on the ASA and includes the following topics:

- Searching the LDAP Hierarchy, page B-3
- Binding the ASA to the LDAP Server, page B-4

Your LDAP configuration should reflect the logical hierarchy of your organization. For example, suppose an employee at your company, Example Corporation, is named Employee1. Employee1 works in the Engineering group. Your LDAP hierarchy could have one or many levels. You might decide to set up a single-level hierarchy in which Employee1 is considered a member of Example Corporation. Or you could set up a multi-level hierarchy in which Employee1 is considered to be a member of the department Engineering, which is a member of an organizational unit called People, which is itself a member of Example Corporation. See Figure B-2 for an example of a multi-level hierarchy.

A multi-level hierarchy has more detail, but searches return results more quickly in a single-level hierarchy.

Figure B-2 A Multi-Level LDAP Hierarchy



Searching the LDAP Hierarchy

The ASA lets you tailor the search within the LDAP hierarchy. You configure the following three fields on the ASA to define where in the LDAP hierarchy that your search begins, the extent, and the type of information it is looking for. Together these fields allow you to limit the search of the hierarchy to only the part that includes the user permissions.

- LDAP Base DN defines where in the LDAP hierarchy that the server should begin searching for user information when it receives an authorization request from the ASA.

- Search Scope defines the extent of the search in the LDAP hierarchy. The search proceeds this many levels in the hierarchy below the LDAP Base DN. You can choose to have the server search only the level immediately below it, or it can search the entire subtree. A single level search is quicker, but a subtree search is more extensive.
- Naming Attribute(s) defines the RDN that uniquely identifies an entry in the LDAP server. Common naming attributes can include cn (Common Name), sAMAccountName, and userPrincipalName.

Figure B-2 shows a sample LDAP hierarchy for Example Corporation. Given this hierarchy, you could define your search in different ways. Table B-1 shows two sample search configurations.

In the first example configuration, when Employee1 establishes the IPsec tunnel with LDAP authorization required, the ASA sends a search request to the LDAP server, indicating it should search for Employee1 in the Engineering group. This search is quick.

In the second example configuration, the ASA sends a search request indicating that the server should search for Employee1 within Example Corporation. This search takes longer.

Table B-1 Example Search Configurations

No.	LDAP Base DN	Search Scope	Naming Attribute	Result
1	group= Engineering,ou=People,dc=ExampleCorporation, dc=com	One Level	cn=Employee1	Quicker search
2	dc=ExampleCorporation,dc=com	Subtree	cn=Employee1	Longer search

Binding the ASA to the LDAP Server

Some LDAP servers (including the Microsoft Active Directory server) require the ASA to establish a handshake via authenticated binding before they accept requests for any other LDAP operations. The ASA uses the Login Distinguished Name (DN) and Login Password to establish a trust relationship (bind) with an LDAP server before a user can search. The Login DN represents a user record in the LDAP server that the administrator uses for binding.

When binding, the ASA authenticates to the server using the Login DN and the Login Password. When performing a Microsoft Active Directory read-only operation (such as for authentication, authorization, or group search), the ASA can bind with a Login DN with fewer privileges. For example, the Login DN can be a user whose AD “Member Of” designation is part of Domain Users. For VPN password management write operations, the Login DN needs elevated privileges and must be part of the Account Operators AD group. Microsoft Active Directory group search (also called “MemberOf retrieval”) was added in ASA Version 8.0.4.

An example of a Login DN includes the following entries:

cn=Binduser1,ou=Admins,ou=Users,dc=company_A,dc=com

See your LDAP Administrator guide for specific Login DN requirements for read and write operations.

The ASA supports the following features:

- Simple LDAP authentication with an unencrypted password using the default port 389 . You can also use other ports instead of the default port.
- Secure LDAP (LDAP-S) using the default port 636. You can also use other ports instead of the default port.
- Simple Authentication and Security Layer (SASL) MD5
- SASL Kerberos

The ASA does not support anonymous authentication.

Note As an LDAP client, the ASA does not support the transmission of anonymous binds or requests.

Defining the ASA LDAP Configuration

This section describes how to define the LDAP AV-pair attribute syntax and includes the following topics:

- Supported Cisco Attributes for LDAP Authorization, page B-5
- Cisco AV Pair Attribute Syntax, page B-12
- Cisco AV Pairs ACL Examples, page B-13

Note The ASA enforces the LDAP attributes based on attribute name, not numeric ID. RADIUS attributes, on the other hand, are enforced by numeric ID, not by name.

Authorization refers to the process of enforcing permissions or attributes. An LDAP server defined as an authentication or authorization server enforces permissions or attributes if they are configured.

For software Version 7.0, LDAP attributes include the cVPN3000 prefix. For software Versions 7.1 and later, this prefix was removed.

Supported Cisco Attributes for LDAP Authorization

This section provides a complete list of attributes (see Table B-2) for the ASA 5500, VPN 3000 concentrator, and PIX 500 series ASAs. The table includes attribute support information for the VPN 3000 concentrator and PIX 500 series ASAs to assist you in configuring networks with a combination of these devices.

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
Access-Hours	Y	Y	Y	String	Single	Name of the time-range (for example, Business-Hours)
Allow-Network-Extension- Mode	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
Authenticated-User-Idle- Timeout	Y	Y	Y	Integer	Single	1 - 35791394 minutes
Authorization-Required	Y			Integer	Single	0 = No 1 = Yes
Authorization-Type	Y			Integer	Single	0 = None 1 = RADIUS 2 = LDAP
Banner1	Y	Y	Y	String	Single	Banner string for clientless and client SSL VPN, and IPsec clients.
Banner2	Y	Y	Y	String	Single	Banner string for clientless and client SSL VPN, and IPsec clients.

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
Cisco-AV-Pair	Y	Y	Y	String	Multi	An octet string in the following format: [Prefix] [Action] [Protocol] [Source] [Source Wildcard Mask] [Destination] [Destination Wildcard Mask] [Established] [Log] [Operator] [Port] For more information, see the "Cisco AV Pair Attribute Syntax" section on page B-12."
Cisco-IP-Phone-Bypass	Y	Y	Y	Integer	Single	0 = Disabled 1 = Enabled
Cisco-LEAP-Bypass	Y	Y	Y	Integer	Single	0 = Disabled 1 = Enabled
Client-Intercept-DHCP-Configure-Msg	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
Client-Type-Version-Limiting	Y	Y	Y	String	Single	IPsec VPN client version number string
Confidence-Interval	Y	Y	Y	Integer	Single	10 - 300 seconds
DHCP-Network-Scope	Y	Y	Y	String	Single	IP address
DN-Field	Y	Y	Y	String	Single	Possible values: UID, OU, O, CN, L, SP, C, EA, T, N, GN, SN, I, GENQ, DNQ, SER, and use-entire-name.
Firewall-ACL-In		Y	Y	String	Single	Access list ID
Firewall-ACL-Out		Y	Y	String	Single	Access list ID
Group-Policy		Y	Y	String	Single	Sets the group policy for the remote access VPN session. For version 8.2 and later, use this attribute instead of IETF-Radius-Class. You can use one of the three following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*:
IE-Proxy-Bypass-Local				Boolean	Single	0=Disabled 1=Enabled
IE-Proxy-Exception-List				String	Single	A list of DNS domains. Entries must be separated by the new line character sequence (\n).

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
IE-Proxy-Method	Y	Y	Y	Integer	Single	1 = Do not modify proxy settings 2 = Do not use proxy 3 = Auto detect 4 = Use ASA setting
IE-Proxy-Server	Y	Y	Y	Integer	Single	IP address
IETF-Radius-Class	Y	Y	Y		Single	Sets the group policy for the remote access VPN session. For versions 8.2 and later, we recommend that you use the Group-Policy attribute. You can use one of the three following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*:
IETF-Radius-Filter-Id	Y	Y	Y	String	Single	Access list name that is defined on the ASA. The setting applies to VPN remote access IPsec and SSL VPN clients.
IETF-Radius-Framed-IP-Address	Y	Y	Y	String	Single	An IP address. The setting applies to VPN remote access IPsec and SSL VPN clients.
IETF-Radius-Framed-IP-Netmask	Y	Y	Y	String	Single	An IP address mask. The setting applies to VPN remote access IPsec and SSL VPN clients.
IETF-Radius-Idle-Timeout	Y	Y	Y	Integer	Single	Seconds
IETF-Radius-Service-Type	Y	Y	Y	Integer	Single	1 = Login 2 = Framed 5 = Remote access 6 = Administrative 7 = NAS prompt
IETF-Radius-Session-Timeout	Y	Y	Y	Integer	Single	Seconds
IKE-Keep-Alives	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Allow-Passwd-Store	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Authentication	Y	Y	Y	Integer	Single	0 = None 1 = RADIUS 2 = LDAP (authorization only) 3 = NT Domain 4 = SDI (RSA) 5 = Internal 6 = RADIUS with Expiry 7 = Kerberos or Active Directory

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
IPsec-Auth-On-Rekey	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Backup-Server-List	Y	Y	Y	String	Single	Server addresses (space delimited)
IPsec-Backup-Servers	Y	Y	Y	String	Single	1 = Use client-configured list 2 = Disabled and clear client list 3 = Use backup server list
IPsec-Client-Firewall-Filter- Name	Y			String	Single	Specifies the name of the filter to be pushed to the client as firewall policy.
IPsec-Client-Firewall-Filter-Optional	Y	Y	Y	Integer	Single	0 = Required 1 = Optional
IPsec-Default-Domain	Y	Y	Y	String	Single	Specifies the single default domain name to send to the client (1 - 255 characters).
IPsec-Extended-Auth-On-Rekey		Y	Y	String	Single	String
IPsec-IKE-Peer-ID-Check	Y	Y	Y	Integer	Single	1 = Required 2 = If supported by peer certificate 3 = Do not check
IPsec-IP-Compression	Y	Y	Y	Integer	Single	0 = Disabled 1 = Enabled
IPsec-Mode-Config	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP-Port	Y	Y	Y	Integer	Single	4001 - 49151; The default is 10000.
IPsec-Required-Client-Firewall-Capability	Y	Y	Y	Integer	Single	0 = None 1 = Policy defined by remote FW Are-You-There (AYT) 2 = Policy pushed CPP 4 = Policy from server
IPsec-Sec-Association	Y			String	Single	Name of the security association
IPsec-Split-DNS-Names	Y	Y	Y	String	Single	Specifies the list of secondary domain names to send to the client (1 - 255 characters).
IPsec-Split-Tunneling-Policy	Y	Y	Y	Integer	Single	0 = Tunnel everything 1 = Split tunneling 2 = Local LAN permitted
IPsec-Split-Tunnel-List	Y	Y	Y	String	Single	Specifies the name of the network or access list that describes the split tunnel inclusion list.
IPsec-Tunnel-Type	Y	Y	Y	Integer	Single	1 = LAN-to-LAN 2 = Remote access

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
IPsec-User-Group-Lock	Y			Boolean	Single	0 = Disabled 1 = Enabled
L2TP-Encryption	Y			Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bit 4 = 128 bits 8 = Stateless-Req 15 = 40/128-Encr/Stateless-Req
L2TP-MPPC-Compression	Y			Integer	Single	0 = Disabled 1 = Enabled
MS-Client-Subnet-Mask	Y	Y	Y	String	Single	An IP address
PFS-Required	Y	Y	Y	Boolean	Single	0 = No 1 = Yes
Port-Forwarding-Name	Y	Y		String	Single	Name string (for example, "Corporate-Apps")
PPTP-Encryption	Y			Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bits 4 = 128 bits 8 = Stateless-Required Example: 15 = 40/128-Encr/Stateless-Req
PPTP-MPPC-Compression	Y			Integer	Single	0 = Disabled 1 = Enabled
Primary-DNS	Y	Y	Y	String	Single	An IP address
Primary-WINS	Y	Y	Y	String	Single	An IP address
Privilege-Level				Integer	Single	For usernames, 0 - 15
Required-Client-Firewall-Vendor-Code	Y	Y	Y	Integer	Single	1 = Cisco Systems (with Cisco Integrated Client) 2 = Zone Labs 3 = NetworkICE 4 = Sygate 5 = Cisco Systems (with Cisco Intrusion Prevention Security Agent)
Required-Client-Firewall-Description	Y	Y	Y	String	Single	—

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
Required-Client-Firewall-Product-Code	Y	Y	Y	Integer	Single	Cisco Systems Products: 1 = Cisco Intrusion Prevention Security Agent or Cisco Integrated Client (CIC) Zone Labs Products: 1 = Zone Alarm 2 = Zone AlarmPro 3 = Zone Labs Integrity NetworkICE Product: 1 = BlackIce Defender/Agent Sygate Products: 1 = Personal Firewall 2 = Personal Firewall Pro 3 = Security Agent
Require-HW-Client-Auth	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
Require-Individual-User-Auth	Y	Y	Y	Integer	Single	0 = Disabled 1 = Enabled
Secondary-DNS	Y	Y	Y	String	Single	An IP address
Secondary-WINS	Y	Y	Y	String	Single	An IP address
SEP-Card-Assignment				Integer	Single	Not used
Simultaneous-Logins	Y	Y	Y	Integer	Single	0 - 2147483647
Strip-Realm	Y	Y	Y	Boolean	Single	0 = Disabled 1 = Enabled
TACACS-Authtype	Y	Y	Y	Interger	Single	—
TACACS-Privilege-Level	Y	Y	Y	Interger	Single	—
Tunnel-Group-Lock		Y	Y	String	Single	Name of the tunnel group or “none”
Tunneling-Protocols	Y	Y	Y	Integer	Single	1 = PPTP 2 = L2TP 4 = IPSec (IKEv1) 8 = L2TP/IPSec 16 = WebVPN 32 = SVC 64 = IPsec (IKEv2) 8 and 4 are mutually exclusive (0 - 11, 16 - 27, 32 - 43, 48 - 59 are legal values).
Use-Client-Address	Y			Boolean	Single	0 = Disabled 1 = Enabled
User-Auth-Server-Name	Y			String	Single	IP address or hostname

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
User-Auth-Server-Port	Y			Integer	Single	Port number for server protocol
User-Auth-Server-Secret	Y			String	Single	Server password
WebVPN-ACL-Filters		Y		String	Single	Webtype access list name
WebVPN-Apply-ACL-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled With Version 8.0 and later, this attribute is not required.
WebVPN-Citrix-Support-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled With Versions 8.0 and later, this attribute is not required.
WebVPN-Enable-functions				Integer	Single	Not used - deprecated
WebVPN-Exchange-Server-Address				String	Single	Not used - deprecated
WebVPN-Exchange-Server-NETBIOS-Name				String	Single	Not used - deprecated
WebVPN-File-Access-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-File-Server-Browsing-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-File-Server-Entry-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Forwarded-Ports		Y		String	Single	Port-forward list name
WebVPN-Homepage	Y	Y		String	Single	A URL such as http://www.example.com
WebVPN-Macro-Substitution-Value1	Y	Y		String	Single	See the *SSL VPN Deployment Guide* for examples at the following URL: http://supportwiki.cisco.com/ViewWiki/index.php/Cisco_ASA_5500_SSL_VPN_Deployment_Guide%2C_Version_8.x
WebVPN-Macro-Substitution-Value2	Y	Y		String	Single	See the *SSL VPN Deployment Guide* for examples at the following URL: http://supportwiki.cisco.com/ViewWiki/index.php/Cisco_ASA_5500_SSL_VPN_Deployment_Guide%2C_Version_8.x
WebVPN-Port-Forwarding-Auto-Download-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Port-Forwarding- Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled

Table B-2 ASA Supported Cisco Attributes for LDAP Authorization (continued)

Attribute Name	VPN 3000	ASA	PIX	Syntax/ Type	Single or Multi-Valued	Possible Values
WebVPN-Port-Forwarding-Exchange-Proxy-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Port-Forwarding-HTTP-Proxy-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Single-Sign-On-Server-Name		Y		String	Single	Name of the SSO Server (1 - 31 characters).
WebVPN-SVC-Client-DPD	Y	Y		Integer	Single	0 = Disabled n = Dead peer detection value in seconds (30 - 3600)
WebVPN-SVC-Compression	Y	Y		Integer	Single	0 = None 1 = Deflate compression
WebVPN-SVC-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SVC-Gateway-DPD	Y	Y		Integer	Single	0 = Disabled n = Dead peer detection value in seconds (30 - 3600)
WebVPN-SVC-Keepalive	Y	Y		Integer	Single	0 = Disabled n = Keepalive value in seconds (15 - 600)
WebVPN-SVC-Keep-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SVC-Rekey-Method	Y	Y		Integer	Single	0 = None 1 = SSL 2 = New tunnel 3 = Any (sets to SSL)
WebVPN-SVC-Rekey-Period	Y	Y		Integer	Single	0 = Disabled n = Retry period in minutes (4 - 10080)
WebVPN-SVC-Required-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-URL-Entry-Enable	Y	Y		Integer	Single	0 = Disabled 1 = Enabled
WebVPN-URL-List		Y		String	Single	URL list name

Cisco AV Pair Attribute Syntax

The Cisco Attribute Value (AV) pair (ID Number 26/9/1) can be used to enforce access lists from a RADIUS server (like Cisco ACS), or from an LDAP server via an LDAP attribute map.

The syntax of each Cisco-AV-Pair rule is as follows:

[Prefix] [Action] [Protocol] [Source] [Source Wildcard Mask] [Destination] [Destination Wildcard Mask] [Established] [Log] [Operator] [Port]

Table B-3 describes the syntax rules.

Table B-3 AV-Pair Attribute Syntax Rules

Field	Description
Action	Action to perform if the rule matches a deny or a permit.
Destination	Network or host that receives the packet. Specify it as an IP address, a hostname, or the **any** keyword. If using an IP address, the source wildcard mask must follow.
Destination Wildcard Mask	The wildcard mask that applies to the destination address.
Log	Generates a FILTER log message. You must use this keyword to generate events of severity level 9.
Operator	Logic operators: greater than, less than, equal to, not equal to.
Port	The number of a TCP or UDP port in the range of 0 - 65535.
Prefix	A unique identifier for the AV pair (for example: ip:inacl#1= for standard access lists or webvpn:inacl# = for clientless SSL VPN access lists). This field only appears when the filter has been sent as an AV pair.
Protocol	Number or name of an IP protocol. Either an integer in the range of 0 - 255 or one of the following keywords: **icmp**, **igmp**, **ip**, **tcp**, **udp**.
Source	Network or host that sends the packet. Specify it as an IP address, a hostname, or the **any** keyword. If using an IP address, the source wildcard mask must follow. This field does not apply to Clientless SSL VPN because the ASA has the role of the source or proxy.
Source Wildcard Mask	The wildcard mask that applies to the source address. This field does not apply to Clientless SSL VPN because the ASA has the role of the source or proxy.

Cisco AV Pairs ACL Examples

Table B-4 shows examples of Cisco AV pairs and describes the permit or deny actions that result.

Note Each ACL # in inacl# must be unique. However, they do not need to be sequential (for example, 1, 2, 3, 4). That is, they could be 5, 45, 135.

Table B-4 Examples of Cisco AV Pairs and Their Permitting or Denying Action

Cisco AV Pair Example	Permitting or Denying Action
`ip:inacl#1=deny ip 10.155.10.0 0.0.0.255 10.159.2.0 0.0.0.255 log`	Allows IP traffic between the two hosts using a full tunnel IPsec or SSL VPN client.
`ip:inacl#2=permit TCP any host 10.160.0.1 eq 80 log`	Allows TCP traffic from all hosts to the specific host on port 80 only using a full tunnel IPsec or SSL VPN client.

`webvpn:inacl#1=permit url http://www.example.com`
`webvpn:inacl#2=deny url smtp://server`
`webvpn:inacl#3=permit url cifs://server/share`
	Allows clientlessSSL VPN traffic to the URL specified, denies SMTP traffic to a specific server, and allows file share access (CIFS) to the specified server.

Table B-4 Examples of Cisco AV Pairs and Their Permitting or Denying Action (continued)

Cisco AV Pair Example	Permitting or Denying Action
`webvpn:inacl#1=permit tcp 10.86.1.2 eq 2222 log` `webvpn:inacl#2=deny tcp 10.86.1.2 eq 2323 log`	Denies Telnet access and permits SSH access on non-default ports 2323 and 2222, respectively, or other application traffic flows using these ports for clientless SSL VPN.

`webvpn:inacl#1=permit url ssh://10.86.1.2`
`webvpn:inacl#35=permit tcp 10.86.1.5 eq 22 log`
`webvpn:inacl#48=deny url telnet://10.86.1.2`
`webvpn:inacl#100=deny tcp 10.86.1.6 eq 23`
	Allows clientless SSL VPN SSH access to default port 22 and denies Telnet access to port 23, respectively. This example assumes that you are using Telnet or SSH Java plug-ins enforced by these ACLs.

URL Types Supported in ACLs

The URL may be a partial URL, contain wildcards for the server, or include a port.

The following URL types are supported.

any All URLs	https://	post://	ssh://
cifs://	ica://	rdp://	telnet://
citrix://	imap4://	rdp2://	vnc://
citrixs://	ftp://	smart-tunnel://	
http://	pop3://	smtp://	

Note The URLs listed in this table appear in CLI or ASDM menus based on whether or not the associated plug-in is enabled.

Guidelines for Using Cisco-AV Pairs (ACLs)

- Use Cisco-AV pair entries with the ip:inacl# prefix to enforce access lists for remote IPsec and SSL VPN Client (SVC) tunnels.
- Use Cisco-AV pair entries with the webvpn:inacl# prefix to enforce access lists for SSL VPN clientless (browser-mode) tunnels.
- For webtype ACLs, you do not specify the source because the ASA is the source.

Table B-5 lists the tokens for the Cisco-AV-pair attribute:

Table B-5 ASA-Supported Tokens

Token	Syntax Field	Description
ip:inacl#*Num*=	N/A (Identifier)	(Where *Num* is a unique integer.) Starts all AV pair access control lists. Enforces access lists for remote IPsec and SSL VPN (SVC) tunnels.
webvpn:inacl#*Num*=	N/A (Identifier)	(Where *Num* is a unique integer.) Starts all clientless SSL AV pair access control lists. Enforces access lists for clientless (browser-mode) tunnels.
deny	Action	Denies action. (Default)

Table B-5 ASA-Supported Tokens (continued)

Token	Syntax Field	Description
permit	Action	Allows action.
icmp	Protocol	Internet Control Message Protocol (ICMP)
1	Protocol	Internet Control Message Protocol (ICMP)
IP	Protocol	Internet Protocol (IP)
0	Protocol	Internet Protocol (IP)
TCP	Protocol	Transmission Control Protocol (TCP)
6	Protocol	Transmission Control Protocol (TCP)
UDP	Protocol	User Datagram Protocol (UDP)
17	Protocol	User Datagram Protocol (UDP)
any	Hostname	Rule applies to any host.
host	Hostname	Any alpha-numeric string that denotes a hostname.
log	Log	When the event occurs, a filter log message appears. (Same as permit and log or deny and log.)
lt	Operator	Less than value
gt	Operator	Greater than value
eq	Operator	Equal to value
neq	Operator	Not equal to value
range	Operator	Inclusive range. Should be followed by two values.

Active Directory/LDAP VPN Remote Access Authorization Examples

This section presents example procedures for configuring authentication and authorization on the ASA using the Microsoft Active Directory server. It includes the following topics:

- User-Based Attributes Policy Enforcement, page B-16
- Placing LDAP Users in a Specific Group Policy, page B-17
- Enforcing Static IP Address Assignment for AnyConnect Tunnels, page B-19
- Enforcing Dial-in Allow or Deny Access, page B-22
- Enforcing Logon Hours and Time-of-Day Rules, page B-24

Other configuration examples available on Cisco.com include the following TechNotes.

- *ASA/PIX: Mapping VPN Clients to VPN Group Policies Through LDAP Configuration Example* at the following URL:

  http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a008089149d.shtml

- *PIX/ASA 8.0: Use LDAP Authentication to Assign a Group Policy at Login* at the following URL:

  http://www.cisco.com/en/US/partner/products/ps6120/products_configuration_example09186a00808d1a7c.shtml

User-Based Attributes Policy Enforcement

You can map any standard LDAP attribute to a well-known Vendor-Specific Attribute (VSA) as well as map one or more LDAP attribute(s) to one or more Cisco LDAP attributes.

The following example shows how to configure the ASA to enforce a simple banner for a user configured on an AD LDAP server. On the server, use the Office field in the General tab to enter the banner text. This field uses the attribute named physicalDeliveryOfficeName. On the ASA, create an attribute map that maps physicalDeliveryOfficeName to the Cisco attribute Banner1. During authentication, the ASA retrieves the value of physicalDeliveryOfficeName from the server, maps the value to the Cisco attribute Banner1, and displays the banner to the user.

This example applies to any connection type, including the IPsec VPN client, AnyConnect SSL VPN client, or clientless SSL VPN. In the example, User1 connects through a clientless SSL VPN connection.

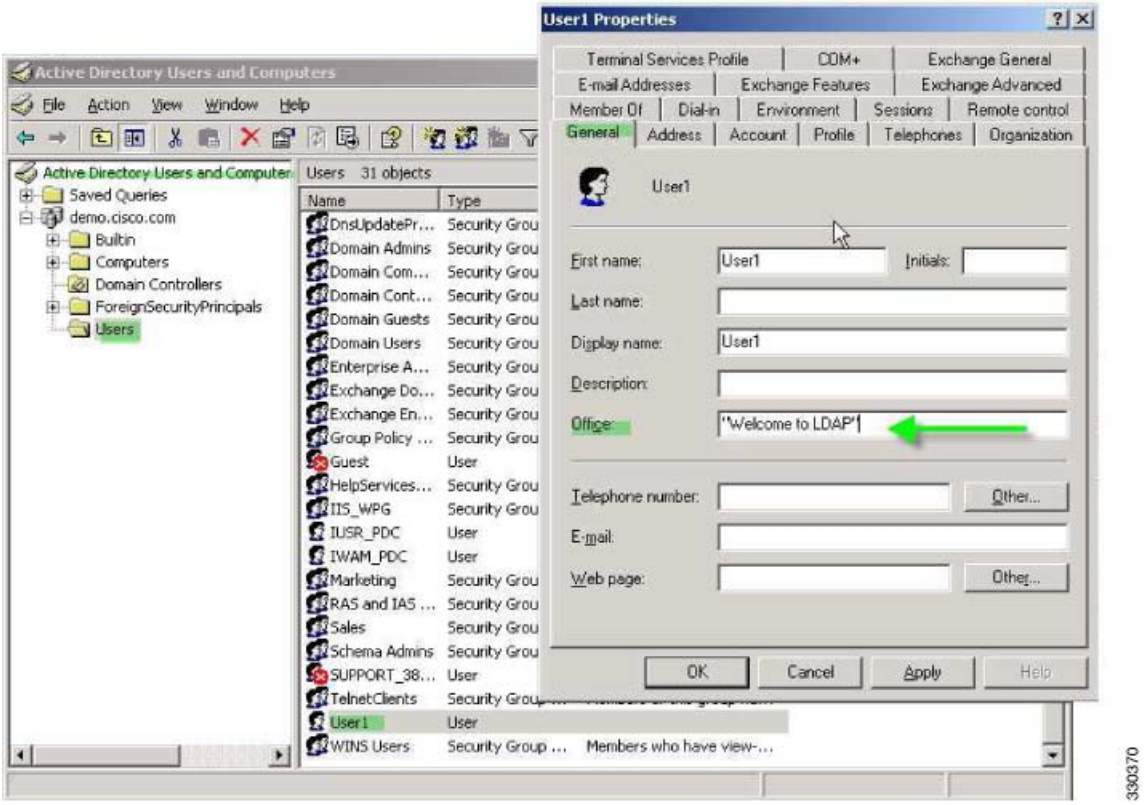
To configure the attributes for a user on the AD or LDAP Server, perform the following steps:

Step 1 Right-click a user.

The Properties dialog box appears (see Figure B-3).

Step 2 Click the **General** tab and enter banner text in the Office field, which uses the AD/LDAP attribute physicalDeliveryOfficeName.

Figure B-3 LDAP User Configuration



Step 3 Create an LDAP attribute map on the ASA.

The following example creates the map Banner and maps the AD/LDAP attribute physicalDeliveryOfficeName to the Cisco attribute Banner1:

```
hostname(config)# ldap attribute-map Banner
hostname(config-ldap-attribute-map)# map-name physicalDeliveryOfficeName Banner1
```

Step 4 Associate the LDAP attribute map to the AAA server.

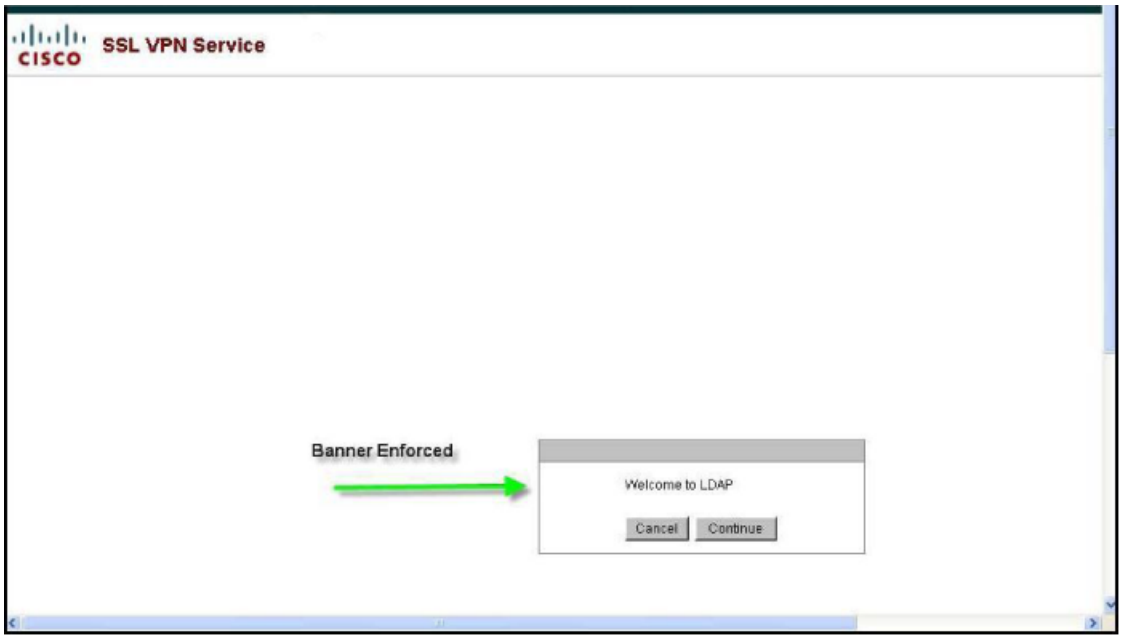
The following example enters the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP, and associates the attribute map Banner that you created in Step 3:

```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map Banner
```

Step 5 Test the banner enforcement.

The following example shows a clientless SSL connection and the banner enforced through the attribute map after the user authenticates (see Figure B-4).

Figure B-4 Banner Displayed



Placing LDAP Users in a Specific Group Policy

The following example shows how to authenticate User1 on the AD LDAP server to a specific group policy on the ASA. On the server, use the Department field of the Organization tab to enter the name of the group policy. Then create an attribute map and map Department to the Cisco attribute IETF-Radius-Class. During authentication, the ASA retrieves the value of Department from the server, maps the value to the IETF-Radius-Class, and places User1 in the group policy.

This example applies to any connection type, including the IPsec VPN client, AnyConnect SSL VPN client, or clientless SSL VPN. In this example, User1 is connecting through a clientless SSL VPN connection.

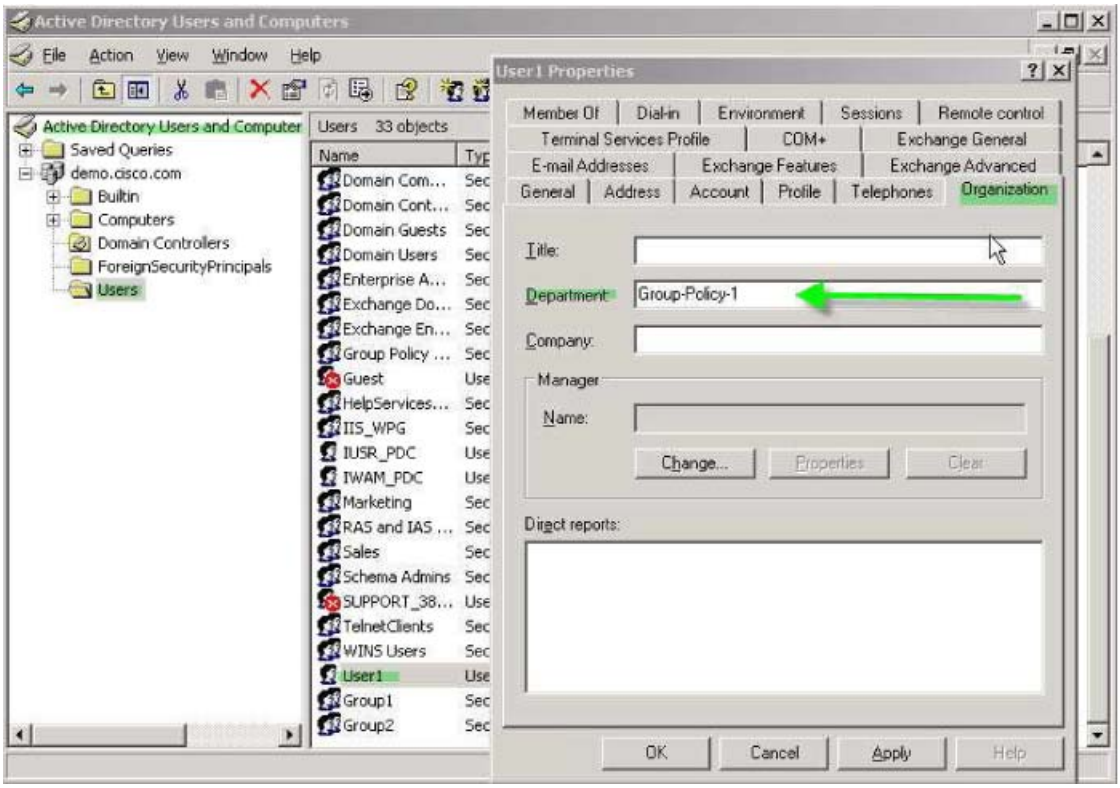
To configure the attributes for the user on the AD LDAP server, perform the following steps:

Step 1 Right-click the user.

The Properties dialog box appears (see Figure B-5).

Step 2 Click the **Organization** tab and enter **Group-Policy-1** in the Department field.

Figure B-5 AD/LDAP Department Attribute



Step 3 Define an attribute map for the LDAP configuration shown in Step 1.

The following example shows how to map the AD attribute Department to the Cisco attribute IETF-Radius-Class.

```
hostname(config)# ldap attribute-map group_policy
hostname(config-ldap-attribute-map)# map-name Department IETF-Radius-Class
```

Step 4 Associate the LDAP attribute map to the AAA server.

The following example enters the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP, and associates the attribute map group_policy that you created in Step 3:

```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map group_policy
```

Step 5 Add the new group-policy on the ASA and configure the required policy attributes that will be assigned to the user. The following example creates Group-policy-1, the name entered in the Department field on the server:

```
hostname(config)# group-policy Group-policy-1 external server-group LDAP_demo
hostname(config-aaa-server-group)#
```

Step 6 Establish the VPN connection as the user would, and verify that the session inherits the attributes from Group-Policy1 (and any other applicable attributes from the default group-policy).

Step 7 Monitor the communication between the ASA and the server by enabling the **debug ldap 255** command from privileged EXEC mode. The following is sample output from this command, which has been edited to provide the key messages:

```
[29] Authentication successful for user1 to 10.1.1.2
[29] Retrieving user attributes from server 10.1.1.2
[29] Retrieved Attributes:
[29] department: value = Group-Policy-1
[29] mapped to IETF-Radius-Class: value = Group-Policy-1
```

Enforcing Static IP Address Assignment for AnyConnect Tunnels

In this example, configure the AnyConnect client user Web1 to receive a static IP address. then enter the address in the Assign Static IP Address field of the Dialin tab on the AD LDAP server. This field uses the msRADIUSFramedIPAddress attribute. Create an attribute map that maps this attribute to the Cisco attribute IETF-Radius-Framed-IP-Address.

During authentication, the ASA retrieves the value of msRADIUSFramedIPAddress from the server, maps the value to the Cisco attribute IETF-Radius-Framed-IP-Address, and provides the static address to User1.

The following example applies to full-tunnel clients, including the IPsec client and the SSL VPN clients (AnyConnect client 2.x and the SSL VPN client).

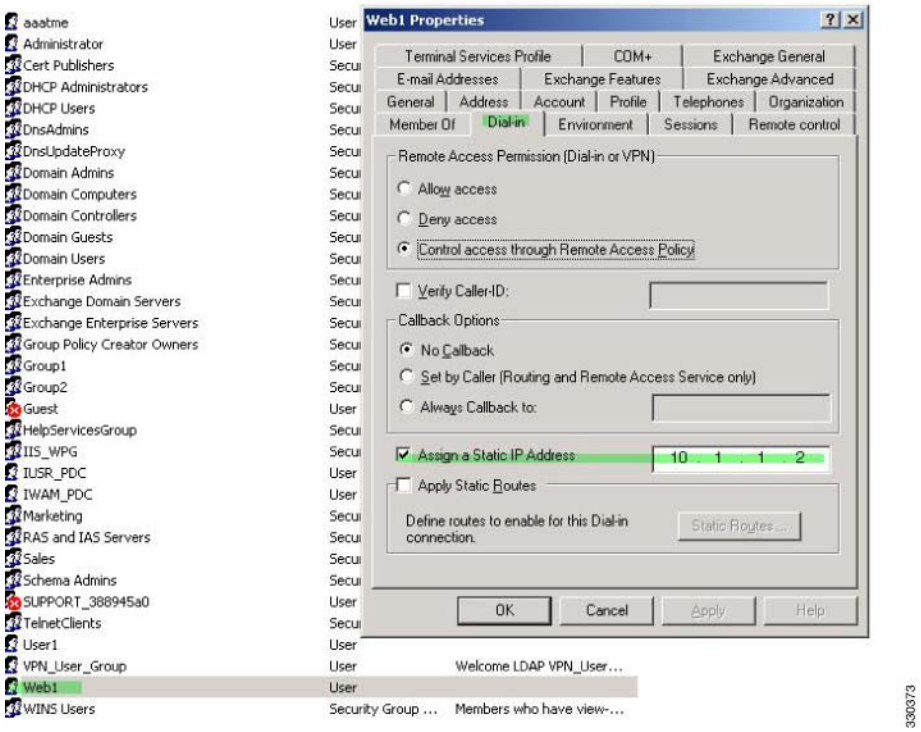
To configure the user attributes on the AD /LDAP server, perform the following steps:

Step 1 Right-click the username.

The Properties dialog box appears (see Figure B-6).

Step 2 Click the **Dialin** tab, check the **Assign Static IP Address** check box, and enter an IP address of 10.1.1.2.

Figure B-6 Assign Static IP Address



Step 3 Create an attribute map for the LDAP configuration shown in Step 1.

The following example shows how to map the AD attribute msRADIUSFramedIPAddress used by the Static Address field to the Cisco attribute IETF-Radius-Framed-IP-Address:

```
hostname(config)# ldap attribute-map static_address
hostname(config-ldap-attribute-map)# map-name msRADIUSFramedIPAddress
IETF-Radius-Framed-IP-Address
```

Step 4 Associate the LDAP attribute map to the AAA server.

The following example enters the aaa server host configuration mode for the host 10.1.1.2, in the AAA server group MS_LDAP, and associates the attribute map static_address that you created in Step 3:

```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map static_address
```

Step 5 Verify that the **vpn-address-assignment** command is configured to specify AAA by viewing this part of the configuration with the **show run all vpn-addr-assign** command:

```
hostname(config)# show run all vpn-addr-assign
vpn-addr-assign aaa    << Make sure this is configured >>
no vpn-addr-assign dhcp
vpn-addr-assign local
hostname(config)#
```

Step 6 Establish a connection to the ASA with the AnyConnect client. Observe the following:

- The banner is received in the same sequence as a clientless connection (see Figure B-7).
- The user receives the IP address configured on the server and mapped to the ASA (see Figure B-8).

Figure B-7 Verify the Banner for the AnyConnect Session

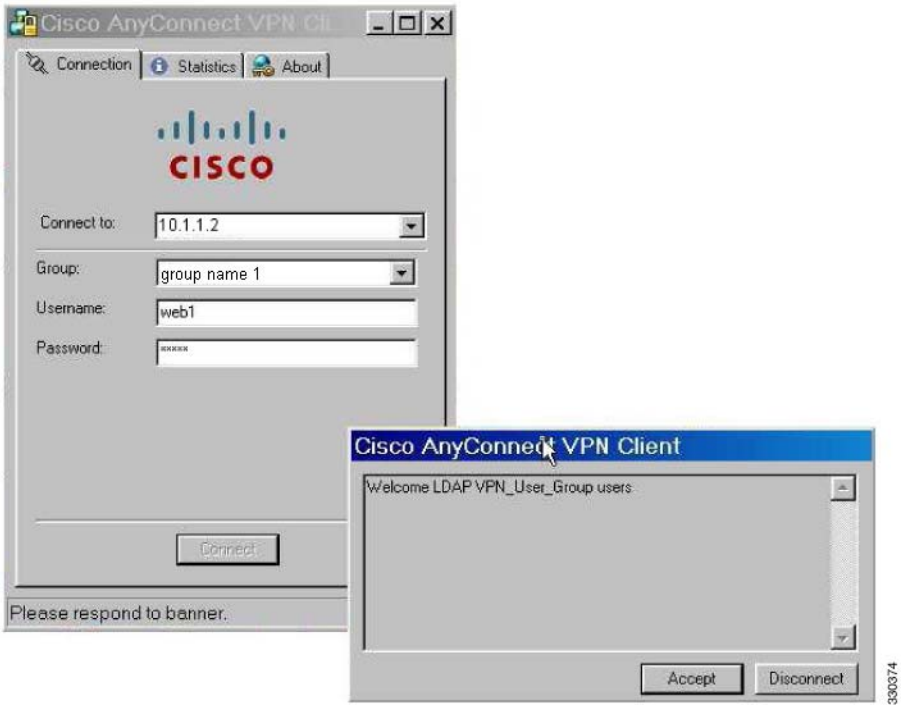


Figure B-8 AnyConnect Session Established

Step 7 Use the **show vpn-sessiondb svc** command to view the session details and verify the address assigned:

```
hostname# show vpn-sessiondb svc

Session Type: SVC
```

```
Username     : web1                    Index        : 31
Assigned IP  : 10.1.1.2               Public IP    : 10.86.181.70
Protocol     : Clientless SSL-Tunnel DTLS-Tunnel
Encryption   : RC4 AES128              Hashing      : SHA1
Bytes Tx     : 304140                  Bytes Rx     : 470506
Group Policy : VPN_User_Group          Tunnel Group : Group1_TunnelGroup
Login Time   : 11:13:05 UTC Tue Aug 28 2007
Duration     : 0h:01m:48s
NAC Result   : Unknown
VLAN Mapping : N/A                     VLAN         : none
```

Enforcing Dial-in Allow or Deny Access

The following example creates an LDAP attribute map that specifies the tunneling protocols allowed by the user. You map the allow access and deny access settings on the Dialin tab to the Cisco attribute Tunneling-Protocol, which supports the bitmap values shown in Table B-6:

Table B-6 Bitmap Values for Cisco Tunneling-Protocol Attribute

Value	Tunneling Protocol
1	PPTP
2	L2TP
4[1]	IPsec (IKEv1)
8[2]	L2TP/IPsec
16	Clientless SSL
32	SSL client—AnyConnect or SSL VPN client
64	IPsec (IKEv2)

1. IPsec and L2TP over IPsec are not supported simultaneously. Therefore, the values 4 and 8 are mutually exclusive.
2. See note 1.

Use this attribute to create an Allow Access (TRUE) or a Deny Access (FALSE) condition for the protocols and enforce the method for which the user is allowed access.

For this simplified example, by mapping the tunnel protocol IPsec/IKEv1 (4), you can create an allow (true) condition for the Cisco VPN client. You also map WebVPN (16) and SVC/AC (32), which are mapped as a value of 48 (16+32) and create a deny (false) condition. This allows the user to connect to the ASA using IPsec, but any attempt to connect using clientless SSL or the AnyConnect client is denied.

Another example of enforcing dial-in allow access or deny access is available in the Tech Note *ASA/PIX: Mapping VPN Clients to VPN Group Policies Through LDAP Configuration Example* at the following URL:

http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a008089149d.shtml

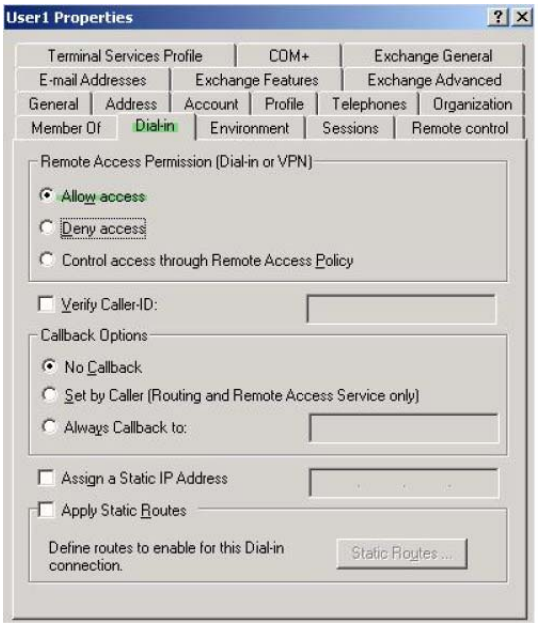
To configure the user attributes on the AD/LDAP server, perform the following steps:

Step 1 Right-click the user.

The Properties dialog box appears.

Step 2 Click the **Dial-in** tab, then click the **Allow Access** radio button (Figure B-9).

Figure B-9 AD/LDAP User1 - Allow Access



Note If you select the Control access through the Remote Access Policy option, then a value is not returned from the server, and the permissions that are enforced are based on the internal group policy settings of the ASA.

Step 3 Create an attribute map to allow both an IPsec and AnyConnect connection, but deny a clientless SSL connection.

The following example shows how to create the map tunneling_protocols, and map the AD attribute msNPAllowDialin used by the Allow Access setting to the Cisco attribute Tunneling-Protocols using the **map-name** command, and add map values with the **map-value** command:

```
hostname(config)# ldap attribute-map tunneling_protocols
hostname(config-ldap-attribute-map)# map-name msNPAllowDialin Tunneling-Protocols
hostname(config-ldap-attribute-map)# map-value msNPAllowDialin FALSE 48
hostname(config-ldap-attribute-map)# map-value msNPAllowDialin TRUE 4
```

Step 4 Associate the LDAP attribute map to the AAA server.

The following example enters the aaa server host configuration mode for the host 10.1.1.2, in the AAA server group MS_LDAP, and associates the attribute map tunneling_protocols that you created in Step 2:

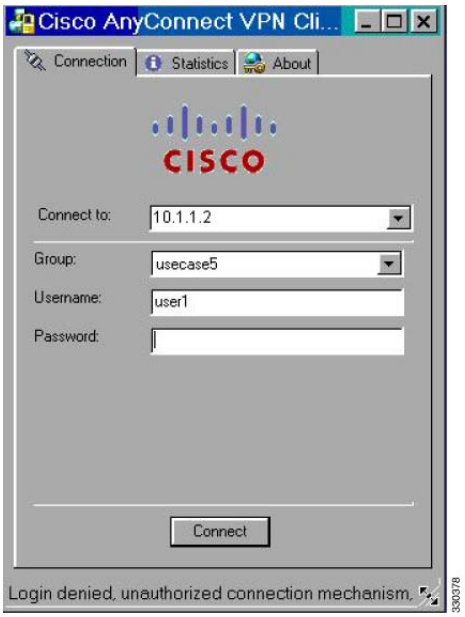
```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map tunneling_protocols
```

Step 5 Verify that the attribute map works as configured.

Step 6 Try connections using clientless SSL, the AnyConnect client, and the IPsec client. The clientless and AnyConnect connections should fail, and the user should be informed that an unauthorized connection mechanism was the reason for the failed connection. The IPsec client should connect because IPsec is an allowed tunneling protocol according to the attribute map (see Figure B-10 and Figure B-11).

Figure B-10 Login Denied Message for Clientless User

Figure B-11 Login Denied Message for AnyConnect Client User



Enforcing Logon Hours and Time-of-Day Rules

The following example shows how to configure and enforce the hours that a clientless SSL user (such as a business partner) is allowed to access the network.

On the AD server, use the Office field to enter the name of the partner, which uses the physicalDeliveryOfficeName attribute. Then we create an attribute map on the ASA to map that attribute to the Cisco attribute Access-Hours. During authentication, the ASA retrieves the value of physicalDeliveryOfficeName and maps it to Access-Hours.

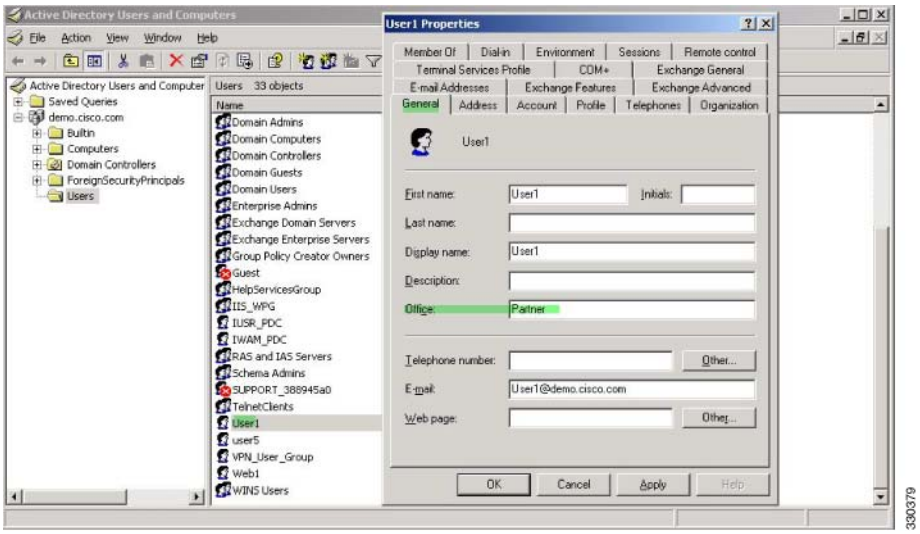
To configure the user attributes on the AD /LDAP server, perform the following steps:

Step 1 Select the user, and right-click **Properties**.

The Properties dialog box appears (see Figure B-12).

Step 2 Click the **General** tab.

Figure B-12 Active Directory Properties Dialog Box



Step 3 Create an attribute map.

The following example shows how to create the attribute map access_hours and map the AD attribute physicalDeliveryOfficeName used by the Office field to the Cisco attribute Access-Hours.

```
hostname(config)# ldap attribute-map access_hours
hostname(config-ldap-attribute-map)# map-name physicalDeliveryOfficeName Access-Hours
```

Step 4 Associate the LDAP attribute map to the AAA server.

The following example enters the aaa server host configuration mode for the host 10.1.1.2, in the AAA server group MS_LDAP, and associates the attribute map access_hours that you created in Step 3:

```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map access_hours
```

Step 5 Configure time ranges for each value allowed on the server.

The following example configures Partner access hours from 9am to 5pm Monday through Friday:

```
hostname(config)# time-range Partner
hostname(config-time-range)# periodic weekdays 09:00 to 17:00
```

Configuring an External RADIUS Server

This section presents an overview of the RADIUS configuration procedure and defines the Cisco RADIUS attributes. It includes the following topics:

- Reviewing the RADIUS Configuration Procedure, page B-26
- ASA RADIUS Authorization Attributes, page B-26
- ASA IETF RADIUS Authorization Attributes, page B-36
- RADIUS Accounting Disconnect Reason Codes, page B-36

Reviewing the RADIUS Configuration Procedure

This section describes the RADIUS configuration steps required to support authentication and authorization of ASA users.

To set up the RADIUS server to interoperate with the ASA, perform the following steps:

Step 1 Load the ASA attributes into the RADIUS server. The method you use to load the attributes depends on which type of RADIUS server you are using:

- If you are using Cisco ACS: the server already has these attributes integrated. You can skip this step.
- For RADIUS servers from other vendors (for example, Microsoft Internet Authentication Service): you must manually define each ASA attribute. To define an attribute, use the attribute name or number, type, value, and vendor code (3076). For a list of ASA RADIUS authorization attributes and values, see Table B-7.

Step 2 Set up the users or groups with the permissions and attributes to send during IPsec or SSL tunnel establishment.

ASA RADIUS Authorization Attributes

Authorization refers to the process of enforcing permissions or attributes. A RADIUS server defined as an authentication server enforces permissions or attributes if they are configured. These attributes have vendor ID 3076.

Table B-7 lists the ASA supported RADIUS attributes that can be used for user authorization.

Note RADIUS attribute names do not contain the cVPN3000 prefix. Cisco Secure ACS 4.x supports this new nomenclature, but attribute names in pre-4.0 ACS releases still include the cVPN3000 prefix. The ASAs enforce the RADIUS attributes based on attribute numeric ID, not attribute name. LDAP attributes are enforced by their name, not by the ID.

All attributes listed in Table B-7 are downstream attributes that are sent from the RADIUS server to the ASA except for the following attribute numbers: 146, 150, 151, and 152. These attribute numbers are upstream attributes that are sent from the ASA to the RADIUS server. RADIUS attributes 146 and 150 are sent from the ASA to the RADIUS server for authentication and authorization requests. All four previously listed attributes are sent from the ASA to the RADIUS server for accounting start, interim-update, and stop requests. Upstream RADIUS attributes 146, 150, 151, and 152 were introduced in ASA version 8.4.3.
Cisco ACS 5.x and Cisco ISE do not support IPv6 framed IP addresses for IP address assignment using RADIUS authentication in ASA Version 9.0.

Table B-7 ASA Supported RADIUS Attributes and Values

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
Access-Hours	Y	1	String	Single	Name of the time range, for example, Business-hours
Access-List-Inbound	Y	86	String	Single	ACL ID
Access-List-Outbound	Y	87	String	Single	ACL ID
Address-Pools	Y	217	String	Single	Name of IP local pool
Allow-Network-Extension-Mode	Y	64	Boolean	Single	0 = Disabled 1 = Enabled
Authenticated-User-Idle-Timeout	Y	50	Integer	Single	1-35791394 minutes
Authorization-DN-Field	Y	67	String	Single	Possible values: UID, OU, O, CN, L, SP, C, EA, T, N, GN, SN, I, GENQ, DNQ, SER, use-entire-name
Authorization-Required		66	Integer	Single	0 = No 1 = Yes
Authorization-Type	Y	65	Integer	Single	0 = None 1 = RADIUS 2 = LDAP
Banner1	Y	15	String	Single	Banner string to display for Cisco VPN remote access sessions: IPsec IKEv1, AnyConnect SSL-TLS/DTLS/IKEv2, and Clientless SSL
Banner2	Y	36	String	Single	Banner string to display for Cisco VPN remote access sessions: IPsec IKEv1, AnyConnect SSL-TLS/DTLS/IKEv2, and Clientless SSL. The Banner2 string is concatenated to the Banner1 string , if configured.
Cisco-IP-Phone-Bypass	Y	51	Integer	Single	0 = Disabled 1 = Enabled
Cisco-LEAP-Bypass	Y	75	Integer	Single	0 = Disabled 1 = Enabled
Client Type	Y	150	Integer	Single	1 = Cisco VPN Client (IKEv1) 2 = AnyConnect Client SSL VPN 3 = Clientless SSL VPN 4 = Cut-Through-Proxy 5 = L2TP/IPsec SSL VPN 6 = AnyConnect Client IPsec VPN (IKEv2)
Client-Type-Version-Limiting	Y	77	String	Single	IPsec VPN version number string
DHCP-Network-Scope	Y	61	String	Single	IP Address
Extended-Authentication-On-Rekey	Y	122	Integer	Single	0 = Disabled 1 = Enabled

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
Group-Policy	Y	25	String	Single	Sets the group policy for the remote access VPN session. For Versions 8.2 and later, use this attribute instead of IETF-Radius-Class. You can use one of the three following formats: • *group policy name* • OU=*group policy name* • OU=*group policy name*;
IE-Proxy-Bypass-Local		83	Integer	Single	0 = None 1 = Local
IE-Proxy-Exception-List		82	String	Single	New line (\n) separated list of DNS domains
IE-Proxy-PAC-URL	Y	133	String	Single	PAC Address String
IE-Proxy-Server		80	String	Single	IP address
IE-Proxy-Server-Policy		81	Integer	Single	1 = No Modify 2 = No Proxy 3 = Auto detect 4 = Use Concentrator Setting
IKE-KeepAlive-Confidence-Interval	Y	68	Integer	Single	10 - 300 seconds
IKE-Keepalive-Retry-Interval	Y	84	Integer	Single	2 - 10 seconds
IKE-Keep-Alives	Y	41	Boolean	Single	0 = Disabled 1 = Enabled
Intercept-DHCP-Configure-Msg	Y	62	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Allow-Passwd-Store	Y	16	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Authentication		13	Integer	Single	0 = None 1 = RADIUS 2 = LDAP (authorization only) 3 = NT Domain 4 = SDI 5 = Internal 6 = RADIUS with Expiry 7 = Kerberos/Active Directory
IPsec-Auth-On-Rekey	Y	42	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Backup-Server-List	Y	60	String	Single	Server Addresses (space delimited)
IPsec-Backup-Servers	Y	59	String	Single	1 = Use Client-Configured list 2 = Disable and clear client list 3 = Use Backup Server list

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
IPsec-Client-Firewall-Filter-Name		57	String	Single	Specifies the name of the filter to be pushed to the client as firewall policy
IPsec-Client-Firewall-Filter-Optional	Y	58	Integer	Single	0 = Required 1 = Optional
IPsec-Default-Domain	Y	28	String	Single	Specifies the single default domain name to send to the client (1-255 characters).
IPsec-IKE-Peer-ID-Check	Y	40	Integer	Single	1 = Required 2 = If supported by peer certificate 3 = Do not check
IPsec-IP-Compression	Y	39	Integer	Single	0 = Disabled 1 = Enabled
IPsec-Mode-Config	Y	31	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP	Y	34	Boolean	Single	0 = Disabled 1 = Enabled
IPsec-Over-UDP-Port	Y	35	Integer	Single	4001 - 49151. The default is10000.
IPsec-Required-Client-Firewall-Capability	Y	56	Integer	Single	0 = None 1 = Policy defined by remote FW Are-You-There (AYT) 2 = Policy pushed CPP 4 = Policy from server
IPsec-Sec-Association		12	String	Single	Name of the security association
IPsec-Split-DNS-Names	Y	29	String	Single	Specifies the list of secondary domain names to send to the client (1-255 characters).
IPsec-Split-Tunneling-Policy	Y	55	Integer	Single	0 = No split tunneling 1 = Split tunneling 2 = Local LAN permitted
IPsec-Split-Tunnel-List	Y	27	String	Single	Specifies the name of the network/ACL that describes the split tunnel inclusion list.
IPsec-Tunnel-Type	Y	30	Integer	Single	1 = LAN-to-LAN 2 = Remote access
IPsec-User-Group-Lock		33	Boolean	Single	0 = Disabled 1 = Enabled
IPv6-Address-Pools	Y	218	String	Single	Name of IP local pool-IPv6
IPv6-VPN-Filter	Y	219	String	Single	ACL value

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
L2TP-Encryption		21	Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bits 4 = 128 bits 8 = Stateless-Req 15= 40/128-Encr/Stateless-Req
L2TP-MPPC-Compression		38	Integer	Single	0 = Disabled 1 = Enabled
Member-Of	Y	145	String	Single	Comma-delimited string, for example: `Engineering, Sales` An administrative attribute that can be used in dynamic access policies. It does not set a group policy.
MS-Client-Subnet-Mask	Y	63	Boolean	Single	An IP address
NAC-Default-ACL		92	String		ACL
NAC-Enable		89	Integer	Single	0 = No 1 = Yes
NAC-Revalidation-Timer		91	Integer	Single	300 - 86400 seconds
NAC-Settings	Y	141	String	Single	Name of the NAC policy
NAC-Status-Query-Timer		90	Integer	Single	30 - 1800 seconds
Perfect-Forward-Secrecy-Enable	Y	88	Boolean	Single	0 = No 1 = Yes
PPTP-Encryption		20	Integer	Single	Bitmap: 1 = Encryption required 2 = 40 bits 4 = 128 bits 8 = Stateless-Required 15= 40/128-Encr/Stateless-Req
PPTP-MPPC-Compression		37	Integer	Single	0 = Disabled 1 = Enabled
Primary-DNS	Y	5	String	Single	An IP address
Primary-WINS	Y	7	String	Single	An IP address
Privilege-Level	Y	220	Integer	Single	An integer between 0 and 15.
Required-Client- Firewall-Vendor-Code	Y	45	Integer	Single	1 = Cisco Systems (with Cisco Integrated Client) 2 = Zone Labs 3 = NetworkICE 4 = Sygate 5 = Cisco Systems (with Cisco Intrusion Prevention Security Agent)

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
Required-Client-Firewall-Description	Y	47	String	Single	String
Required-Client-Firewall-Product-Code	Y	46	Integer	Single	Cisco Systems Products: 1 = Cisco Intrusion Prevention Security Agent or Cisco Integrated Client (CIC) Zone Labs Products: 1 = Zone Alarm 2 = Zone AlarmPro 3 = Zone Labs Integrity NetworkICE Product: 1 = BlackIce Defender/Agent Sygate Products: 1 = Personal Firewall 2 = Personal Firewall Pro 3 = Security Agent
Required-Individual-User-Auth	Y	49	Integer	Single	0 = Disabled 1 = Enabled
Require-HW-Client-Auth	Y	48	Boolean	Single	0 = Disabled 1 = Enabled
Secondary-DNS	Y	6	String	Single	An IP address
Secondary-WINS	Y	8	String	Single	An IP address
SEP-Card-Assignment		9	Integer	Single	Not used
Session Subtype	Y	152	Integer	Single	0 = None 1 = Clientless 2 = Client 3 = Client Only Session Subtype applies only when the Session Type (151) attribute has the following values: 1, 2, 3, and 4.
Session Type	Y	151	Integer	Single	0 = None 1 = AnyConnect Client SSL VPN 2 = AnyConnect Client IPSec VPN (IKEv2) 3 = Clientless SSL VPN 4 = Clientless Email Proxy 5 = Cisco VPN Client (IKEv1) 6 = IKEv1 LAN-LAN 7 = IKEv2 LAN-LAN 8 = VPN Load Balancing
Simultaneous-Logins	Y	2	Integer	Single	0 - 2147483647
Smart-Tunnel	Y	136	String	Single	Name of a Smart Tunnel

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
Smart-Tunnel-Auto	Y	138	Integer	Single	0 = Disabled 1 = Enabled 2 = AutoStart
Smart-Tunnel-Auto-Signon-Enable	Y	139	String	Single	Name of a Smart Tunnel Auto Signon list appended by the domain name
Strip-Realm	Y	135	Boolean	Single	0 = Disabled 1 = Enabled
SVC-Ask	Y	131	String	Single	0 = Disabled 1 = Enabled 3 = Enable default service 5 = Enable default clientless (2 and 4 not used)
SVC-Ask-Timeout	Y	132	Integer	Single	5 - 120 seconds
SVC-DPD-Interval-Client	Y	108	Integer	Single	0 = Off 5 - 3600 seconds
SVC-DPD-Interval-Gateway	Y	109	Integer	Single	0 = Off) 5 - 3600 seconds
SVC-DTLS	Y	123	Integer	Single	0 = False 1 = True
SVC-Keepalive	Y	107	Integer	Single	0 = Off 15 - 600 seconds
SVC-Modules	Y	127	String	Single	String (name of a module)
SVC-MTU	Y	125	Integer	Single	MTU value 256 - 1406 in bytes
SVC-Profiles	Y	128	String	Single	String (name of a profile)
SVC-Rekey-Time	Y	110	Integer	Single	0 = Disabled 1- 10080 minutes
Tunnel Group Name	Y	146	String	Single	1 - 253 characters
Tunnel-Group-Lock	Y	85	String	Single	Name of the tunnel group or “none”
Tunneling-Protocols	Y	11	Integer	Single	1 = PPTP 2 = L2TP 4 = IPSec (IKEv1) 8 = L2TP/IPSec 16 = WebVPN 32 = SVC 64 = IPsec (IKEv2) 8 and 4 are mutually exclusive (0 - 11, 16 - 27, 32 - 43, 48 - 59 are legal values).

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
Use-Client-Address		17	Boolean	Single	0 = Disabled 1 = Enabled
VLAN	Y	140	Integer	Single	0 - 4094
WebVPN-Access-List	Y	73	String	Single	Access-List name
WebVPN ACL	Y	73	String	Single	Name of a WebVPN ACL on the device
WebVPN-ActiveX-Relay	Y	137	Integer	Single	0 = Disabled Otherwise = Enabled
WebVPN-Apply-ACL	Y	102	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Auto-HTTP-Signon	Y	124	String	Single	Reserved
WebVPN-Citrix-Metaframe-Enable	Y	101	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Content-Filter-Parameters	Y	69	Integer	Single	1 = Java ActiveX 2 = Java Script 4 = Image 8 = Cookies in images
WebVPN-Customization	Y	113	String	Single	Name of the customization
WebVPN-Default-Homepage	Y	76	String	Single	A URL such as http://example-example.com
WebVPN-Deny-Message	Y	116	String	Single	Valid string (up to 500 characters)
WebVPN-Download_Max-Size	Y	157	Integer	Single	0x7fffffff
WebVPN-File-Access-Enable	Y	94	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-File-Server-Browsing-Enable	Y	96	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-File-Server-Entry-Enable	Y	95	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Group-based-HTTP/HTTPS-Proxy -Exception-List	Y	78	String	Single	Comma-separated DNS/IP with an optional wildcard (*) (for example *.cisco.com, 192.168.1.*, wwwin.cisco.com)
WebVPN-Hidden-Shares	Y	126	Integer	Single	0 = None 1 = Visible
WebVPN-Home-Page-Use-Smart-Tunnel	Y	228	Boolean	Single	Enabled if clientless home page is to be rendered through Smart Tunnel.
WebVPN-HTML-Filter	Y	69	Bitmap	Single	1 = Java ActiveX 2 = Scripts 4 = Image 8 = Cookies
WebVPN-HTTP-Compression	Y	120	Integer	Single	0 = Off 1 = Deflate Compression

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
WebVPN-HTTP-Proxy-IP-Address	Y	74	String	Single	Comma-separated DNS/IP:port, with http= or https= prefix (for example http=10.10.10.10:80, https=11.11.11.11:443)
WebVPN-Idle-Timeout-Alert-Interval	Y	148	Integer	Single	0 (Disabled) - 30
WebVPN-Keepalive-Ignore	Y	121	Integer	Single	0-900
WebVPN-Macro-Substitution	Y	223	String	Single	Unbounded. For examples, see the *SSL VPN Deployment Guide* at the following URL: http://supportwiki.cisco.com/ViewWiki/index.php/Cisco_ASA_5500_SSL_VPN_Deployment_Guide%2C_Version_8.x
WebVPN-Macro-Substitution	Y	224	String	Single	Unbounded. For examples, see the *SSL VPN Deployment Guide* at the following URL: http://supportwiki.cisco.com/ViewWiki/index.php/Cisco_ASA_5500_SSL_VPN_Deployment_Guide%2C_Version_8.x
WebVPN-Port-Forwarding-Enable	Y	97	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Port-Forwarding-Exchange-Proxy-Enable	Y	98	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Port-Forwarding-HTTP-Proxy	Y	99	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-Port-Forwarding-List	Y	72	String	Single	Port forwarding list name
WebVPN-Port-Forwarding-Name	Y	79	String	Single	String name (example, “Corporate-Apps”). This text replaces the default string, “Application Access,” on the clientless portal home page.
WebVPN-Post-Max-Size	Y	159	Integer	Single	0x7fffffff
WebVPN-Session-Timeout-Alert-Interval	Y	149	Integer	Single	0 (Disabled) - 30
WebVPN Smart-Card-Removal-Disconnect	Y	225	Boolean	Single	0 = Disabled 1 = Enabled
WebVPN-Smart-Tunnel	Y	136	String	Single	Name of a smart tunnel
WebVPN-Smart-Tunnel-Auto-Sign-On	Y	139	String	Single	Name of a Smart Tunnel auto sign-on list appended by the domain name
WebVPN-Smart-Tunnel-Auto-Start	Y	138	Integer	Single	0 = Disabled 1 = Enabled 2 = Auto Start

Table B-7 ASA Supported RADIUS Attributes and Values (continued)

Attribute Name	ASA	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
WebVPN-Smart-Tunnel-Tunnel-Policy	Y	227	String	Single	One of "e networkname," "i networkname," or "a," where networkname is the name of a smart tunnel network list, e indicates the tunnel excluded, i indicates the tunnel specified, and a indicates all tunnels.
WebVPN-SSL-VPN-Client-Enable	Y	103	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SSL-VPN-Client-Keep-Installation	Y	105	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SSL-VPN-Client-Required	Y	104	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SSO-Server-Name	Y	114	String	Single	Valid string
WebVPN-Storage-Key	Y	162	String	Single	
WebVPN-Storage-Objects	Y	161	String	Single	
WebVPN-SVC-Keepalive-Frequency	Y	107	Integer	Single	15-600 seconds, 0=Off
WebVPN-SVC-Client-DPD-Frequency	Y	108	Integer	Single	5-3600 seconds, 0=Off
WebVPN-SVC-DTLS-Enable	Y	123	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-SVC-DTLS-MTU	Y	125	Integer	Single	MTU value is from 256-1406 bytes.
WebVPN-SVC-Gateway-DPD-Frequency	Y	109	Integer	Single	5-3600 seconds, 0=Off
WebVPN-SVC-Rekey-Time	Y	110	Integer	Single	4-10080 minutes, 0=Off
WebVPN-SVC-Rekey-Method	Y	111	Integer	Single	0 (Off), 1 (SSL), 2 (New Tunnel)
WebVPN-SVC-Compression	Y	112	Integer	Single	0 (Off), 1 (Deflate Compression)
WebVPN-UNIX-Group-ID (GID)	Y	222	Integer	Single	Valid UNIX group IDs
WebVPN-UNIX-User-ID (UIDs)	Y	221	Integer	Single	Valid UNIX user IDs
WebVPN-Upload-Max-Size	Y	158	Integer	Single	0x7fffffff
WebVPN-URL-Entry-Enable	Y	93	Integer	Single	0 = Disabled 1 = Enabled
WebVPN-URL-List	Y	71	String	Single	URL list name
WebVPN-User-Storage	Y	160	String	Single	
WebVPN-VDI	Y	163	String	Single	List of settings

ASA IETF RADIUS Authorization Attributes

Table B-8 lists the supported IETF RADIUS attributes.

Table B-8 ASA Supported IETF RADIUS Attributes and Values

Attribute Name	VPN 3000	ASA	PIX	Attr. No.	Syntax/ Type	Single or Multi-Valued	Description or Value
IETF-Radius-Class	Y	Y	Y	25		Single	For Versions 8.2.x and later, we recommend that you use the Group-Policy attribute (VSA 3076, #25) as described in Table B-7: • *group policy name* • OU=*group policy name* • OU=*group policy name*
IETF-Radius-Filter-Id	Y	Y	Y	11	String	Single	Access list name that is defined on the ASA, which applies only to full tunnel IPsec and SSL VPN clients
IETF-Radius-Framed-IP-Address	Y	Y	Y	n/a	String	Single	An IP address
IETF-Radius-Framed-IP-Netmask	Y	Y	Y	n/a	String	Single	An IP address mask
IETF-Radius-Idle-Timeout	Y	Y	Y	28	Integer	Single	Seconds
IETF-Radius-Service-Type	Y	Y	Y	6	Integer	Single	Seconds. Possible Service Type values: .Administrative—User is allowed access to configure prompt. .NAS-Prompt—User is allowed access to exec prompt. .remote-access—User is allowed network access
IETF-Radius-Session-Timeout	Y	Y	Y	27	Integer	Single	Seconds

RADIUS Accounting Disconnect Reason Codes

These codes are returned if the ASA encounters a disconnect when sending packets:

Table B-9

Disconnect Reason Code
ACCT_DISC_USER_REQ = 1
ACCT_DISC_LOST_CARRIER = 2
ACCT_DISC_LOST_SERVICE = 3
ACCT_DISC_IDLE_TIMEOUT = 4
ACCT_DISC_SESS_TIMEOUT = 5

Table B-9

Disconnect Reason Code
ACCT_DISC_ADMIN_RESET = 6
ACCT_DISC_ADMIN_REBOOT = 7
ACCT_DISC_PORT_ERROR = 8
ACCT_DISC_NAS_ERROR = 9
ACCT_DISC_NAS_REQUEST = 10
ACCT_DISC_NAS_REBOOT = 11
ACCT_DISC_PORT_UNNEEDED = 12
ACCT_DISC_PORT_PREEMPTED = 13
ACCT_DISC_PORT_SUSPENDED = 14
ACCT_DISC_SERV_UNAVAIL = 15
ACCT_DISC_CALLBACK = 16
ACCT_DISC_USER_ERROR = 17
ACCT_DISC_HOST_REQUEST = 18
ACCT_DISC_ADMIN_SHUTDOWN = 19
ACCT_DISC_SA_EXPIRED = 21
ACCT_DISC_MAX_REASONS = 22

Configuring an External TACACS+ Server

The ASA provides support for TACACS+ attributes. TACACS+ separates the functions of authentication, authorization, and accounting. The protocol supports two types of attributes: mandatory and optional. Both the server and client must understand a mandatory attribute, and the mandatory attribute must be applied to the user. An optional attribute may or may not be understood or used.

Note To use TACACS+ attributes, make sure that you have enabled AAA services on the NAS.

Table B-10 lists supported TACACS+ authorization response attributes for cut-through-proxy connections. Table B-11 lists supported TACACS+ accounting attributes.

Table B-10 Supported TACACS+ Authorization Response Attributes

Attribute	Description
acl	Identifies a locally configured access list to be applied to the connection.
idletime	Indicates the amount of inactivity in minutes that is allowed before the authenticated user session is terminated.
timeout	Specifies the absolute amount of time in minutes that authentication credentials remain active before the authenticated user session is terminated.

Table B-11 Supported TACACS+ Accounting Attributes

Attribute	Description
bytes_in	Specifies the number of input bytes transferred during this connection (stop records only).
bytes_out	Specifies the number of output bytes transferred during this connection (stop records only).
cmd	Defines the command executed (command accounting only).
disc-cause	Indicates the numeric code that identifies the reason for disconnecting (stop records only).
elapsed_time	Defines the elapsed time in seconds for the connection (stop records only).
foreign_ip	Specifies the IP address of the client for tunnel connections. Defines the address on the lowest security interface for cut-through-proxy connections.
local_ip	Specifies the IP address that the client connected to for tunnel connections. Defines the address on the highest security interface for cut-through-proxy connections.
NAS port	Contains a session ID for the connection.
packs_in	Specifies the number of input packets transferred during this connection.
packs_out	Specifies the number of output packets transferred during this connection.
priv-level	Set to the user privilege level for command accounting requests or to 1 otherwise.
rem_iddr	Indicates the IP address of the client.
service	Specifies the service used. Always set to “shell” for command accounting only.
task_id	Specifies a unique task ID for the accounting transaction.
username	Indicates the name of the user.

Numerics

3DES See DES.

A

AAA Authentication, authorization, and accounting. See also TACACS+ and RADIUS.

ABR Area Border Router. In OSPF, a router with interfaces in multiple areas.

ACE access control entry. Information entered into the configuration that lets you specify what type of traffic to permit or deny on an interface. By default, traffic that is not explicitly permitted is denied.

Access Modes The ASA CLI uses several command modes. The commands available in each mode vary. See also user EXEC mode, privileged EXEC mode, global configuration mode, command-specific configuration mode.

ACL access control list. A collection of ACEs. An ACL lets you specify what type of traffic to allow on an interface. By default, traffic that is not explicitly permitted is denied. ACLs are usually applied to the interface which is the source of inbound traffic. See also rule, outbound ACL.

ActiveX A set of object-oriented programming technologies and tools used to create mobile or portable programs. An ActiveX program is roughly equivalent to a Java applet.

Address Resolution Protocol See ARP.

address translation The translation of a network address and/or port to another network address/or port. See also IP address, interface PAT, NAT, PAT, Static PAT, xlate.

AES Advanced Encryption Standard. A symmetric block cipher that can encrypt and decrypt information. The AES algorithm is capable of using cryptographic keys of 128, 192 and 256 bits to encrypt and decrypt data in blocks of 128 bits. See also DES.

AH Authentication Header. An IP protocol (type 51) that can ensure data integrity, authentication, and replay detection. AH is embedded in the data to be protected (a full IP datagram, for example). AH can be used either by itself or with ESP. AH is an older IPsec protocol that is less important in most networks than ESP. AH provides authentication services but does not provide encryption services. It is provided to ensure compatibility with IPsec peers that do not support ESP, which provides both authentication and encryption. See also encryption and VPN. Refer to the RFC 2402.

AIP Advanced Inspection and Prevention. For example, the AIP SSM or AIP SSC, which runs IPS software.

A record address "A" stands for address, and refers to name-to-address mapped records in DNS.

APCF Application Profile Customization Framework. Lets the security appliance handle nonstandard applications so that they render correctly over a clientless SSL VPN connection.

ARP Address Resolution Protocol. A low-level TCP/IP protocol that maps a hardware address, or MAC address, to an IP address. An example hardware address is 00:00:a6:00:01:ba. The first three groups of characters (00:00:a6) identify the manufacturer; the rest of the characters (00:01:ba) identify the system card. ARP is defined in RFC 826.

ASA Adaptive Security Algorithm. Used by the ASA to perform inspections. ASA allows one-way (inside to outside) connections without an explicit configuration for each internal system and application. See also inspection engine.

ASA adaptive ASA.

ASDM Adaptive Security Device Manager. An application for managing and configuring a single ASA.

asymmetric encryption Also called public key systems, asymmetric encryption allows anyone to obtain access to the public key of anyone else. Once the public key is accessed, you can send an encrypted message to that person using the public key. See also encryption, public key.

authentication Cryptographic protocols and services that verify the identity of users and the integrity of data. One of the functions of the IPsec framework. Authentication establishes the integrity of the datastream and ensures that it is not tampered with in transit. It also provides confirmation about the origin of the datastream. See also AAA, encryption, and VPN.

Auto Applet Download Automatically downloads the clientless SSL VPN port-forwarding applet when the user first logs in to clientless SSL VPN.

auto-signon This command provides a single sign-on method for clientless SSL VPN users. It passes the clientless SSL VPN login credentials (username and password) to internal servers for authentication using NTLM authentication, basic authentication, or both.

B

backup server IPsec backup servers let a VPN client connect to the central site when the primary security appliance is unavailable.

BGP Border Gateway Protocol. BGP performs interdomain routing in TCP/IP networks. BGP is an Exterior Gateway Protocol, which means that it performs routing between multiple autonomous systems or domains and exchanges routing and access information with other BGP systems. The ASA does not support BGP. See also EGP.

BLT stream Bandwidth Limited Traffic stream. Stream or flow of packets whose bandwidth is constrained.

BOOTP Bootstrap Protocol. Lets diskless workstations boot over the network as is described in RFC 951 and RFC 1542.

BPDU Bridge Protocol Data Unit. Spanning-Tree Protocol hello packet that is sent out at configurable intervals to exchange information among bridges in the network. Protocol data unit is the OSI term for packet.

C

CA Certificate Authority, Certification Authority. A third-party entity that is responsible for issuing and revoking certificates. Each device with the public key of the CA can authenticate a device that has a certificate issued by the CA. The term CA also refers to software that provides CA services. See also certificate, CRL, public key, RA.

cache A temporary repository of information accumulated from previous task executions that can be reused, decreasing the time required to perform the tasks. Caching stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content.

CBC Cipher Block Chaining. A cryptographic technique that increases the encryption strength of an algorithm. CBC requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPsec packet.

certificate A signed cryptographic object that contains the identity of a user or device and the public key of the CA that issued the certificate. Certificates have an expiration date and may also be placed on a CRL if known to be compromised. Certificates also establish non-repudiation for IKE negotiation, which means that you can prove to a third party that IKE negotiation was completed with a specific peer.

CHAP Challenge Handshake Authentication Protocol.

CIFS Common Internet File System. It is a platform-independent file sharing system that provides users with network access to files, printers, and other machine resources. Microsoft implemented CIFS for networks of Windows computers, however, open source implementations of CIFS provide file access to servers running other operating systems, such as Linux, UNIX, and Mac OS X.

Citrix An application that virtualizes client-server applications and optimizes web applications.

CLI command-line interface. The primary interface for entering configuration and monitoring commands to the ASA.

client/server computing Distributed computing (processing) network systems in which transaction responsibilities are divided into two parts: client (front end) and server (back end). Also called distributed computing. See also RPC.

Client update Lets you update revisions of clients to which the update applies; provide a URL or IP address from which to get the update; and, in the case of Windows clients, optionally notify users that they should update their VPN client version.

command-specific configuration mode From global configuration mode, some commands enter a command-specific configuration mode. All user EXEC, privileged EXEC, global configuration, and command-specific configuration commands are available in this mode. See also global configuration mode, privileged EXEC mode, user EXEC mode.

compression The process of encoding information using fewer bits or other information-bearing units than an unencoded representation would use. Compression can reduce the size of transferring packets and increase communication performance.

configuration, config, config file A file on the ASA that represents the equivalent of settings, preferences, and properties administered by ASDM or the CLI.

Content Rewriting/Transformation Interprets and modifies applications so that they render correctly over a clientless SSL VPN connection.

cookie A cookie is a object stored by a browser. Cookies contain information, such as user preferences, to persistent storage.

CPU Central Processing Unit. Main processor.

CRC Cyclical Redundancy Check. Error-checking technique in which the frame recipient calculates a remainder by dividing frame contents by a prime binary divisor and compares the calculated remainder to a value stored in the frame by the sending node.

CRL Certificate Revocation List. A digitally signed message that lists all of the current but revoked certificates listed by a given CA. A CRL is analogous to a book of stolen charge card numbers that allow stores to reject bad credit cards. When certificates are revoked, they are added to a CRL. When you implement authentication using certificates, you can choose to use CRLs or not. Using CRLs lets you easily revoke certificates before they expire, but the CRL is generally only maintained by the CA or an RA. If you are using CRLs and the connection to the CA or RA is not available when authentication is requested, the authentication request will fail. See also CA, certificate, public key, RA.

CRV Call Reference Value. Used by H.225.0 to distinguish call legs signaled between two entities.

cryptography Encryption, authentication, integrity, keys and other services used for secure communication over networks. See also VPN and IPsec.

crypto map A data structure with a unique name and sequence number that is used for configuring VPNs on the ASA. A crypto map selects data flows that need security processing and defines the policy for these flows and the crypto peer that traffic needs to go to. A crypto map is applied to an interface. Crypto maps contain the ACLs, encryption standards, peers, and other parameters necessary to specify security policies for VPNs using IKE and IPsec. See also VPN.

CTIQBE Computer Telephony Interface Quick Buffer Encoding. A protocol used in IP telephony between the Cisco CallManager and CTI TAPI and JTAPI applications. CTIQBE is used by the TAPI/JTAPI protocol inspection module and supports NAT, PAT, and bidirectional NAT. This protocol enables Cisco IP SoftPhone and other Cisco TAPI/JTAPI applications to communicate with Cisco CallManager for call setup and voice traffic across the ASA.

cut-through proxy Enables the ASA to provide faster traffic flow after user authentication. The cut-through proxy challenges a user initially at the application layer. After the security appliance authenticates the user, it shifts the session flow and all traffic flows directly and quickly between the source and destination while maintaining session state information.

D

data confidentiality Describes any method that manipulates data so that no attacker can read it. This is commonly achieved by data encryption and keys that are only available to the parties involved in the communication.

data integrity Describes mechanisms that, through the use of encryption based on secret key or public key algorithms, allow the recipient of a piece of protected data to verify that the data has not been modified in transit.

data origin authentication A security service where the receiver can verify that protected data could have originated only from the sender. This service requires a data integrity service plus a key distribution mechanism, where a secret key is shared only between the sender and receiver.

decryption Application of a specific algorithm or cipher to encrypted data so as to render the data comprehensible to those who are authorized to see the information. See also encryption.

DES Data encryption standard. DES was published in 1977 by the National Bureau of Standards and is a secret key encryption scheme based on the Lucifer algorithm from IBM. Cisco uses DES in classic crypto (40-bit and 56-bit key lengths), IPsec crypto (56-bit key), and 3DES (triple DES), which performs encryption three times using a 56-bit key. 3DES is more secure than DES but requires more processing for encryption and decryption. See also AES, ESP.

DHCP Dynamic Host Configuration Protocol. Provides a mechanism for allocating IP addresses to hosts dynamically, so that addresses can be reused when hosts no longer need them and so that mobile computers, such as laptops, receive an IP address applicable to the LAN to which it is connected.

Diffie-Hellman A public key cryptography protocol that allows two parties to establish a shared secret over insecure communications channels. Diffie-Hellman is used within IKE to establish session keys. Diffie-Hellman is a component of Oakley key exchange.

Diffie-Hellman Group 1, Group 2, Group 5, Group 7 Diffie-Hellman refers to a type of public key cryptography using asymmetric encryption based on large prime numbers to establish both Phase 1 and Phase 2 SAs. Group 1 provides a smaller prime number than Group 2 but may be the only version supported by some IPsec peers. Diffe-Hellman Group 5 uses a 1536-bit prime number, is the most secure, and is recommended for use with AES. Group 7 has an elliptical curve field size of 163 bits and is for use with the Movian VPN client, but works with any peer that supports Group 7 (ECC). See also VPN and encryption.

Note The **group 7** command option was deprecated in ASA Version 8.0(4). Attempts to configure group 7 will generate an error message and use group 5 instead.

digital certificate See certificate.

DMZ See interface.

DN Distinguished Name. Global, authoritative name of an entry in the OSI Directory (X.500).

DNS Domain Name System (or Service). An Internet service that translates domain names into IP addresses.

DoS Denial of Service. A type of network attack in which the goal is to render a network service unavailable.

DSL digital subscriber line. Public network technology that delivers high bandwidth over conventional copper wiring at limited distances. DSL is provisioned via modem pairs, with one modem located at a central office and the other at the customer site. Because most DSL technologies do not use the whole bandwidth of the twisted pair, there is room remaining for a voice channel.

DSP digital signal processor. A DSP segments a voice signal into frames and stores them in voice packets.

DSS Digital Signature Standard. A digital signature algorithm designed by The US National Institute of Standards and Technology and based on public-key cryptography. DSS does not do user datagram encryption. DSS is a component in classic crypto, as well as the Redcreek IPsec card, but not in IPsec implemented in Cisco IOS software.

Dynamic NAT See NAT and address translation.

Dynamic PAT Dynamic Port Address Translation. Dynamic PAT lets multiple outbound sessions appear to originate from a single IP address. With PAT enabled, the ASA chooses a unique port number from the PAT IP address for each outbound translation slot (xlate). This feature is valuable when an ISP cannot allocate enough unique IP addresses for your outbound connections. The global pool addresses always come first, before a PAT address is used. See also NAT, Static PAT, and xlate.

E

ECHO See ping, ICMP. See also inspection engine.

EGP Exterior Gateway Protocol. Replaced by BGP. The ASA does not support EGP. See also BGP.

EIGRP Enhanced Interior Gateway Routing Protocol. The ASA does not support EIGRP.

EMBLEM Enterprise Management BaseLine Embedded Manageability. A syslog format designed to be consistent with the Cisco IOS system log format and is more compatible with CiscoWorks management applications.

encryption Application of a specific algorithm or cipher to data so as to render the data incomprehensible to those unauthorized to see the information. See also decryption.

ESMTP Extended SMTP. Extended version of SMTP that includes additional functionality, such as delivery notification and session delivery. ESMTP is described in RFC 1869, SMTP Service Extensions.

ESP Encapsulating Security Payload. An IPsec protocol, ESP provides authentication and encryption services for establishing a secure tunnel over an insecure network. For more information, refer to RFCs 2406 and 1827.

F

failover, failover mode Failover lets you configure two ASAs so that one will take over operation if the other one fails. The ASA supports two failover configurations, Active/Active failover and Active/Standby failover. Each failover configuration has its own method for determining and performing failover. With Active/Active failover, both units can pass network traffic. Active/Active failover lets you configure load balancing on your network. Active/Active failover is only available on units running in multiple context mode. With Active/Standby failover, only one unit passes traffic while the other unit waits in a standby state. Active/Standby failover is available on units running in either single or multiple context mode.

Fixup See inspection engine.

Flash, Flash memory A nonvolatile storage device used to store the configuration file when the ASA is powered down.

FQDN/IP Fully qualified domain name/IP address. IPsec parameter that identifies peers that are security gateways.

FragGuard Provides IP fragment protection and performs full reassembly of all ICMP error messages and virtual reassembly of the remaining IP fragments that are routed through the ASA.

FTP File Transfer Protocol. Part of the TCP/IP protocol stack, used for transferring files between hosts.

G

GGSN gateway GPRS support node. A wireless gateway that allows mobile cell phone users to access the public data network or specified private IP networks.

global configuration mode Global configuration mode lets you change the ASA configuration. All user EXEC, privileged EXEC, and global configuration commands are available in this mode. See also user EXEC mode, privileged EXEC mode, command-specific configuration mode.

GMT Greenwich Mean Time. Replaced by UTC (Coordinated Universal Time) in 1967 as the world time standard.

GPRS general packet radio service. A service defined and standardized by the European Telecommunication Standards Institute. GPRS is an IP-packet-based extension of GSM networks and provides mobile, wireless, data communications

GRE Generic Routing Encapsulation described in RFCs 1701 and 1702. GRE is a tunneling protocol that can encapsulate a wide variety of protocol packet types inside IP tunnels, creating a virtual point-to-point link to routers at remote points over an IP network. By connecting multiprotocol subnetworks in a single-protocol backbone environment, IP tunneling using GRE allows network expansion across a single protocol backbone environment.

GSM Global System for Mobile Communication. A digital, mobile, radio standard developed for mobile, wireless, voice communications.

GTP GPRS tunneling protocol. GTP handles the flow of user packet data and signaling information between the SGSN and GGSN in a GPRS network. GTP is defined on both the Gn and Gp interfaces of a GPRS network.

H

H.225 A protocol used for TCP signaling in applications such as video conferencing. See also H.323 and inspection engine.

H.225.0 An ITU standard that governs H.225.0 session establishment and packetization. H.225.0 actually describes several different protocols: RAS, use of Q.931, and use of RTP.

H.245 An ITU standard that governs H.245 endpoint control.

H.320 Suite of ITU-T standard specifications for video conferencing over circuit-switched media, such as ISDN, fractional T-1, and switched-56 lines. Extensions of ITU-T standard H.320 enable video conferencing over LANs and other packet-switched networks, as well as video over the Internet.

H.323 Allows dissimilar communication devices to communicate with each other by using a standardized communication protocol. H.323 defines a common set of CODECs, call setup and negotiating procedures, and basic data transport methods.

H.323 RAS Registration, admission, and status signaling protocol. Enables devices to perform registration, admissions, bandwidth changes, and status and disengage procedures between VoIP gateway and the gatekeeper.

H.450.2 Call transfer supplementary service for H.323.

H.450.3 Call diversion supplementary service for H.323.

Hash, Hash Algorithm A hash algorithm is a one-way function that operates on a message of arbitrary length to create a fixed-length message digest used by cryptographic services to ensure its data integrity. MD5 has a smaller digest and is considered to be slightly faster than SHA-1. Cisco uses both SHA-1 and MD5 hashes within our implementation of the IPsec framework. See also encryption, HMAC, and VPN.

headend A firewall, concentrator, or other host that serves as the entry point into a private network for VPN client connections over the public network. See also ISP and VPN.

HMAC A mechanism for message authentication using cryptographic hashes such as SHA-1 and MD5.

host The name for any device on a TCP/IP network that has an IP address. See also network and node.

host/network An IP address and netmask used with other information to identify a single host or network subnet for ASA configuration, such as an address translation (xlate) or ACE.

HTTP Hypertext Transfer Protocol. A protocol used by browsers and web servers to transfer files. When a user views a web page, the browser can use HTTP to request and receive the files used by the web page. HTTP transmissions are not encrypted.

HTTPS Hypertext Transfer Protocol Secure. An SSL-encrypted version of HTTP.

I

IANA Internet Assigned Number Authority. Assigns all port and protocol numbers for use on the Internet.

ICMP Internet Control Message Protocol. Network-layer Internet protocol that reports errors and provides other information relevant to IP packet processing.

IDS Intrusion Detection System. A method of detecting malicious network activity by signatures and then implementing a policy for that signature.

IETF The Internet Engineering Task Force. A technical standards organization that develops RFC documents defining protocols for the Internet.

IGMP Internet Group Management Protocol. IGMP is a protocol used by IPv4 systems to report IP multicast memberships to neighboring multicast routers.

IKE Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IPsec) that require keys. Before any IPsec traffic can be passed, each ASA must verify the identity of its peer. Identification can be done by manually entering preshared keys into both hosts or by a CA service. IKE is a hybrid protocol that uses part Oakley and part of another protocol suite called SKEME inside the ISAKMP framework. IKE (formerly known as ISAKMP/Oakley) is defined in RFC 2409.

IKE Extended Authentication IKE Extended Authenticate (Xauth) is implemented per the IETF draft-ietf-ipsec-isakmp-xauth-04.txt (extended authentication). This protocol provides the capability of authenticating a user within IKE using TACACS+ or RADIUS.

IKE Mode Configuration IKE Mode Configuration is implemented per the IETF draft-ietf-ipsec-isakmp-mode-cfg-04.txt. IKE Mode Configuration provides a method for a security gateway to download an IP address (and other network level configuration) to the VPN client as part of an IKE negotiation.

ILS Internet Locator Service. ILS is based on LDAP and is ILSv2 compliant. ILS was developed by Microsoft for use with its NetMeeting, SiteServer, and Active Directory products.

IMAP Internet Message Access Protocol. Method of accessing e-mail or bulletin board messages kept on a mail server that can be shared. IMAP permits client e-mail applications to access remote message stores as if they were local without actually transferring the message.

implicit rule An access rule automatically created by the ASA based on default rules or as a result of user-defined rules.

IMSI International Mobile Subscriber Identity. One of two components of a GTP tunnel ID, the other being the NSAPI. See also NSAPI.

inside The first interface, usually port 1, that connects your internal, trusted network protected by the ASA. See also interface, interface name.

inspection engine The ASA inspects certain application-level protocols to identify the location of embedded addressing information in traffic. Inspection allows NAT to translate these embedded addresses and to update any checksum or other fields that are affected by the translation. Because many protocols open secondary TCP or UDP ports, each application inspection engine also monitors sessions to determine the port numbers for secondary channels. The initial session on a well-known port is used to negotiate dynamically assigned port numbers. The application inspection engine monitors these sessions, identifies the dynamic port assignments, and permits data exchange on these ports for the duration of the specific session. Some of the protocols that the ASA can inspect are CTIQBE, FTP, H.323, HTTP, MGCP, SMTP, and SNMP.

interface The physical connection between a particular network and a ASA.

interface IP address The IP address of the ASA network interface. Each interface IP address must be unique. Two or more interfaces must not be given the same IP address or IP addresses that are on the same IP network.

interface name Human-readable name assigned to the ASA network interface. The inside interface default name is “inside” and the outside interface default name is “outside.” See also inside and outside.

interface PAT The use of PAT where the PAT IP address is also the IP address of the outside interface. See Dynamic PAT, Static PAT.

Internet The global network that uses IP. Not a LAN. See also intranet.

intranet Intranetwork. A LAN that uses IP. See also network and Internet.

IP Internet Protocol. IP protocols are the most popular nonproprietary protocols because they can be used to communicate across any set of interconnected networks and are equally well suited for LAN and WAN communications.

IPS Intrusion Prevention Service. An in-line, deep-packet inspection-based solution that helps mitigate a wide range of network attacks.

IP address An IP protocol address. A ASA interface ip_address. IP version 4 addresses are 32 bits in length. This address space is used to designate the network number, optional subnetwork number, and a host number. The 32 bits are grouped into four octets (8 binary bits), represented by 4 decimal numbers separated by periods, or dots. The meaning of each of the four octets is determined by their use in a particular network.

IP pool A range of local IP addresses specified by a name, and a range with a starting IP address and an ending address. IP pools are used by DHCP and VPNs to assign local IP addresses to clients on the inside interface.

IPsec IP Security. A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer. IPsec uses IKE to handle the negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

IPsec Phase 1 The first phase of negotiating IPsec, includes the key exchange and the ISAKMP portions of IPsec.

IPsec Phase 2 The second phase of negotiating IPsec. Phase 2 determines the type of encryption rules used for payload, the source and destination that will be used for encryption, the definition of interesting traffic according to access lists, and the IPsec peer. IPsec is applied to the interface in Phase 2.

IPsec transform set A transform set specifies the IPsec protocol, encryption algorithm, and hash algorithm to use on traffic matching the IPsec policy. A transform describes a security protocol (AH or ESP) with its corresponding algorithms. The IPsec protocol used in almost all transform sets is ESP with the DES algorithm and HMAC-SHA for authentication.

ISAKMP Internet Security Association and Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association. See IKE.

ISP Internet Service Provider. An organization that provides connection to the Internet via their services, such as modem dial in over telephone voice lines or DSL.

J

JTAPI Java Telephony Application Programming Interface. A Java-based API supporting telephony functions. See also TAPI.

K

key A data object used for encryption, decryption, or authentication.

L

L2TP Layer Two Tunneling Protocol. An IETF standards track protocol defined in RFC 2661 that provides tunneling of PPP. L2TP is an extension to the PPP. L2TP merges the older Cisco Layer Two Forwarding (L2F) protocol with PPTP. L2TP can be used with IPsec encryption and is considered more secure against attack than PPTP.

LAN Local area network. A network residing in one location, such as a single building or campus. See also Internet, intranet, and network.

layer, layers Networking models implement layers with which different protocols are associated. The most common networking model is the OSI model, which consists of the following seven layers, in order: physical, data link, network, transport, session, presentation, and application.

LCN Logical channel number.

LDAP Lightweight Directory Access Protocol. LDAP provides management and browser applications with access to X.500 directories.

M

mask A 32-bit mask that shows how an Internet address is divided into network, subnet, and host parts. The mask has ones in the bit positions to be used for the network and subnet parts, and zeros for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion.

MCR See multicast.

MC router Multicast (MC) routers route multicast data transmissions to the hosts on each LAN in an internetwork that are registered to receive specific multimedia or other broadcasts. See also multicast.

MD5 Message Digest 5. A one-way hashing algorithm that produces a 128-bit hash. Both MD5 and SHA-1 are variations on MD4 and are designed to strengthen the security of the MD4 hashing algorithm. SHA-1 is more secure than MD4 and MD5. Cisco uses hashes for authentication within the IPsec framework. Also used for message authentication in SNMP v.2. MD5 verifies the integrity of the communication, authenticates the origin, and checks for timeliness. MD5 has a smaller digest and is considered to be slightly faster than SHA-1.

MDI media dependent interface.

MDIX media dependent interface crossover.

message digest A message digest is created by a hash algorithm, such as MD5 or SHA-1, that is used for ensuring message integrity.

MGCP Media Gateway Control Protocol. Media Gateway Control Protocol is a protocol for the control of VoIP calls by external call-control elements known as media gateway controllers or call agents. MGCP merges the IPDC and SGCP protocols.

Mode See Access Modes.

Mode Config See IKE Mode Configuration.

Modular Policy Framework A means of configuring ASA features in a manner similar to Cisco IOS software Modular QoS CLI.

MS mobile station. Refers generically to any mobile device, such as a mobile handset or computer, that is used to access network services. GPRS networks support three classes of MS, which describe the type of operation supported within the GPRS and the GSM mobile wireless networks. For example, a Class A MS supports simultaneous operation of GPRS and GSM services.

MS-CHAP Microsoft CHAP.

MTU maximum transmission unit. The maximum number of bytes in a packet that can flow efficiently across the network with best response time. For Ethernet, the default MTU is 1500 bytes, but each network can have different values, with serial connections having the smallest values. The MTU is described in RFC 1191.

multicast Refers to a network addressing method in which the source transmits a packet to multiple destinations, a multicast group, simultaneously. See also PIM, SMR.

N

N2H2 A third-party, policy-oriented filtering application that works with the ASA to control user web access. N2H2 can filter HTTP requests based on the destination hostname, destination IP address, username, and password. The N2H2 corporation was acquired by Secure Computing in October, 2003.

NAT Network Address Translation. Mechanism for reducing the need for globally unique IP addresses. NAT allows an organization with addresses that are not globally unique to connect to the Internet by translating those addresses into a globally routable address space.

NEM Network Extension Mode. Lets VPN hardware clients present a single, routable network to the remote private network over the VPN tunnel.

NetBIOS Network Basic Input/Output System. A Microsoft protocol that supports Windows hostname registration, session management, and data transfer. The ASA supports NetBIOS by performing NAT of the packets for NBNS UDP port 137 and NBDS UDP port 138.

netmask See mask.

network In the context of ASA configuration, a network is a group of computing devices that share part of an IP address space and not a single host. A network consists of multiple nodes or hosts. See also host, Internet, intranet, IP, LAN, and node.

NMS network management system. System responsible for managing at least part of a network. An NMS is generally a reasonably powerful and well-equipped computer, such as an engineering workstation. NMSs communicate with agents to help keep track of network statistics and resources.

node Devices such as routers and printers that would not normally be called hosts. See also host, network.

nonvolatile storage, memory Storage or memory that, unlike RAM, retains its contents without power. Data in a nonvolatile storage device survives a power-off, power-on cycle.

NSAPI network service access point identifier. One of two components of a GTP tunnel ID, the other component being the IMSI. See also IMSI.

NSSA not-so-stubby-area. An OSPF feature described by RFC 1587. NSSA was first introduced in Cisco IOS software release 11.2. It is a nonproprietary extension of the existing stub area feature that allows the injection of external routes in a limited fashion into the stub area.

NTLM NT Lan Manager. A Microsoft Windows challenge-response authentication method.

NTP Network Time Protocol.

O

Oakley A key exchange protocol that defines how to acquire authenticated keying material. The basic mechanism for Oakley is the Diffie-Hellman key exchange algorithm. Oakley is defined in RFC 2412.

object grouping Simplifies access control by letting you apply access control statements to groups of network objects, such as protocol, services, hosts, and networks.

OSPF Open Shortest Path First. OSPF is a routing protocol for IP networks. OSPF is a routing protocol widely deployed in large networks because of its efficient use of network bandwidth and its rapid convergence after changes in topology. The ASA supports OSPF.

OU Organizational Unit. An X.500 directory attribute.

outbound Refers to traffic whose destination is on an interface with lower security than the source interface.

outbound ACL An ACL applied to outbound traffic.

outside The first interface, usually port 0, that connects to other untrusted networks outside the ASA; the Internet. See also interface, interface name, outbound.

P

PAC PPTP Access Concentrator. A device attached to one or more PSTN or ISDN lines capable of PPP operation and of handling the PPTP protocol. The PAC needs to implement TCP/IP to pass traffic to one or more PNSs. It may also tunnel non-IP protocols.

PAT See Dynamic PAT, interface PAT, and Static PAT.

PDP Packet Data Protocol.

Perfmon The ASA feature that gathers and reports a wide variety of feature statistics, such as connections/second, xlates/second, and so on.

PFS Perfect Forwarding Secrecy. PFS enhances security by using a different security key for the IPsec Phase 1 and Phase 2 SAs. Without PFS, the same security key is used to establish SAs in both phases. PFS ensures that a given IPsec SA key was not derived from any other secret (like some other keys). In other words, if someone were to break a key, PFS ensures that the attacker would not be able to derive any other key. If PFS were not enabled, someone could hypothetically break the IKE SA secret key, copy all the IPsec protected data, and then use knowledge of the IKE SA secret to compromise the IPsec SA setup by this IKE SA. With PFS, breaking IKE would not give an attacker immediate access to IPsec. The attacker would have to break each IPsec SA individually.

Phase 1 See IPsec Phase 1.

Phase 2 See IPsec Phase 2.

PIM Protocol Independent Multicast. PIM provides a scalable method for determining the best paths for distributing a specific multicast transmission to a group of hosts. Each host has registered using IGMP to receive the transmission. See also PIM-SM.

PIM-SM Protocol Independent Multicast-Sparse Mode. With PIM-SM, which is the default for Cisco routers, when the source of a multicast transmission begins broadcasting, the traffic is forwarded from one MC router to the next, until the packets reach every registered host. See also PIM.

ping An ICMP request sent by a host to determine if a second host is accessible.

PIX Private Internet eXchange. The Cisco PIX 500 series ASAs ranged from compact, plug-and-play desktop models for small/home offices to carrier-class gigabit models for the most demanding enterprise and service provider environments. Cisco PIX ASAs provided robust, enterprise-class integrated network security services to create a strong multilayered defense for fast changing network environments. The PIX has been replaced by the Cisco ASA 5500 series.

PKCS12 A standard for the transfer of PKI-related data, such as private keys, certificates, and other data. Devices supporting this standard let administrators maintain a single set of personal identity information.

PNS PPTP Network Server. A PNS is envisioned to operate on general-purpose computing/server platforms. The PNS handles the server side of PPTP. Because PPTP relies completely on TCP/IP and is independent of the interface hardware, the PNS may use any combination of IP interface hardware including LAN and WAN devices.

Policy NAT Lets you identify local traffic for address translation by specifying the source and destination addresses (or ports) in an access list.

POP Post Office Protocol. Protocol that client e-mail applications use to retrieve mail from a mail server.

Pool See IP pool.

Port A field in the packet headers of TCP and UDP protocols that identifies the higher level service which is the source or destination of the packet.

PPP Point-to-Point Protocol. Developed for dial-up ISP access using analog phone lines and modems.

PPPoE Point-to-Point Protocol over Ethernet. An IP protocol that encapsulates PPP packets and sends them over a local network or the internet to establish a connection to a host, usually between a client and an ISP.

PPTP Point-to-Point Tunneling Protocol. PPTP was introduced by Microsoft to provide secure remote access to Windows networks; however, because it is vulnerable to attack, PPTP is commonly used only when stronger security methods are not available or are not required. PPTP Ports are pptp, 1723/tcp, 1723/udp, and pptp. For more information about PPTP, see RFC 2637. See also PAC, PPTP GRE, PPTP GRE tunnel, PNS, PPTP session, and PPTP TCP.

PPTP GRE Version 1 of GRE for encapsulating PPP traffic.

PPTP GRE tunnel A tunnel defined by a PNS-PAC pair. The tunnel protocol is defined by a modified version of GRE. The tunnel carries PPP datagrams between the PAC and the PNS. Many sessions are multiplexed on a single tunnel. A control connection operating over TCP controls the establishment, release, and maintenance of sessions and of the tunnel itself.

PPTP session PPTP is connection-oriented. The PNS and PAC maintain the state for each user that is attached to a PAC. A session is created when an end-to-end PPP connection is attempted between a dial-up user and the PNS. The datagrams related to a session are sent over the tunnel between the PAC and PNS.

PPTP TCP Standard TCP session over which PPTP call control and management information is passed. The control session is logically associated with, but separate from, the sessions being tunneled through a PPTP tunnel.

preshared key A preshared key provides a method of IKE authentication that is suitable for networks with a limited, static number of IPsec peers. This method is limited in scalability because the key must be configured for each pair of IPsec peers. When a new IPsec peer is added to the network, the preshared key must be configured for every IPsec peer with which it communicates. Using certificates and CAs provides a more scalable method of IKE authentication.

primary, primary unit The ASA normally operating when two units, a primary and secondary, are operating in failover mode.

privileged EXEC mode The highest privilege level at the ASA CLI. Any user EXEC mode command will work in privileged EXEC mode. The privileged EXEC mode prompt appears as follows after you enter the **enable** command:

```
hostname> enable
hostname#
```

See also command-specific configuration mode, global configuration mode, user EXEC mode.

protocol, protocol literals A standard that defines the exchange of packets between network nodes for communication. Protocols work together in layers. Protocols are specified in the ASA configuration as part of defining a security policy by their literal values or port numbers. Possible ASA protocol literal values are ahp, eigrp, esp, gre, icmp, igmp, igrp, ip, ipinip, ipsec, nos, ospf, pcp, snp, tcp, and udp.

Proxy-ARP Enables the ASA to reply to an ARP request for IP addresses in the global pool. See also ARP.

public key A public key is one of a pair of keys that are generated by devices involved in public key infrastructure. Data encrypted with a public key can only be decrypted using the associated private key. When a private key is used to produce a digital signature, the receiver can use the public key of the sender to verify that the message was signed by the sender. These characteristics of key pairs provide a scalable and secure method of authentication over an insecure media, such as the Internet.

Q

QoS quality of service. Measure of performance for a transmission system that reflects its transmission quality and service availability.

R

RA Registration Authority. An authorized proxy for a CA. RAs can perform certificate enrollment and can issue CRLs. See also CA, certificate, public key.

RADIUS Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. RFC 2058 and RFC 2059 define the RADIUS protocol standard. See also AAA and TACACS+.

refresh Retrieve the running configuration from the ASA and update the screen. The icon and the button perform the same function.

registration authority See RA.

replay-detection A security service where the receiver can reject old or duplicate packets to defeat replay attacks. Replay attacks rely on the attacker sending out older or duplicate packets to the receiver and the receiver thinking that the bogus traffic is legitimate. Replay-detection is done by using sequence numbers combined with authentication and is a standard feature of IPsec.

RFC Request for Comments. RFC documents define protocols and standards for communications over the Internet. RFCs are developed and published by IETF.

RIP Routing Information Protocol. Interior Gateway Protocol (IGP) supplied with UNIX BSD systems. The most common IGP in the Internet. RIP uses hop count as a routing metric.

RLLA Reserved Link Local Address. Multicast addresses range from 224.0.0.0 to 239.255.255.255; however only the range 224.0.1.0 to 239.255.255.255 is available to users. The first part of the multicast address range, 224.0.0.0 to 224.0.0.255, is reserved and referred to as the RLLA. These addresses are unavailable.

route, routing The path through a network.

routed firewall mode In routed firewall mode, the ASA is counted as a router hop in the network. It performs NAT between connected networks and can use OSPF or RIP. See also transparent firewall mode.

RPC Remote Procedure Call. RPCs are procedure calls that are built or specified by clients and executed on servers, with the results returned over the network to the clients.

RSA A public key cryptographic algorithm (named after its inventors, Rivest, Shamir, and Adelman) with a variable key length. The main weakness of RSA is that it is significantly slow to compute compared to popular secret-key algorithms, such as DES. The Cisco implementation of IKE uses a Diffie-Hellman exchange to get the secret keys. This exchange can be authenticated with RSA (or preshared keys). With the Diffie-Hellman exchange, the DES key never crosses the network (not even in encrypted form), which is not the case with the RSA encrypt and sign technique. RSA is not public domain, and must be licensed from RSA Data Security.

RSH Remote Shell. A protocol that allows a user to execute commands on a remote system without having to log in to the system. For example, RSH can be used to remotely examine the status of a number of access servers without connecting to each communication server, executing the command, and then disconnecting from the communication server.

RTCP RTP Control Protocol. Protocol that monitors the QoS of an IPv6 RTP connection and conveys information about the ongoing session. See also RTP.

RTP Real-Time Transport Protocol. Commonly used with IP networks. RTP is designed to provide end-to-end network transport functions for applications transmitting real-time data, such as audio, video, or simulation data, over multicast or unicast network services. RTP provides such services as payload type identification, sequence numbering, timestamping, and delivery monitoring to real-time applications.

RTSP Real Time Streaming Protocol. Enables the controlled delivery of real-time data, such as audio and video. RTSP is designed to work with established protocols, such as RTP and HTTP.

rule Conditional statements added to the ASA configuration to define security policy for a particular situation. See also ACE, ACL, NAT.

running configuration The configuration currently running in RAM on the ASA. The configuration that determines the operational characteristics of the ASA.

S

SA security association. An instance of security policy and keying material applied to a data flow. SAs are established in pairs by IPsec peers during both phases of IPsec. SAs specify the encryption algorithms and other security parameters used to create a secure tunnel. Phase 1 SAs (IKE SAs) establish a secure tunnel for negotiating Phase 2 SAs. Phase 2 SAs (IPsec SAs) establish the secure tunnel used for sending user data. Both IKE and IPsec use SAs, although SAs are independent of one another. IPsec SAs are unidirectional and they are unique in each security protocol. A set of SAs are needed for a protected data pipe, one per direction per protocol. For example, if you have a pipe that supports ESP between peers, one ESP SA is required for each direction. SAs are uniquely identified by destination (IPsec endpoint) address, security protocol (AH or ESP), and Security Parameter Index. IKE negotiates and establishes SAs on behalf of IPsec. A user can also establish IPsec SAs manually. An IKE SA is used by IKE only, and unlike the IPsec SA, it is bidirectional.

SCCP Skinny Client Control Protocol. A Cisco-proprietary protocol used between Cisco Call Manager and Cisco VoIP phones.

SCEP Simple Certificate Enrollment Protocol. A method of requesting and receiving (also known as enrolling) certificates from CAs.

SDP Session Definition Protocol. An IETF protocol for the definition of Multimedia Services. SDP messages can be part of SGCP and MGCP messages.

secondary unit The backup ASA when two are operating in failover mode.

secret key A secret key is a key shared only between the sender and receiver. See key, public key.

security context You can partition a single ASA into multiple virtual firewalls, known as security contexts. Each context is an independent firewall, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple stand-alone firewalls.

security services See cryptography.

serial transmission A method of data transmission in which the bits of a data character are transmitted sequentially over a single channel.

SGCP Simple Gateway Control Protocol. Controls VoIP gateways by an external call control element (called a call-agent).

SGSN Serving GPRS Support Node. The SGSN ensures mobility management, session management, and packet relaying functions.

SHA-1 Secure Hash Algorithm 1. SHA-1 [NIS94c] is a revision to SHA that was published in 1994. SHA is closely modeled after MD4 and produces a 160-bit digest. Because SHA produces a 160-bit digest, it is more resistant to brute-force attacks than 128-bit hashes (such as MD5), but it is slower. Secure Hash Algorithm 1 is a joint creation of the National Institute of Standards and Technology and the National Security Agency. This algorithm, like other hash algorithms, is used to generate a hash value, also known as a message digest, that acts like a CRC used in lower-layer protocols to ensure that message contents are not changed during transmission. SHA-1 is generally considered more secure than MD5.

SIP Session Initiation Protocol. Enables call handling sessions, particularly two-party audio conferences, or calls. SIP works with SDP for call signaling. SDP specifies the ports for the media stream. Using SIP, the ASA can support any SIP VoIP gateways and VoIP proxy servers.

site-to-site VPN A site-to-site VPN is established between two IPsec peers that connect remote networks into a single VPN. In this type of VPN, neither IPsec peer is the destination nor source of user traffic. Instead, each IPsec peer provides encryption and authentication services for hosts on the LANs connected to each IPsec peer. The hosts on each LAN send and receive data through the secure tunnel established by the pair of IPsec peers.

SKEME A key exchange protocol that defines how to derive authenticated keying material, with rapid key refreshment.

SMR Stub Multicast Routing. SMR allows the ASA to function as a stub router. A stub router is a device that acts as an IGMP proxy agent. IGMP is used to dynamically register specific hosts in a multicast group on a particular LAN with a multicast router. Multicast routers route multicast data transmissions to hosts that are registered to receive specific multimedia or other broadcasts. A stub router forwards IGMP messages between hosts and MC routers.

SMTP Simple Mail Transfer Protocol. SMTP is an Internet protocol that supports email services.

SNMP Simple Network Management Protocol. A standard method for managing network devices using data structures called Management Information Bases.

split tunneling Allows a remote VPN client simultaneous encrypted access to a private network and clear unencrypted access to the Internet. If you do not enable split tunneling, all traffic between the VPN client and the ASA is sent through an IPsec tunnel. All traffic originating from the VPN client is sent to the outside interface through a tunnel, and client access to the Internet from its remote site is denied.

spoofing A type of attack designed to foil network security mechanisms such as filters and access lists. A spoofing attack sends a packet that claims to be from an address from which it was not actually sent.

SQL*Net Structured Query Language Protocol. An Oracle protocol used to communicate between client and server processes.

SSC Security Services Card for the ASA 5505. For example, the AIP SSC.

SSH Secure Shell. An application running on top of a reliable transport layer, such as TCP/IP, that provides strong authentication and encryption capabilities.

SSL Secure Sockets Layer. A protocol that resides between the application layer and TCP/IP to provide transparent encryption of data traffic.

SSM Security Services Module. For example, the AIP SSM or CSC SSM.

standby unit See secondary unit.

stateful inspection Network protocols maintain certain data, called state information, at each end of a network connection between two hosts. State information is necessary to implement the features of a protocol, such as guaranteed packet delivery, data sequencing, flow control, and transaction or session IDs. Some of the protocol state information is sent in each packet while each protocol is being used. For example, a browser connected to a web server uses HTTP and supporting TCP/IP protocols. Each protocol layer maintains state information in the packets it sends and receives. The ASA and some other firewalls inspect the state information in each packet to verify that it is current and valid for every protocol it contains. This feature is called stateful inspection and is designed to create a powerful barrier to certain types of computer security threats.

Static PAT Static Port Address Translation. Static PAT is a static address that also maps a local port to a global port. See also Dynamic PAT, NAT.

subnetmask See mask.

T

TACACS+ Terminal Access Controller Access Control System Plus. A client-server protocol that supports AAA services, including command authorization. See also AAA, RADIUS.

TAPI Telephony Application Programming Interface. A programming interface in Microsoft Windows that supports telephony functions.

TCP Transmission Control Protocol. Connection-oriented transport layer protocol that provides reliable full-duplex data transmission.

TCP Intercept With the TCP intercept feature, once the optional embryonic connection limit is reached, and until the embryonic connection count falls below this threshold, every SYN bound for the affected server is intercepted. For each SYN, the ASA responds on behalf of the server with an empty SYN/ACK segment. The ASA retains pertinent state information, drops the packet, and waits for the client acknowledgment. If the ACK is received, a copy of the client SYN segment is sent to the server and the TCP three-way handshake is performed between the ASA and the server. If this three-way handshake completes, the connection may resume as normal. If the client does not respond during any part of the connection phase, then the ASA retransmits the necessary segment using exponential back-offs.

TDP Tag Distribution Protocol. TDP is used by tag switching devices to distribute, request, and release tag binding information for multiple network layer protocols in a tag switching network. TDP does not replace routing protocols. Instead, it uses information learned from routing protocols to create tag bindings. TDP is also used to open, monitor, and close TDP sessions and to indicate errors that occur during those sessions. TDP operates over a connection-oriented transport layer protocol with guaranteed sequential delivery (such as TCP). The use of TDP does not preclude the use of other mechanisms to distribute tag binding information, such as piggybacking information on other protocols.

Telnet A terminal emulation protocol for TCP/IP networks such as the Internet. Telnet is a common way to control web servers remotely; however, its security vulnerabilities have led to its replacement by SSH.

TFTP Trivial File Transfer Protocol. TFTP is a simple protocol used to transfer files. It runs on UDP and is explained in depth in RFC 1350.

TID Tunnel Identifier.

TLS Transport Layer Security. A future IETF protocol to replace SSL.

traffic policing The traffic policing feature ensures that no traffic exceeds the maximum rate (bits per second) that you configure, which ensures that no one traffic flow can take over the entire resource.

transform set See IPsec transform set.

translate, translation See xlate.

transparent firewall mode A mode in which the ASA is not a router hop. You can use transparent firewall mode to simplify your network configuration or to make the ASA invisible to attackers. You can also use transparent firewall mode to allow traffic through that would otherwise be blocked in routed firewall mode. See also routed firewall mode.

transport mode An IPsec encryption mode that encrypts only the data portion (payload) of each packet but leaves the header untouched. Transport mode is less secure than tunnel mode.

TSP TAPI Service Provider. See also TAPI.

tunnel mode An IPsec encryption mode that encrypts both the header and data portion (payload) of each packet. Tunnel mode is more secure than transport mode.

tunnel A method of transporting data in one protocol by encapsulating it in another protocol. Tunneling is used for reasons of incompatibility, implementation simplification, or security. For example, a tunnel lets a remote VPN client have encrypted access to a private network.

Turbo ACL Increases ACL lookup speeds by compiling them into a set of lookup tables. Packet headers are used to access the tables in a small, fixed number of lookups, independent of the existing number of ACL entries.

U

UDP User Datagram Protocol. A connectionless transport layer protocol in the IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, which requires other protocols to handle error processing and retransmission. UDP is defined in RFC 768.

UMTS Universal Mobile Telecommunication System. An extension of GPRS networks that moves toward an all-IP network by delivering broadband information, including commerce and entertainment services, to mobile users via fixed, wireless, and satellite networks.

Unicast RPF Unicast Reverse Path Forwarding. Unicast RPF guards against spoofing by ensuring that packets have a source IP address that matches the correct source interface according to the routing table.

URL Uniform Resource Locator. A standardized addressing scheme for accessing hypertext documents and other services using a browser. For example, http://www.cisco.com.

user EXEC mode The lowest privilege level at the ASA CLI. The user EXEC mode prompt appears as follows when you first access the ASA:

```
hostname>
```

See also command-specific configuration mode, global configuration mode, and privileged EXEC mode.

UTC Coordinated Universal Time. The time zone at zero degrees longitude, previously called Greenwich Mean Time (GMT) and Zulu time. UTC replaced GMT in 1967 as the world time standard. UTC is based on an atomic time scale rather than an astronomical time scale.

UTRAN Universal Terrestrial Radio Access Network. Networking protocol used for implementing wireless networks in UMTS. GTP allows multi-protocol packets to be tunneled through a UMTS/GPRS backbone between a GGSN, an SGSN and the UTRAN.

UUIE User-User Information Element. An element of an H.225 packet that identifies the users implicated in the message.

V

VLAN Virtual LAN. A group of devices on one or more LANs that are configured (using management software) so that they can communicate as if they were attached to the same physical network cable, when they are located on a number of different LAN segments. Because VLANs are based on logical instead of physical connections, they are extremely flexible.

VoIP Voice over IP. VoIP carries normal voice traffic, such as telephone calls and faxes, over an IP-based network. DSP segments the voice signal into frames, which are coupled in groups of two and stored in voice packets. These voice packets are transported using IP in compliance with ITU-T specification H.323.

VPN Virtual Private Network. A network connection between two peers over the public network that is made private by strict authentication of users and the encryption of all data traffic. You can establish VPNs between clients, such as PCs, or a headend, such as the ASA.

virtual firewall See security context.

VSA Vendor-specific attribute. An attribute in a RADIUS packet that is defined by a vendor rather than by RADIUS RFCs. The RADIUS protocol uses IANA-assigned vendor numbers to help identify VSAs. This lets different vendors have VSAs of the same number. The combination of a vendor number and a VSA number makes a VSA unique. For example, the cisco-av-pair VSA is attribute 1 in the set of VSAs related to vendor number 9. Each vendor can define up to 256 VSAs. A RADIUS packet contains any VSAs attribute 26, named Vendor-specific. VSAs are sometimes referred to as subattributes.

W

WAN wide-area network. Data communications network that serves users across a broad geographic area and often uses transmission devices provided by common carriers.

WCCP Web Cache Communication Protocol. Transparently redirects selected types of traffic to a group of web cache engines to optimize resource usage and lower response times.

Websense A content filtering solution that manages employee access to the Internet. Websense uses a policy engine and a URL database to control user access to websites.

WEP Wired Equivalent Privacy. A security protocol for wireless LANs, defined in the IEEE 802.11b standard.

WINS Windows Internet Naming Service. A Windows system that determines the IP address associated with a particular network device, also known as name resolution. WINS uses a distributed database that is automatically updated with the NetBIOS names of network devices currently available and the IP address assigned to each one.WINS provides a distributed database for registering and querying dynamic NetBIOS names to IP address mapping in a routed network environment. It is the best choice for NetBIOS name resolution in such a routed network because it is designed to solve the problems that occur with name resolution in complex networks.

X

X.509 A widely used standard for defining digital certificates. X.509 is actually an ITU recommendation, which means that it has not yet been officially defined or approved for standardized usage.

xauth See IKE Extended Authentication.

xlate An xlate, also referred to as a translation entry, represents the mapping of one IP address to another, or the mapping of one IP address/port pair to another.
