Cisco ASA Series ASDM Configuration Guide

Software Version 7.0 for the ASA 5505, ASA 5510, ASA 5520, ASA 5540, ASA 5550, ASA 5512-X, ASA 5515-X, ASA 5525-X, ASA 5545-X, ASA 5555-X, ASA 5580, ASA 5585-X, and the ASA Services Module

Released: October 29, 2012
Updated: February 25, 2013

Cisco Systems, Inc.

PART 1 **Getting Started with the ASA**

CHAPTER 1 **Introduction to the Cisco ASA** 1-1

ASDM Client Operating System and Browser Requirements 1-1

Hardware and Software Compatibility 1-4

VPN Specifications 1-4

New Features 1-5

New Features in ASA 8.4(5)/ASDM 7.0(2) 1-5

New Features in ASA 9.0(1)/ASDM 7.0(1) 1-5

How the ASA Services Module Works with the Switch 1-19

Firewall Functional Overview 1-20

Security Policy Overview 1-21

Firewall Mode Overview 1-23

Stateful Inspection Overview 1-24

VPN Functional Overview 1-25

Security Context Overview 1-25

ASA Clustering Overview 1-26

CHAPTER 2 **Configuring the Switch for Use with the ASA Services Module** 2-1

Information About the Switch 2-1

Guidelines and Limitations 2-2

Verifying the Module Installation 2-3

Assigning VLANs to the ASA Services Module 2-4

Using the MSFC as a Directly Connected Router 2-5

Information About SVIs 2-6

Configuring SVIs 2-8

Configuring the Switch for ASA Failover 2-9
Assigning VLANs to the Secondary ASA Services Module 2-10
Adding a Trunk Between a Primary Switch and Secondary Switch 2-10
Ensuring Compatibility with Transparent Firewall Mode 2-10
Enabling Autostate Messaging for Rapid Link Failure Detection 2-10
Resetting the ASA Services Module 2-11
Monitoring the ASA Services Module 2-11
Feature History for the Switch for Use with the ASA Services Module 2-13

CHAPTER 3 **Getting Started** 3-1
Accessing the Appliance Command-Line Interface 3-1
Accessing the ASA Services Module Command-Line Interface 3-2
Logging Into the ASA Services Module 3-2
Logging Out of a Console Session 3-4
Logging Out of a Telnet Session 3-6
Configuring ASDM Access for Appliances 3-6
Accessing ASDM Using the Factory Default Configuration 3-6
Accessing ASDM Using a Non-Default Configuration (ASA 5505) 3-7
Accessing ASDM Using a Non-Default Configuration (ASA 5510 and Higher) 3-9
Configuring ASDM Access for the ASA Services Module 3-11
Starting ASDM 3-13
Connecting to ASDM for the First Time 3-14
Starting ASDM from the ASDM-IDM Launcher 3-15
Starting ASDM from the Java Web Start Application 3-15
Using ASDM in Demo Mode 3-16
Factory Default Configurations 3-17
Restoring the Factory Default Configuration 3-18
ASA 5505 Default Configuration 3-20
ASA 5510 and Higher Default Configuration 3-24
Getting Started with the Configuration 3-24
Using the Command Line Interface Tool in ASDM 3-25
Using the Command Line Interface Tool 3-25
Handling Command Errors 3-26
Using Interactive Commands 3-26
Avoiding Conflicts with Other Administrators 3-26
Showing Commands Ignored by ASDM on the Device 3-26
Applying Configuration Changes to Connections 3-27

CHAPTER 4 **Using ASDM** 4-1

Information About the ASDM User Interface 4-1

Navigating in the ASDM User Interface 4-3

Menus 4-4

File Menu 4-4

View Menu 4-5

Tools Menu 4-6

Wizards Menu 4-8

Window Menu 4-9

Help Menu 4-9

Toolbar 4-10

ASDM Assistant 4-10

Status Bar 4-11

Connection to Device 4-11

Device List 4-11

Common Buttons 4-12

Keyboard Shortcuts 4-12

Find Function 4-14

Using the Find Function in Most ASDM Panes 4-14

Using the Find Function in the ACL Manager Pane 4-15

Enabling Extended Screen Reader Support 4-16

Organizational Folder 4-16

About the Help Window 4-16

Header Buttons 4-17

Browser Window 4-17

Home Pane (Single Mode and Context) 4-17

Device Dashboard Tab 4-18

Firewall Dashboard Tab 4-22

Cluster Dashboard Tab 4-25

Cluster Firewall Dashboard Tab 4-26

Content Security Tab 4-27

Intrusion Prevention Tab 4-28

ASA CX Status Tab 4-30

Home Pane (System) 4-31

Defining ASDM Preferences 4-32

Using the ASDM Assistant 4-33

Enabling History Metrics 4-34

Unsupported Commands 4-34
Ignored and View-Only Commands 4-35
Effects of Unsupported Commands 4-35
Discontinuous Subnet Masks Not Supported 4-36
Interactive User Commands Not Supported by the ASDM CLI Tool 4-36

CHAPTER 5 **Managing Feature Licenses** 5-1

Supported Feature Licenses Per Model 5-1
Licenses Per Model 5-1
License Notes 5-18
VPN License and Feature Compatibility 5-23
Information About Feature Licenses 5-23
Preinstalled License 5-24
Permanent License 5-24
Time-Based Licenses 5-24
Shared AnyConnect Premium Licenses 5-27
Failover or ASA Cluster Licenses 5-31
No Payload Encryption Models 5-33
Licenses FAQ 5-33
Guidelines and Limitations 5-34
Configuring Licenses 5-36
Obtaining an Activation Key 5-36
Activating or Deactivating Keys 5-37
Configuring a Shared License 5-38
Monitoring Licenses 5-40
Viewing Your Current License 5-40
Monitoring the Shared License 5-41
Feature History for Licensing 5-41

CHAPTER 6 **Configuring the Transparent or Routed Firewall** 6-1

Configuring the Firewall Mode 6-1
Information About the Firewall Mode 6-1
Licensing Requirements for the Firewall Mode 6-6
Default Settings 6-6
Guidelines and Limitations 6-6
Setting the Firewall Mode (Single Mode) 6-8
Feature History for Firewall Mode 6-9
Configuring ARP Inspection for the Transparent Firewall 6-10
Information About ARP Inspection 6-11

Licensing Requirements for ARP Inspection 6-11
Default Settings 6-11
Guidelines and Limitations 6-11
Configuring ARP Inspection 6-12
Feature History for ARP Inspection 6-14
Customizing the MAC Address Table for the Transparent Firewall 6-14
Information About the MAC Address Table 6-15
Licensing Requirements for the MAC Address Table 6-15
Default Settings 6-15
Guidelines and Limitations 6-15
Configuring the MAC Address Table 6-16
Feature History for the MAC Address Table 6-17
Firewall Mode Examples 6-17
How Data Moves Through the ASA in Routed Firewall Mode 6-17
How Data Moves Through the Transparent Firewall 6-23

CHAPTER 7 **Using the Startup Wizard** 7-1
Accessing the Startup Wizard 7-1
Licensing Requirements for the Startup Wizard 7-1
Guidelines and Limitations 7-1
Startup Wizard Screens 7-2
Starting Point or Welcome 7-2
Basic Configuration 7-3
Interface Screens 7-3
Static Routes 7-4
Easy VPN Remote Configuration (ASA 5505, Single Mode, Routed Mode) 7-4
DHCP Server 7-4
Address Translation (NAT/PAT) 7-5
Administrative Access 7-5
IPS Basic Configuration 7-5
Time Zone and Clock Configuration 7-5
Auto Update Server (Single Mode) 7-5
Startup Wizard Summary 7-6
Feature History for the Startup Wizard 7-6

PART 1 **Configuring High Availability and Scalability**

CHAPTER 9 **Configuring Multiple Context Mode** 9-1

Information About Security Contexts 9-1
Common Uses for Security Contexts 9-2
Context Configuration Files 9-2
How the ASA Classifies Packets 9-3
Cascading Security Contexts 9-6
Management Access to Security Contexts 9-7
Information About Resource Management 9-8
Information About MAC Addresses 9-11
Licensing Requirements for Multiple Context Mode 9-13
Prerequisites 9-14
Guidelines and Limitations 9-14
Default Settings 9-15
Configuring Multiple Contexts 9-15
Task Flow for Configuring Multiple Context Mode 9-15
Enabling or Disabling Multiple Context Mode 9-16
Configuring a Class for Resource Management 9-17
Configuring a Security Context 9-20
Automatically Assigning MAC Addresses to Context Interfaces 9-24
Changing Between Contexts and the System Execution Space 9-25
Managing Security Contexts 9-26
Removing a Security Context 9-26
Changing the Admin Context 9-27
Changing the Security Context URL 9-28
Reloading a Security Context 9-29
Monitoring Security Contexts 9-30
Monitoring Context Resource Usage 9-31
Viewing Assigned MAC Addresses 9-32
Feature History for Multiple Context Mode 9-33

CHAPTER 10 **Configuring a Cluster of ASAs** 10-1

Information About ASA Clustering 10-1
How the ASA Cluster Fits into Your Network 10-2
Performance Scaling Factor 10-2
Cluster Members 10-2
ASA Cluster Interfaces 10-4
Cluster Control Link 10-6
High Availability within the ASA Cluster 10-7

Configuration Replication 10-8
ASA Cluster Management 10-9
Load Balancing Methods 10-10
How the ASA Cluster Manages Connections 10-13
ASA Features and Clustering 10-14
Licensing Requirements for ASA Clustering 10-21
Prerequisites for ASA Clustering 10-21
Guidelines and Limitations 10-23
Default Settings 10-24
Configuring ASA Clustering 10-24
Task Flow for ASA Cluster Configuration 10-25
Cabling the Cluster Units and Configuring Upstream and Downstream Equipment 10-25
Configuring the Cluster Interface Mode on the Master Unit 10-27
Configuring the Management Interface on Each Unit 10-29
Enabling the Cluster Control Link Interface on the Master Unit 10-29
Backing Up Your Configurations (Recommended) 10-32
Configuring Interfaces on the Master Unit 10-32
Adding or Joining an ASA Cluster 10-44
Managing ASA Cluster Members 10-50
Configuring ASA Cluster Parameters 10-51
Adding a New Slave from the Master Unit 10-54
Becoming an Inactive Member 10-56
Inactivating a Slave Member from the Master Unit 10-57
Leaving the Cluster 10-58
Changing the Master Unit 10-61
Executing a Command Cluster-Wide 10-62
Monitoring the ASA Cluster 10-63
Cluster Dashboards 10-63
Monitoring Screens 10-64
Related Features 10-65
Configuration Examples for ASA Clustering 10-66
Firewall on a Stick 10-66
Traffic Segregation 10-67
Redundant Interface (PBR or ECMP) 10-67
Spanned EtherChannel With Backup Links 10-68
Feature History for ASA Clustering 10-71

CHAPTER 11 **Information About Failover** 11-1

Introduction to Failover and High Availability 11-1

Failover System Requirements 11-2

Hardware Requirements 11-2

Software Requirements 11-2

License Requirements 11-2

Failover and Stateful Failover Links 11-3

Failover Link 11-3

Stateful Failover Link 11-4

Avoiding Interrupted Failover Links 11-5

Active/Active and Active/Standby Failover 11-8

Determining Which Type of Failover to Use 11-8

Stateless (Regular) and Stateful Failover 11-9

Stateless (Regular) Failover 11-9

Stateful Failover 11-10

Intra- and Inter-Chassis Module Placement for the ASA Services Module 11-11

Intra-Chassis Failover 11-11

Inter-Chassis Failover 11-12

Transparent Firewall Mode Requirements 11-15

Auto Update Server Support in Failover Configurations 11-16

Auto Update Process Overview 11-16

Monitoring the Auto Update Process 11-17

Failover Health Monitoring 11-18

Unit Health Monitoring 11-19

Interface Monitoring 11-19

Failover Times 11-20

Failover Messages 11-20

Failover System Messages 11-20

Debug Messages 11-21

SNMP 11-21

CHAPTER 12 **Configuring Active/Standby Failover** 12-1

Information About Active/Standby Failover 12-1

Active/Standby Failover Overview 12-1

Primary/Secondary Status and Active/Standby Status 12-2

Device Initialization and Configuration Synchronization 12-2

Command Replication 12-3

Failover Triggers 12-4

Failover Actions 12-4
Optional Active/Standby Failover Settings 12-5
Licensing Requirements for Active/Standby Failover 12-5
Prerequisites for Active/Standby Failover 12-6
Guidelines and Limitations 12-6
Configuring Active/Standby Failover 12-7
Using the High Availability and Scalability Wizard 12-7
Configuring Failover (Without the Wizard) 12-10
Configuring Interface Standby Addresses 12-12
Configuring Optional Active/Standby Failover Settings 12-13
Controlling Failover 12-16
Forcing Failover 12-16
Disabling Failover 12-17
Restoring a Failed Unit 12-17
Monitoring Active/Standby Failover 12-17
Feature History for Active/Standby Failover 12-17

CHAPTER 13 **Configuring Active/Active Failover** 13-1
Information About Active/Active Failover 13-1
Active/Active Failover Overview 13-1
Primary/Secondary Status and Active/Standby Status 13-2
Device Initialization and Configuration Synchronization 13-3
Command Replication 13-3
Failover Triggers 13-4
Failover Actions 13-4
Optional Active/Active Failover Settings 13-6
Licensing Requirements for Active/Active Failover 13-6
Prerequisites for Active/Active Failover 13-6
Guidelines and Limitations 13-7
Configuring Active/Active Failover 13-8
Task Flow for Using the High Availability and Scalability Wizard 13-8
Configuring Failover (Without the Wizard) 13-12
Configuring Asymmetric Routing Groups in Multiple Context Mode 13-20
Controlling Failover 13-21
Forcing Failover 13-21
Disabling Failover 13-21
Restoring a Failed Unit or Failover Group 13-22
Monitoring Active/Active Failover 13-22

System 13-22
Failover Group 1 and Failover Group 2 13-23
Feature History for Active/Active Failover 13-23

PART 2 Configuring Interfaces

CHAPTER 15 Starting Interface Configuration (ASA 5510 and Higher) 15-1
Information About Starting ASA 5510 and Higher Interface Configuration 15-2
Auto-MDI/MDIX Feature 15-2
Interfaces in Transparent Mode 15-2
Management Interface 15-2
Redundant Interfaces 15-5
EtherChannels 15-5
Licensing Requirements for ASA 5510 and Higher Interfaces 15-8
Guidelines and Limitations 15-10
Default Settings 15-12
Starting Interface Configuration (ASA 5510 and Higher) 15-12
Task Flow for Starting Interface Configuration 15-13
Converting In-Use Interfaces to a Redundant or EtherChannel Interface 15-14
Enabling the Physical Interface and Configuring Ethernet Parameters 15-23
Configuring a Redundant Interface 15-25
Configuring an EtherChannel 15-28
Configuring VLAN Subinterfaces and 802.1Q Trunking 15-34
Enabling Jumbo Frame Support (Supported Models) 15-37
Monitoring Interfaces 15-37
ARP Table 15-38
MAC Address Table 15-38
Interface Graphs 15-38
Where to Go Next 15-41
Feature History for ASA 5510 and Higher Interfaces 15-41

CHAPTER 16 Starting Interface Configuration (ASA 5505) 16-1
Information About ASA 5505 Interfaces 16-1
Understanding ASA 5505 Ports and Interfaces 16-2
Maximum Active VLAN Interfaces for Your License 16-2
VLAN MAC Addresses 16-4
Power over Ethernet 16-4
Monitoring Traffic Using SPAN 16-4

Auto-MDI/MDIX Feature 16-4
Licensing Requirements for ASA 5505 Interfaces 16-4
Guidelines and Limitations 16-5
Default Settings 16-5
Starting ASA 5505 Interface Configuration 16-6
Task Flow for Starting Interface Configuration 16-6
Configuring VLAN Interfaces 16-6
Configuring and Enabling Switch Ports as Access Ports 16-8
Configuring and Enabling Switch Ports as Trunk Ports 16-10
Monitoring Interfaces 16-12
ARP Table 16-12
MAC Address Table 16-12
Interface Graphs 16-13
Where to Go Next 16-15
Feature History for ASA 5505 Interfaces 16-16

CHAPTER 17 **Completing Interface Configuration (Routed Mode)** 17-1
Information About Completing Interface Configuration in Routed Mode 17-1
Security Levels 17-1
Dual IP Stack (IPv4 and IPv6) 17-2
Licensing Requirements for Completing Interface Configuration in Routed Mode 17-2
Guidelines and Limitations 17-5
Default Settings 17-6
Completing Interface Configuration in Routed Mode 17-6
Task Flow for Completing Interface Configuration 17-7
Configuring General Interface Parameters 17-7
Configuring the MAC Address and MTU 17-13
Configuring IPv6 Addressing 17-15
Allowing Same Security Level Communication 17-20
Turning Off and Turning On Interfaces 17-22
Monitoring Interfaces 17-22
ARP Table 17-23
DHCP 17-23
MAC Address Table 17-26
Dynamic ACLs 17-26
Interface Graphs 17-26
PPPoE Client 17-29
Interface Connection 17-29

Feature History for Interfaces in Routed Mode 17-30

CHAPTER 18 **Completing Interface Configuration (Transparent Mode, 8.4 and Later)** 18-1

Information About Completing Interface Configuration in Transparent Mode (8.4 and Later) 18-1
Bridge Groups in Transparent Mode 18-2
Security Levels 18-2
Licensing Requirements for Completing Interface Configuration in Transparent Mode 18-3
Guidelines and Limitations 18-5
Default Settings 18-6
Completing Interface Configuration in Transparent Mode (8.4 and Later) 18-7
Task Flow for Completing Interface Configuration 18-7
Configuring Bridge Groups 18-8
Configuring General Interface Parameters 18-9
Configuring a Management Interface (ASA 5510 and Higher) 18-11
Configuring the MAC Address and MTU 18-14
Configuring IPv6 Addressing 18-16
Allowing Same Security Level Communication 18-21
Turning Off and Turning On Interfaces 18-21
Monitoring Interfaces 18-22
ARP Table 18-22
DHCP 18-23
MAC Address Table 18-25
Dynamic ACLs 18-25
Interface Graphs 18-26
PPPoE Client 18-28
Interface Connection 18-28
Feature History for Interfaces in Transparent Mode 18-30

CHAPTER 19 **Completing Interface Configuration (Transparent Mode, 8.3 and Earlier)** 19-1

Information About Completing Interface Configuration in Transparent Mode (8.3 and Earlier) 19-1
Information About the Global Management IP Address 19-2
Security Levels 19-2
Licensing Requirements for Completing Interface Configuration in Transparent Mode 19-3
Guidelines and Limitations 19-3
Default Settings 19-4
Setting the Management IP Address for a Transparent Firewall (8.3 and Earlier) 19-4
Configuring the IPv4 Address 19-4
Configuring the IPv6 Address 19-5

Completing Interface Configuration in Transparent Mode (8.3 and Earlier) 19-9
Task Flow for Completing Interface Configuration 19-9
Configuring General Interface Parameters 19-10
Configuring a Management Interface (ASA 5510 and Higher) 19-11
Configuring the MAC Address and MTU 19-15
Allowing Same Security Level Communication 19-17
Monitoring Interfaces 19-17
Feature History for Interfaces in Transparent Mode 19-18

PART 3 **Configuring Basic Settings**

CHAPTER 21 **Configuring Basic Settings** 21-1
Configuring the Hostname, Domain Name, and Passwords 21-1
Setting the Hostname, Domain Name, and the enable and Telnet Passwords 21-1
Setting the Date and Time 21-2
Setting the Date and Time Using an NTP Server 21-3
Setting the Date and Time Manually 21-4
Configuring the Master Passphrase 21-4
Information About the Master Passphrase 21-5
Licensing Requirements for the Master Passphrase 21-5
Guidelines and Limitations 21-5
Adding or Changing the Master Passphrase 21-5
Disabling the Master Passphrase 21-6
Recovering the Master Passphrase 21-7
Feature History for the Master Passphrase 21-7
Configuring the DNS Server 21-8
Changing the Heap Memory Size 21-9
Monitoring DNS Cache 21-9

CHAPTER 22 **Configuring Dynamic DNS** 22-1
Information About DDNS 22-1
Licensing Requirements for DDNS 22-2
Guidelines and Limitations 22-2
Configuring Dynamic DNS 22-2
DDNS Monitoring 22-4
Feature History for DDNS 22-4

CHAPTER 23 **Configuring DHCP** 23-1

Information About DHCP 23-1

Licensing Requirements for DHCP 23-2

Guidelines and Limitations 23-2

Configuring a DHCP Server 23-3

Editing DHCP Server Settings 23-4

Configuring Advanced DHCP Options 23-5

Configuring the DHCP Relay Service 23-6

Editing DHCP Relay Agent Settings 23-7

Adding or Editing Global DHCP Relay Server Settings 23-8

Additional References 23-8

RFCs 23-9

DHCP Monitoring 23-9

Feature History for DHCP 23-10

PART 4 **Configuring Objects and ACLs**

CHAPTER 25 **Configuring Objects** 25-1

Information About Objects 25-1

Licensing Requirements for Objects 25-1

Guidelines and Limitations 25-1

Configuring Objects 25-2

Configuring Network Objects and Groups 25-2

Configuring Service Objects and Service Groups 25-4

Configuring Local User Groups 25-7

Configuring Security Group Object Groups 25-8

Configuring Regular Expressions 25-10

Configuring Time Ranges 25-15

Monitoring Objects 25-16

Feature History for Objects 25-16

CHAPTER 26 **Using the ACL Manager** 26-1

Information About the ACL Manager 26-1

Licensing Requirements for the ACL Manager 26-1

Guidelines and Limitations 26-2

Adding ACLs and ACEs 26-2

Using Standard ACLs in the ACL Manager 26-4

Feature History for the ACL Manager 26-5

CHAPTER 27 **Adding a Standard Access Control List** 27-1

Information About Standard ACLs 27-1

Licensing Requirements for Standard ACLs 27-1

Guidelines and Limitations 27-1

Default Settings 27-2

Adding Standard ACLs 27-3

Using Standard ACLs 27-3

Feature History for Standard ACLs 27-4

CHAPTER 28 **Adding a Webtype Access Control List** 28-1

Licensing Requirements for Webtype ACLs 28-1

Guidelines and Limitations 28-1

Default Settings 28-2

Using Webtype ACLs 28-2

Task Flow for Configuring Webtype ACLs 28-2

Adding a Webtype ACL and ACE 28-3

Editing Webtype ACLs and ACEs 28-4

Deleting Webtype ACLs and ACEs 28-5

Feature History for Webtype Access Lists 28-6

PART 5 **Configuring IP Routing**

CHAPTER 30 **Routing Overview** 30-1

Information About Routing 30-1

Switching 30-1

Path Determination 30-2

Supported Route Types 30-2

How Routing Behaves Within the ASA 30-4

Egress Interface Selection Process 30-4

Next Hop Selection Process 30-4

Supported Internet Protocols for Routing 30-5

Information About the Routing Table 30-5

Displaying the Routing Table 30-6

How the Routing Table Is Populated 30-6

How Forwarding Decisions Are Made 30-8

Dynamic Routing and Failover 30-8
Dynamic Routing and Clustering 30-9
Dynamic Routing in Multiple Context Mode 30-10
Disabling Proxy ARPs 30-11

CHAPTER 31 **Configuring Static and Default Routes** 31-1
Information About Static and Default Routes 31-1
Licensing Requirements for Static and Default Routes 31-2
Guidelines and Limitations 31-2
Configuring Static and Default Routes 31-2
Configuring a Static Route 31-3
Configuring a Default Static Route 31-6
Configuring IPv6 Default and Static Routes 31-7
Monitoring a Static or Default Route 31-8
Configuration Examples for Static or Default Routes 31-8
Feature History for Static and Default Routes 31-9

CHAPTER 32 **Defining Route Maps** 32-1
Information About Route Maps 32-1
Permit and Deny Clauses 32-2
Match and Set Clause Values 32-2
Licensing Requirements for Route Maps 32-3
Guidelines and Limitations 32-3
Defining a Route Map 32-4
Customizing a Route Map 32-5
Defining a Route to Match a Specific Destination Address 32-5
Configuring Prefix Lists 32-6
Configuring Prefix Rules 32-7
Configuring the Metric Values for a Route Action 32-7
Configuration Example for Route Maps 32-8
Feature History for Route Maps 32-8

CHAPTER 33 **Configuring OSPF** 33-1
Information About OSPF 33-1
Implementation Differences Between OSPFv2 and OSPFv3 33-3
Using Clustering 33-3
Licensing Requirements for OSPF 33-3

Guidelines and Limitations 33-3
Configuring OSPFv2 33-5
Customizing OSPFv2 33-6
Redistributing Routes Into OSPFv2 33-6
Configuring Route Summarization When Redistributing Routes Into OSPFv2 33-8
Configuring Route Summarization Between OSPFv2 Areas 33-10
Configuring OSPFv2 Interface Parameters 33-11
Configuring OSPFv2 Area Parameters 33-13
Configuring an OSPFv2 NSSA 33-14
Configuring an IP Address Pool for Clustering (OSPFv2 and OSPFv3) 33-15
Defining Static OSPFv2 Neighbors 33-17
Configuring Route Calculation Timers 33-18
Logging Neighbors Going Up or Down 33-18
Configuring Filtering in OSPF 33-19
Configuring a Virtual Link in OSPF 33-20
Configuring OSPFv3 33-21
Enabling OSPFv3 33-22
Configuring OSPFv3 Interface Parameters 33-22
Configuring OSPFv3 Area Parameters 33-23
Configuring a Virtual Link Neighbor 33-24
Configuring OSPFv3 Passive Interfaces 33-25
Configuring OSPFv3 Administrative Distance 33-26
Configuring OSPFv3 Timers 33-27
Defining Static OSPFv3 Neighbors 33-28
Sending Syslog Messages 33-29
Suppressing Syslog Messages 33-29
Calculating Summary Route Costs 33-29
Generating a Default External Route into an OSPFv3 Routing Domain 33-30
Configuring an IPv6 Summary Prefix 33-30
Redistributing IPv6 Routes 33-31
Removing the OSPF Configuration 33-32
Configuration Example for OSPFv2 33-32
Configuration Example for OSPFv3 33-34
Monitoring OSPF 33-35
Additional References 33-36
RFCs 33-36
Feature History for OSPF 33-37

CHAPTER 34 **Configuring RIP** 34-1

Information About RIP 34-1
Routing Update Process 34-2
RIP Routing Metric 34-2
RIP Stability Features 34-2
RIP Timers 34-2
Using Clustering 34-3
Licensing Requirements for RIP 34-3
Guidelines and Limitations 34-3
Configuring RIP 34-4
Enabling RIP 34-4
Customizing RIP 34-5
Configuring the RIP Version 34-5
Configuring Interfaces for RIP 34-5
Configuring the RIP Send and Receive Version on an Interface 34-7
Configuring Route Summarization 34-8
Filtering Networks in RIP 34-8
Redistributing Routes into the RIP Routing Process 34-10
Enabling RIP Authentication 34-11
Restarting the RIP Process 34-12
Monitoring RIP 34-12
Configuration Example for RIP 34-12
Feature History for RIP 34-13

CHAPTER 35 **Configuring Multicast Routing** 35-1

Information About Multicast Routing 35-1
Stub Multicast Routing 35-2
PIM Multicast Routing 35-2
Multicast Group Concept 35-2
Clustering 35-2
Licensing Requirements for Multicast Routing 35-3
Guidelines and Limitations 35-3
Enabling Multicast Routing 35-3
Customizing Multicast Routing 35-4
Configuring Stub Multicast Routing and Forwarding IGMP Messages 35-4
Configuring a Static Multicast Route 35-5
Configuring IGMP Features 35-6
Configuring PIM Features 35-10

Configuring a Multicast Group 35-14
Configuring a Bidirectional Neighbor Filter 35-15
Configuring a Multicast Boundary 35-16
Configuration Example for Multicast Routing 35-17
Additional References 35-18
Related Documents 35-19
RFCs 35-19
Feature History for Multicast Routing 35-19

CHAPTER 36 **Configuring EIGRP** 36-1
Information About EIGRP 36-1
Using Clustering 36-2
Licensing Requirements for EIGRP 36-2
Guidelines and Limitations 36-3
Task List to Configure an EIGRP Process 36-3
Configuring EIGRP 36-4
Enabling EIGRP 36-4
Enabling EIGRP Stub Routing 36-5
Customizing EIGRP 36-6
Defining a Network for an EIGRP Routing Process 36-7
Configuring Interfaces for EIGRP 36-7
Configuring the Summary Aggregate Addresses on Interfaces 36-9
Changing the Interface Delay Value 36-10
Enabling EIGRP Authentication on an Interface 36-10
Defining an EIGRP Neighbor 36-11
Redistributing Routes Into EIGRP 36-12
Filtering Networks in EIGRP 36-13
Customizing the EIGRP Hello Interval and Hold Time 36-14
Disabling Automatic Route Summarization 36-15
Configuring Default Information in EIGRP 36-16
Disabling EIGRP Split Horizon 36-17
Restarting the EIGRP Process 36-17
Monitoring EIGRP 36-18
Feature History for EIGRP 36-19

CHAPTER 37 **Configuring IPv6 Neighbor Discovery** 37-1
Information About IPv6 Neighbor Discovery 37-1
Neighbor Solicitation Messages 37-2

Neighbor Reachable Time 37-3
Duplicate Address Detection 37-3
Router Advertisement Messages 37-3
Static IPv6 Neighbors 37-5
Licensing Requirements for IPv6 Neighbor Discovery 37-5
Prerequisites for IPv6 Neighbor Discovery 37-5
Guidelines and Limitations 37-5
Default Settings for IPv6 Neighbor Discovery 37-7
Configuring IPv6 Neighbor Discovery 37-7
Configuring the Neighbor Solicitation Message Interval 37-8
Configuring the Neighbor Reachable Time 37-8
Configuring the Router Advertisement Transmission Interval 37-9
Configuring the Router Lifetime Value 37-9
Configuring DAD Settings 37-10
Suppressing Router Advertisement Messages 37-10
Configuring Address Config Flags for IPv6 DHCP Relay 37-11
Configuring the IPv6 Prefix in Router Advertisements 37-11
Configuring a Static IPv6 Neighbor 37-12
Viewing and Clearing Dynamically Discovered Neighbors 37-13
Additional References 37-13
Related Documents for IPv6 Prefixes 37-14
RFCs for IPv6 Prefixes and Documentation 37-14
Feature History for IPv6 Neighbor Discovery 37-14

PART 6 **Configuring Network Address Translation**

CHAPTER 39 **Information About NAT (ASA 8.3 and Later)** 39-1
Why Use NAT? 39-1
NAT Terminology 39-2
NAT Types 39-3
NAT Types Overview 39-3
Static NAT 39-3
Dynamic NAT 39-8
Dynamic PAT 39-10
Identity NAT 39-12
NAT in Routed and Transparent Mode 39-12
NAT in Routed Mode 39-13
NAT in Transparent Mode 39-13

NAT and IPv6 39-15
How NAT is Implemented 39-15
Main Differences Between Network Object NAT and Twice NAT 39-15
Information About Network Object NAT 39-16
Information About Twice NAT 39-16
NAT Rule Order 39-20
NAT Interfaces 39-21
Routing NAT Packets 39-21
Mapped Addresses and Routing 39-22
Transparent Mode Routing Requirements for Remote Networks 39-24
Determining the Egress Interface 39-24
NAT for VPN 39-24
NAT and Remote Access VPN 39-24
NAT and Site-to-Site VPN 39-26
NAT and VPN Management Access 39-28
Troubleshooting NAT and VPN 39-30
DNS and NAT 39-30
Where to Go Next 39-34

CHAPTER 40 **Configuring Network Object NAT (ASA 8.3 and Later)** 40-1
Information About Network Object NAT 40-1
Licensing Requirements for Network Object NAT 40-2
Prerequisites for Network Object NAT 40-2
Guidelines and Limitations 40-2
Default Settings 40-3
Configuring Network Object NAT 40-4
Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool 40-4
Configuring Dynamic PAT (Hide) 40-8
Configuring Static NAT or Static NAT-with-Port-Translation 40-11
Configuring Identity NAT 40-15
Configuring Per-Session PAT Rules 40-18
Monitoring Network Object NAT 40-19
Configuration Examples for Network Object NAT 40-20
Providing Access to an Inside Web Server (Static NAT) 40-21
NAT for Inside Hosts (Dynamic NAT) and NAT for an Outside Web Server (Static NAT) 40-23
Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many) 40-28
Single Address for FTP, HTTP, and SMTP (Static NAT-with-Port-Translation) 40-32

DNS Server on Mapped Interface, Web Server on Real Interface (Static NAT with DNS Modification) 40-35
DNS Server and FTP Server on Mapped Interface, FTP Server is Translated (Static NAT with DNS Modification) 40-38
IPv4 DNS Server and FTP Server on Mapped Interface, IPv6 Host on Real Interface (Static NAT64 with DNS64 Modification) 40-40
Feature History for Network Object NAT 40-45

CHAPTER 41 **Configuring Twice NAT (ASA 8.3 and Later)** 41-1
Information About Twice NAT 41-1
Licensing Requirements for Twice NAT 41-2
Prerequisites for Twice NAT 41-2
Guidelines and Limitations 41-2
Default Settings 41-4
Configuring Twice NAT 41-4
Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool 41-4
Configuring Dynamic PAT (Hide) 41-12
Configuring Static NAT or Static NAT-with-Port-Translation 41-18
Configuring Identity NAT 41-24
Configuring Per-Session PAT Rules 41-29
Monitoring Twice NAT 41-30
Configuration Examples for Twice NAT 41-30
Different Translation Depending on the Destination (Dynamic PAT) 41-31
Different Translation Depending on the Destination Address and Port (Dynamic PAT) 41-39
Feature History for Twice NAT 41-48

CHAPTER 42 **Configuring NAT (ASA 8.2 and Earlier)** 42-1
NAT Overview 42-1
Introduction to NAT 42-1
NAT in Routed Mode 42-2
NAT in Transparent Mode 42-3
NAT Control 42-4
NAT Types 42-6
Policy NAT 42-10
NAT and Same Security Level Interfaces 42-12
Order of NAT Rules Used to Match Real Addresses 42-13
Mapped Address Guidelines 42-13
DNS and NAT 42-13
Configuring NAT Control 42-15

Using Dynamic NAT 42-16
Dynamic NAT Implementation 42-16
Managing Global Pools 42-21
Configuring Dynamic NAT, PAT, or Identity NAT 42-22
Configuring Dynamic Policy NAT or PAT 42-24
Using Static NAT 42-26
Configuring Static NAT, PAT, or Identity NAT 42-27
Configuring Static Policy NAT, PAT, or Identity NAT 42-30
Using NAT Exemption 42-32

PART 7 Configuring Service Policies

CHAPTER 44 Configuring a Service Policy 44-1
Information About Service Policies 44-1
Supported Features 44-1
Feature Directionality 44-2
Feature Matching Within a Service Policy 44-3
Order in Which Multiple Feature Actions are Applied 44-4
Incompatibility of Certain Feature Actions 44-4
Feature Matching for Multiple Service Policies 44-5
Licensing Requirements for Service Policies 44-5
Guidelines and Limitations 44-6
Default Settings 44-7
Default Configuration 44-7
Default Traffic Classes 44-8
Task Flows for Configuring Service Policies 44-8
Task Flow for Configuring a Service Policy Rule 44-8
Adding a Service Policy Rule for Through Traffic 44-8
Adding a Service Policy Rule for Management Traffic 44-13
Configuring a Service Policy Rule for Management Traffic 44-13
Managing the Order of Service Policy Rules 44-16
Feature History for Service Policies 44-17

PART 8 Configuring AAA Servers and the Local Database

CHAPTER 46 Configuring AAA Servers and the Local Database 46-1
Information About AAA 46-1
Information About Authentication 46-2

Information About Authorization 46-2
Information About Accounting 46-3
Summary of Server Support 46-3
RADIUS Server Support 46-4
TACACS+ Server Support 46-5
RSA/SDI Server Support 46-5
NT Server Support 46-6
Kerberos Server Support 46-6
LDAP Server Support 46-6
HTTP Forms Authentication for Clientless SSL VPN 46-7
Local Database Support, Including as a Fallback Method 46-7
How Fallback Works with Multiple Servers in a Group 46-8
Using Certificates and User Login Credentials 46-8
Licensing Requirements for AAA Servers 46-9
Guidelines and Limitations 46-10
Configuring AAA 46-10
Task Flow for Configuring AAA 46-10
Configuring AAA Server Groups 46-11
Adding a Server to a Group 46-12
Configuring AAA Server Parameters 46-13
Configuring LDAP Attribute Maps 46-19
Adding a User Account to the Local Database 46-20
Authenticating Users with a Public Key for SSH 46-25
Adding an Authentication Prompt 46-26
Testing Server Authentication and Authorization 46-27
Monitoring AAA Servers 46-27
Additional References 46-28
RFCs 46-28
Feature History for AAA Servers 46-28

CHAPTER 47 **Configuring the Identity Firewall** 47-1
Information About the Identity Firewall 47-1
Overview of the Identity Firewall 47-1
Architecture for Identity Firewall Deployments 47-2
Features of the Identity Firewall 47-3
Deployment Scenarios 47-4
Licensing for the Identity Firewall 47-7
Guidelines and Limitations 47-7

Prerequisites 47-8
Configuring the Identity Firewall 47-9
Task Flow for Configuring the Identity Firewall 47-9
Configuring the Active Directory Domain 47-10
Configuring Active Directory Server Groups 47-10
Configuring Active Directory Agents 47-11
Configuring Active Directory Agent Groups 47-12
Configuring Identity Options 47-12
Configuring Identity-Based Security Policy 47-15
Monitoring the Identity Firewall 47-16
Monitoring AD Agents 47-16
Monitoring Groups 47-16
Monitoring Memory Usage for the Identity Firewall 47-17
Monitoring Users for the Identity Firewall 47-17
Feature History for the Identity Firewall 47-18

CHAPTER 48 **Configuring the ASA to Integrate with Cisco TrustSec** 48-1
Information About the ASA Integrated with Cisco TrustSec 48-1
Information about Cisco TrustSec 48-1
About SGT and SXP Support in Cisco TrustSec 48-2
Roles in the Cisco TrustSec Solution 48-3
Security Group Policy Enforcement 48-3
How the ASA Enforces Security Group Based Policies 48-4
About Speaker and Listener Roles on the ASA 48-6
Features of the ASA-Cisco TrustSec Integration 48-6
Licensing Requirements when Integrating the ASA with Cisco TrustSec 48-8
Prerequisites for Integrating the ASA with Cisco TrustSec 48-8
Guidelines and Limitations 48-9
Configuring the ASA for Cisco TrustSec Integration 48-11
Task Flow for Configuring the ASA to Integrate with Cisco TrustSec 48-11
Configuring the AAA Server for Cisco TrustSec Integration 48-12
Importing a Protected Access Credential (PAC) File 48-13
Configuring the Security Exchange Protocol (SXP) 48-14
Adding an SXP Connection Peer 48-15
Refreshing Environment Data 48-16
Configuring the Security Policy 48-17
Monitoring the ASA Integrated with Cisco TrustSec 48-17
Monitoring SXP Connections 48-17

Monitoring Environment Data 48-18
Monitoring Cisco TrustSec IP-SGT Mappings 48-19
Monitoring the PAC File 48-20
Feature History for the ASA-Cisco TrustSec Integration 48-21

CHAPTER 49 **Configuring Digital Certificates** 49-1
Information About Digital Certificates 49-1
Public Key Cryptography 49-3
Certificate Scalability 49-3
Key Pairs 49-4
Trustpoints 49-4
Revocation Checking 49-5
The Local CA 49-7
Licensing Requirements for Digital Certificates 49-8
Prerequisites for Local Certificates 49-8
Prerequisites for SCEP Proxy Support 49-9
Guidelines and Limitations 49-9
Configuring Digital Certificates 49-10
Configuring CA Certificate Authentication 49-11
Adding or Installing a CA Certificate 49-11
Editing or Removing a CA Certificate Configuration 49-12
Showing CA Certificate Details 49-13
Configuring CA Certificate Authentication 49-13
Adding or Installing a CA Certificate 49-13
Editing or Removing a CA Certificate Configuration 49-14
Showing CA Certificate Details 49-14
Configuring CA Certificates for Revocation 49-15
Configuring CRL Retrieval Policy 49-15
Configuring CRL Retrieval Methods 49-16
Configuring OCSP Rules 49-16
Configuring Advanced CRL and OCSP Settings 49-17
Monitoring CRLs 49-18
Configuring CA Certificates for Revocation 49-19
Configuring CRL Retrieval Policy 49-19
Configuring CRL Retrieval Methods 49-20
Configuring OCSP Rules 49-20
Configuring Advanced CRL and OCSP Settings 49-21
Configuring Identity Certificates Authentication 49-22
Adding or Importing an Identity Certificate 49-22

Showing Identity Certificate Details 49-24
Deleting an Identity Certificate 49-25
Exporting an Identity Certificate 49-25
Generating a Certificate Signing Request 49-25
Installing Identity Certificates 49-26
Configuring Code Signer Certificates 49-27
Showing Code Signer Certificate Details 49-28
Deleting a Code Signer Certificate 49-28
Importing a Code Signer Certificate 49-28
Exporting a Code Signer Certificate 49-29
Authenticating Using the Local CA 49-29
Configuring the Local CA Server 49-30
Deleting the Local CA Server 49-32
Managing the User Database 49-33
Adding a Local CA User 49-33
Sending an Initial OTP or Replacing OTPs 49-34
Editing a Local CA User 49-34
Deleting a Local CA User 49-35
Allowing User Enrollment 49-35
Viewing or Regenerating an OTP 49-35
Managing User Certificates 49-35
Monitoring CRLs 49-36
Feature History for Certificate Management 49-37

PART 9 **Configuring Access Control**

CHAPTER 51 **Configuring Access Rules** 51-1
Information About Access Rules 51-1
General Information About Rules 51-2
Information About Access Rules 51-4
Information About EtherType Rules 51-5
Licensing Requirements for Access Rules 51-6
Guidelines and Limitations 51-6
Default Settings 51-7
Configuring Access Rules 51-7
Adding an Access Rule 51-7
Adding an EtherType Rule (Transparent Mode Only) 51-8
Configuring Management Access Rules 51-9

Advanced Access Rule Configuration 51-10
Configuring HTTP Redirect 51-12
Feature History for Access Rules 51-13

CHAPTER 52 **Configuring Management Access** 52-1
Configuring ASA Access for ASDM, Telnet, or SSH 52-1
Licensing Requirements for ASA Access for ASDM, Telnet, or SSH 52-1
Guidelines and Limitations 52-2
Configuring Management Access 52-3
Using a Telnet Client 52-4
Using an SSH Client 52-4
Configuring CLI Parameters 52-5
Licensing Requirements for CLI Parameters 52-5
Guidelines and Limitations 52-5
Configuring a Login Banner 52-5
Customizing a CLI Prompt 52-6
Changing the Console Timeout 52-8
Configuring File Access 52-8
Licensing Requirements for File Access 52-8
Guidelines and Limitations 52-8
Configuring the FTP Client Mode 52-9
Configuring the ASA as a Secure Copy Server 52-9
Configuring the ASA as a TFTP Client 52-10
Adding Mount Points 52-10
Configuring ICMP Access 52-12
Information About ICMP Access 52-12
Licensing Requirements for ICMP Access 52-12
Guidelines and Limitations 52-13
Default Settings 52-13
Configuring ICMP Access 52-13
Configuring Management Access Over a VPN Tunnel 52-14
Licensing Requirements for a Management Interface 52-14
Guidelines and Limitations 52-14
Configuring a Management Interface 52-15
Configuring AAA for System Administrators 52-15
Information About AAA for System Administrators 52-16
Licensing Requirements for AAA for System Administrators 52-19
Prerequisites 52-19
Guidelines and Limitations 52-20

Default Settings 52-20
Configuring Authentication for CLI, ASDM, and enable command Access 52-20
Limiting User CLI and ASDM Access with Management Authorization 52-21
Configuring Command Authorization 52-23
Configuring Management Access Accounting 52-29
Viewing the Currently Logged-In User 52-29
Recovering from a Lockout 52-30
Monitoring Device Access 52-31
Feature History for Management Access 52-32

CHAPTER 53 **Configuring AAA Rules for Network Access** 53-1
AAA Performance 53-1
Licensing Requirements for AAA Rules 53-1
Guidelines and Limitations 53-2
Configuring Authentication for Network Access 53-2
Information About Authentication 53-2
Configuring Network Access Authentication 53-6
Enabling the Redirection Method of Authentication for HTTP and HTTPS 53-7
Enabling Secure Authentication of Web Clients 53-8
Authenticating Directly with the ASA 53-9
Configuring the Authentication Proxy Limit 53-11
Configuring Authorization for Network Access 53-11
Configuring TACACS+ Authorization 53-11
Configuring RADIUS Authorization 53-13
Configuring Accounting for Network Access 53-17
Using MAC Addresses to Exempt Traffic from Authentication and Authorization 53-18
Feature History for AAA Rules 53-19

CHAPTER 54 **Configuring Web Cache Services Using WCCP** 54-1
Information About WCCP 54-1
Guidelines and Limitations 54-1
Licensing Requirements for WCCP 54-3
Configuring WCCP Service Groups 54-3
Adding or Editing WCCP Service Groups 54-3
Configuring Packet Redirection 54-4
Adding or Editing Packet Redirection 54-4
WCCP Monitoring 54-4

Feature History for WCCP 54-5

CHAPTER 55 **Configuring Public Servers** 55-1

Information About Public Servers 55-1

Licensing Requirements for Public Servers 55-1

Guidelines and Limitations 55-1

Adding a Public Server that Enables Static NAT 55-2

Adding a Public Server that Enables Static NAT with PAT 55-2

Editing Settings for a Public Server 55-3

Feature History for Public Servers 55-4

PART 10 **Configuring Application Inspection**

CHAPTER 57 **Getting Started with Application Layer Protocol Inspection** 57-1

Information about Application Layer Protocol Inspection 57-1

How Inspection Engines Work 57-1

When to Use Application Protocol Inspection 57-2

Guidelines and Limitations 57-3

Default Settings 57-4

Configuring Application Layer Protocol Inspection 57-6

CHAPTER 58 **Configuring Inspection of Basic Internet Protocols** 58-1

DNS Inspection 58-1

How DNS Application Inspection Works 58-2

How DNS Rewrite Works 58-3

Configuring DNS Rewrite 58-3

Select DNS Inspect Map 58-5

DNS Class Map 58-6

Add/Edit DNS Traffic Class Map 58-6

Add/Edit DNS Match Criterion 58-7

DNS Inspect Map 58-8

Add/Edit DNS Policy Map (Security Level) 58-9

Add/Edit DNS Policy Map (Details) 58-11

FTP Inspection 58-12

FTP Inspection Overview 58-12

Using Strict FTP 58-13

Select FTP Map 58-14

FTP Class Map 58-14

Add/Edit FTP Traffic Class Map 58-15
Add/Edit FTP Match Criterion 58-15
FTP Inspect Map 58-16
File Type Filtering 58-17
Add/Edit FTP Policy Map (Security Level) 58-18
Add/Edit FTP Policy Map (Details) 58-18
Add/Edit FTP Map 58-19
Verifying and Monitoring FTP Inspection 58-21
HTTP Inspection 58-21
HTTP Inspection Overview 58-21
Select HTTP Map 58-22
HTTP Class Map 58-22
Add/Edit HTTP Traffic Class Map 58-23
Add/Edit HTTP Match Criterion 58-23
HTTP Inspect Map 58-27
URI Filtering 58-28
Add/Edit HTTP Policy Map (Security Level) 58-28
Add/Edit HTTP Policy Map (Details) 58-29
Add/Edit HTTP Map 58-30
ICMP Inspection 58-34
ICMP Error Inspection 58-34
Instant Messaging Inspection 58-35
IM Inspection Overview 58-35
Adding a Class Map for IM Inspection 58-35
Select IM Map 58-36
IP Options Inspection 58-36
IP Options Inspection Overview 58-37
Configuring IP Options Inspection 58-37
Select IP Options Inspect Map 58-39
IP Options Inspect Map 58-39
Add/Edit IP Options Inspect Map 58-39
IPsec Pass Through Inspection 58-40
IPsec Pass Through Inspection Overview 58-40
Select IPsec-Pass-Thru Map 58-41
IPsec Pass Through Inspect Map 58-41
Add/Edit IPsec Pass Thru Policy Map (Security Level) 58-42
Add/Edit IPsec Pass Thru Policy Map (Details) 58-42
IPv6 Inspection 58-43
Configuring an IPv6 Inspection Policy Map 58-44

NetBIOS Inspection 58-45
NetBIOS Inspection Overview 58-45
Select NETBIOS Map 58-45
NetBIOS Inspect Map 58-45
Add/Edit NetBIOS Policy Map 58-46
PPTP Inspection 58-46
SMTP and Extended SMTP Inspection 58-47
SMTP and ESMTP Inspection Overview 58-47
Select ESMTP Map 58-48
ESMTP Inspect Map 58-48
MIME File Type Filtering 58-49
Add/Edit ESMTP Policy Map (Security Level) 58-50
Add/Edit ESMTP Policy Map (Details) 58-51
Add/Edit ESMTP Inspect 58-52
TFTP Inspection 58-55

CHAPTER 59 **Configuring Inspection for Voice and Video Protocols** 59-1

CTIQBE Inspection 59-1
CTIQBE Inspection Overview 59-1
Limitations and Restrictions 59-2
H.323 Inspection 59-2
H.323 Inspection Overview 59-3
How H.323 Works 59-3
H.239 Support in H.245 Messages 59-4
Limitations and Restrictions 59-4
Select H.323 Map 59-5
H.323 Class Map 59-5
Add/Edit H.323 Traffic Class Map 59-6
Add/Edit H.323 Match Criterion 59-6
H.323 Inspect Map 59-7
Phone Number Filtering 59-8
Add/Edit H.323 Policy Map (Security Level) 59-8
Add/Edit H.323 Policy Map (Details) 59-9
Add/Edit HSI Group 59-11
Add/Edit H.323 Map 59-11
MGCP Inspection 59-12
MGCP Inspection Overview 59-12
Select MGCP Map 59-14
MGCP Inspect Map 59-14

Gateways and Call Agents 59-15
Add/Edit MGCP Policy Map 59-15
Add/Edit MGCP Group 59-16
RTSP Inspection 59-16
RTSP Inspection Overview 59-17
Using RealPlayer 59-17
Restrictions and Limitations 59-18
Select RTSP Map 59-18
RTSP Inspect Map 59-18
Add/Edit RTSP Policy Map 59-18
Add/Edit RTSP Inspect 59-19
SIP Inspection 59-20
SIP Inspection Overview 59-20
SIP Instant Messaging 59-21
Select SIP Map 59-22
SIP Class Map 59-23
Add/Edit SIP Traffic Class Map 59-23
Add/Edit SIP Match Criterion 59-24
SIP Inspect Map 59-26
Add/Edit SIP Policy Map (Security Level) 59-27
Add/Edit SIP Policy Map (Details) 59-28
Add/Edit SIP Inspect 59-29
Skinny (SCCP) Inspection 59-31
SCCP Inspection Overview 59-32
Supporting Cisco IP Phones 59-32
Restrictions and Limitations 59-33
Select SCCP (Skinny) Map 59-33
SCCP (Skinny) Inspect Map 59-34
Message ID Filtering 59-35
Add/Edit SCCP (Skinny) Policy Map (Security Level) 59-35
Add/Edit SCCP (Skinny) Policy Map (Details) 59-36
Add/Edit Message ID Filter 59-37

CHAPTER 60 **Configuring Inspection of Database and Directory Protocols** 60-1
ILS Inspection 60-1
SQL*Net Inspection 60-2
Sun RPC Inspection 60-3
Sun RPC Inspection Overview 60-3
SUNRPC Server 60-4

Add/Edit SUNRPC Service 60-4

CHAPTER 61 **Configuring Inspection for Management Application Protocols** 61-1

DCERPC Inspection 61-1
DCERPC Overview 61-1
Select DCERPC Map 61-2
DCERPC Inspect Map 61-2
Add/Edit DCERPC Policy Map 61-3
GTP Inspection 61-4
GTP Inspection Overview 61-5
Select GTP Map 61-5
GTP Inspect Map 61-6
IMSI Prefix Filtering 61-7
Add/Edit GTP Policy Map (Security Level) 61-7
Add/Edit GTP Policy Map (Details) 61-8
Add/Edit GTP Map 61-9
RADIUS Accounting Inspection 61-10
RADIUS Accounting Inspection Overview 61-11
Select RADIUS Accounting Map 61-11
Add RADIUS Accounting Policy Map 61-11
RADIUS Inspect Map 61-12
RADIUS Inspect Map Host 61-12
RADIUS Inspect Map Other 61-13
RSH Inspection 61-13
SNMP Inspection 61-13
SNMP Inspection Overview 61-14
Select SNMP Map 61-14

XDMCP Inspection 61-15

PART 11 **Configuring Unified Communications**

CHAPTER 63 **Information About Cisco Unified Communications Proxy Features** 63-1

Information About the Adaptive Security Appliance in Cisco Unified Communications 63-1
TLS Proxy Applications in Cisco Unified Communications 63-3
Licensing for Cisco Unified Communications Proxy Features 63-4

CHAPTER 64 **Using the Cisco Unified Communication Wizard** 64-1

Information about the Cisco Unified Communication Wizard 64-1

Licensing Requirements for the Unified Communication Wizard 64-3

Guidelines and Limitations 64-4

Configuring the Phone Proxy by using the Unified Communication Wizard 64-4

Configuring the Private Network for the Phone Proxy 64-5

Configuring Servers for the Phone Proxy 64-6

Enabling Certificate Authority Proxy Function (CAPF) for IP Phones 64-8

Configuring the Public IP Phone Network 64-9

Configuring the Media Termination Address for Unified Communication Proxies 64-10

Configuring the Mobility Advantage by using the Unified Communication Wizard 64-11

Configuring the Topology for the Cisco Mobility Advantage Proxy 64-12

Configuring the Server-Side Certificates for the Cisco Mobility Advantage Proxy 64-12

Configuring the Client-Side Certificates for the Cisco Mobility Advantage Proxy 64-13

Configuring the Presence Federation Proxy by using the Unified Communication Wizard 64-14

Configuring the Topology for the Cisco Presence Federation Proxy 64-14

Configuring the Local-Side Certificates for the Cisco Presence Federation Proxy 64-15

Configuring the Remote-Side Certificates for the Cisco Presence Federation Proxy 64-15

Configuring the UC-IME by using the Unified Communication Wizard 64-16

Configuring the Topology for the Cisco Intercompany Media Engine Proxy 64-17

Configuring the Private Network Settings for the Cisco Intercompany Media Engine Proxy 64-18

Adding a Cisco Unified Communications Manager Server for the UC-IME Proxy 64-20

Configuring the Public Network Settings for the Cisco Intercompany Media Engine Proxy 64-20

Configuring the Local-Side Certificates for the Cisco Intercompany Media Engine Proxy 64-21

Configuring the Remote-Side Certificates for the Cisco Intercompany Media Engine Proxy 64-22

Working with Certificates in the Unified Communication Wizard 64-23

Exporting an Identity Certificate 64-23

Installing a Certificate 64-23

Generating a Certificate Signing Request (CSR) for a Unified Communications Proxy 64-24

Saving the Identity Certificate Request 64-25

Installing the ASA Identity Certificate on the Mobility Advantage Server 64-26

Installing the ASA Identity Certificate on the Presence Federation and Cisco Intercompany Media Engine Servers 64-26

CHAPTER 65 **Configuring the Cisco Phone Proxy** 65-1

Information About the Cisco Phone Proxy 65-1

Phone Proxy Functionality 65-1

Supported Cisco UCM and IP Phones for the Phone Proxy 65-3

Licensing Requirements for the Phone Proxy 65-4
Prerequisites for the Phone Proxy 65-6
Media Termination Instance Prerequisites 65-6
Certificates from the Cisco UCM 65-7
DNS Lookup Prerequisites 65-7
Cisco Unified Communications Manager Prerequisites 65-7
Access List Rules 65-7
NAT and PAT Prerequisites 65-8
Prerequisites for IP Phones on Multiple Interfaces 65-8
7960 and 7940 IP Phones Support 65-9
Cisco IP Communicator Prerequisites 65-10
Prerequisites for Rate Limiting TFTP Requests 65-10
End-User Phone Provisioning 65-11
Phone Proxy Guidelines and Limitations 65-12
Configuring the Phone Proxy 65-14
Task Flow for Configuring the Phone Proxy 65-14
Creating the CTL File 65-14
Adding or Editing a Record Entry in a CTL File 65-16
Creating the Media Termination Instance 65-17
Creating the Phone Proxy Instance 65-18
Adding or Editing the TFTP Server for a Phone Proxy 65-20
Configuring Linksys Routers with UDP Port Forwarding for the Phone Proxy 65-21
Feature History for the Phone Proxy 65-22

CHAPTER 66 **Configuring the TLS Proxy for Encrypted Voice Inspection** 66-1
Information about the TLS Proxy for Encrypted Voice Inspection 66-1
Decryption and Inspection of Unified Communications Encrypted Signaling 66-2
Supported Cisco UCM and IP Phones for the TLS Proxy 66-3
Licensing for the TLS Proxy 66-4
Prerequisites for the TLS Proxy for Encrypted Voice Inspection 66-6
Configuring the TLS Proxy for Encrypted Voice Inspection 66-6
CTL Provider 66-6
Add/Edit CTL Provider 66-7
Configure TLS Proxy Pane 66-8
Adding a TLS Proxy Instance 66-9
Add TLS Proxy Instance Wizard – Server Configuration 66-9
Add TLS Proxy Instance Wizard – Client Configuration 66-10
Add TLS Proxy Instance Wizard – Other Steps 66-12
Edit TLS Proxy Instance – Server Configuration 66-13

Edit TLS Proxy Instance – Client Configuration 66-14
TLS Proxy 66-15
Feature History for the TLS Proxy for Encrypted Voice Inspection 66-17

CHAPTER 67 **Configuring Cisco Mobility Advantage** 67-1
Information about the Cisco Mobility Advantage Proxy Feature 67-1
Cisco Mobility Advantage Proxy Functionality 67-1
Mobility Advantage Proxy Deployment Scenarios 67-2
Trust Relationships for Cisco UMA Deployments 67-4
Licensing for the Cisco Mobility Advantage Proxy Feature 67-6
Configuring Cisco Mobility Advantage 67-6
Task Flow for Configuring Cisco Mobility Advantage 67-7
Feature History for Cisco Mobility Advantage 67-7

CHAPTER 68 **Configuring Cisco Unified Presence** 68-1
Information About Cisco Unified Presence 68-1
Architecture for Cisco Unified Presence for SIP Federation Deployments 68-1
Trust Relationship in the Presence Federation 68-4
Security Certificate Exchange Between Cisco UP and the Security Appliance 68-5
XMPP Federation Deployments 68-5
Configuration Requirements for XMPP Federation 68-6
Licensing for Cisco Unified Presence 68-7
Configuring Cisco Unified Presence Proxy for SIP Federation 68-8
Task Flow for Configuring Cisco Unified Presence Federation Proxy for SIP Federation 68-9
Feature History for Cisco Unified Presence 68-9

CHAPTER 69 **Configuring Cisco Intercompany Media Engine Proxy** 69-1
Information About Cisco Intercompany Media Engine Proxy 69-1
Features of Cisco Intercompany Media Engine Proxy 69-1
How the UC-IME Works with the PSTN and the Internet 69-2
Tickets and Passwords 69-3
Call Fallback to the PSTN 69-5
Architecture and Deployment Scenarios for Cisco Intercompany Media Engine 69-5
Licensing for Cisco Intercompany Media Engine 69-8
Guidelines and Limitations 69-9
Configuring Cisco Intercompany Media Engine Proxy 69-11
Task Flow for Configuring Cisco Intercompany Media Engine 69-11
Configuring NAT for Cisco Intercompany Media Engine Proxy 69-12

Configuring PAT for the Cisco UCM Server 69-14
Creating Access Lists for Cisco Intercompany Media Engine Proxy 69-16
Creating the Media Termination Instance 69-17
Creating the Cisco Intercompany Media Engine Proxy 69-18
Creating Trustpoints and Generating Certificates 69-21
Creating the TLS Proxy 69-24
Enabling SIP Inspection for the Cisco Intercompany Media Engine Proxy 69-25
(Optional) Configuring TLS within the Local Enterprise 69-27
(Optional) Configuring Off Path Signaling 69-30
Configuring the Cisco UC-IMC Proxy by using the UC-IME Proxy Pane 69-31
Configuring the Cisco UC-IMC Proxy by using the Unified Communications Wizard 69-33
Feature History for Cisco Intercompany Media Engine Proxy 69-37

PART 12 **Configuring Connection Settings and QoS**

CHAPTER 71 **Configuring Connection Settings** 71-1
Information About Connection Settings 71-1
TCP Intercept and Limiting Embryonic Connections 71-2
Disabling TCP Intercept for Management Packets for Clientless SSL Compatibility 71-2
Dead Connection Detection (DCD) 71-2
TCP Sequence Randomization 71-3
TCP Normalization 71-3
TCP State Bypass 71-3
Licensing Requirements for Connection Settings 71-4
Guidelines and Limitations 71-5
TCP State Bypass Guidelines and Limitations 71-5
Default Settings 71-5
Configuring Connection Settings 71-5
Task Flow For Configuring Configuration Settings (Except Global Timeouts) 71-6
Customizing the TCP Normalizer with a TCP Map 71-6
Configuring Connection Settings 71-8
Configuring Global Timeouts 71-9
Feature History for Connection Settings 71-11

CHAPTER 72 **Configuring QoS** 72-1
Information About QoS 72-1
Supported QoS Features 72-2
What is a Token Bucket? 72-2

Information About Policing 72-3
Information About Priority Queuing 72-3
Information About Traffic Shaping 72-4
How QoS Features Interact 72-4
DSCP and DiffServ Preservation 72-5
Licensing Requirements for QoS 72-5
Guidelines and Limitations 72-5
Configuring QoS 72-6
Determining the Queue and TX Ring Limits for a Standard Priority Queue 72-7
Configuring the Standard Priority Queue for an Interface 72-8
Configuring a Service Rule for Standard Priority Queuing and Policing 72-9
Configuring a Service Rule for Traffic Shaping and Hierarchical Priority Queuing 72-10
Monitoring QoS 72-11
Viewing QoS Police Statistics 72-12
Viewing QoS Standard Priority Statistics 72-12
Viewing QoS Shaping Statistics 72-12
Viewing QoS Standard Priority Queue Statistics 72-13
Feature History for QoS 72-14

CHAPTER 73 **Troubleshooting Connections and Resources** 73-1
Testing Your Configuration 73-1
Pinging ASA Interfaces 73-1
Verifying ASA Configuration and Operation, and Testing Interfaces Using Ping 73-3
Determining Packet Routing with Traceroute 73-6
Tracing Packets with Packet Tracer 73-7
Monitoring Performance 73-8
Monitoring System Resources 73-9
Blocks 73-9
CPU 73-10
Memory 73-10
Monitoring Connections 73-11
Monitoring Per-Process CPU Usage 73-12

PART 13 **Configuring Advanced Network Protection**

CHAPTER 75 **Configuring the ASA for Cisco Cloud Web Security** 75-1
Information About Cisco Cloud Web Security 75-2
Redirection of Web Traffic to Cloud Web Security 75-2

User Authentication and Cloud Web Security 75-2
Authentication Keys 75-3
ScanCenter Policy 75-4
Cloud Web Security Actions 75-5
Bypassing Scanning with Whitelists 75-5
IPv4 and IPv6 Support 75-6
Failover from Primary to Backup Proxy Server 75-6
Licensing Requirements for Cisco Cloud Web Security 75-7
Prerequisites for Cloud Web Security 75-7
Guidelines and Limitations 75-7
Default Settings 75-8
Configuring Cisco Cloud Web Security 75-8
Configuring Communication with the Cloud Web Security Proxy Server 75-8
(Multiple Context Mode) Allowing Cloud Web Security Per Security Context 75-9
Configuring a Service Policy to Send Traffic to Cloud Web Security 75-10
(Optional) Configuring Whitelisted Traffic 75-23
(Optional) Configuring the User Identity Monitor 75-25
Configuring the Cloud Web Security Policy 75-26
Monitoring Cloud Web Security 75-26
Related Documents 75-27
Feature History for Cisco Cloud Web Security 75-27

CHAPTER 76 **Configuring the Botnet Traffic Filter** 76-1
Information About the Botnet Traffic Filter 76-1
Botnet Traffic Filter Address Types 76-2
Botnet Traffic Filter Actions for Known Addresses 76-2
Botnet Traffic Filter Databases 76-2
How the Botnet Traffic Filter Works 76-5
Licensing Requirements for the Botnet Traffic Filter 76-6
Guidelines and Limitations 76-6
Default Settings 76-6
Configuring the Botnet Traffic Filter 76-6
Task Flow for Configuring the Botnet Traffic Filter 76-7
Configuring the Dynamic Database 76-7
Adding Entries to the Static Database 76-9
Enabling DNS Snooping 76-9
Enabling Traffic Classification and Actions for the Botnet Traffic Filter 76-10
Blocking Botnet Traffic Manually 76-12

Searching the Dynamic Database 76-13
Monitoring the Botnet Traffic Filter 76-14
Botnet Traffic Filter Syslog Messaging 76-14
Botnet Traffic Filter Monitor Panes 76-15
Where to Go Next 76-16
Feature History for the Botnet Traffic Filter 76-16

CHAPTER 77 **Configuring Threat Detection** 77-1
Information About Threat Detection 77-1
Licensing Requirements for Threat Detection 77-1
Configuring Basic Threat Detection Statistics 77-2
Information About Basic Threat Detection Statistics 77-2
Guidelines and Limitations 77-3
Default Settings 77-3
Configuring Basic Threat Detection Statistics 77-4
Monitoring Basic Threat Detection Statistics 77-4
Feature History for Basic Threat Detection Statistics 77-5
Configuring Advanced Threat Detection Statistics 77-5
Information About Advanced Threat Detection Statistics 77-5
Guidelines and Limitations 77-5
Default Settings 77-6
Configuring Advanced Threat Detection Statistics 77-6
Monitoring Advanced Threat Detection Statistics 77-7
Feature History for Advanced Threat Detection Statistics 77-8
Configuring Scanning Threat Detection 77-8
Information About Scanning Threat Detection 77-9
Guidelines and Limitations 77-9
Default Settings 77-10
Configuring Scanning Threat Detection 77-10
Feature History for Scanning Threat Detection 77-11

CHAPTER 78 **Using Protection Tools** 78-1
Preventing IP Spoofing 78-1
Configuring the Fragment Size 78-2
Show Fragment 78-2
Configuring TCP Options 78-3
TCP Reset Settings 78-4
Configuring IP Audit for Basic IPS Support 78-5

IP Audit Policy 78-5
Add/Edit IP Audit Policy Configuration 78-5
IP Audit Signatures 78-6
IP Audit Signature List 78-6

CHAPTER 79 **Configuring Filtering Services** 79-1
Information About Web Traffic Filtering 79-1
Filtering URLs and FTP Requests with an External Server 79-2
Information About URL Filtering 79-2
Licensing Requirements for URL Filtering 79-3
Guidelines and Limitations for URL Filtering 79-3
Identifying the Filtering Server 79-3
Configuring Additional URL Filtering Settings 79-4
Configuring Filtering Rules 79-6
Filtering the Rule Table 79-11
Defining Queries 79-12
Feature History for URL Filtering 79-12

PART 14 **Configuring Modules**

CHAPTER 81 **Configuring the ASA IPS Module** 81-1
Information About the ASA IPS module 81-1
How the ASA IPS module Works with the ASA 81-2
Operating Modes 81-3
Using Virtual Sensors (ASA 5510 and Higher) 81-3
Information About Management Access 81-4
Licensing Requirements for the ASA IPS module 81-5
Guidelines and Limitations 81-5
Default Settings 81-6
Configuring the ASA IPS module 81-7
Task Flow for the ASA IPS Module 81-7
Connecting the ASA IPS Management Interface 81-8
Sessioning to the Module from the ASA (May Be Required) 81-11
(ASA 5512-X through ASA 5555-X) Booting the Software Module 81-12
Configuring Basic IPS Module Network Settings 81-12
Configuring the Security Policy on the ASA IPS Module 81-15
Assigning Virtual Sensors to a Security Context (ASA 5510 and Higher) 81-17
Diverting Traffic to the ASA IPS module 81-18

Managing the ASA IPS module 81-19
Monitoring the ASA IPS module 81-24
Feature History for the ASA IPS module 81-24

CHAPTER 82 **Configuring the ASA CX Module** 82-1
Information About the ASA CX Module 82-1
How the ASA CX Module Works with the ASA 82-2
Information About ASA CX Management 82-2
Information About Authentication Proxy 82-3
Information About VPN and the ASA CX Module 82-4
Compatibility with ASA Features 82-4
Licensing Requirements for the ASA CX Module 82-4
Guidelines and Limitations 82-4
Default Settings 82-5
Configuring the ASA CX Module 82-5
Task Flow for the ASA CX Module 82-6
Connecting the ASA CX Management Interface 82-7
Configuring the ASA CX Management IP Address 82-8
Configuring Basic ASA CX Settings at the ASA CX CLI 82-9
Configuring the Security Policy on the ASA CX Module Using PRSM 82-11
(Optional) Configuring the Authentication Proxy Port 82-12
Redirecting Traffic to the ASA CX Module 82-12
Managing the ASA CX Module 82-14
Resetting the Password 82-14
Reloading or Resetting the Module 82-15
Shutting Down the Module 82-15
Monitoring the ASA CX Module 82-15
Showing Module Status 82-16
Showing Module Statistics 82-16
Monitoring Module Connections 82-17
Capturing Module Traffic 82-20
Troubleshooting the ASA CX Module 82-20
Problems with the Authentication Proxy 82-20
Feature History for the ASA CX Module 82-21

CHAPTER 83 **Configuring the ASA CSC Module** 83-1
Information About the CSC SSM 83-1
Determining What Traffic to Scan 83-3

Licensing Requirements for the CSC SSM 83-5
Prerequisites for the CSC SSM 83-5
Guidelines and Limitations 83-6
Default Settings 83-6
Configuring the CSC SSM 83-7
Before Configuring the CSC SSM 83-7
Connecting to the CSC SSM 83-8
Determining Service Policy Rule Actions for CSC Scanning 83-9
CSC SSM Setup Wizard 83-10
Activation/License 83-11
IP Configuration 83-11
Host/Notification Settings 83-12
Management Access Host/Networks 83-13
Password 83-13
Restoring the Default Password 83-14
Wizard Setup 83-15
Using the CSC SSM GUI 83-20
Web 83-20
Mail 83-21
SMTP Tab 83-21
POP3 Tab 83-22
File Transfer 83-22
Updates 83-23
Monitoring the CSC SSM 83-24
Threats 83-24
Live Security Events 83-25
Live Security Events Log 83-25
Software Updates 83-26
Resource Graphs 83-27
Troubleshooting the CSC Module 83-27
Additional References 83-31
Feature History for the CSC SSM 83-31

PART 15 **Configuring VPN**

CHAPTER 85 **VPN Wizards** 85-1
VPN Overview 85-1
IPsec IKEv1 Remote Access Wizard 85-2

Remote Access Client 85-2
VPN Client Authentication Method and Tunnel Group Name 85-3
Client Authentication 85-3
User Accounts 85-4
Address Pool 85-4
Attributes Pushed to Client (Optional) 85-4
IKE Policy 85-5
IPsec Settings (Optional) 85-6
Summary 85-6
IPsec Site-to-Site VPN Wizard 85-7
Peer Device Identification 85-7
IKE Version 85-7
Traffic to Protects 85-7
Authentication Methods 85-7
Encryption Algorithm 85-8
Miscellaneous 85-8
Summary 85-9
AnyConnect VPN Wizard 85-9
Connection Profile Identification 85-9
VPN Protocols 85-9
Client Images 85-10
Authentication Methods 85-10
Client Address Assignment 85-11
Network Name Resolution Servers 85-11
NAT Exempt 85-11
AnyConnect Client Deployment 85-11
Summary 85-12
Clientless SSL VPN Wizard 85-12
SSL VPN Interface 85-12
User Authentication 85-12
Group Policy 85-13
Bookmark List 85-13
Summary 85-13

CHAPTER 86 **Configuring IKE, Load Balancing, and NAC 86-1**
Setting IKE Parameters 86-1
Creating IKE Policies 86-5
Add/Edit IKEv1 Policy 86-6
Add/Edit IKEv2 Policy (Proposal) 86-7

Assignment Policy 86-9
Configuring IPsec 86-10
Adding Crypto Maps 86-10
Pre-Fragmentation 86-17
IPsec Transform Sets 86-18
Configuring Load Balancing 86-20
Creating Virtual Clusters 86-21
Geographical Load Balancing 86-22
Mixed Cluster Scenarios 86-22
Comparing Load Balancing to Failover 86-23
Load Balancing Licensing Requirements 86-24
Eligible Clients 86-24
Load Balancing Prerequisites 86-24
Configuring VPN Cluster Load Balancing with the High Availability and Scalability Wizard 86-25
Configuring Load Balancing (Without the Wizard) 86-26
Enable Clientless SSL VPN Load Balancing Using FQDNs 86-28
Setting Global NAC Parameters 86-29
Configuring Network Admission Control Policies 86-30

CHAPTER 87 **General VPN Setup** 87-1
Client Software 87-1
Edit Client Update Entry 87-3
Default Tunnel Gateway 87-4
Group Policies 87-4
Configuring External Group Policies 87-5
Configuring Network (Client) Access Internal Group Policies 87-7
Configuring Clientless SSL VPN Internal Group Policies 87-23
Configuring Site-to-Site Internal Group Policies 87-28
Defining Time Ranges 87-29
Access Control List Manager 87-31
Standard Access Control List 87-31
Extended Access Control List 87-31
Configuring AnyConnect VPN Client Connections 87-42
Using AnyConnect Client Profiles 87-45
Exempting AnyConnect Traffic from Network Address Translation 87-46
Configuring AnyConnect VPN Connections 87-52
Specifying a Device Certificate for AnyConnect Access 87-53
Configuring Port Settings 87-54

Setting the Basic Attributes for an AnyConnect VPN Connection 87-54
Setting Advanced Attributes for a Connection Profile 87-56
Setting General Attributes for an AnyConnect SSL VPN Connection 87-56
Setting Client Addressing Attributes for an AnyConnect SSL VPN Connection 87-58
Configuring Authentication Attributes for a Connection Profile 87-58
Configuring Secondary Authentication Attributes for an SSL VPN Connection Profile 87-59
Configuring Authorization Attributes for an SSL VPN Connection Profile 87-61
Adding or Editing Content to a Script for Certificate Pre-Fill-Username 87-62
Configuring AnyConnect Secure Mobility 87-64
Add or Edit MUS Access Control 87-66
Configuring Clientless SSL VPN Connections 87-66
Add or Edit Clientless SSL VPN Connections 87-67
Add or Edit Clientless SSL VPN Connections > Basic 87-67
Add or Edit Clientless SSL VPN Connections > Advanced 87-68
Add or Edit Clientless SSL VPN Connections > Advanced > General 87-68
Add or Edit Clientless or SSL VPN Client Connection Profile or IPsec Connection Profiles> Advanced > Authentication 87-69
Assign Authentication Server Group to Interface 87-69
Add or Edit SSL VPN Connections > Advanced > Authorization 87-69
Assign Authorization Server Group to Interface 87-70
Add or Edit SSL VPN Connections > Advanced > SSL VPN 87-70
Add or Edit Clientless SSL VPN Connections > Advanced > Clientless SSL VPN 87-71
Add or Edit Clientless SSL VPN Connections > Advanced > NetBIOS Servers 87-72
Configure DNS Server Groups 87-73
Add or Edit Clientless SSL VPN Connections > Advanced > Clientless SSL VPN 87-73
IPsec Remote Access Connection Profiles 87-73
Add or Edit an IPsec Remote Access Connection Profile 87-74
Add or Edit IPsec Remote Access Connection Profile Basic 87-74
Mapping Certificates to IPsec or SSL VPN Connection Profiles 87-75
Site-to-Site Connection Profiles 87-79
Add/Edit Site-to-Site Connection 87-80
Adding or Editing a Site-to-Site Tunnel Group 87-81
Crypto Map Entry 87-83
Crypto Map Entry for Static Peer Address 87-84
Managing CA Certificates 87-85
Install Certificate 87-85
Configure Options for CA Certificate 87-85
Add/Edit Remote Access Connections > Advanced > General 87-86
Configuring Client Addressing 87-87

Configuring Internal Group Policy IPsec Client Attributes 87-100
Configuring Client Addressing for SSL VPN Connections 87-101
Assign Address Pools to Interface 87-101
Select Address Pools 87-102
Add or Edit an IP Address Pool 87-102
Authenticating SSL VPN Connections 87-102
System Options 87-102
Zone Labs Integrity Server 87-103
Easy VPN Remote 87-105
Advanced Easy VPN Properties 87-107
AnyConnect Essentials 87-108
DTLS Settings 87-109
SSL VPN Client Settings 87-109
Add/Replace SSL VPN Client Image 87-111
Upload Image 87-111
Add/Edit SSL VPN Client Profiles 87-111
Upload Package 87-112
Bypass Interface Access List 87-112
Configuring AnyConnect Host Scan 87-113
Host Scan Dependencies and System Requirements 87-113
Host Scan Packaging 87-114
Installing and Enabling Host Scan on the ASA 87-115
Other Important Documentation Addressing Host Scan 87-119
Configuring Maximum VPN Sessions 87-119
Configuring the Pool of Cryptographic Cores 87-119

CHAPTER 88 **Configuring IP Addresses for VPNs** 88-1

Configuring an IP Address Assignment Policy 88-1
Configuring IPv4 and IPv6 Address Assignments using ASDM 88-2
Viewing Address Assignment Methods 88-3
Configuring Local IP Address Pools 88-3
Configuring Local IPv4 Address Pools Using ASDM 88-3
Configuring Local IPv6 Address Pools Using ASDM 88-4
Configuring AAA Addressing 88-5
Configuring DHCP Addressing 88-6
Configuring DHCP Addressing Using ASDM 88-6

CHAPTER 89 **Configuring Dynamic Access Policies** 89-1

Information About Dynamic Access Policies 89-1
DAP and Endpoint Security 89-2
DAP Support for Remote Access Connection Types 89-2
Remote Access Connection Sequence with DAPs 89-2
Licensing Requirements for Dynamic Access Policies 89-3
Advanced Endpoint Assessment license 89-3
SSL VPN license (client) 89-3
AnyConnect Mobile License 89-3
Dynamic Access Policies Interface 89-4
Configuring Dynamic Access Policies 89-6
Testing Dynamic Access Policies 89-8
DAP and Authentication, Authorization, and Accounting Services 89-9
Configuring AAA Attributes in a DAP 89-9
Retrieving Active Directory Groups 89-11
Configuring Endpoint Attributes Used in DAPs 89-13
Adding an Anti-Spyware or Anti-Virus Endpoint Attribute to a DAP 89-14
Adding an Application Attribute to a DAP 89-15
Adding Mobile Posture Attributes to a DAP 89-16
Adding a File Endpoint Attribute to a DAP 89-17
Adding a Device Endpoint Attribute to a DAP 89-18
Adding a NAC Endpoint Attribute to a DAP 89-19
Adding an Operating System Endpoint Attribute to a DAP 89-20
Adding a Personal Firewall Endpoint Attribute to a DAP 89-20
Adding a Policy Endpoint Attribute to a DAP 89-21
Adding a Process Endpoint Attribute to a DAP 89-22
Adding a Registry Endpoint Attribute to a DAP 89-23
DAP and AntiVirus, AntiSpyware, and Personal Firewall Programs 89-24
Endpoint Attribute Definitions 89-24
Configuring DAP Access and Authorization Policy Attributes 89-27
Performing a DAP Trace 89-31
Guide to Creating DAP Logical Expressions using LUA 89-31
Syntax for Creating Lua EVAL Expressions 89-32
The DAP CheckAndMsg Function 89-33
Additional Lua Functions 89-35
CheckAndMsg with Custom Function Example 89-38
Further Information on Lua 89-38
Operator for Endpoint Category 89-38

DAP Examples 89-38

CHAPTER 90 **Clientless SSL VPN End User Set-up** 90-1

Requiring Usernames and Passwords 90-1

Communicating Security Tips 90-2

Configuring Remote Systems to Use Clientless SSL VPN Features 90-2

Capturing Clientless SSL VPN Data 90-7

Creating a Capture File 90-7

Using a Browser to Display Capture Data 90-8

CHAPTER 91 **Configuring Clientless SSL VPN** 91-1

Information About Clientless SSL VPN 91-2

Licensing Requirements 91-2

Prerequisites for Clientless SSL VPN 91-5

Guidelines and Limitations 91-5

Observing Clientless SSL VPN Security Precautions 91-5

Configuring Clientless SSL VPN Access 91-6

Clientless SSL VPN Server Certificate Verification 91-7

Configuring ACLs 91-11

Configuring the Setup for Cisco Secure Desktop 91-13

GLOSSARY

INDEX

About This Guide

This preface introduces *Cisco ASA Series ASDM Configuration Guide* and includes the following sections:

- Document Objectives, page lxi
- Audience, page lxi
- Related Documentation, page lxii
- Conventions, page lxii
- Obtaining Documentation and Submitting a Service Request, page lxiii

Document Objectives

The purpose of this guide is to help you configure the ASA using ASDM. This guide does not cover every feature, but describes only the most common configuration scenarios.

This guide applies to the Cisco ASA series. Throughout this guide, the term "ASA" applies generically to supported models, unless specified otherwise.

Note ASDM supports many ASA versions. The ASDM documentation and online help includes all of the latest features supported by the ASA. If you are running an older version of ASA software, the documentation might include features that are not supported in your version. Similarly, if a feature was added into a maintenance release for an older major or minor version, then the ASDM documentation includes the new feature even though that feature might not be available in all later ASA releases. Please refer to the feature history table for each chapter to determine when features were added. For the minimum supported version of ASDM for each ASA version, see *Cisco ASA Series Compatibility*.

Audience

This guide is for network managers who perform any of the following tasks:

- Manage network security
- Install and configure firewalls/ASAs
- Configure VPNs
- Configure intrusion detection software

Related Documentation

For more information, see *Navigating the Cisco ASA Series Documentation* at http://www.cisco.com/en/US/docs/security/asa/roadmap/asaroadmap.html.

Conventions

This document uses the following conventions:

Convention	Indication
bold font	Commands and keywords and user-entered text appear in **bold** font.
italic font	Document titles, new or emphasized terms, and arguments for which you supply values are in *italic* font.
[ ]	Elements in square brackets are optional.
{x | y | z }	Required alternative keywords are grouped in braces and separated by vertical bars.
[x | y | z]	Optional alternative keywords are grouped in brackets and separated by vertical bars.
string	A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks.
`courier` font	Terminal sessions and information the system displays appear in `courier` font.
`courier bold` font	Commands and keywords and user-entered text appear in **`bold courier`** font.
`courier italic` font	Arguments for which you supply values are in *`courier italic`* font.
< >	Nonprinting characters such as passwords are in angle brackets.
[ ]	Default responses to system prompts are in square brackets.
!, #	An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line.

Note Means *reader take note*.

Tip Means *the following information will help you solve a problem.*

Caution Means *reader be careful*. In this situation, you might perform an action that could result in equipment damage or loss of data.

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see *What's New in Cisco Product Documentation* at: http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html.

Subscribe to *What's New in Cisco Product Documentation*, which lists all new and revised Cisco technical documentation, as an RSS feed and deliver content directly to your desktop using a reader application. The RSS feeds are a free service.

PART 1

Getting Started with the ASA

Introduction to the Cisco ASA

The Cisco ASA provides advanced stateful firewall and VPN concentrator functionality in one device, and for some models, integrated services modules such as IPS. The ASA includes many advanced features, such as multiple security contexts (similar to virtualized firewalls), clustering (combining multiple firewalls into a single firewall), transparent (Layer 2) firewall or routed (Layer 3) firewall operation, advanced inspection engines, IPsec VPN, SSL VPN, and clientless SSL VPN support, and many more features.

Note ASDM supports many ASA versions. The ASDM documentation and online help includes all of the latest features supported by the ASA. If you are running an older version of ASA software, the documentation might include features that are not supported in your version. Similarly, if a feature was added into a maintenance release for an older major or minor version, then the ASDM documentation includes the new feature even though that feature might not be available in all later ASA releases. Please refer to the feature history table for each chapter to determine when features were added. For the minimum supported version of ASDM for each ASA version, see *Cisco ASA 5500 Series Hardware and Software Compatibility*.

This chapter includes the following sections:

- ASDM Client Operating System and Browser Requirements, page 1-1
- Hardware and Software Compatibility, page 1-4
- VPN Specifications, page 1-4
- New Features, page 1-5
- How the ASA Services Module Works with the Switch, page 1-19
- Firewall Functional Overview, page 1-20
- VPN Functional Overview, page 1-25
- Security Context Overview, page 1-25
- ASA Clustering Overview, page 1-26

ASDM Client Operating System and Browser Requirements

Table 1-1 lists the supported and recommended client operating systems and Java for ASDM.

Table 1-1 Operating System and Browser Requirements

Operating System	Browser				Java SE Plug-in
	Internet Explorer	Firefox	Safari	Chrome	
Microsoft Windows (English and Japanese): • 7 • Vista • 2008 Server • XP	6.0 or later	1.5 or later	No support	18.0 or later	6.0 or later
Apple Macintosh OS X: • 10.8 • 10.7 • 10.6 • 10.5 • 10.4	No support	1.5 or later	2.0 or later	18.0 or later	6.0 or later
Red Hat Enterprise Linux 5 (GNOME or KDE): • Desktop • Desktop with Workstation	N/A	1.5 or later	N/A	18.0 or later	6.0 or later

See the following caveats:

- If you upgrade from a previous version to Java 7 update 5, you may not be able to open ASDM using the Java Web Start from an IPv6 address; you can either download the ASDM Launcher, or follow the instructions at: http://java.com/en/download/help/clearcache_upgrade.xml.
- ASDM requires you to make an SSL connection to the ASA in the following situations:
  - When you first connect your browser to the ASA and access the ASDM splash screen.
  - When you launch ASDM using the launcher or the Java web start application.

  If the ASA only has the base encryption license (DES), and therefore has weak encryption ciphers for the SSL connection, you may not be able to access the splash screen or launch ASDM. See the following issues:
  - When using Java 7 when launching ASDM, you must have the strong encryption license (3DES/AES) on the ASA. With only the base encryption license (DES), you cannot launch ASDM. Even if you can connect with a browser to the ASDM splash screen and download the launcher or web start application, you cannot then launch ASDM. You must uninstall Java 7, and install Java 6.
  - When using Java 6 for accessing the splash screen in a browser, by default, Internet Explorer on Windows Vista and later and Firefox on all operating systems do not support DES for SSL; therefore without the strong encryption license (3DES/AES), see the following workarounds:

If available, use an already downloaded ASDM launcher or Java web start application. The launcher works with Java 6 and weak encryption, even if the browsers do not.

For Windows Internet Explorer, you can enable DES as a workaround. See http://support.microsoft.com/kb/929708 for details.

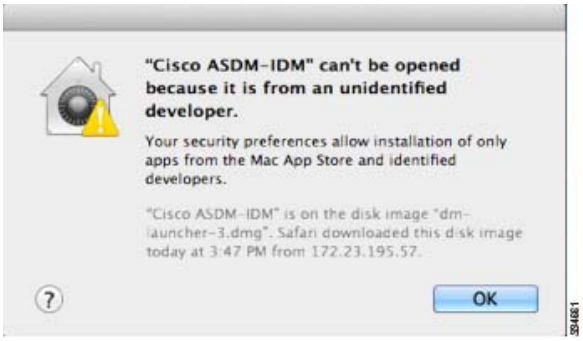
For Firefox on any operating system, you can enable the security.ssl3.dhe_dss_des_sha setting as a workaround. See http://kb.mozillazine.org/About:config to learn how to change hidden configuration preferences.

- When the ASA uses a self-signed certificate or an untrusted certificate, Firefox 4 and later and Safari are unable to add security exceptions when browsing using HTTPS over IPv6. See: https://bugzilla.mozilla.org/show_bug.cgi?id=633001. This caveat affects all SSL connections originating from Firefox or Safari to the ASA (including ASDM connections). To avoid this caveat, configure a proper certificate for the ASA that is issued by a trusted certificate authority.
- If you change the SSL encryption on the ASA to exclude both RC4-MD5 and RC4-SHA1 algorithms (these algorithms are enabled by default), then Chrome cannot launch ASDM due to the Chrome "SSL false start" feature. We suggest re-enabling one of these algorithms (see the Configuration > Device Management > Advanced > SSL Settings pane); or you can disable SSL false start in Chrome using the **--disable-ssl-false-start** flag according to http://www.chromium.org/developers/how-tos/run-chromium-with-flags.
- For Internet Explorer 9.0 for servers, the "Do not save encrypted pages to disk" option is enabled by default (See Tools > Internet Options > Advanced). This option causes the initial ASDM download to fail. Be sure to disable this option to allow ASDM to download.
- On MacOS, you may be prompted to install Java the first time you run ASDM; follow the prompts as necessary. ASDM will launch after the installation completes.
- On MacOS, you may see the following error message when opening the ASDM Launcher:

```
Cannot launch Cisco ASDM-IDM. No compatible version of Java 1.5+ is available.
```

In this case, Java 7 is the currently-preferred Java version; you need to set Java 6 as the preferred Java version: Open the **Java Preferences** application (under Applications > Utilities), select the preferred Java version, and drag it up to be the first line in the table.

- On MacOS 10.8 and later, you need to allow applications that are not signed with an Apple Developer ID. If you do not change your security preferences, you see an error screen.



a. To change the security setting, open System Preferences, and click **Security & Privacy**.

b. On the General tab, under Allow applications downloaded from, click **Anywhere**.

Hardware and Software Compatibility

For a complete list of supported hardware and software, see the *Cisco ASA Compatibility*:

http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html

VPN Specifications

See *Supported VPN Platforms, Cisco ASA 5500 Series*:

http://www.cisco.com/en/US/docs/security/asa/compatibility/asa-vpn-compatibility.html

New Features

- New Features in ASA 9.0(2)/ASDM 7.1(2), page 1-5
- New Features in ASA 8.4(5)/ASDM 7.0(2), page 1-5
- New Features in ASA 9.0(1)/ASDM 7.0(1), page 1-5

Note New, changed, and deprecated syslog messages are listed in syslog messages guide.

New Features in ASA 9.0(2)/ASDM 7.1(2)

Released: February 25, 2013

Table 1 lists the new features for ASA Version 9.0(2)/ASDM Version 7.1(2).

Note Features added in 8.4(4.x) and 8.4(5) are not included in 9.0(2) unless they were listed in the 9.0(1) feature table.

Table 1-2 New Features for ASA Version 9.0(2)/ASDM Version 7.1(2)

Feature	Description
Remote Access Features	
Clientless SSL VPN: Windows 8 Support	This release adds support for Windows 8 x86 (32-bit) and Windows 8 x64 (64-bit) operating systems. We support the following browsers on Windows 8: • Internet Explorer 10 (desktop only) • Firefox (all supported Windows 8 versions) • Chrome (all supported Windows 8 versions) See the following limitations: • Internet Explorer 10: – The Modern (AKA Metro) browser is not supported. – If you enable Enhanced Protected Mode, we recommend that you add the ASA to the trusted zone. – If you enable Enhanced Protected Mode, Smart Tunnel and Port Forwarder are not supported. • A Java Remote Desktop Protocol (RDP) plugin connection to a Windows 8 PC is not supported.
Cisco Secure Desktop: Windows 8 Support	CSD 3.6.6215 was updated to enable selection of Windows 8 in the Prelogin Policy operating system check. See the following limitations: • Secure Desktop (Vault) is not supported with Windows 8.
Dynamic Access Policies: Windows 8 Support	ASDM was updated to enable selection of Windows 8 in the DAP Operating System attribute.

New Features in ASA 8.4(5)/ASDM 7.0(2)

Released: October 31, 2012

Table 1 lists the new features for ASA Version 8.4(5)/ASDM Version 7.0(2).

Table 1-3 New Features for ASA Version 8.4(5)/ASDM Version 7.0(2)

Feature	Description
Firewall Features	
EtherType ACL support for IS-IS traffic (transparent firewall mode)	In transparent firewall mode, the ASA can now pass IS-IS traffic using an EtherType ACL. We modified the following command: **access-list ethertype** {**permit** | **deny**} **is-is**. We modified the following screen: Configuration > Device Management > Management Access > EtherType Rules. *This feature is not available in 8.5(1), 8.6(1), 8.7(1), 9.0(1), or 9.1(1).*
ARP cache additions for non-connected subnets	The ASA ARP cache only contains entries from directly-connected subnets by default. You can now enable the ARP cache to also include non-directly-connected subnets. We do not recommend enabling this feature unless you know the security risks. This feature could facilitate denial of service (DoS) attack against the ASA; a user on any interface could send out many ARP replies and overload the ASA ARP table with false entries. You may want to use this feature if you use: • Secondary subnets. • Proxy ARP on adjacent routes for traffic forwarding. We modified the following screen: Configuration > Device Management > Advanced > ARP > ARP Static Table. *This feature is not available in 8.5(1), 8.6(1), or 8.7(1).*
Increased maximum connection limits for service policy rules	The maximum number of connections for service policy rules was increased from 65535 to 2000000. We modified the following screen: Configuration > Firewall > Service Policy Rules > Connection Settings. *This feature is not available in 8.5(1), 8.6(1), or 8.7(1).*
Remote Access Features	
Improved Host Scan and ASA Interoperability	Host Scan and the ASA use an improved process to transfer posture attributes from the client to the ASA. This gives the ASA more time to establish a VPN connection with the client and apply a dynamic access policy. *This feature is not available in 8.5(1), 8.6(1), 8.7(1), 9.0(1), or 9.1(1).*
Monitoring Features	
NAT-MIB cnatAddrBindNumberOfEntries and cnatAddrBindSessionCount OIDs to allow polling for Xlate count.	Support was added for the NAT-MIB cnatAddrBindNumberOfEntries and cnatAddrBindSessionCount OIDs to support xlate_count and max_xlate_count for SNMP. This data is equivalent to the **show xlate count** command. *This feature is not available in 8.5(1), 8.6(1), 8.7(1), 9.0(1), or 9.1(1).*

Table 1-3 New Features for ASA Version 8.4(5)/ASDM Version 7.0(2) (continued)

Feature	Description
NSEL	Flow-update events have been introduced to provide periodic byte counters for flow traffic. You can change the time interval at which flow-update events are sent to the NetFlow collector. You can filter to which collectors flow-update records will be sent. We modified the following screens: Configuration > Device Management > Logging > NetFlow. Configuration > Firewall > Service Policy Rules > Add Service Policy Rule Wizard - Rule Actions > NetFlow > Add Flow Event *This feature is not available in 8.5(1), 8.6(1), 8.7(1), 9.0(1), or 9.1(1).*
Hardware Features	
ASA 5585-X DC power supply support	Support was added for the ASA 5585-X DC power supply. *This feature is not available in 8.5(1), 8.6(1), 8.7(1), 9.0(1), or 9.1(1).*

New Features in ASA 9.0(1)/ASDM 7.0(1)

Released: October 29, 2012

Table 1-2 lists the new features for ASA Version 9.0(1)/ASDM Version 7.0(1).

Note Features added in 8.4(4.x) and 8.4(5) are not included in 9.0(1) unless they are explicitly listed in this table.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1)

Feature	Description
Firewall Features	
Cisco TrustSec integration	Cisco TrustSec provides an access-control solution that builds upon an existing identity-aware infrastructure to ensure data confidentiality between network devices and integrate security access services on one platform. In the Cisco TrustSec solution, enforcement devices utilize a combination of user attributes and end-point attributes to make role-based and identity-based access control decisions. In this release, the ASA integrates with Cisco TrustSec to provide security group based policy enforcement. Access policies within the Cisco TrustSec domain are topology-independent, based on the roles of source and destination devices rather than on network IP addresses. The ASA can utilize the Cisco TrustSec solution for other types of security group based policies, such as application inspection; for example, you can configure a class map containing an access policy based on a security group. We introduced the following MIB: CISCO-TRUSTSEC-SXP-MIB. We introduced or modified the following screens: Configuration > Firewall > Identity by TrustSec Configuration > Firewall > Objects > Security Groups Object Groups Configuration > Firewall > Access Rules > Add Access Rules Monitoring > Properties > Identity by TrustSec > PAC Monitoring > Properties > Identity by TrustSec > Environment Data Monitoring > Properties > Identity by TrustSec > SXP Connections Monitoring > Properties > Identity by TrustSec > IP Mappings Monitoring > Properties > Connections Tools > Packet Tracer
Cisco Cloud Web Security (ScanSafe)	Cisco Cloud Web Security provides content scanning and other malware protection service for web traffic. It can also redirect and report about web traffic based on user identity. **Note** Clientless SSL VPN is not supported with Cloud Web Security; be sure to exempt any clientless SSL VPN traffic from the ASA service policy for Cloud Web Security. We introduced or modified the following screens: Configuration > Device Management > Cloud Web Security Configuration > Firewall > Objects > Class Maps > Cloud Web Security Configuration > Firewall > Objects > Class Maps > Cloud Web Security > Add/Edit Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security > Add/Edit Configuration > Firewall > Objects > Inspect Maps > Cloud Web Security > Add/Edit > Manage Cloud Web Security Class Maps Configuration > Firewall > Identity Options Configuration > Firewall > Service Policy Rules Monitoring > Properties > Cloud Web Security

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Extended ACL and object enhancement to filter ICMP traffic by ICMP code	ICMP traffic can now be permitted/denied based on ICMP code. We introduced or modified the following screens: Configuration > Firewall > Objects > Service Objects/Groups Configuration > Firewall > Access Rule
Unified communications support on the ASASM	The ASASM now supports all Unified Communications features.
Per-session PAT	The per-session PAT feature improves the scalability of PAT and, for ASA clustering, allows each member unit to own PAT connections; multi-session PAT connections have to be forwarded to and owned by the master unit. At the end of a per-session PAT session, the ASA sends a reset and immediately removes the xlate. This reset causes the end node to immediately release the connection, avoiding the TIME_WAIT state. Multi-session PAT, on the other hand, uses the PAT timeout, by default 30 seconds. For "hit-and-run" traffic, such as HTTP or HTTPS, the per-session feature can dramatically increase the connection rate supported by one address. Without the per-session feature, the maximum connection rate for one address for an IP protocol is approximately 2000 per second. With the per-session feature, the connection rate for one address for an IP protocol is 65535/*average-lifetime*. By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that can benefit from multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT by creating a per-session deny rule. We introduced the following screen: Configuration > Firewall > Advanced > Per-Session NAT Rules.
ARP cache additions for non-connected subnets	The ASA ARP cache only contains entries from directly-connected subnets by default. You can now enable the ARP cache to also include non-directly-connected subnets. We do not recommend enabling this feature unless you know the security risks. This feature could facilitate denial of service (DoS) attack against the ASA; a user on any interface could send out many ARP replies and overload the ASA ARP table with false entries. You may want to use this feature if you use: • Secondary subnets. • Proxy ARP on adjacent routes for traffic forwarding. We modified the following screen: Configuration > Device Management > Advanced > ARP > ARP Static Table. *Also available in 8.4(5).*

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
SunRPC change from dynamic ACL to pin-hole mechanism	Previously, Sun RPC inspection does not support outbound access lists because the inspection engine uses dynamic access lists instead of secondary connections. In this release, when you configure dynamic access lists on the ASA, they are supported on the ingress direction only and the ASA drops egress traffic destined to dynamic ports. Therefore, Sun RPC inspection implements a pinhole mechanism to support egress traffic. Sun RPC inspection uses this pinhole mechanism to support outbound dynamic access lists. *Also available in 8.4(4.1).*
Inspection reset action change	Previously, when the ASA dropped a packet due to an inspection engine rule, the ASA sent only one RST to the source device of the dropped packet. This behavior could cause resource issues. In this release, when you configure an inspection engine to use a reset action and a packet triggers a reset, the ASA sends a TCP reset under the following conditions: • The ASA sends a TCP reset to the inside host when the **service resetoutbound** command is enabled. (The **service resetoutbound** command is disabled by default.) • The ASA sends a TCP reset to the outside host when the **service resetinbound** command is enabled. (The **service resetinbound** command is disabled by default.) For more information, see the **service** command in the ASA command reference. This behavior ensures that a reset action will reset the connections on the ASA and on inside servers; therefore countering denial of service attacks. For outside hosts, the ASA does not send a reset by default and information is not revealed through a TCP reset. *Also available in 8.4(4.1).*
Increased maximum connection limits for service policy rules	The maximum number of connections for service policy rules was increased from 65535 to 2000000. We modified the following screen: Configuration > Firewall > Service Policy Rules > Connection Settings. *Also available in 8.4(5)*
High Availability and Scalability Features	

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
ASA Clustering for the ASA 5580 and 5585-X	ASA Clustering lets you group multiple ASAs together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. ASA clustering is supported for the ASA 5580 and the ASA 5585-X; all units in a cluster must be the same model with the same hardware specifications. See the configuration guide for a list of unsupported features when clustering is enabled. We introduced or modified the following screens: Home > Device Dashboard Home > Cluster Dashboard Home > Cluster Firewall Dashboard Configuration > Device Management > Advanced > Address Pools > MAC Address Pools Configuration > Device Management > High Availability and Scalability > ASA Cluster Configuration > Device Management > Logging > Syslog Setup > Advanced Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced Configuration > Device Setup > Interfaces > Add/Edit Interface > IPv6 Configuration > Device Setup > Interfaces > Add/Edit EtherChannel Interface > Advanced Configuration > Firewall > Advanced > Per-Session NAT Rules Monitoring > ASA Cluster Monitoring > Properties > System Resources Graphs > Cluster Control Link Tools > Preferences > General Tools > System Reload Tools > Upgrade Software from Local Computer Wizards > High Availability and Scalability Wizard Wizards > Packet Capture Wizard Wizards > Startup Wizard
OSPF, EIGRP, and Multicast for clustering	For OSPFv2 and OSPFv3, bulk synchronization, route synchronization, and spanned EtherChannels are supported in the clustering environment. For EIGRP, bulk synchronization, route synchronization, and spanned EtherChannels are supported in the clustering environment. Multicast routing supports clustering.
Packet capture for clustering	To support cluster-wide troubleshooting, you can enable capture of cluster-specific traffic on the master unit using the **cluster exec capture** command, which is then automatically enabled on all of the slave units in the cluster. The **cluster exec** keywords are the new keywords that you place in front of the **capture** command to enable cluster-wide capture. We modified the following screen: Wizards > Packet Capture Wizard.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Logging for clustering	Each unit in the cluster generates syslog messages independently. You can use the **logging device-id** command to generate syslog messages with identical or different device IDs to make messages appear to come from the same or different units in the cluster. We modified the following screen: Configuration > Logging > Syslog Setup > Advanced > Advanced Syslog Configuration.
Configure the connection replication rate during a bulk sync	You can now configure the rate at which the ASA replicates connections to the standby unit when using Stateful Failover. By default, connections are replicated to the standby unit during a 15 second period. However, when a bulk sync occurs (for example, when you first enable failover), 15 seconds may not be long enough to sync large numbers of connections due to a limit on the maximum connections per second. For example, the maximum connections on the ASA is 8 million; replicating 8 million connections in 15 seconds means creating 533 K connections per second. However, the maximum connections allowed per second is 300 K. You can now specify the rate of replication to be less than or equal to the maximum connections per second, and the sync period will be adjusted until all the connections are synchronized. *Also available in 8.4(4.1) and 8.5(1.7).*
IPv6 Features	
IPv6 Support on the ASA's outside interface for VPN Features.	This release of the ASA adds support for IPv6 VPN connections to its outside interface using SSL and IKEv2/IPsec protocols. This release of the ASA continues to support IPv6 VPN traffic on its inside interface using the SSL protocol as it has in the past. This release does not provide IKEv2/IPsec protocol on the inside interface.
Remote Access VPN support for IPv6: IPv6 Address Assignment Policy	You can configure the ASA to assign an IPv4 address, an IPv6 address, or both an IPv4 and an IPv6 address to an AnyConnect client by creating internal pools of addresses on the ASA or by assigning a dedicated address to a local user on the ASA. The endpoint must have the dual-stack protocol implemented in its operating system to be assigned both types of addresses. Assigning an IPv6 address to the client is supported for the SSL protocol. This feature is not supported for the IKEv2/IPsec protocol. We modified the following screens: Configuration > Remote Access VPN > Network (Client) Access > Address Assignment > Assignment Policy Configuration > Remote Access VPN > AAA/Local Users > Local Users > (Edit local user account) > VPN Policy

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Remote Access VPN support for IPv6: Assigning DNS Servers with IPv6 Addresses to group policies	DNS servers can be defined in a Network (Client) Access internal group policy on the ASA. You can specify up to four DNS server addresses including up to two IPv4 addresses and up to two IPv6 addresses. DNS servers with IPv6 addresses can be reached by VPN clients when they are configured to use the SSL protocol. This feature is not supported for clients configured to use the IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Network (Client) Access > Group Policies > (Edit group policy) > Servers.
Remote Access VPN support for IPv6: Split tunneling	Split tunneling enables you to route some network traffic through the VPN tunnel (encrypted) and to route other network traffic outside the VPN tunnel (unencrypted or "in the clear"). You can now perform split tunneling on IPv6 network traffic by defining an IPv6 policy which specifies a unified access control rule. IPv6 split tunneling is reported with the telemetric data sent by the Smart Call Home feature. If either IPv4 or IPv6 split tunneling is enabled, Smart Call Home reports split tunneling as "enabled." For telemetric data, the VPN session database displays the IPv6 data typically reported with session management. You can include or exclude IPv6 traffic from the VPN "tunnel" for VPN clients configured to use the SSL protocol. This feature is not supported for the IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Network (Client) Access > Group Policies > (Edit group policy) > Advanced > Split Tunneling.
Remote Access VPN support for IPv6: AnyConnect Client Firewall Rules	Access control rules for client firewalls support access list entries for both IPv4 and IPv6 addresses. ACLs containing IPv6 addresses can be applied to clients configured to use the SSL protocol. This feature is not supported for the IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Network (Client) Access > Group Policies > (Edit group policy) > Advanced > AnyConnect Client > Client Firewall.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Remote Access VPN support for IPv6: Client Protocol Bypass	The Client Protocol Bypass feature allows you to configure how the ASA manages IPv4 traffic when it is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic. When the AnyConnect client makes a VPN connection to the ASA, the ASA could assign it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the ASA assigns the AnyConnect connection only an IPv4 address or only an IPv6 address, you can now configure the Client Bypass Protocol to drop network traffic for which the ASA did not assign an IP address, or allow that traffic to bypass the ASA and be sent from the client unencrypted or "in the clear." For example, assume that the ASA assigns only an IPv4 address to an AnyConnect connection and the endpoint is dual stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear. This feature can be used by clients configured to use the SSL or IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Network (Client) Access > Group Policies > (Group Policy) Advanced > AnyConnect Client > Client Bypass Protocol.
Remote Access VPN support for IPv6: IPv6 Interface ID and prefix	You can now specify a dedicated IPv6 address for local VPN users. This feature benefits users configured to use the SSL protocol. This feature is not supported for the IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > AAA/Local Users > Local Users > (Edit User) > VPN Policy.
Remote Access VPN support for IPv6: Sending ASA FQDN to AnyConnect client	You can return the FQDN of the ASA to the AnyConnect client to facilitate load balancing and session roaming. This feature can be used by clients configured to use the SSL or IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Network (Client) Access > Group Policies > (Edit group policy) > Advanced > AnyConnect.
Remote Access VPN support for IPv6: ASA VPN Load Balancing	Clients with IPv6 addresses can make AnyConnect connections through the public-facing IPv6 address of the ASA cluster or through a GSS server. Likewise, clients with IPv6 addresses can make AnyConnect VPN connections through the public-facing IPv4 address of the ASA cluster or through a GSS server. Either type of connection can be load-balanced within the ASA cluster. For clients with IPv6 addresses to successfully connect to the ASAs public-facing IPv4 address, a device that can perform network address translation from IPv6 to IPv4 needs to be in the network. This feature can be used by clients configured to use the SSL or IKEv2/IPsec protocol. We modified the following screen: Configuration > Remote Access VPN > Load Balancing.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Remote Access VPN support for IPv6: Dynamic Access Policies support IPv6 attributes	When using ASA 9.0 or later with ASDM 6.8 or later, you can now specify these attributes as part of a dynamic access policy (DAP): • IPv6 addresses as a Cisco AAA attribute • IPv6 TCP and UDP ports as part of a Device endpoint attribute • Network ACL Filters (client) This feature can be used by clients configured to use the SSL or IKEv2/IPsec protocol. We modified the following screens: Configuration > Remote Access VPN > Network (Client) Access > Dynamic Access Policies > Add > Cisco AAA attribute Configuration > Remote Access VPN > Network (Client) Access > Dynamic Access Policies > Add > Device > Add Endpoint Attribute Configuration > Remote Access VPN > Network (Client) Access > Dynamic Access Policies > Network ACL Filters (client) Configuration > Remote Access VPN > Network (Client) Access > Dynamic Access Policies > Webtype ACL Filters (clientless)
Remote Access VPN support for IPv6: Session Management	Session management output displays the IPv6 addresses in Public/Assigned address fields for AnyConnect connections, site-to-site VPN connections, and Clientless SSL VPN connections. You can add new filter keywords to support filtering the output to show only IPv6 (outside or inside) connections. No changes to IPv6 User Filters exist. This feature can be used by clients configured to use the SSL protocol. This feature does not support IKEv2/IPsec protocol. We modified these screen: Monitoring > VPN > VPN Statistics > Sessions.
NAT support for IPv6	NAT now supports IPv6 traffic, as well as translating between IPv4 and IPv6 (NAT64). Translating between IPv4 and IPv6 is not supported in transparent mode. We modified the following screens: Configuration > Firewall > Objects > Network Objects/Group Configuration > Firewall > NAT Rules
DHCPv6 relay	DHCP relay is supported for IPv6. We modified the following screen: Configuration > Device Management > DHCP > DHCP Relay.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
OSPFv3	OSPFv3 routing is supported for IPv6. Note the following additional guidelines and limitations for OSPFv2 and OSPFv3: **Clustering** • OSPFv2 and OSPFv3 support clustering. • When clustering is configured, OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment. • When using individual interfaces, make sure that you establish the master and slave units as either OSPFv2 or OSPFv3 neighbors. • When using individual interfaces, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the master unit. Configuring static neighbors is supported only on point-to-point links; therefore, only one neighbor statement is allowed on an interface. **Other** • OSPFv2 and OSPFv3 support multiple instances on an interface. • The ESP and AH protocol is supported for OSPFv3 authentication. • OSPFv3 supports Non-Payload Encryption. We introduced the following screens: Configuration > Device Setup > Routing > OSPFv3 > Setup Configuration > Device Setup > Routing > OSPFv3 > Interface Configuration > Device Setup > Routing > OSPFv3 > Redistribution Configuration > Device Setup > Routing > OSPFv3 > Summary Prefix Configuration > Device Setup > Routing > OSPFv3 > Virtual Link Monitoring > Routing > OSPFv3 LSAs Monitoring > Routing > OSPFv3 Neighbors
Unified ACL for IPv4 and IPv6	ACLs now support IPv4 and IPv6 addresses. You can also specify a mix of IPv4 and IPv6 addresses for the source and destination. The IPv6-specific ACLs are deprecated. Existing IPv6 ACLs are migrated to extended ACLs. ACLs containing IPv6 addresses can be applied to clients configured to use the SSL protocol. This feature is not supported for the IKEv2/IPsec protocol. We modified the following screens: Configuration > Firewall > Access Rules Configuration > Remote Access VPN > Network (Client) Access > Group Policies > General > More Options

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Mixed IPv4 and IPv6 object groups	Previously, network object groups could only contain all IPv4 addresses or all IPv6 addresses. Now network object groups can support a mix of both IPv4 and IPv6 addresses. **Note** You cannot use a mixed object group for NAT. We modified the following screen: Configuration > Firewall > Objects > Network Objects/Groups.
Range of IPv6 addresses for a Network object	You can now configure a range of IPv6 addresses for a network object. We modified the following screen: Configuration > Firewall > Objects > Network Objects/Groups.
Inspection support for IPv6 and NAT64	We now support DNS inspection for IPv6 traffic. We also support translating between IPv4 and IPv6 for the following inspections: • DNS • FTP • HTTP • ICMP You can now also configure the service policy to generate a syslog message (767001) when unsupported inspections receive and drop IPv6 traffic. We modified the following screen: Configuration > Firewall > Service Policy Rules > Add Service Policy Rule Wizard - Service Policy.
Remote Access Features	
Clientless SSL VPN: Additional Support	We have added additional support for these browsers, operating systems, web technologies and applications: **Internet browser support**: Microsoft Internet Explorer 9, Firefox 4, 5, 6, 7, and 8 **Operating system support**: Mac OS X 10.7 **Web technology support**: HTML 5 **Application Support**: Sharepoint 2010
Clientless SSL VPN: Enhanced quality for rewriter engines	The clientless SSL VPN rewriter engines were significantly improved to provide better quality and efficacy. As a result, you can expect a better end-user experience for clientless SSL VPN users. We did not add or modify any ASDM screens for this feature. *Also available in 8.4(4.1).*

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Clientless SSL VPN: Citrix Mobile Receiver	This feature provides secure remote access for Citrix Receiver applications running on mobile devices to XenApp and XenDesktop VDI servers through the ASA. For the ASA to proxy Citrix Receiver to a Citrix Server, when users try to connect to Citrix virtualized resource, instead of providing the Citrix Server's address and credentials, users enter the ASA's SSL VPN IP address and credentials. We modified the following screen: Configuration > Remote Access VPN > Clientless SSL VPN Access > Group Policy > Edit > More Options > VDI Access > Add VDI Server.
Clientless SSL VPN: Enhanced Auto-sign-on	This feature improves support for web applications that require dynamic parameters for authentication. We modified the following screen: Configuration > Remote Access VPN > Clientless SSL VPN Access > Portal > Bookmarks.
Clientless SSL VPN: Clientless Java Rewriter Proxy Support	This feature provides proxy support for clientless Java plug-ins when a proxy is configured in client machines' browsers. We did not add or modify any ASDM screens for this feature.
Clientless SSL VPN: Remote File Explorer	The Remote File Explorer provides users with a way to browse the corporate network from their web browser. When users click the Remote File System icon on the Cisco SSL VPN portal page, an applet is launched on the user's system displaying the remote file system in a tree and folder view. We did not add or modify any ASDM screens for this feature.
Clientless SSL VPN: Server Certificate Validation	This feature enhances clientless SSL VPN support to enable SSL server certificate verification for remote HTTPS sites against a list of trusted CA certificates. We modified the following screen: Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool.
AnyConnect Performance Improvements	This feature improves throughput performance for AnyConnect TLS/DTLS traffic in multi-core platforms. It accelerates the SSL VPN datapath and provides customer-visible performance gains in AnyConnect, smart tunnels, and port forwarding. We modified the following screen: Configuration > Remote Access VPN > Advanced > Crypto Engine.
Custom Attributes	Custom attributes define and configure AnyConnect features that have not yet been added to ASDM. You add custom attributes to a group policy, and define values for those attributes. For AnyConnect 3.1, custom attributes are available to support AnyConnect Deferred Upgrade. Custom attributes can benefit AnyConnect clients configured for either IKEv2/IPsec or SSL protocols. A new screen was added: Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Custom Attributes.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Next Generation Encryption	The National Standards Association (NSA) specified a set of cryptographic algorithms that devices must support to meet U.S. federal standards for cryptographic strength. RFC 6379 defines the Suite B cryptographic suites. Because the collective set of algorithms defined as NSA Suite B are becoming a standard, the AnyConnect IPsec VPN (IKEv2 only) and public key infrastructure (PKI) subsystems now support them. The next generation encryption (NGE) includes a larger superset of this set adding cryptographic algorithms for IPsec V3 VPN, Diffie-Hellman Groups 14 and 24 for IKEv2, and RSA certificates with 4096 bit keys for DTLS and IKEv2. The following functionality is added to ASA to support the Suite B algorithms: • AES-GCM/GMAC support (128-, 192-, and 256-bit keys) – IKEv2 payload encryption and authentication – ESP packet encryption and authentication – Hardware supported only on multi-core platforms • SHA-2 support (256-, 384-, and 512-bit hashes) – ESP packet authentication – Hardware and software supported only on multi-core platforms • ECDH support (groups 19, 20, and 21) – IKEv2 key exchange – IKEv2 PFS – Software only supported on single- or multi-core platforms • ECDSA support (256-, 384-, and 521-bit elliptic curves) – IKEv2 user authentication – PKI certificate enrollment – PKI certificate generation and verification – Software only supported on single- or multi-core platforms New cryptographic algorithms are added for IPsecV3. **Note** Suite B algorithm support requires an AnyConnect Premium license for IKEv2 remote access connections, but Suite B usage for other connections or purposes (such as PKI) has no limitations. IPsecV3 has no licensing restrictions. We introduced or modified the following screens: Monitor > VPN > Sessions Monitor > VPN > Encryption Statistics Configuration > Site-to-Site VPN > Certificate Management > Identity Certificates Configuration > Site-to-Site VPN > Advanced > System Options Configuration > Remote Access VPN > Network (Client) Access > Advanced > IPsec > Crypto Maps
Support for VPN on the ASASM	The ASASM now supports all VPN features.

Table 1-4 New Features for ASA Version 9.0(1)/ASDM Version 7.0(1) (continued)

Feature	Description
Multiple Context Mode Features	
Site-to-Site VPN in multiple context mode	Site-to-site VPN tunnels are now supported in multiple context mode.
New resource type for site-to-site VPN tunnels	New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context. We modified the following screen: Configuration > Context Management > Resource Class > Add Resource Class.
Dynamic routing in Security Contexts	EIGRP and OSPFv2 dynamic routing protocols are now supported in multiple context mode. OSPFv3, RIP, and multicast routing are not supported.
New resource type for routing table entries	A new resource class, routes, was created to set the maximum number of routing table entries in each context. We modified the following screen: Configuration > Context Management > Resource Class > Add Resource Class.
Mixed firewall mode support in multiple context mode	You can set the firewall mode independently for each security context in multiple context mode, so some can run in transparent mode while others run in routed mode. You cannot set the firewall mode in ASDM; you must use the command-line interface. *Also available in Version 8.5(1).*
Module Features	
ASA Services Module support on the Cisco 7600 switch	The Cisco 7600 series now supports the ASASM. For specific hardware and software requirements, see: http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html.
ASA 5585-X support for the ASA CX SSP-10 and -20	The ASA CX module lets you enforce security based on the complete context of a situation. This context includes the identity of the user (who), the application or website that the user is trying to access (what), the origin of the access attempt (where), the time of the attempted access (when), and the properties of the device used for the access (how). With the ASA CX module, you can extract the full context of a flow and enforce granular policies such as permitting access to Facebook but denying access to games on Facebook or permitting finance employees access to a sensitive enterprise database but denying the same to other employees. We introduced the following screens: Home > ASA CX Status Wizards > Startup Wizard > ASA CX Basic Configuration Configuration > Firewall > Service Policy Rules > Add Service Policy Rule > Rule Actions > ASA CX Inspection *Also available in 8.4(4.1).*
ASA 5585-X Dual SSP support for the SSP-10 and SSP-20 (in addition to the SSP-40 and SSP-60); VPN support for Dual SSPs	The ASA 5585-X now supports dual SSPs using all SSP models (you can use two SSPs of the same level in the same chassis). VPN is now supported when using dual SSPs. We did not modify any screens.

How the ASA Services Module Works with the Switch

You can install the ASASM in the Catalyst 6500 series and Cisco 7600 series switches with Cisco IOS software on both the switch supervisor and the integrated MSFC.

Note The Catalyst Operating System (OS) is not supported.

The ASA runs its own operating system.

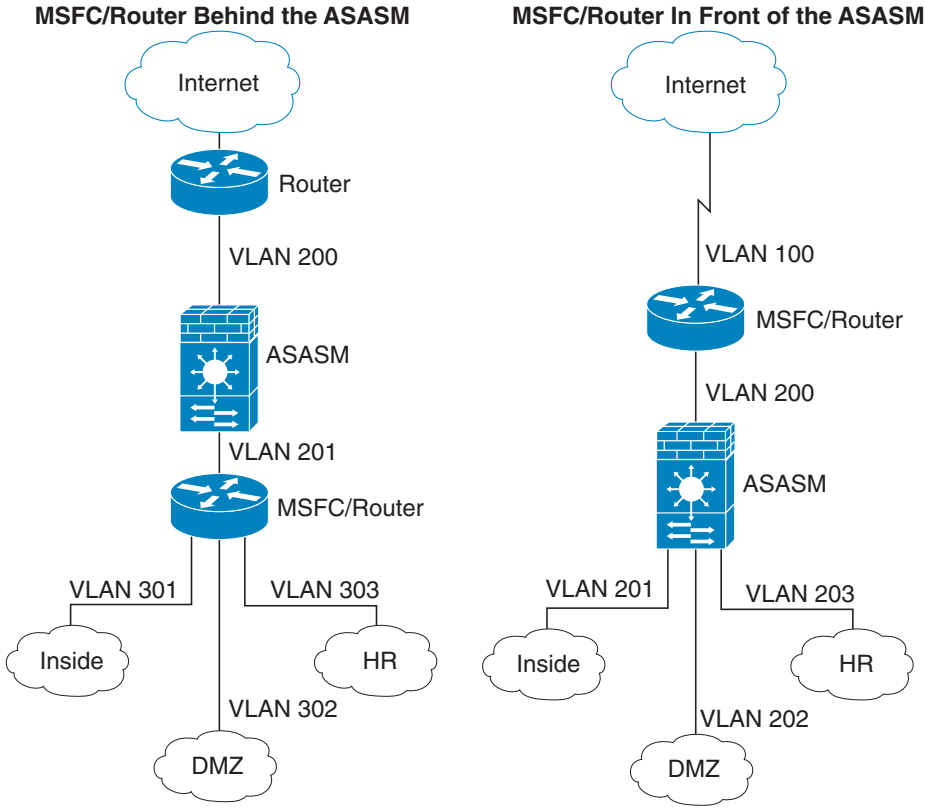
The switch includes a switching processor (the supervisor) and a router (the MSFC). Although you need the MSFC as part of your system, you do not have to use it. If you choose to do so, you can assign one or more VLAN interfaces to the MSFC. You can alternatively use external routers instead of the MSFC.

In single context mode, you can place the router in front of the firewall or behind the firewall (see Figure 1-1).

The location of the router depends entirely on the VLANs that you assign to it. For example, the router is behind the firewall in the example shown on the left side of Figure 1-1 because you assigned VLAN 201 to the inside interface of the ASASM. The router is in front of the firewall in the example shown on the right side of Figure 1-1 because you assigned VLAN 200 to the outside interface of the ASASM.

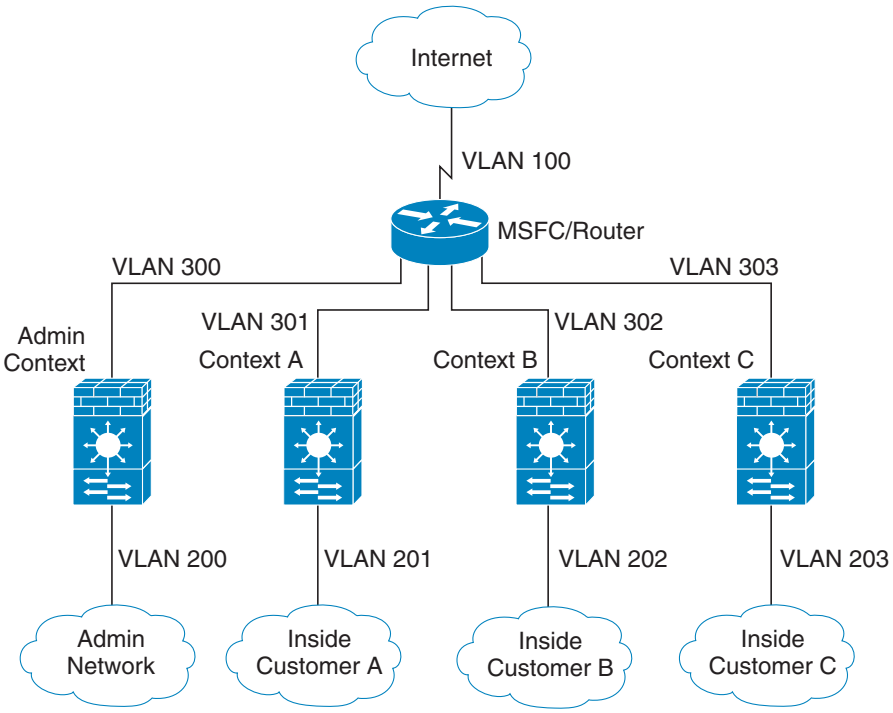
In the left-hand example, the MSFC or router routes between VLANs 201, 301, 302, and 303, and no inside traffic goes through the ASASM unless it is destined for the Internet. In the right-hand example, the ASASM processes and protects all traffic between the inside VLANs 201, 202, and 203.

Figure 1-1 MSFC/Router Placement



For multiple context mode, if you place the router behind the ASASM, you should only connect it to a single context. If you connect the router to multiple contexts, the router will route between the contexts, which might not be your intention. The typical scenario for multiple contexts is to use a router in front of all the contexts to route between the Internet and the switched networks (see Figure 1-2).

Figure 1-2 MSFC/Router Placement with Multiple Contexts



Firewall Functional Overview

Firewalls protect inside networks from unauthorized access by users on an outside network. A firewall can also protect inside networks from each other, for example, by keeping a human resources network separate from a user network. If you have network resources that need to be available to an outside user, such as a web or FTP server, you can place these resources on a separate network behind the firewall, called a *demilitarized zone* (DMZ). The firewall allows limited access to the DMZ, but because the DMZ only includes the public servers, an attack there only affects the servers and does not affect the other inside networks. You can also control when inside users access outside networks (for example, access to the Internet), by allowing only certain addresses out, by requiring authentication or authorization, or by coordinating with an external URL filtering server.

When discussing networks connected to a firewall, the *outside* network is in front of the firewall, the *inside* network is protected and behind the firewall, and a *DMZ*, while behind the firewall, allows limited access to outside users. Because the ASA lets you configure many interfaces with varied security policies, including many inside interfaces, many DMZs, and even many outside interfaces if desired, these terms are used in a general sense only.

This section includes the following topics:

- Security Policy Overview, page 1-21
- Firewall Mode Overview, page 1-23
- Stateful Inspection Overview, page 1-24

Security Policy Overview

A security policy determines which traffic is allowed to pass through the firewall to access another network. By default, the ASA allows traffic to flow freely from an inside network (higher security level) to an outside network (lower security level). You can apply actions to traffic to customize the security policy. This section includes the following topics:

- Permitting or Denying Traffic with Access Rules, page 1-21
- Applying NAT, page 1-21
- Protecting from IP Fragments, page 1-22
- Using AAA for Through Traffic, page 1-22
- Applying HTTP, HTTPS, or FTP Filtering, page 1-22
- Applying Application Inspection, page 1-22
- Sending Traffic to the IPS Module, page 1-22
- Sending Traffic to the Content Security and Control Module, page 1-22
- Applying QoS Policies, page 1-22
- Applying Connection Limits and TCP Normalization, page 1-23
- Enabling Threat Detection, page 1-23
- Enabling the Botnet Traffic Filter, page 1-23
- Configuring Cisco Unified Communications, page 1-23

Permitting or Denying Traffic with Access Rules

You can apply an access rule to limit traffic from inside to outside, or allow traffic from outside to inside. For transparent firewall mode, you can also apply an EtherType access list to allow non-IP traffic.

Applying NAT

Some of the benefits of NAT include the following:

- You can use private addresses on your inside networks. Private addresses are not routable on the Internet.
- NAT hides the local addresses from other networks, so attackers cannot learn the real address of a host.
- NAT can resolve IP routing problems by supporting overlapping IP addresses.

Protecting from IP Fragments

The ASA provides IP fragment protection. This feature performs full reassembly of all ICMP error messages and virtual reassembly of the remaining IP fragments that are routed through the ASA. Fragments that fail the security check are dropped and logged. Virtual reassembly cannot be disabled.

Using AAA for Through Traffic

You can require authentication and/or authorization for certain types of traffic, for example, for HTTP. The ASA also sends accounting information to a RADIUS or TACACS+ server.

Applying HTTP, HTTPS, or FTP Filtering

Although you can use access lists to prevent outbound access to specific websites or FTP servers, configuring and managing web usage this way is not practical because of the size and dynamic nature of the Internet. We recommend that you use the ASA in conjunction with a separate server running one of the following Internet filtering products:

- Websense Enterprise
- Secure Computing SmartFilter

Applying Application Inspection

Inspection engines are required for services that embed IP addressing information in the user data packet or that open secondary channels on dynamically assigned ports. These protocols require the ASA to do a deep packet inspection.

Sending Traffic to the IPS Module

If your model supports the IPS module for intrusion prevention, then you can send traffic to the module for inspection. The IPS module monitors and performs real-time analysis of network traffic by looking for anomalies and misuse based on an extensive, embedded signature library. When the system detects unauthorized activity, it can terminate the specific connection, permanently block the attacking host, log the incident, and send an alert to the device manager. Other legitimate connections continue to operate independently without interruption. For more information, see the documentation for your IPS module.

Sending Traffic to the Content Security and Control Module

If your model supports it, the CSC SSM provides protection against viruses, spyware, spam, and other unwanted traffic. It accomplishes this by scanning the FTP, HTTP, POP3, and SMTP traffic that you configure the ASA to send to it.

Applying QoS Policies

Some network traffic, such as voice and streaming video, cannot tolerate long latency times. QoS is a network feature that lets you give priority to these types of traffic. QoS refers to the capability of a network to provide better service to selected network traffic.

Applying Connection Limits and TCP Normalization

You can limit TCP and UDP connections and embryonic connections. Limiting the number of connections and embryonic connections protects you from a DoS attack. The ASA uses the embryonic limit to trigger TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

TCP normalization is a feature consisting of advanced TCP connection settings designed to drop packets that do not appear normal.

Enabling Threat Detection

You can configure scanning threat detection and basic threat detection, and also how to use statistics to analyze threats.

Basic threat detection detects activity that might be related to an attack, such as a DoS attack, and automatically sends a system log message.

A typical scanning attack consists of a host that tests the accessibility of every IP address in a subnet (by scanning through many hosts in the subnet or sweeping through many ports in a host or subnet). The scanning threat detection feature determines when a host is performing a scan. Unlike IPS scan detection that is based on traffic signatures, the ASA scanning threat detection feature maintains an extensive database that contains host statistics that can be analyzed for scanning activity.

The host database tracks suspicious activity such as connections with no return activity, access of closed service ports, vulnerable TCP behaviors such as non-random IPID, and many more behaviors.

You can configure the ASA to send system log messages about an attacker or you can automatically shun the host.

Enabling the Botnet Traffic Filter

Malware is malicious software that is installed on an unknowing host. Malware that attempts network activity such as sending private data (passwords, credit card numbers, key strokes, or proprietary data) can be detected by the Botnet Traffic Filter when the malware starts a connection to a known bad IP address. The Botnet Traffic Filter checks incoming and outgoing connections against a dynamic database of known bad domain names and IP addresses (the blacklist), and then logs any suspicious activity. When you see syslog messages about the malware activity, you can take steps to isolate and disinfect the host.

Configuring Cisco Unified Communications

The Cisco ASA 5500 series is a strategic platform to provide proxy functions for unified communications deployments. The purpose of a proxy is to terminate and reoriginate connections between a client and server. The proxy delivers a range of security functions such as traffic inspection, protocol conformance, and policy control to ensure security for the internal network. An increasingly popular function of a proxy is to terminate encrypted connections in order to apply security policies while maintaining confidentiality of connections.

Firewall Mode Overview

The ASA runs in two different firewall modes:

- Routed

- Transparent

In routed mode, the ASA is considered to be a router hop in the network.

In transparent mode, the ASA acts like a "bump in the wire," or a "stealth firewall," and is not considered a router hop. The ASA connects to the same network on its inside and outside interfaces.

You might use a transparent firewall to simplify your network configuration. Transparent mode is also useful if you want the firewall to be invisible to attackers. You can also use a transparent firewall for traffic that would otherwise be blocked in routed mode. For example, a transparent firewall can allow multicast streams using an EtherType access list.

Stateful Inspection Overview

All traffic that goes through the ASA is inspected using the Adaptive Security Algorithm and either allowed through or dropped. A simple packet filter can check for the correct source address, destination address, and ports, but it does not check that the packet sequence or flags are correct. A filter also checks every packet against the filter, which can be a slow process.

Note The TCP state bypass feature allows you to customize the packet flow. See the "TCP State Bypass" section on page 71-3.

A stateful firewall like the ASA, however, takes into consideration the state of a packet:

- Is this a new connection?

  If it is a new connection, the ASA has to check the packet against access lists and perform other tasks to determine if the packet is allowed or denied. To perform this check, the first packet of the session goes through the "session management path," and depending on the type of traffic, it might also pass through the "control plane path."

  The session management path is responsible for the following tasks:

  - Performing the access list checks
  - Performing route lookups
  - Allocating NAT translations (xlates)
  - Establishing sessions in the "fast path"

  The ASA creates forward and reverse flows in the fast path for TCP traffic; the ASA also creates connection state information for connectionless protocols like UDP, ICMP (when you enable ICMP inspection), so that they can also use the fast path.

  Note For other IP protocols, like SCTP, the ASA does not create reverse path flows. As a result, ICMP error packets that refer to these connections are dropped.

  Some packets that require Layer 7 inspection (the packet payload must be inspected or altered) are passed on to the control plane path. Layer 7 inspection engines are required for protocols that have two or more channels: a data channel, which uses well-known port numbers, and a control channel, which uses different port numbers for each session. These protocols include FTP, H.323, and SNMP.

- Is this an established connection?

If the connection is already established, the ASA does not need to re-check packets; most matching packets can go through the "fast" path in both directions. The fast path is responsible for the following tasks:

- IP checksum verification
- Session lookup
- TCP sequence number check
- NAT translations based on existing sessions
- Layer 3 and Layer 4 header adjustments

Data packets for protocols that require Layer 7 inspection can also go through the fast path.

Some established session packets must continue to go through the session management path or the control plane path. Packets that go through the session management path include HTTP packets that require inspection or content filtering. Packets that go through the control plane path include the control packets for protocols that require Layer 7 inspection.

VPN Functional Overview

A VPN is a secure connection across a TCP/IP network (such as the Internet) that appears as a private connection. This secure connection is called a tunnel. The ASA uses tunneling protocols to negotiate security parameters, create and manage tunnels, encapsulate packets, transmit or receive them through the tunnel, and unencapsulate them. The ASA functions as a bidirectional tunnel endpoint: it can receive plain packets, encapsulate them, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets, unencapsulate them, and send them to their final destination. The ASA invokes various standard protocols to accomplish these functions.

The ASA performs the following functions:

- Establishes tunnels
- Negotiates tunnel parameters
- Authenticates users
- Assigns user addresses
- Encrypts and decrypts data
- Manages security keys
- Manages data transfer across the tunnel
- Manages data transfer inbound and outbound as a tunnel endpoint or router

The ASA invokes various standard protocols to accomplish these functions.

Security Context Overview

You can partition a single ASA into multiple virtual devices, known as security contexts. Each context is an independent device, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple standalone devices. Many features are supported in multiple context mode, including routing tables, firewall features, IPS, and management. Some features are not supported, including VPN and dynamic routing protocols.

In multiple context mode, the ASA includes a configuration for each context that identifies the security policy, interfaces, and almost all the options you can configure on a standalone device. The system administrator adds and manages contexts by configuring them in the system configuration, which, like a single mode configuration, is the startup configuration. The system configuration identifies basic settings for the ASA. The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the admin context.

The admin context is just like any other context, except that when a user logs into the admin context, then that user has system administrator rights and can access the system and all other contexts.

ASA Clustering Overview

ASA Clustering lets you group multiple ASAs together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

You perform all configuration (aside from the bootstrap configuration) on the master unit only; the configuration is then replicated to the member units.

Configuring the Switch for Use with the ASA Services Module

This chapter describes how to configure the Catalyst 6500 series or Cisco 7600 series switch for use with the ASASM. Before completing the procedures in this chapter, configure the basic properties of your switch, including assigning VLANs to switch ports, according to the documentation that came with your switch.

This chapter includes the following sections:

- Information About the Switch, page 2-1
- Guidelines and Limitations, page 2-2
- Verifying the Module Installation, page 2-3
- Assigning VLANs to the ASA Services Module, page 2-4
- Using the MSFC as a Directly Connected Router, page 2-5
- Configuring the Switch for ASA Failover, page 2-9
- Resetting the ASA Services Module, page 2-11
- Monitoring the ASA Services Module, page 2-11
- Feature History for the Switch for Use with the ASA Services Module, page 2-13

Information About the Switch

You can install the ASASM in the Catalyst 6500 series or Cisco 7600 series switches. The switch includes a switch (the supervisor engine) as well as a router (the MSFC). The connection between the ASASM and the switch is a single 20-GB interface.

The switch supports Cisco IOS software on both the switch supervisor engine and the integrated MSFC router.

Note The Catalyst operating system software is not supported.

The ASASM runs its own operating system.

Note Because the ASASM runs its own operating system, upgrading the Cisco IOS software does not affect the operation of the ASASM.

To view a matrix of hardware and software compatibility for the ASASM and Cisco IOS versions, see the *Cisco ASA 5500 Series Hardware and Software Compatibility*:

http://www.cisco.com/en/US/docs/security/asa/compatibility/asamatrx.html

Some ASASM features interact with Cisco IOS features. The following features involve Cisco IOS software:

- Virtual Switching System (VSS)—No ASASM configuration is required.
- Autostate—The supervisor informs the ASASM when the last interface on a given VLAN has gone down, which assists in determining whether or not a failover switch is required.
- Clearing entries in the supervisor MAC address table on a failover switch—No ASASM configuration is required.
- Version compatibility—The ASASM will be automatically powered down if the supervisor/ASASM version compatibility matrix check fails.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

VLAN Guidelines and Limitations

- Use VLAN IDs 2 to 1000 and from 1025 to 4094.
- Routed ports and WAN ports consume internal VLANs, so it is possible that VLANs in the 1020-1100 range might already be in use.
- You cannot use reserved VLANs.
- You cannot use VLAN 1.
- If you are using ASASM failover within the same switch chassis, do not assign the VLAN(s) that you are reserving for failover and stateful communications to a switch port. However, if you are using failover between chassis, you must include the VLANs in the trunk port between the chassis.
- If you do not add the VLANs to the switch before you assign them to the ASASM, the VLANs are stored in the supervisor engine database and are sent to the ASASM as soon as they are added to the switch.
- You can configure a VLAN in the ASASM configuration before it has been assigned on the switch. Note that when the switch sends the VLAN to the ASASM, the VLAN defaults to be administratively up on the ASASM, regardless of whether the you shut them down in the ASASM configuration. You need to shut them down again in this case.

SPAN Reflector Guidelines

In Cisco IOS software Version 12.2SXJ1 and earlier, for each ASASM in a switch, the SPAN reflector feature is enabled. This feature allows multicast traffic (and other traffic that requires a central rewrite engine) to be switched when coming from the ASASM. The SPAN reflector feature uses one SPAN session. To disable this feature, enter the following command:

```
Router(config)# no monitor session servicemodule
```

Verifying the Module Installation

To verify that the switch acknowledges the ASASM and has brought it online, enter the following command.

Detailed Steps

Command	Purpose
show module [**switch** {**1** |**2**}] [*mod-num* | **all**]	Displays module information. For a switch in a VSS, enter the **switch** keyword.
Example: `Router# show module 1`	Ensure that the Status column shows "Ok" for the ASASM.

Examples

The following is sample output from the **show module** command:

```
Router# show module
Mod Ports Card Type                                Model              Serial No.
--- ----- -------------------------------------- ------------------ -----------

Assigning VLANs to the ASA Services Module

This section describes how to assign VLANs to the ASASM. The ASASM does not include any external physical interfaces. Instead, it uses VLAN interfaces. Assigning VLANs to the ASASM is similar to assigning a VLAN to a switch port; the ASASM includes an internal interface to the Switch Fabric Module (if present) or the shared bus.

Prerequisites

See the switch documentation for information about adding VLANs to the switch and assigning them to switch ports.

Guidelines

- You can assign up to 16 firewall VLAN groups to each ASASM. (You can create more than 16 VLAN groups in Cisco IOS software, but only 16 can be assigned per ASASM.) For example, you can assign all the VLANs to one group; or you can create an inside group and an outside group; or you can create a group for each customer.
- There is no limit on the number of VLANs per group, but the ASASM can only use VLANs up to the ASASM system limit (see the ASASM licensing documentation for more information).
- You cannot assign the same VLAN to multiple firewall groups.
- You can assign a single firewall group to multiple ASASMs. VLANs that you want to assign to multiple ASASMs, for example, can reside in a separate group from VLANs that are unique to each ASASM.
- See the "VLAN Guidelines and Limitations" section on page 2-2.

Detailed Steps

	Command	Purpose
Step 1	**firewall vlan-group** *firewall_group vlan_range* **Example:** `Router(config)# firewall vlan-group 50 55-57`	Assigns VLANs to a firewall group. The *firewall_group* argument is an integer. The *vlan_range* argument can be one or more VLANs (2 to 1000 and from 1025 to 4094) identified in one of the following ways: • A single number (*n*) • A range (*n-x*) Separate numbers or ranges by commas, as shown in the following example: **5,7-10,13,45-100**
Step 2	**firewall** [**switch** {**1** |**2**}] **module** *slot* **vlan-group** *firewall_group* **Example:** `Router(config)# firewall module 5 vlan-group 50,52`	Assigns the firewall groups to the ASASM. For a switch in a VSS, enter the **switch** argument. To view the slots where the ASASM is installed, enter the **show module** command. The *firewall_group* argument is one or more group numbers, which can be one of the following: • A single number (*n*) • A range (*n-x*) Separate numbers or ranges by commas, as shown in the following example: **5,7-10**

Examples

The following example shows how to create three firewall VLAN groups: one for each ASASM, and one that includes VLANs assigned to both ASASMs:

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall vlan-group 52 100
Router(config)# firewall module 5 vlan-group 50,52
Router(config)# firewall module 8 vlan-group 51,52
```

Using the MSFC as a Directly Connected Router

If you want to use the MSFC as a directly connected router (for example, as the default gateway connected to the ASASM outside interface), then add an ASASM VLAN interface to the MSFC as a switched virtual interface (SVI).

This section includes the following topics:

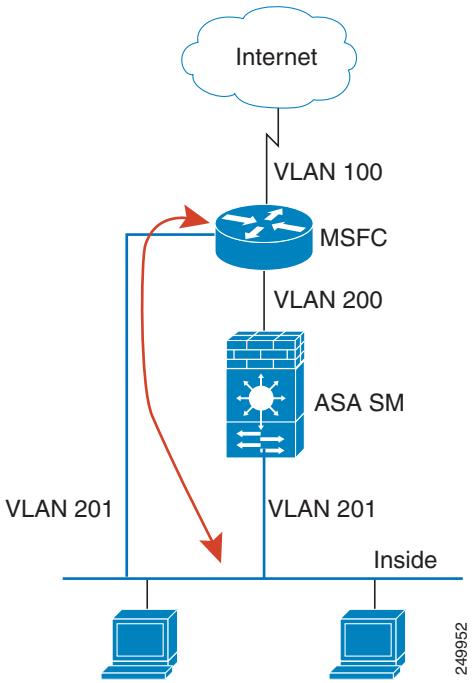
• Information About SVIs, page 2-6
• Configuring SVIs, page 2-8

Information About SVIs

For security reasons, by default, you can configure one SVI between the MSFC and the ASASM; you can enable multiple SVIs, but be sure you do not misconfigure your network.

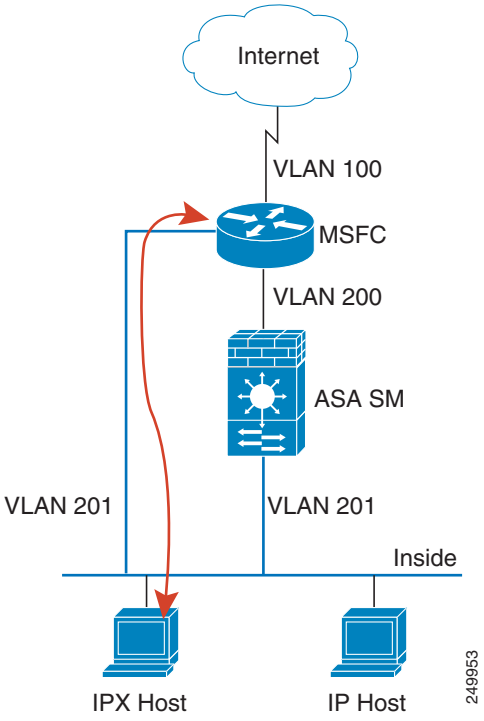
For example, with multiple SVIs, you could accidentally allow traffic to pass around the ASASM by assigning both the inside and outside VLANs to the MSFC. (See Figure 2-1.)

Figure 2-1 Multiple SVI Misconfiguration



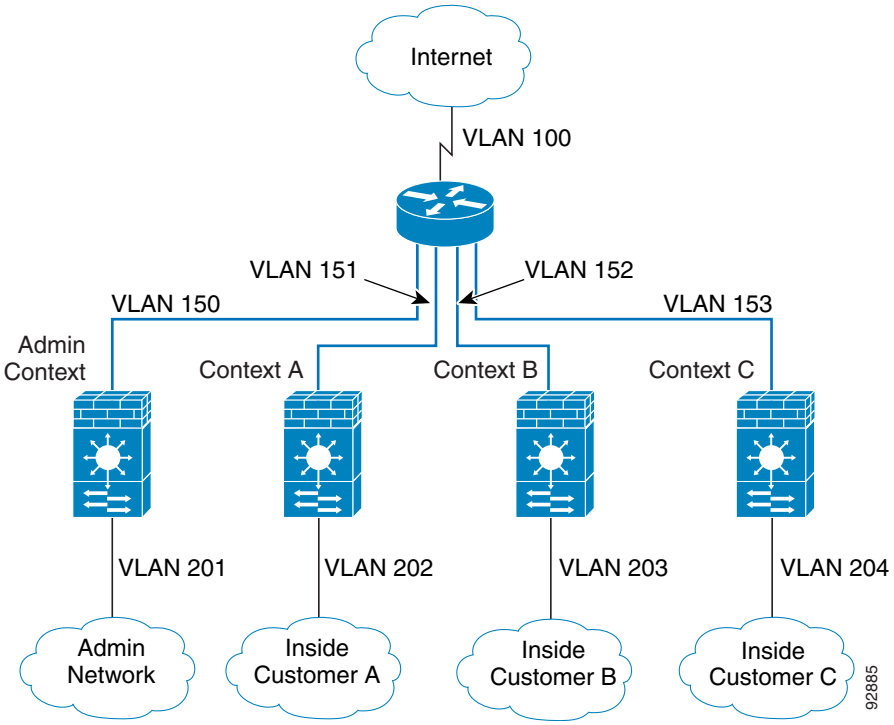
You might need to bypass the ASASM in some network scenarios. Figure 2-2 shows an IPX host on the same Ethernet segment as IP hosts. Because the ASASM in routed firewall mode only handles IP traffic and drops other protocol traffic like IPX (transparent firewall mode can optionally allow non-IP traffic), you might want to bypass the ASASM for IPX traffic. Make sure that you configure the MSFC with an access list that allows only IPX traffic to pass on VLAN 201.

Figure 2-2 Multiple SVIs for IPX



For transparent firewalls in multiple context mode, you need to use multiple SVIs because each context requires a unique VLAN on its outside interface (see Figure 2-3). You might also choose to use multiple SVIs in routed mode so that you do not have to share a single VLAN for the outside interface.

Figure 2-3 Multiple SVIs in Multiple Context Mode



Configuring SVIs

To add an SVI to the MSFC, perform the following steps.

Detailed Steps

	Command	Purpose
Step 1	(Optional) **`firewall multiple-vlan-interfaces`** **Example:** `Router(config)# firewall multiple-vlan-interfaces`	Allows you to add more than one SVI to the ASASM.
Step 2	**`interface vlan`** *`vlan_number`* **Example:** `Router(config)# interface vlan 55`	Adds a VLAN interface to the MSFC.

	Command	Purpose
Step 3	**ip address** *address mask* **Example:** `Router(config-if)# ip address 10.1.1.1 255.255.255.0`	Sets the IP address for this interface on the MSFC.
Step 4	**no shutdown** **Example:** `Router(config-if)# no shutdown`	Enables the interface.

Examples

The following example shows a typical configuration with multiple SVIs:

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall module 8 vlan-group 50-51
Router(config)# firewall multiple-vlan-interfaces
Router(config)# interface vlan 55
Router(config-if)# ip address 10.1.1.1 255.255.255.0
Router(config-if)# no shutdown
Router(config-if)# interface vlan 56
Router(config-if)# ip address 10.1.2.1 255.255.255.0
Router(config-if)# no shutdown
Router(config-if)# end
Router#
```

Configuring the Switch for ASA Failover

This section includes the following topics:

- Assigning VLANs to the Secondary ASA Services Module, page 2-10
- Adding a Trunk Between a Primary Switch and Secondary Switch, page 2-10
- Ensuring Compatibility with Transparent Firewall Mode, page 2-10
- Enabling Autostate Messaging for Rapid Link Failure Detection, page 2-10

Assigning VLANs to the Secondary ASA Services Module

Because both units require the same access to the inside and outside networks, you must assign the same VLANs to both ASASMs on the switch(es). See the "Assigning VLANs to the Secondary ASA Services Module" section on page 2-10.

Adding a Trunk Between a Primary Switch and Secondary Switch

If you are using inter-switch failover, then you should configure an 802.1Q VLAN trunk between the two switches to carry the failover and state links. The trunk should have QoS enabled so that failover VLAN packets, which have a CoS value of 5 (higher priority), are treated with higher priority in these ports.

To configure the EtherChannel and trunk, see the documentation for your switch.

Ensuring Compatibility with Transparent Firewall Mode

To avoid loops when you use failover in transparent mode, use switch software that supports BPDU forwarding. Do not enable LoopGuard globally on the switch if the ASASM is in transparent mode. LoopGuard is automatically applied to the internal EtherChannel between the switch and the ASASM, so after a failover and a failback, LoopGuard causes the secondary unit to be disconnected because the EtherChannel goes into the err-disable state.

Enabling Autostate Messaging for Rapid Link Failure Detection

The supervisor engine can send autostate messages to the ASASM about the status of physical interfaces associated with ASASM VLANs. For example, when all physical interfaces associated with a VLAN go down, the autostate message tells the ASASM that the VLAN is down. This information lets the ASASM declare the VLAN as down, bypassing the interface monitoring tests normally required for determining which side suffered a link failure. Autostate messaging provides a dramatic improvement in the time the ASASM takes to detect a link failure (a few milliseconds as compared to up to 45 seconds without autostate support).

The switch supervisor sends an autostate message to the ASASM when:

- The last interface belonging to a VLAN goes down.
- The first interface belonging to a VLAN comes up.

Detailed Steps

Command	Purpose
firewall autostate **Example:** `Router(config)# firewall autostate`	Enables autostate messaging in Cisco IOS software. Autostate messaging is disabled by default.

Resetting the ASA Services Module

This section describes how to reset the ASASM. You might need to reset the ASASM if you cannot reach it through the CLI or an external Telnet session. The reset process might take several minutes.

Detailed Steps

Command	Purpose
hw-module [**switch** {**1** |**2**}] **module** *slot* **reset** **Example:** `Router# hw-module module 9 reset`	Resets the ASASM. For a switch in a VSS, enter the **switch** argument. The *slot* argument indicates the slot number in which the module is installed. To view the slots where the ASASM is installed, enter the **show module** command. **Note** To reset the ASASM when you are already logged in to it. enter either the **reload** or **reboot** command.

Examples

The following is sample output from the **hw-module module reset** command:

```
Router# hw-module module 9 reset

Proceed with reload of module? [confirm] y
% reset issued for module 9

Router#
00:26:55:%SNMP-5-MODULETRAP:Module 9 [Down] Trap
00:26:55:SP:The PC in slot 8 is shutting down. Please wait ...
```

Monitoring the ASA Services Module

To monitor the ASA, enter one of the following commands:

Command	Purpose
show firewall module [*mod-num*] **state**	Verifies the state of the ASA.
show firewall module [*mod-num*] **traffic**	Verifies that traffic is flowing through the ASA.
show firewall module [*mod-num*] **version**	Shows the software version of the ASA.
show firewall multiple-vlan-interfaces	Indicates the status of multiple VLAN interfaces (enabled or disabled).
show firewall vlan-group	Displays all configured VLAN groups.
show interface vlan	Displays the status and information about the configured VLAN interface.

Examples

The following is sample output from the **show firewall module** [*mod-num*] **state** command:

```
Router> show firewall module 11 state
Firewall module 11:
Switchport: Enabled
Administrative Mode: trunk
Operational Mode: trunk
Administrative Trunking Encapsulation: dot1q
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: Off
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: 3,6,7,20-24,40,59,85,87-89,99-115,150,188-191,200,250,
     501-505,913,972
Pruning VLANs Enabled: 2-1001
Vlans allowed on trunk:
Vlans allowed and active in management domain:
Vlans in spanning tree forwarding state and not pruned:
```

The following is sample output from the **show firewall module** [*mod-num*] **traffic** command:

```
Router> show firewall module 11 traffic
Firewall module 11:

Specified interface is up, line protocol is up (connected)
  Hardware is EtherChannel, address is 0014.1cd5.bef6 (bia 0014.1cd5.bef6)
  MTU 1500 bytes, BW 6000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Full-duplex, 1000Mb/s, media type is unknown
  input flow-control is on, output flow-control is on
  Members in this channel: Gi11/1 Gi11/2 Gi11/3 Gi11/4 Gi11/5 Gi11/6
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/2000/0/0 (size/max/drops/flushes); Total output drops: 0
  Queuing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 10000 bits/sec, 17 packets/sec
     8709 packets input, 845553 bytes, 0 no buffer
     Received 745 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     18652077 packets output, 1480488712 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The following is sample output from the **show firewall multiple-vlan-interfaces** command:

```
Router# show firewall multiple-vlan-interfaces
Multiple firewall vlan interfaces feature is enabled
```

The following is sample output from the **show firewall module** command:

```
Router# show firewall module
Module Vlan-groups
  5    50,52
  8    51,52
```

The following is sample output from the **show firewall module** [*mod-num*] **version** command:

```
Router# show firewall module 2 version
ASA Service Module 2:

Sw Version: 100.7(8)19
```

The following is sample output from the **show firewall vlan-group** command:

```
Router# show firewall vlan-group
Group vlans
----- ------
   50 55-57
   51 70-85
   52 100
```

The following is sample output from the **show interface vlan** command:

```
Router# show interface vlan 55
Vlan55 is up, line protocol is up
  Hardware is EtherSVI, address is 0008.20de.45ca (bia 0008.20de.45ca)
  Internet address is 10.1.1.1/24
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:08, output hang never
  Last clearing of "show interface" counters never
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo

```

Feature History for the Switch for Use with the ASA Services Module

Table 2-1 lists each feature change and the platform release in which it was implemented.

Table 2-1 Feature History for the Switch for Use with the ASASM

Feature Name	Platform Releases	Feature Information
ASA Services Module support on the Cisco Catalyst 6500 switch	8.5(1)	The ASASM is a high-performance security services module for the Catalyst 6500 series switch, which you configure according to the procedures in this chapter. We introduced or modified the following commands: **firewall transparent, mac address auto, firewall autostate** (IOS), **interface vlan**.
ASA Services Module support on the Cisco 7600 switch	9.0(1)	The Cisco 7600 series now supports the ASASM.

Getting Started

This chapter describes how to get started with your ASA. This chapter includes the following sections:

- Accessing the Appliance Command-Line Interface, page 3-1
- Accessing the ASA Services Module Command-Line Interface, page 3-2
- Configuring ASDM Access for Appliances, page 3-6
- Configuring ASDM Access for the ASA Services Module, page 3-11
- Starting ASDM, page 3-13
- Factory Default Configurations, page 3-17
- Getting Started with the Configuration, page 3-24
- Using the Command Line Interface Tool in ASDM, page 3-25
- Applying Configuration Changes to Connections, page 3-27

Accessing the Appliance Command-Line Interface

In some cases, you may need to use the CLI to configure basic settings for ASDM access. See the "Configuring ASDM Access for Appliances" section on page 3-6 to determine if you need to use the CLI.

For initial configuration, access the CLI directly from the console port. Later, you can configure remote access using Telnet or SSH according to Chapter 52, "Configuring Management Access." If your system is already in multiple context mode, then accessing the console port places you in the system execution space. See Chapter 9, "Configuring Multiple Context Mode," for more information about multiple context mode.

Detailed Steps

Step 1 Connect a PC to the console port using the provided console cable, and connect to the console using a terminal emulator set for 9600 baud, 8 data bits, no parity, 1 stop bit, no flow control.

See the hardware guide for your ASA for more information about the console cable.

Step 2 Press the **Enter** key to see the following prompt:

hostname>

This prompt indicates that you are in user EXEC mode. Only basic commands are available from user EXEC mode.

Step 3 To access privileged EXEC mode, enter the following command:

```
hostname> enable
```

The following prompt appears:

```
Password:
```

All non-configuration commands are available in privileged EXEC mode. You can also enter configuration mode from privileged EXEC mode.

Step 4 Enter the enable password at the prompt.

By default, the password is blank, and you can press the **Enter** key to continue. See the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1 to change the enable password.

The prompt changes to:

```
hostname#
```

To exit privileged mode, enter the **disable**, **exit**, or **quit** command.

Step 5 To access global configuration mode, enter the following command:

```
hostname# configure terminal
```

The prompt changes to the following:

```
hostname(config)#
```

You can begin to configure the ASA from global configuration mode. To exit global configuration mode, enter the **exit**, **quit**, or **end** command.

Accessing the ASA Services Module Command-Line Interface

For initial configuration, access the command-line interface by connecting to the switch (either to the console port or remotely using Telnet or SSH) and then connecting to the ASASM. The ASASM does not include a factory default configuration, so you must perform some configuration at the CLI before you can access it using ASDM. This section describes how to access the ASASM CLI, and includes the following sections:

- Logging Into the ASA Services Module, page 3-2
- Logging Out of a Console Session, page 3-4
- Logging Out of a Telnet Session, page 3-6

Logging Into the ASA Services Module

For initial configuration, access the command-line interface by connecting to the switch (either to the switch console port or remotely using Telnet or SSH) and then connecting to the ASASM.

If your system is already in multiple context mode, then accessing the ASASM from the switch places you in the system execution space. See Chapter 9, "Configuring Multiple Context Mode," for more information about multiple context mode.

Later, you can configure remote access directly to the ASASM using Telnet or SSH according to the "Configuring ASA Access for ASDM, Telnet, or SSH" section on page 52-1.

This section includes the following topics:

- Information About Connection Methods, page 3-3
- Logging In, page 3-3

Information About Connection Methods

From the switch CLI, you can use two methods to connect to the ASASM:

- Telnet connection—Using the **session** command, you create a Telnet connection to the ASASM.

  Benefits include:

  - You can have multiple sessions to the ASASM at the same time.
  - The Telnet session is a fast connection.

  Limitations include:

  - The Telnet session is terminated when the ASASM reloads, and can time out.
  - You cannot access the ASASM until it completely loads; you cannot access ROMMON.

- Virtual console connection—Using the **service-module session** command, you create a virtual console connection to the ASASM, with all the benefits and limitations of an actual console connection.

  Benefits include:

  - The connection is persistent across reloads and does not time out.
  - You can stay connected through ASASM reloads and view startup messages.
  - You can access ROMMON if the ASASM cannot load the image.

  Limitations include:

  - The connection is slow (9600 baud).
  - You can only have one console connection active at a time.
  - You cannot use this command in conjunction with a terminal server where **Ctrl-Shift-6**, **x** is the escape sequence to return to the terminal server prompt. **Ctrl-Shift-6**, **x** is also the sequence to escape the ASASM console and return to the switch prompt. Therefore, if you try to exit the ASASM console in this situation, you instead exit all the way to the terminal server prompt. If you reconnect the terminal server to the switch, the ASASM console session is still active; you can never exit to the switch prompt. You must use a direct serial connection to return the console to the switch prompt. In this case, either change the terminal server or switch escape character in Cisco IOS, or use the Telnet **session** command instead.

Note Because of the persistence of the console connection, if you do not properly log out of the ASASM, the connection may exist longer than intended. If someone else wants to log in, they will need to kill the existing connection. See the "Logging Out of a Console Session" section on page 3-4 for more information.

Logging In

Perform the following steps to log into the ASASM and access global configuration mode.

Detailed Steps

	Command	Purpose
Step 1	From the switch, perform one of the following:	

	session [**switch** {**1** |**2**}] **slot** *number* **processor 1**
	
	You are prompted for the login password:
	`hostname passwd:`
	
	Example:
	`Router# session slot number processor 1`
	`hostname passwd: cisco`
	`hostname>`
		From the switch CLI, enter this command to Telnet to the ASASM over the backplane.
		
		For a switch in a VSS, enter the **switch** argument.
		
		Note The **session** *slot* **processor 0** command, which is supported on other services modules, is not supported on the ASASM; the ASASM does not have a processor 0.
		
		To view the module slot numbers, enter the **show module** command at the switch prompt.
		
		Enter the login password to the ASASM. By default, the password is **cisco**.
		
		You access user EXEC mode.

	service-module session [**switch** {**1** | **2**}] **slot** *number*
	
	Example:
	`Router# service-module session slot 3`
	`hostname>`
		From the switch CLI, enter this command to gain console access to the ASASM.
		
		For a switch in a VSS, enter the **switch** argument.
		
		To view the module slot numbers, enter the **show module** command at the switch prompt.
		
		You access user EXEC mode.

Step 2	**enable**
	
	Example:
	`hostname> enable`
	`Password:`
	`hostname#`
		Accesses privileged EXEC mode, which is the highest privilege level.
		
		Enter the enable password at the prompt. By default, the password is blank. To change the enable password, see the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1.
		
		To exit privileged EXEC mode, enter the **disable**, **exit**, or **quit** command.

Step 3	**configure terminal**
	
	Example:
	`hostname# configure terminal`
	`hostname(config)#`
		Accesses global configuration mode.
		
		To exit global configuration mode, enter the **disable**, **exit**, or **quit** command.

Logging Out of a Console Session

This section includes the following topics:

- Logging Out, page 3-5
- Killing an Active Console Connection, page 3-5

Logging Out

If you do not log out of the ASASM, the console connection persists; there is no timeout. To end the ASASM console session and access the switch CLI, perform the following steps.

To kill another user's active connection, which may have been unintentionally left open, see the "Killing an Active Console Connection" section on page 3-5.

Detailed Steps

Step 1 To return to the switch CLI, type the following:

Ctrl-Shift-6, **x**

You return to the switch prompt:

```
asasm# [Ctrl-Shift-6, x]
Router#
```

Note Shift-6 on US and UK keyboards issues the caret (^) character. If you have a different keyboard and cannot issue the caret (^) character as a standalone character, you can temporarily or permanently change the escape character to a different character. In Cisco IOS, before you session to the ASASM, use the **terminal escape-character** *ascii_number* command (to change temporarily) or the **default escape-character** *ascii_number* command (to change permanently). For example, to temporarily change the sequence to **Ctrl-w**, **x**, enter **terminal escape-character 23**. The next time you log into the switch, the escape character reverts back to the default.

Killing an Active Console Connection

Because of the persistence of a console connection, if you do not properly log out of the ASASM, the connection may exist longer than intended. If someone else wants to log in, they will need to kill the existing connection.

Detailed Steps

Step 1 From the switch CLI, show the connected users using the **show users** command. A console user is called "con". The Host address shown is 127.0.0.*slot*0, where *slot* is the slot number of the module.

```
Router# show users
```

For example, the following command output shows a user "con" on line 0 on a module in slot 2:

```
Router# show users
Line       User       Host(s)              Idle       Location
*  0       con 0     127.0.0.20            00:00:02
```

Step 2 To clear the line with the console connection, enter the following command:

```
Router# clear line number
```

For example:

```
Router# clear line 0
```

Logging Out of a Telnet Session

To end the Telnet session and access the switch CLI, perform the following steps.

Detailed Steps

Step 1 To return to the switch CLI, type **exit** from the ASASM privileged or user EXEC mode. If you are in a configuration mode, enter **exit** repeatedly until you exit the Telnet session.

You return to the switch prompt:

```
asasm# exit
Router#
```

Note You can alternatively escape the Telnet session using the escape sequence **Ctrl-Shift-6**, **x**; this escape sequence lets you resume the Telnet session by pressing the **Enter** key at the switch prompt. To disconnect your Telnet session from the switch, enter **disconnect** at the switch CLI. If you do not disconnect the session, it will eventually time out according to the ASASM configuration.

Configuring ASDM Access for Appliances

ASDM access requires some minimal configuration so you can communicate over the network with a management interface. This section includes the following topics:

- Accessing ASDM Using the Factory Default Configuration, page 3-6
- Accessing ASDM Using a Non-Default Configuration (ASA 5505), page 3-7
- Accessing ASDM Using a Non-Default Configuration (ASA 5510 and Higher), page 3-9

Accessing ASDM Using the Factory Default Configuration

With a factory default configuration (see the "Factory Default Configurations" section on page 3-17), ASDM connectivity is pre-configured with default network settings. Connect to ASDM using the following interface and network settings:

- The management interface depends on your model:
  - ASA 5505—The switch port to which you connect to ASDM can be any port, except for Ethernet 0/0.
  - ASA 5510 and higher—The interface to which you connect to ASDM is Management 0/0.
- The default management address is 192.168.1.1.

- The clients allowed to access ASDM must be on the 192.168.1.0/24 network. The default configuration enables DHCP so your management station can be assigned an IP address in this range. To allow other client IP addresses to access ASDM, see the "Configuring ASA Access for ASDM, Telnet, or SSH" section on page 52-1.

To launch ASDM, see the "Starting ASDM" section on page 3-13.

Note To change to multiple context mode, see the "Enabling or Disabling Multiple Context Mode" section on page 9-16. After changing to multiple context mode, you can access ASDM from the admin context using the network settings above.

Accessing ASDM Using a Non-Default Configuration (ASA 5505)

If you do not have a factory default configuration, want to change the configuration, or want to change to transparent firewall mode, perform the following steps. See also the sample configurations in the "ASA 5505 Default Configuration" section on page 3-20.

Prerequisites

Access the CLI according to the "Accessing the Appliance Command-Line Interface" section on page 3-1.

Detailed Steps

	Command	Purpose
Step 1	(Optional) **firewall transparent** **Example:** `hostname(config)# firewall transparent`	Enables transparent firewall mode. This command clears your configuration. See the "Configuring the Firewall Mode" section on page 6-1 for more information.
Step 2	Do one of the following to configure a management interface, depending on your mode:	

	Routed mode:
	interface vlan *number*
	ip address *ip_address* [*mask*]
	nameif *name*
	security-level *level*
	
	Example:
	`hostname(config)# interface vlan 1`
	`hostname(config-if)# ip address 192.168.1.1 255.255.255.0`
	`hostname(config-if)# nameif inside`
	`hostname(config-if)# security-level 100`
		Configures an interface in routed mode. The **security-level** is a number between 1 and 100, where 100 is the most secure.

	Command	Purpose

	Transparent mode:
	interface bvi *number*
	  ip address *ip_address* [*mask*]
	
	interface vlan *number*
	  bridge-group *bvi_number*
	  nameif *name*
	  security-level *level*
	
	Example:
	`hostname(config)# interface bvi 1`
	`hostname(config-if)# ip address 192.168.1.1 255.255.255.0`
	
	`hostname(config)# interface vlan 1`
	`hostname(config-if)# bridge-group 1`
	`hostname(config-if)# nameif inside`
	`hostname(config-if)# security-level 100`
		Configures a bridge virtual interface and assigns a management VLAN to the bridge group. The **security-level** is a number between 1 and 100, where 100 is the most secure.

Step 3	**interface ethernet 0/***n*
	  switchport access vlan *number*
	  no shutdown
	
	Example:
	`hostname(config)# interface ethernet 0/1`
	`hostname(config-if)# switchport access vlan 1`
	`hostname(config-if)# no shutdown`
		Enables the management switchport and assigns it to the management VLAN.

Step 4	**dhcpd address** *ip_address-ip_address interface_name*
	dhcpd enable *interface_name*
	
	Example:
	`hostname(config)# dhcpd address 192.168.1.5-192.168.1.254 inside`
	`hostname(config)# dhcpd enable inside`
		Enables DHCP for the management host on the management interface network. Make sure you do not include the management address in the range.
		
		Note By default, the IPS module, if installed, uses 192.168.1.2 for its internal management address, so be sure not to use this address in the DHCP range. You can later change the IPS module management address using the ASA if required.

Step 5	**http server enable** **Example:** `hostname(config)# http server enable`	Enables the HTTP server for ASDM.
Step 6	**http** *ip_address mask interface_name* **Example:** `hostname(config)# http 192.168.1.0 255.255.255.0 inside`	Allows the management host to access ASDM.
Step 7	**write memory** **Example:** `hostname(config)# write memory`	Saves the configuration.
Step 8	To launch ASDM, see the "Starting ASDM" section on page 3-13.	

Examples

The following configuration converts the firewall mode to transparent mode, configures the VLAN 1 interface and assigns it to BVI 1, enables a switchport, and enables ASDM for a management host:

```
firewall transparent
interface bvi 1
    ip address 192.168.1.1 255.255.255.0
interface vlan 1
    bridge-group 1
    nameif inside
    security-level 100
interface ethernet 0/1
    switchport access vlan 1
    no shutdown
dhcpd address 192.168.1.5-192.168.1.254 inside
dhcpd enable inside
http server enable
http 192.168.1.0 255.255.255.0 inside
```

Accessing ASDM Using a Non-Default Configuration (ASA 5510 and Higher)

If you do not have a factory default configuration, or want to change the firewall or context mode, perform the following steps.

Prerequisites

Access the CLI according to the "Accessing the Appliance Command-Line Interface" section on page 3-1.

Detailed Steps

	Command	Purpose
Step 1	(Optional) **firewall transparent** **Example:** `hostname(config)# firewall transparent`	Enables transparent firewall mode. This command clears your configuration. See the "Configuring the Firewall Mode" section on page 6-1 for more information.

Step 2	**interface management 0/0**
	ip address *ip_address mask*
	nameif *name*
	security-level *number*
	no shutdown
	
	Example:
	`hostname(config)# interface management 0/0`
	`hostname(config-if)# ip address 192.168.1.1 255.255.255.0`
	`hostname(config-if)# nameif management`
	`hostname(config-if)# security-level 100`
	`hostname(config-if)# no shutdown`
		Configures the Management 0/0 interface. The **security-level** is a number between 1 and 100, where 100 is the most secure.

	Command	Purpose

Step 3	(For directly-connected management hosts)
	dhcpd address *ip_address-ip_address interface_name*
	dhcpd enable *interface_name*
	
	Example:
	`hostname(config)# dhcpd address 192.168.1.2-192.168.1.254 management`
	`hostname(config)# dhcpd enable management`
		Enables DHCP for the management host on the management interface network. Make sure you do not include the Management 0/0 address in the range.

Step 4	(For remote management hosts) **route** *management_ifc management_host_ip mask gateway_ip* **1** **Example:** `hostname(config)# route management 10.1.1.0 255.255.255.0 192.168.1.50`	Configures a route to the management hosts.
Step 5	**http server enable** **Example:** `hostname(config)# http server enable`	Enables the HTTP server for ASDM.
Step 6	**http** *ip_address mask interface_name* **Example:** `hostname(config)# http 192.168.1.0 255.255.255.0 management`	Allows the management host to access ASDM.
Step 7	**write memory** **Example:** `hostname(config)# write memory`	Saves the configuration.
Step 8	(Optional) **mode multiple** **Example:** `hostname(config)# mode multiple`	Sets the mode to multiple mode. When prompted, confirm that you want to convert the existing configuration to be the admin context. You are then prompted to reload the ASASM. See Chapter 9, "Configuring Multiple Context Mode," for more information.
Step 9	To launch ASDM, see the "Starting ASDM" section on page 3-13.	

Examples

The following configuration converts the firewall mode to transparent mode, configures the Management 0/0 interface, and enables ASDM for a management host:

```
firewall transparent
interface management 0/0
    ip address 192.168.1.1 255.255.255.0
    nameif management
    security-level 100
```

```
    no shutdown
dhcpd address 192.168.1.2-192.168.1.254 management
dhcpd enable management
http server enable
http 192.168.1.0 255.255.255.0 management
```

Configuring ASDM Access for the ASA Services Module

Because the ASASM does not have physical interfaces, it does not come pre-configured for ASDM access; you must configure ASDM access using the CLI on the ASASM. To configure the ASASM for ASDM access, perform the following steps.

Prerequisites

- Assign a VLAN interface to the ASASM according to the "Assigning VLANs to the ASA Services Module" section on page 2-4.
- Connect to the ASASM and access global configuration mode according to the "Accessing the ASA Services Module Command-Line Interface" section on page 3-2.

Detailed Steps

	Command	Purpose
Step 1	(Optional) **firewall transparent** **Example:** `hostname(config)# firewall transparent`	Enables transparent firewall mode. This command clears your configuration. See the "Configuring the Firewall Mode" section on page 6-1 for more information.
Step 2	Do one of the following to configure a management interface, depending on your mode:	

	Routed mode:
	interface vlan *number*
	ip address *ip_address* [*mask*]
	nameif *name*
	security-level *level*
	
	Example:
	`hostname(config)# interface vlan 1`
	`hostname(config-if)# ip address 192.168.1.1 255.255.255.0`
	`hostname(config-if)# nameif inside`
	`hostname(config-if)# security-level 100`
		Configures an interface in routed mode. The **security-level** is a number between 1 and 100, where 100 is the most secure.

	Command	Purpose

	Transparent mode:
	interface bvi *number*
	  ip address *ip_address* [*mask*]
	
	interface vlan *number*
	  bridge-group *bvi_number*
	  nameif *name*
	  security-level *level*
	
	Example:
	`hostname(config)# interface bvi 1`
	`hostname(config-if)# ip address 192.168.1.1 255.255.255.0`
	
	`hostname(config)# interface vlan 1`
	`hostname(config-if)# bridge-group 1`
	`hostname(config-if)# nameif inside`
	`hostname(config-if)# security-level 100`
		Configures a bridge virtual interface and assigns a management VLAN to the bridge group. The **security-level** is a number between 1 and 100, where 100 is the most secure.

Step 3	(For directly-connected management hosts)
	dhcpd address *ip_address-ip_address interface_name*
	dhcpd enable *interface_name*
	
	Example:
	`hostname(config)# dhcpd address 192.168.1.2-192.168.1.254 inside`
	`hostname(config)# dhcpd enable inside`
		Enables DHCP for the management host on the management interface network. Make sure you do not include the management address in the range.

Step 4	(For remote management hosts) **route** *management_ifc management_host_ip mask gateway_ip* **1** **Example:** `hostname(config)# route management 10.1.1.0 255.255.255.0 192.168.1.50`	Configures a route to the management hosts.
Step 5	**http server enable** **Example:** `hostname(config)# http server enable`	Enables the HTTP server for ASDM.
Step 6	**http** *ip_address mask interface_name* **Example:** `hostname(config)# http 192.168.1.0 255.255.255.0 management`	Allows the management host to access ASDM.
Step 7	**write memory** **Example:** `hostname(config)# write memory`	Saves the configuration.

	Command	Purpose
Step 8	(Optional) **mode multiple** **Example:** `hostname(config)# mode multiple`	Sets the mode to multiple mode. When prompted, confirm that you want to convert the existing configuration to be the admin context. You are then prompted to reload the ASASM. See Chapter 9, "Configuring Multiple Context Mode," for more information.
Step 9	To launch ASDM, see the "Starting ASDM" section on page 3-13.	

Examples

The following routed mode configuration configures the VLAN 1 interface and enables ASDM for a management host:

```
interface vlan 1
    nameif inside
    ip address 192.168.1.1 255.255.255.0
    security-level 100
dhcpd address 192.168.1.3-192.168.1.254 inside
dhcpd enable inside
http server enable
http 192.168.1.0 255.255.255.0 inside
```

The following configuration converts the firewall mode to transparent mode, configures the VLAN 1 interface and assigns it to BVI 1, and enables ASDM for a management host:

```
firewall transparent
interface bvi 1
    ip address 192.168.1.1 255.255.255.0
interface vlan 1
    bridge-group 1
    nameif inside
    security-level 100
dhcpd address 192.168.1.3-192.168.1.254 inside
dhcpd enable inside
http server enable
http 192.168.1.0 255.255.255.0 inside
```

Starting ASDM

You can start ASDM using two methods:

- ASDM-IDM Launcher—The Launcher is an application downloaded from the ASA using a web browser that you can use to connect to any ASA IP address. You do not need to re-download the launcher if you want to connect to other ASAs. The Launcher also lets you run a virtual ASDM in Demo mode using files downloaded locally.
- Java Web Start—For each ASA that you manage, you need to connect with a web browser and then save or launch the Java Web Start application. You can optionally save the application to your PC; however you need separate applications for each ASA IP address.

Note Within ASDM, you can choose a different ASA IP address to manage; the difference between the Launcher and Java Web Start application functionality rests primarily in how you initially connect to the ASA and launch ASDM.

This section describes how to connect to ASDM initially, and then launch ASDM using the Launcher or the Java Web Start application. This section includes the following topics:

- Connecting to ASDM for the First Time, page 3-14
- Starting ASDM from the ASDM-IDM Launcher, page 3-15
- Starting ASDM from the Java Web Start Application, page 3-15
- Using ASDM in Demo Mode, page 3-16

Note ASDM allows multiple PCs or workstations to each have one browser session open with the same ASA software. A single ASA can support up to five concurrent ASDM sessions in single, routed mode. Only one session per browser per PC or workstation is supported for a specified ASA. In multiple context mode, five concurrent ASDM sessions are supported per context, up to a maximum of 32 total connections for each ASA.

Connecting to ASDM for the First Time

To connect to ASDM for the first time to download the ASDM-IDM Launcher or Java Web Start application, perform the following steps:

Step 1 From a supported web browser on the ASA network, enter the following URL:

https://*interface_ip_address***/admin**

Where *interface_ip_address* is the management IP address of the ASA. See the "Configuring ASDM Access for Appliances" section on page 3-6 or the "Configuring ASDM Access for the ASA Services Module" section on page 3-11 for more information about management access.

See the ASDM release notes for your release for the requirements to run ASDM.

The ASDM launch page appears with the following buttons:

- **Install ASDM Launcher and Run ASDM**
- **Run ASDM**
- **Run Startup Wizard**

Step 2 To download the Launcher:

a. Click **Install ASDM Launcher and Run ASDM**.

b. Enter the username and password, and click **OK**. For a factory default configuration, leave these fields empty. With no HTTPS authentication configured, you can gain access to ASDM with no username and the **enable** password, which is blank by default. With HTTPS authentication enabled, enter your username and associated password.

c. Save the installer to your PC, and then start the installer. The ASDM-IDM Launcher opens automatically after installation is complete.

d. See the "Starting ASDM from the ASDM-IDM Launcher" section on page 3-15 to use the Launcher to connect to ASDM.

Step 3 To use the Java Web Start application:

a. Click **Run ASDM** or **Run Startup Wizard**.

b. Save the application to your PC when prompted. You can optionally open it instead of saving it.

c. See the "Starting ASDM from the Java Web Start Application" section on page 3-15 to use the Java Web Start application to connect to ASDM.

Starting ASDM from the ASDM-IDM Launcher

To start ASDM from the ASDM-IDM Launcher, perform the following steps.

Prerequisites

Download the ASDM-IDM Launcher according to the "Connecting to ASDM for the First Time" section on page 3-14.

Detailed Steps

Step 1 Start the ASDM-IDM Launcher application.

Step 2 Enter or choose the ASA IP address or hostname to which you want to connect. To clear the list of IP addresses, click the trash can icon next to the Device/IP Address/Name field.

Step 3 Enter your username and your password, and then click **OK**.

For a factory default configuration, leave these fields empty. With no HTTPS authentication configured, you can gain access to ASDM with no username and the **enable** password, which is blank by default. With HTTPS authentication enabled, enter your username and associated password.

If there is a new version of ASDM on the ASA, the ASDM Launcher automatically downloads the new version and requests that you update the current version before starting ASDM.

The main ASDM window appears.

Starting ASDM from the Java Web Start Application

To start ASDM from the Java Web Start application, perform the following steps.

Prerequisites

Download the Java Web Start application according to the "Connecting to ASDM for the First Time" section on page 3-14.

Detailed Steps

Step 1 Start the Java Web Start application.

Step 2 Accept any certificates according to the dialog boxes that appear. The Cisco ASDM-IDM Launcher appears.

Step 3 Enter the username and password, and click **OK**. For a factory default configuration, leave these fields empty. With no HTTPS authentication configured, you can gain access to ASDM with no username and the **enable** password, which is blank by default. With HTTPS authentication enabled, enter your username and associated password.

The main ASDM window appears.

Using ASDM in Demo Mode

The ASDM Demo Mode, a separately installed application, lets you run ASDM without having a live device available. In this mode, you can do the following:

- Perform configuration and selected monitoring tasks via ASDM as though you were interacting with a real device.
- Demonstrate ASDM or ASA features using the ASDM interface.
- Perform configuration and monitoring tasks with the CSC SSM.
- Obtain simulated monitoring and logging data, including real-time syslog messages. The data shown is randomly generated; however, the experience is identical to what you would see when you are connected to a real device.

This mode has been updated to support the following features:

- For global policies, an ASA in single, routed mode and intrusion prevention
- For object NAT, an ASA in single, routed mode and a firewall DMZ.
- For the Botnet Traffic Filter, an ASA in single, routed mode and security contexts.
- Site-to-Site VPN with IPv6 (Clientless SSL VPN and IPsec VPN)
- Promiscuous IDS (intrusion prevention)
- Unified Communication Wizard

This mode does not support the following:

- Saving changes made to the configuration that appear in the GUI.
- File or disk operations.
- Historical monitoring data.
- Non-administrative users.
- These features:
  - File menu:

    Save Running Configuration to Flash

    Save Running Configuration to TFTP Server

    Save Running Configuration to Standby Unit

    Save Internal Log Buffer to Flash

    Clear Internal Log Buffer
  - Tools menu:

Command Line Interface

Ping

File Management

Update Software

File Transfer

Upload Image from Local PC

System Reload

  - Toolbar/Status bar > Save
  - Configuration > Interface > Edit Interface > Renew DHCP Lease
  - Configuring a standby device after failover
- Operations that cause a rereading of the configuration, in which the GUI reverts to the original configuration:
  - Switching contexts
  - Making changes in the Interface pane
  - NAT pane changes
  - Clock pane changes

To run ASDM in Demo Mode, perform the following steps:

Step 1 Download the ASDM Demo Mode installer, asdm-demo-*version*.msi, from the following location: http://www.cisco.com/cisco/web/download/index.html.

Step 2 Double-click the installer to install the software.

Step 3 Double-click the Cisco ASDM Launcher shortcut on your desktop, or open it from the **Start** menu.

Step 4 Check the **Run in Demo Mode** check box.

The Demo Mode window appears.

Factory Default Configurations

The factory default configuration is the configuration applied by Cisco to new ASAs.

- ASA 5505—The factory default configuration configures interfaces and NAT so that the ASA is ready to use in your network immediately.
- ASA 5510 and higher—The factory default configuration configures an interface for management so you can connect to it using ASDM, with which you can then complete your configuration.

The factory default configuration is available only for routed firewall mode and single context mode. See Chapter 9, “Configuring Multiple Context Mode,” for more information about multiple context mode. See Chapter 6, “Configuring the Transparent or Routed Firewall,” for more information about routed and transparent firewall mode. For the ASA 5505, a sample transparent mode configuration is provided in this section.

Note In addition to the image files and the (hidden) default configuration, the following folders and files are standard in flash memory: log/, crypto_archive/, and coredumpinfo/coredump.cfg. The date on these files may not match the date of the image files in flash memory. These files aid in potential troubleshooting; they do not indicate that a failure has occurred.

This section includes the following topics:

- Restoring the Factory Default Configuration, page 3-18
- ASA 5505 Default Configuration, page 3-20
- ASA 5510 and Higher Default Configuration, page 3-24

Restoring the Factory Default Configuration

This section describes how to restore the factory default configuration.

Note On the ASASM, restoring the factory default configuration simply erases the configuration; there is no factory default configuration.

Limitations

This feature is available only in routed firewall mode; transparent mode does not support IP addresses for interfaces. In addition, this feature is available only in single context mode; an ASA with a cleared configuration does not have any defined contexts to configure automatically using this feature.

Detailed Steps

Using the CLI:

	Command	Purpose
Step 1	**configure factory-default** [*ip_address* [*mask*]] **Example:** hostname(config)# **configure factory-default 10.1.1.1 255.255.255.0**	Restores the factory default configuration. If you specify the *ip_address*, then you set the inside or management interface IP address, depending on your model, instead of using the default IP address of 192.168.1.1. The **http** command uses the subnet you specify. Similarly, the **dhcpd address** command range consists of addresses within the subnet that you specify. **Note** This command also clears the **boot system** command, if present, along with the rest of the configuration. The **boot system** command lets you boot from a specific image, including an image on the external flash memory card. The next time you reload the ASA after restoring the factory configuration, it boots from the first image in internal flash memory; if you do not have an image in internal flash memory, the ASA does not boot.
Step 2	**write memory** **Example:** active(config)# write memory	Saves the default configuration to flash memory. This command saves the running configuration to the default location for the startup configuration, even if you previously configured the **boot config** command to set a different location; when the configuration was cleared, this path was also cleared.

Using ASDM:

Step 1 In the main ASDM application window, choose **File > Reset Device to the Factory Default Configuration**.

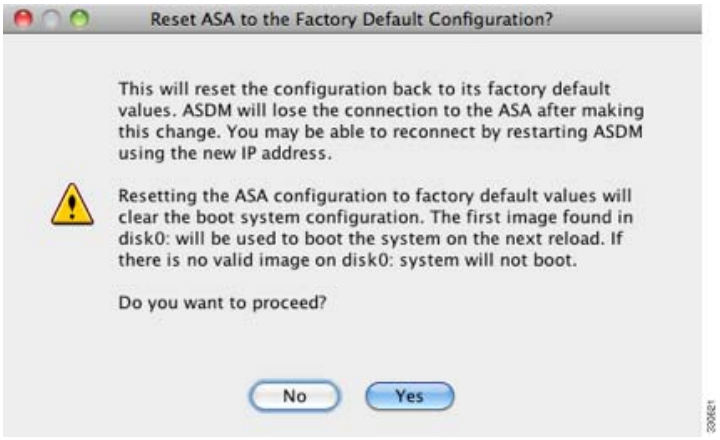
The Reset Device to the Default Configuration dialog box appears.

Step 2 (Optional) Enter the Management IP address of the management interface, instead of using the default address, 192.168.1.1. (For an ASA with a dedicated management interface, the interface is called "Management0/0.")

Step 3 (Optional) Choose the Management Subnet Mask from the drop-down list.

Step 4 Click **OK**.

A confirmation dialog box appears.



Note This action also clears the location of the boot image location, if present, along with the rest of the configuration. The Configuration > Device Management > System Image/Configuration > Boot Image/Configuration pane lets you boot from a specific image, including an image on the external memory. The next time you reload the ASA after restoring the factory configuration, it boots from the first image in internal flash memory; if you do not have an image in *internal* flash memory, the ASA does not boot.

Step 5 Click **Yes**.

Step 6 After you restore the default configuration, save this configuration to internal flash memory. Choose **File > Save Running Configuration to Flash**.

Choosing this option saves the running configuration to the default location for the startup configuration, even if you have previously configured a different location. When the configuration was cleared, this path was also cleared.

What to Do Next

See the "Getting Started with the Configuration" section on page 3-24 to start configuring the ASA.

ASA 5505 Default Configuration

The default configuration is available for routed mode only. This section describes the default configuration and also provides a sample transparent mode configuration that you can copy and paste as a starting point. This section includes the following topics:

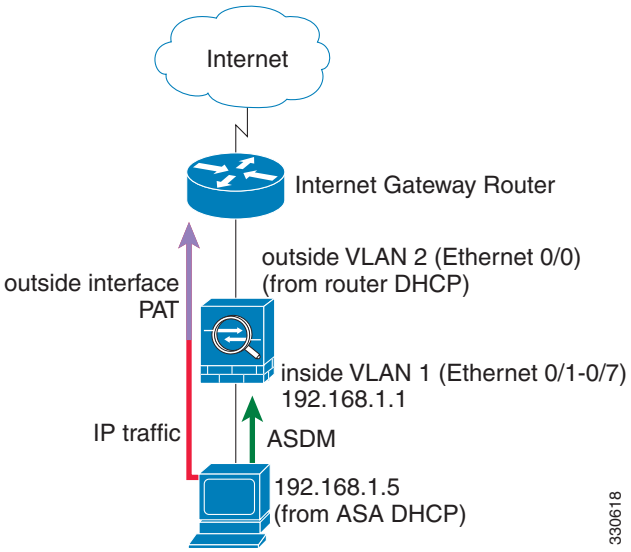
- ASA 5505 Routed Mode Default Configuration, page 3-21
- ASA 5505 Transparent Mode Sample Configuration, page 3-22

ASA 5505 Routed Mode Default Configuration

The default factory configuration for the ASA 5505 configures the following:

- Interfaces—Inside (VLAN 1) and outside (VLAN 2).
- Switchports enabled and assigned—Ethernet 0/1 through 0/7 switch ports assigned to inside. Ethernet 0/0 assigned to outside.
- IP addresses— Outside address from DHCP; inside address set manually to 192.168.1.1/24.
- Network address translation (NAT)—All inside IP addresses are translated when accessing the outside using interface PAT.
- Traffic flow—IPv4 and IPv6 traffic allowed from inside to outside (this behavior is implicit on the ASA). Outside users are prevented from accessing the inside.
- DHCP server—Enabled for inside hosts, so a PC connecting to the inside interface receives an address between 192.168.1.5 and 192.168.1.254. DNS, WINS, and domain information obtained from the DHCP client on the outside interface is passed to the DHCP clients on the inside interface.
- Default route—Derived from DHCP.
- ASDM access—Inside hosts allowed.

Figure 3-1 ASA 5505 Routed Mode



The configuration consists of the following commands:

```
interface Ethernet 0/0
   switchport access vlan 2
   no shutdown
interface Ethernet 0/1
   switchport access vlan 1
   no shutdown
interface Ethernet 0/2
   switchport access vlan 1
   no shutdown
interface Ethernet 0/3
   switchport access vlan 1
   no shutdown
interface Ethernet 0/4
```

```
   switchport access vlan 1
   no shutdown
interface Ethernet 0/5
   switchport access vlan 1
   no shutdown
interface Ethernet 0/6
   switchport access vlan 1
   no shutdown
interface Ethernet 0/7
   switchport access vlan 1
   no shutdown
interface vlan2
   nameif outside
   no shutdown
   ip address dhcp setroute
interface vlan1
   nameif inside
   ip address 192.168.1.1 255.255.255.0
   security-level 100
   no shutdown
object network obj_any
   subnet 0 0
   nat (inside,outside) dynamic interface
http server enable
http 192.168.1.0 255.255.255.0 inside
dhcpd address 192.168.1.5-192.168.1.254 inside
dhcpd auto_config outside
dhcpd enable inside
logging asdm informational
```

Note For testing purposes, you can allow ping from inside to outside by enabling ICMP inspection. Add the following commands to the default configuration:

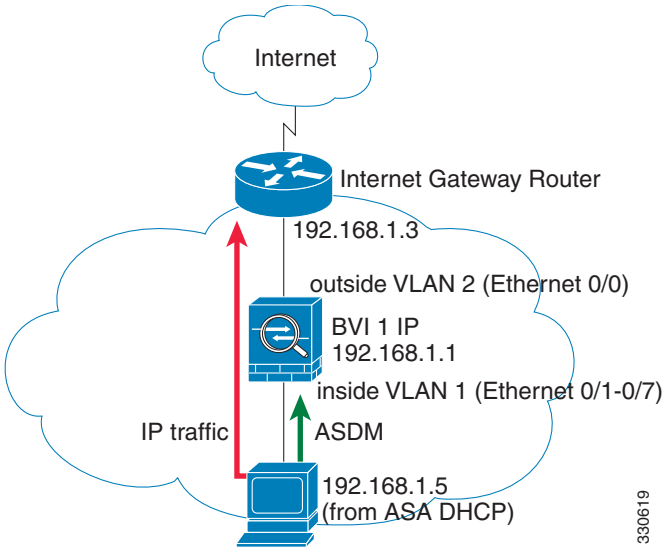
```
policy-map global_policy
   class inspection_default
      inspect icmp
```

ASA 5505 Transparent Mode Sample Configuration

When you change the mode to transparent mode, the configuration is erased. You can copy and paste the following sample configuration at the CLI to get started. This configuration uses the default configuration as a starting point. Note the following areas you may need to modify:

- IP addresses—The IP addresses configured should be changed to match the network to which you are connecting.
- Static routes—For some kinds of traffic, static routes are required. See the "MAC Address vs. Route Lookups" section on page 6-4.

Figure 3-2 ASA 5505 Transparent Mode



```
firewall transparent
interface Ethernet 0/0
   switchport access vlan 2
   no shutdown
interface Ethernet 0/1
   switchport access vlan 1
   no shutdown
interface Ethernet 0/2
   switchport access vlan 1
   no shutdown
interface Ethernet 0/3
   switchport access vlan 1
   no shutdown
interface Ethernet 0/4
   switchport access vlan 1
   no shutdown
interface Ethernet 0/5
   switchport access vlan 1
   no shutdown
interface Ethernet 0/6
   switchport access vlan 1
   no shutdown
interface Ethernet 0/7
   switchport access vlan 1
   no shutdown
interface bvi 1
   ip address 192.168.1.1 255.255.255.0
interface vlan2
   nameif outside
   security-level 0
   bridge-group 1
   no shutdown
interface vlan1
   nameif inside
   security-level 100
   bridge-group 1
   no shutdown
http server enable
http 192.168.1.0 255.255.255.0 inside
dhcpd address 192.168.1.5-192.168.1.254 inside
```

```
dhcpd enable inside
```

Note For testing purposes, you can allow ping from inside to outside by enabling ICMP inspection. Add the following commands to the sample configuration:

```
policy-map global_policy
   class inspection_default
      inspect icmp
```

ASA 5510 and Higher Default Configuration

The default factory configuration for the ASA 5510 and higher configures the following:

- Management interface—Management 0/0 (management).
- IP address—The management address is 192.168.1.1/24.
- DHCP server—Enabled for management hosts, so a PC connecting to the management interface receives an address between 192.168.1.2 and 192.168.1.254.
- ASDM access—Management hosts allowed.

The configuration consists of the following commands:

```
interface management 0/0
   ip address 192.168.1.1 255.255.255.0
   nameif management
   security-level 100
   no shutdown
asdm logging informational 100
asdm history enable
http server enable
http 192.168.1.0 255.255.255.0 management
dhcpd address 192.168.1.2-192.168.1.254 management
dhcpd lease 3600
dhcpd ping_timeout 750
dhcpd enable management
```

Getting Started with the Configuration

To configure and monitor the ASA, perform the following steps:

Step 1 For initial configuration using the Startup Wizard, choose **Wizards > Startup Wizard**.

Step 2 To use the IPsec VPN Wizard to configure IPsec VPN connections, choose **Wizards > IPsec VPN Wizard** and complete each screen that appears.

Step 3 To use the SSL VPN Wizard to configure SSL VPN connections, choose **Wizards > SSL VPN Wizard** and complete each screen that appears.

Step 4 To configure high availability and scalability settings, choose **Wizards > High Availability and Scalability Wizard**.

Step 5 To use the Packet Capture Wizard to configure packet capture, choose **Wizards > Packet Capture Wizard**.

Step 6 To display different colors and styles available in the ASDM GUI, choose **View > Office Look and Feel**.

Step 7 To configure features, click the **Configuration** button on the toolbar and then click one of the feature buttons to display the associated configuration pane.

Note If the Configuration screen is blank, click **Refresh** on the toolbar to display the screen content.

Step 8 To monitor the ASA, click the **Monitoring** button on the toolbar and then click a feature button to display the associated monitoring pane.

Note ASDM supports up to a maximum of a 512 KB configuration. If you exceed this amount, you may experience performance issues.

Using the Command Line Interface Tool in ASDM

This section tells how to enter commands using ASDM, and how to work with the CLI. This section includes the following topics:

- Using the Command Line Interface Tool, page 3-25
- Handling Command Errors, page 3-26
- Using Interactive Commands, page 3-26
- Avoiding Conflicts with Other Administrators, page 3-26
- Showing Commands Ignored by ASDM on the Device, page 3-26

Using the Command Line Interface Tool

This feature provides a text-based tool for sending commands to the ASA and viewing the results.

The commands you can enter with the CLI tool depend on your user privileges. See the "Information About Authorization" section on page 46-2 for more information. Review your privilege level in the status bar at the bottom of the main ASDM application window to ensure that you have the required privileges to execute privileged-level CLI commands.

Note Commands entered via the ASDM CLI tool might function differently from those entered through a terminal connection to the ASA.

To use the CLI tool, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Command Line Interface**.

The Command Line Interface dialog box appears.

Step 2 Choose the type of command (single line or multiple line) that you want, and then choose the command from the drop-down list, or type it in the field provided.

Step 3 Click **Send** to execute the command.

Step 4 To enter a new command, click **Clear Response**, and then choose (or type) another command to execute.

Step 5 Check the **Enable context-sensitive help (?)** check box to provide context-sensitive help for this feature. Uncheck this check box to disable the context-sensitive help.

Step 6 After you have closed the Command Line Interface dialog box, if you changed the configuration, click **Refresh** to view the changes in ASDM.

Handling Command Errors

If an error occurs because you entered an incorrect command, the incorrect command is skipped and the remaining commands are processed. A message appears in the Response area to inform you whether or not any error occurred, as well as other related information.

Note ASDM supports almost all CLI commands. See the command reference for a list of commands.

Using Interactive Commands

Interactive commands are not supported in the CLI tool. To use these commands in ASDM, use the **noconfirm** keyword if available, as shown in the following command:

```
crypto key generate rsa modulus 1024 noconfirm
```

Avoiding Conflicts with Other Administrators

Multiple administrative users can update the running configuration of the ASA. Before using the ASDM CLI tool to make configuration changes, check for other active administrative sessions. If more than one user is configuring the ASA at the same time, the most recent changes take effect.

To view other administrative sessions that are currently active on the same ASA, choose **Monitoring > Properties > Device Access**.

Showing Commands Ignored by ASDM on the Device

This feature lets you show the list of commands that ASDM does not support. Typically, ASDM ignores them. ASDM does not change or remove these commands from your running configuration. See the "Unsupported Commands" section on page 4-34 for more information.

To display the list of unsupported commands for ASDM, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Show Commands Ignored by ASDM on Device**.

Step 2 Click **OK** when you are done.

Applying Configuration Changes to Connections

When you make security policy changes to the configuration, all *new* connections use the new security policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. **show** command output for old connections reflect the old configuration, and in some cases will not include data about the old connections.

For example, if you remove a QoS **service-policy** from an interface, then re-add a modified version, then the **show service-policy** command only displays QoS counters associated with new connections that match the new service policy; existing connections on the old policy no longer show in the command output.

To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy.

To disconnect connections, enter one of the following commands.

Detailed Steps

Command	Purpose
clear local-host [*ip_address*] [**all**] **Example:** `hostname(config)# clear local-host all`	This command reinitializes per-client run-time states such as connection limits and embryonic limits. As a result, this command removes any connection that uses those limits. See the **show local-host all** command to view all current connections per host. With no arguments, this command clears all affected through-the-box connections. To also clear to-the-box connections (including your current management session), use the **all** keyword. To clear connections to and from a particular IP address, use the *ip_address* argument.
clear conn [**all**] [**protocol** {**tcp** | **udp**}] [**address** *src_ip*[**-***src_ip*] [**netmask** *mask*]] [**port** *src_port*[**-***src_port*]] [**address** *dest_ip*[**-***dest_ip*] [**netmask** *mask*]] [**port** *dest_port*[**-***dest_port*]] **Example:** `hostname(config)# clear conn all`	This command terminates connections in any state. See the **show conn** command to view all current connections. With no arguments, this command clears all through-the-box connections. To also clear to-the-box connections (including your current management session), use the **all** keyword. To clear specific connections based on the source IP address, destination IP address, port, and/or protocol, you can specify the desired options.

Using ASDM

This chapter describes how to use the ASDM user interface, and includes the following sections:

- Information About the ASDM User Interface, page 4-1
- Navigating in the ASDM User Interface, page 4-3
- Menus, page 4-4
- Toolbar, page 4-10
- ASDM Assistant, page 4-10
- Status Bar, page 4-11
- Device List, page 4-11
- Common Buttons, page 4-12
- Keyboard Shortcuts, page 4-12
- Find Function, page 4-14
- Enabling Extended Screen Reader Support, page 4-16
- Organizational Folder, page 4-16
- About the Help Window, page 4-16
- Home Pane (Single Mode and Context), page 4-17
- Home Pane (System), page 4-31
- Defining ASDM Preferences, page 4-32
- Using the ASDM Assistant, page 4-33
- Enabling History Metrics, page 4-34
- Unsupported Commands, page 4-34

Information About the ASDM User Interface

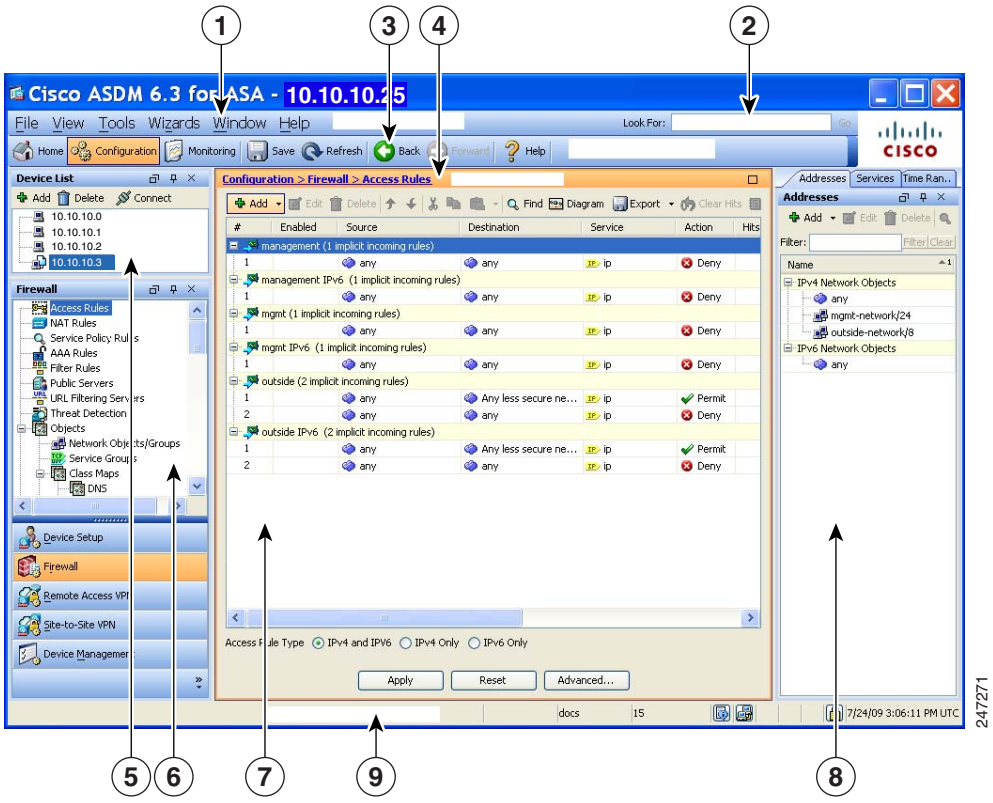
The ASDM user interface is designed to provide easy access to the many features that the ASA supports. The ASDM user interface includes the following elements:

- A menu bar that provides quick access to files, tools, wizards, and help. Many menu items also have keyboard shortcuts.
- A toolbar that enables you to navigate ASDM. From the toolbar you can access the home, configuration, and monitoring panes. You can also get help and navigate between panes.

- A dockable left Navigation pane to move through the Configuration and Monitoring panes. You can click one of the three buttons in the header to maximize or restore this pane, make it a floating pane that you can move, hide it, or close it. To access the Configuration and Monitoring panes, you can do one of the following:
  - Click links on the left side of the application window in the left Navigation pane. The Content pane then displays the path (for example, Configuration > Device Setup > Startup Wizard) in the title bar of the selected pane.
  - If you know the exact path, you can type it directly into the title bar of the Content pane on the right side of the application window, without clicking any links in the left Navigation pane.
- A maximize and restore button in the right corner of the Content pane that lets you hide and show the left Navigation pane.
- A dockable device list pane with a list of devices that you can access through ASDM. You can click one of the three buttons in the header to maximize or restore this pane, make it a floating pane that you can move, hide it, or close it. For more information, see the "Device List" section on page 4-11.
- A status bar that shows the time, connection status, user, memory status, running configuration status, privilege level, and SSL status at the bottom of the application window.
- A left Navigation pane that shows various objects that you can use in the rules tables when you create access rules, NAT rules, AAA rules, filter rules, and service rules. The tab titles within the pane change according to the feature that you are viewing. In addition, the ASDM Assistant appears in this pane.

Figure 4-1 on page 4-2 shows the elements of the ASDM user interface.

Figure 4-1 ASDM User Interface



Legend

GUI Element	Description
1	Menu Bar
2	Search Field
3	Toolbar
4	Navigation Path
5	Device List Pane
6	Left Navigation Pane
7	Content Pane
8	Right Navigation Pane
9	Status Bar

Note Tool tips have been added for various parts of the GUI, including Wizards, the Configuration and Monitoring panes, and the Status Bar. To view tool tips, hover your mouse over a specific user interface element, such as an icon in the status bar.

Navigating in the ASDM User Interface

To move efficiently throughout the ASDM user interface, you may use a combination of menus, the toolbar, dockable panes, and the left and right Navigation panes, which are described in the previous section. The available functions appear in a list of buttons below the Device List pane. An example list could include the following function buttons:

- Device Setup
- Firewall
- Trend Micro Content Security
- Botnet Traffic Filter
- Remote Access VPN
- Site to Site VPN
- Device Management

The list of function buttons that appears is based on the licensed features that you have purchased. Click each button to access the first pane in the selected function for either the Configuration view or the Monitoring view. The function buttons are not available in the Home view.

To change the display of function buttons, perform the following steps:

Step 1 Choose the drop-down list below the last function button to display a context menu.

Step 2 Choose one of the following options:

- To show more buttons, click **Show More Buttons**.
- To show fewer buttons, click **Show Fewer Buttons**.

- To add or remove buttons, click **Add or Remove Buttons**, then click the button to add or remove from the list that appears.
- To change the sequence of the buttons, choose **Option** to display the Option dialog box, which displays a list of the buttons in their current order. Then choose one of the following:
  - To move up a button in the list, click **Move Up**.
  - To move down a button in the list, click **Move Down**.
  - To return the order of the items in the list to the default setting, click **Reset**.

Step 3 To save your settings and close this dialog box, click **OK**.

Menus

You can access ASDM menus using the mouse or keyboard. For information about accessing the menu bar from the keyboard, see the "Keyboard Shortcuts" section on page 4-12.

ASDM has the following menus:

- File Menu, page 4-4
- View Menu, page 4-5
- Tools Menu, page 4-6
- Wizards Menu, page 4-8
- Window Menu, page 4-9
- Help Menu

File Menu

The File menu lets you manage ASA configurations. The following table lists the tasks that you can perform using the File menu.

File Menu Item	Description
Refresh ASDM with the Running Configuration on the Device	Loads a copy of the running configuration into ASDM.
Refresh	Ensures that ASDM has a current copy of the running configuration.
Reset Device to the Factory Default Configuration	Restores the configuration to the factory default. See the "Restoring the Factory Default Configuration" section on page 3-18 for more information.
Show Running Configuration in New Window	Displays the current running configuration in a new window.
Save Running Configuration to Flash	Writes a copy of the running configuration to flash memory.

File Menu Item	Description
Save Running Configuration to TFTP Server	Stores a copy of the current running configuration file on a TFTP server. See the "Saving the Running Configuration to a TFTP Server" section on page 101-27 for more information.
Save Running Configuration to Standby Unit	Sends a copy of the running configuration file on the primary unit to the running configuration of a failover standby unit.
Save Internal Log Buffer to Flash	Saves the internal log buffer to flash memory.
Print	Prints the current page. We recommend landscape page orientation when you print rules. When you use Internet Explorer, permission to print was already granted when you originally accepted the signed applet.
Clear ASDM Cache	Removes local ASDM images. ASDM downloads images locally when you connect to ASDM.
Clear ASDM Password Cache	Removes the password cache if you have defined a new password and still have a existing password that is different than the new password.
Clear Internal Log Buffer	Empties the syslog message buffer.
Exit	Closes ASDM.

View Menu

The View menu lets you display various parts of the ASDM user interface. Certain items are dependent on the current view. You cannot select items that cannot be displayed in the current view. The following table lists the tasks that you can perform using the View menu.

View Menu Item	Description
Home	Displays the Home view.
Configuration	Displays the Configuration view.
Monitoring	Displays the Monitoring view.
Device List	Display a list of devices in a dockable pane. See the "Device List" section on page 4-11 for more information.
Navigation	Shows and hides the display of the Navigation pane in the Configuration and Monitoring views.
ASDM Assistant	Searches and finds useful ASDM procedural help about certain tasks. See the "ASDM Assistant" section on page 4-10 for more information.
SIP Details	Shows and hides voice network information.
Latest ASDM Syslog Messages	Shows and hides the display of the Latest ASDM Syslog Messages pane in the Home view. This pane is only available in the Home view. If you do not have sufficient memory to upgrade to the most current release, syslog message %ASA-1-211004 is generated, indicating what the installed memory is and what the required memory is. This message reappears every 24 hours until the memory is upgraded.

View Menu Item	Description
Addresses	Shows and hides the display of the Addresses pane. The Addresses pane is only available for the Access Rules, NAT Rules, Service Policy Rules, AAA Rules, and Filter Rules panes in the Configuration view.
Services	Shows and hides the display of the Services pane. The Services pane is only available for the Access Rules, NAT Rules, Service Policy Rules, AAA Rules, and Filter Rules panes in the Configuration view.
Time Ranges	Shows and hides the display of the Time Ranges pane. The Time Ranges pane is only available for the Access Rules, Service Policy Rules, AAA Rules, and Filter Rules panes in the Configuration view.
Global Pools	Shows and hides the display of the Global Pools pane. The Global Pools pane is only available for the NAT Rules pane in the Configuration view.
Find in ASDM	Locates an item for which you are searching, such as a feature or the ASDM Assistant.
Back	Returns to the previous pane. See the "Common Buttons" section on page 4-12 for more information.
Forward	Goes to the next pane previously visited. See the "Common Buttons" section on page 4-12 for more information.
Reset Layout	Returns the layout to the default configuration.
Office Look and Feel	Changes the screen fonts and colors to the Microsoft Office settings.

Tools Menu

The Tools menu provides you with the following series of tools to use in ASDM.

Tools Menu Item	Description
Command Line Interface	Sends commands to the ASA and view the results. See the "Using the Command Line Interface Tool in ASDM" section on page 3-25 for more information.
Show Commands Ignored by ASDM on Device	Displays unsupported commands that have been ignored by ASDM. See the "Showing Commands Ignored by ASDM on the Device" section on page 3-26 for more information.
Packet Tracer	Traces a packet from a specified source address and interface to a destination. You can specify the protocol and port of any type of data and view the lifespan of a packet, with detailed information about actions taken on it. See the "Tracing Packets with Packet Tracer" section on page 73-7 for more information.

Tools Menu Item	Description
Ping	Verifies the configuration and operation of the ASA and surrounding communications links, as well as performs basic testing of other network devices. See the "Verifying ASA Configuration and Operation, and Testing Interfaces Using Ping" section on page 73-3 for more information.
Traceroute	Determines the route that packets will take to their destination. See the "Determining Packet Routing with Traceroute" section on page 73-6 for more information.
File Management	Views, moves, copies, and deletes files stored in flash memory. You can also create a directory in flash memory. See the "Managing Files" section on page 101-14 for more information. You can also transfer files between various file systems, including TFTP, flash memory, and your local PC. See the "Transferring Files" section on page 101-17 for more information.
Upgrade Software from Local Computer	Uploads an ASA image, ASDM image, or another image on your PC to flash memory. See the "Managing Files" section on page 101-14 dialog box for more information.
Check for ASA/ASDM Updates	Upgrades ASA software and ASDM software through a wizard. See the "The Upgrade Software from Cisco.com Wizard lets you automatically upgrade the ASDM and ASA to more current versions." section on page 101-4 for more information.
Backup Configurations	Backs up the ASA configuration, a Cisco Secure Desktop image, and SSL VPN Client images and profiles. See the "Backing Up Configurations" section on page 101-21 for more information.
Restore Configurations	Restores the ASA configuration, a Cisco Secure Desktop image, and SSL VPN Client images and profiles. See the "Restoring Configurations" section on page 101-25 for more information.
System Reload	Restarts the ASDM and reload the saved configuration into memory. See the "Scheduling a System Restart" section on page 101-27 for more information.
Administrator's Alerts to Clientless SSL VPN Users	Enables an administrator to send an alert message to clientless SSL VPN users. See the "Sending an Administrator's Alert to Clientless SSL VPN Users" section on page 91-149 for more information.
Preferences	Changes the behavior of specified ASDM functions between sessions. See the "Defining ASDM Preferences" section on page 4-32 for more information.
ASDM Java Console	Shows the Java console. See the "Viewing and Copying Logged Entries with the ASDM Java Console" section on page 96-13 for more information.

Wizards Menu

The Wizards menu lets you run a wizard to configure multiple features. The following table lists the available Wizards and their features.

Wizards Menu Item	Description
Startup Wizard	Guides you, step-by-step, through the initial configuration of the ASA. For more information, see Chapter 7, "Using the Startup Wizard.".
IPsec VPN Wizard	Enables you to configure an IPsec VPN policy on the ASA. For more information, see Chapter 85, "VPN Wizards.".
SSL VPN Wizard	Enables you to configure an SSL VPN policy on the ASA. For more information, see Chapter 85, "VPN Wizards.".
High Availability and Scalability Wizard	Allows you to configure failover: VPN cluster load balancing, or ASA clustering on the ASA. For more information, see: • Active/Standby failover—See the "Using the High Availability and Scalability Wizard" section on page 12-7. • Active/Active failover—See the "Task Flow for Using the High Availability and Scalability Wizard" section on page 13-8. • VPN cluster load balancing—See the "Configuring VPN Cluster Load Balancing with the High Availability and Scalability Wizard" section on page 86-25. • ASA clustering—See the "Adding or Joining an ASA Cluster" section on page 10-44.
Unified Communication Wizard	Enables you to configure unified communication features, such as an IP phone, on the ASA. For more information, see Chapter 64, "Information about the Cisco Unified Communication Wizard.".
Packet Capture Wizard	Allows you to configure packet capture on the ASA. The wizard runs one packet capture on each ingress and egress interface. After you run the capture, you can save it on your computer, and then examine and analyze the capture with a packet analyzer. For more information, see the "Configuring and Running Captures with the Packet Capture Wizard" section on page 102-1.

Window Menu

The Window menu enables you to move between ASDM windows. The active window appears as the selected window.

Help Menu

The Help menu provides links to online Help, as well as information about ASDM and the ASA. The following table lists the tasks that you can perform using the Help menu.

Help Menu Items	Description
Help Topics	Opens a new browser window with help organized by contents, window name, and indexed in the left frame. Use these methods to find help for any topic, or search using the Search tab.
Help for Current Screen	Opens context-sensitive help about that screen. The wizard runs the screen, pane, or dialog box that is currently open. Alternatively, you can also click the question mark (**?**) help icon.
Release Notes	Opens the most current version of the *ASDM release notes* on Cisco.com. The release notes contain the most current information about ASDM software and hardware requirements, and the most current information about changes in the software.
ASDM Assistant	Opens the ASDM Assistant, which lets you search downloadable content from Cisco.com, with details about performing certain tasks.
About Cisco Adaptive Security Appliance (ASA)	Displays information about the ASA, including the software version, hardware set, configuration file loaded at startup, and software image loaded at startup. This information is helpful in troubleshooting.
About Cisco ASDM 6.3	Displays information about ASDM such as the software version, hostname, privilege level, operating system, device type, and Java version.

Toolbar

The Toolbar below the menus provides access to the Home view, Configuration view, and Monitoring view. It also lets you choose between the system and security contexts in multiple context mode, and provides navigation and other commonly used features. The following table lists the tasks that you can perform using the Toolbar.

Toolbar Button	Description
System/Contexts	Shows which context you are in. To open the context list in the left-hand pane, click the down arrow, then click the up arrow to restore the context drop-down list. After you have expanded this list, click the left arrow to collapse the pane, then the right arrow to restore the pane. To manage the system, choose **System** from the drop-down list. To manage the context, choose one from the drop-down list.
Home	Displays the Home pane, which lets you view important information about your ASA such as the status of your interfaces, the version you are running, licensing information, and performance. See the "Home Pane (Single Mode and Context)" section on page 4-17 for more information. In multiple mode, the system does not have a Home pane.
Configuration	Configures the ASA. Click a function button in the left Navigation pane to configure that function.
Monitoring	Monitors the ASA. Click a function button in the left Navigation pane to configure that function.
Back	Returns to the last pane of ASDM that you visited.
Forward	Goes forward to the last pane of ASDM that you visited.
Search	Searches for a feature in ASDM. The Search function looks through the titles of each pane and presents you with a list of matches, and gives you a hyperlink directly to that pane. If you need to switch quickly between two different panes that you found, click **Back** or **Forward**. See the "ASDM Assistant" section on page 4-10 for more information.
Refresh	Refreshes ASDM with the current running configuration, except for graphs in any of the Monitoring panes.
Save	Saves the running configuration to the startup configuration for write-accessible contexts only.
Help	Shows context-sensitive help for the screen that is currently open.

ASDM Assistant

The ASDM Assistant lets you search and view useful ASDM procedural help about certain tasks. This feature is available in routed and transparent modes, and in the single and system contexts.

To access information, choose **View > ASDM Assistant > How Do I?** or enter a search request from the Look For field in the menu bar. From the Find drop-down list, choose **How Do I?** to begin the search.

To use the ASDM Assistant, perform the following steps:

Step 1 In the main ASDM application window, choose **View > ASDM Assistant**.

The ASDM Assistant pane appears.

Step 2 In the Search field, enter the information that you want to find, and click **Go**.

The requested information appears in the Search Results pane.

Step 3 Click any links that appear in the Search Results and Features areas to obtain more details.

Status Bar

The status bar appears at the bottom of the ASDM window. The following table lists the areas shown from left to right.

Area	Description
Status	The status of the configuration (for example, "Device configuration loaded successfully.")
Failover	The status of the failover unit, either active or standby.
User Name	The username of the ASDM user. If you logged in without a username, the username is "admin."
User Privilege	The privilege of the ASDM user.
Commands Ignored by ASDM	Click the icon to show a list of commands from your configuration that ASDM did not process. These commands will not be removed from the configuration.
Connection to Device	The ASDM connection status to the ASA. See the "Connection to Device" section on page 4-11 for more information.
Syslog Connection	The syslog connection is up, and the ASA is being monitored.
SSL Secure	The connection to ASDM is secure because it uses SSL.
Time	The time that is set on the ASA.

Connection to Device

ASDM maintains a constant connection to the ASA to maintain up-to-date Monitoring and Home pane data. This dialog box shows the status of the connection. When you make a configuration change, ASDM opens a second connection for the duration of the configuration, and then closes it; however, this dialog box does not represent the second connection.

Device List

The device list is a dockable pane. You can click one of the three buttons in the header to maximize or restore this pane, make it a floating pane that you can move, hide it, or close it. This pane is available in the Home, Configuration, Monitoring, and System views. You can use this pane to switch to another device; however, that device must run the same version of ASDM that you are currently running. To display the pane fully, you must have at least two devices listed. This feature is available in routed and transparent modes, and in the single, multiple, and system contexts.

To use this pane to connect to another device, perform the following steps:

Step 1 Click **Add** to add another device to the list.

The Add Device dialog box appears.

Step 2 In the Device/IP Address/Name field, type the device name or IP address of the device, and then click **OK**.

Step 3 Click **Delete** to remove a selected device from the list.

Step 4 Click **Connect** to connect to another device.

The Enter Network Password dialog box appears.

Step 5 Type your username and password in the applicable fields, and then click **Login**.

Common Buttons

Many ASDM panes include buttons that are listed in the following table. Click the applicable button to complete the desired task:

Button	Description
Apply	Sends changes made in ASDM to the ASA and applies them to the running configuration.
Save	Writes a copy of the running configuration to flash memory.
Reset	Discards changes and reverts to the information displayed before changes were made or the last time that you clicked Refresh or Apply. After you click **Reset**, click **Refresh** to make sure that information from the current running configuration appears.
Restore Default	Clears the selected settings and returns to the default settings.
Cancel	Discards changes and returns to the previous pane.
Enable	Displays read-only statistics for a feature.
Close	Closes an open dialog box.
Clear	Remove information from a field, or remove a check from a check box.
Back	Returns to the previous pane.
Forward	Goes to the next pane.
Help	Displays help for the selected pane or dialog box.

Keyboard Shortcuts

You can use the keyboard to navigate the ASDM user interface.

Table 4-1 lists the keyboard shortcuts you can use to move across the three main areas of the ASDM user interface.

Table 4-1 Keyboard Shortcuts Within the Main Window

To display the	Windows/Linux	MacOS
Home Pane	Ctrl+H	Shift+Command+H
Configuration Pane	Ctrl+G	Shift+Command+G
Monitoring Pane	Ctrl+M	Shift+Command+M
Help	F1	Command+?
Back	Alt+Left Arrow	Command+[
Forward	Alt+Rightarrow	Command+]
Refresh the display	F5	Command+R
Cut	Ctrl+X	Command+X
Copy	Ctrl+C	Command+C
Paste	Ctrl+V	Command+V
Save the configuration	Ctrl+S	Command+S
Popup menus	Shift+F10	—
Close a secondary window	Alt+F4	Command+W
Find	Ctrl+F	Command+F
Exit	Alt+F4	Command+Q
Exit a table or text area	Ctrl_Shift or Ctrl+Shift+Tab	Ctril+Shift or Ctrl+Shift+Tab

Table 4-2 lists the keyboard shortcut you can use to navigate within a pane.

Table 4-2 Keyboard Shortcuts Within a Pane

To move the focus to the	Press
Next field	Tab
Previous field	Shift+Tab

Previous Menu	Left Arrow
Next Menu Option	Down Arrow
Previous Menu Option	Up Arrow
Selected Menu Option	Enter

Find Function

This section includes the following topics:

- Using the Find Function in Most ASDM Panes, page 4-14d
- Using the Find Function in the ACL Manager Pane, page 4-15

Using the Find Function in Most ASDM Panes

Some ASDM panes contain tables with many elements. To make it easier for you to search, highlight, and then edit a particular entry, several ASDM panes have a find function that allows you to search on objects within those panes.

To perform a search, you can type a phrase into the Find field to search on all columns within any given pane. The phrase can contain the wild card characters “*” and “?”. The * matches one or more characters, and ? matches one character. The up and down arrows to the right of the Find field locate the next (up) or previous (down) occurrence of the phrase. Check the Match Case check box to find entries with the exact uppercase and lowercase characters that you enter.

For example, entering B*ton-L* might return the following matches:

```
Boston-LA, Boston-Lisbon, Boston-London
```

Entering Bo?ton might return the following matches:

```
Boston, Bolton
```

The following list shows the ASDM panes in which you can use the find function:

- AAA Server Groups panes
- ACL Manager panes—The find function in the ACL Manager pane differs from that of the other panes. See the "Using the Find Function in the ACL Manager Pane" section on page 4-15 for more information.
- Certificate-to-Conn Profile Maps-Rules pane
- DAP panes
- Identity Certificates pane
- IKE Policies pane
- IPSec Proposals (Transform Sets) pane
- Local User panes
- Portal-Bookmark pane
- Portal-Customization panes
- Portal-Port Forwarding pane
- CA Certificates pane
- Portal-Smart Tunnels pane
- Portal-Web Contents pane
- VPN Connection Profiles panes
- VPN Group Policies panes

Using the Find Function in the ACL Manager Pane

Because ACLs and ACEs contain many elements of different types, the find function in the ACL Manager pane allows for a more targeted search than the find function in other panes.

To find elements within the ACL Manager pane, perform the following steps:

Step 1 In the ACL Manager pane, click **Find**.

Step 2 In the Filter field, choose one of the following options from the drop-down list:

- Source—The search includes a source IP address of a the network object group, interface IP, or any address from which traffic is permitted or denied. You specify this address in Step 4.
- Destination—The search includes a destination IP address (host or network) that is permitted or denied to send traffic to the IP addresses listed in the Source section. You specify this address in Step 4.
- Source or Destination—The search includes either a source or a destination address that you specify in Step 4.
- Service—The search includes a service group or predefined service policy that you specify in Step 4.

- Query—When you choose Query from the drop-down list, click **Query** to specify a detailed search by all four of the preceding options: Source, Destination, Source or Destination, and Service.

Step 3 In the second field, choose one of the following options from the drop-down list:

- is—Specifies an exact match of the detail that you enter in Step 4.
- contains—Specifies to search for ACLs or ACEs that contain, but are not limited to, the detail you enter in Step 4.

Step 4 In the third field, enter specific criteria about ACLs or ACEs that you would like to find, or click the browse button to search for key elements in your ACL/ACE configuration.

Step 5 Click **Filter** to perform the search.

The ASDM find function returns a list of ACLs and ACEs that contain your specified criteria.

Step 6 Click **Clear** to clear the list of found ACLs and ACEs.

Step 7 Click the red **x** to close the find function box.

Enabling Extended Screen Reader Support

By default, labels and descriptions are not included in tab order when you press the Tab key to navigate a pane. Some screen readers, such as JAWS, only read screen objects that have the focus. You can include the labels and descriptions in the tab order by enabling extended screen reader support.

To enable extended screen reader support, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Preferences**.

The Preferences dialog box appears.

Step 2 On the General tab, check the **Enable screen reader support** check box.

Step 3 Click **OK**.

Step 4 Restart ASDM to activate screen reader support.

Organizational Folder

Some folders in the navigation pane for the configuration and monitoring views do not have associated configuration or monitoring panes. These folders are used to organize related configuration and monitoring tasks. Clicking these folders displays a list of sub-items in the right Navigation pane. You can click the name of a sub-item to go to that item.

About the Help Window

This section includes the following topics:

- Header Buttons, page 4-17
- Browser Window, page 4-17

Header Buttons

To obtain the information that you need, click the applicable button listed in the following table.

Button	Description
About ASDM	Displays information about ASDM, including the hostname, version number, device type, ASA software version number, privilege level, username, and operating system being used.
Search	Searches for information among online help topics.
Using Help	Describes the most efficient methods for using online help.
Glossary	Lists terms found in ASDM and ASAs.
Contents	Displays a table of contents.
Screens	Lists help files by screen name.
Index	Displays an index of help topics found in ASDM online help.

Browser Window

When you open help and a help page is already open, the new help page will appear in the same browser window. If no help page is open, then the help page will appear in a new browser window.

When you open help and Netscape Communicator is the default browser, the help page will appear in a new browser window. If Internet Explorer is the default browser, the help page may appear either in the last-visited browser window or in a new browser window, according to your browser settings. You can control this behavior in Internet Explorer by choosing **Tools > Internet Options > Advanced > Reuse windows for launching shortcuts**.

Home Pane (Single Mode and Context)

The ASDM Home pane lets you view important information about your ASA. Status information in the home pane is updated every ten seconds. This pane usually has two tabs: Device Dashboard and Firewall Dashboard.

If you have a CSC SSM installed in your ASA, the Content Security tab also appears in the Home pane. The additional tab displays status information about the CSC SSM software.

If you have IPS software installed in your ASA, the Intrusion Prevention tab also appears in the Home pane. The additional tab displays status information about the IPS software.

This section includes the following topics:

- Device Dashboard Tab, page 4-18
- Firewall Dashboard Tab, page 4-22
- Cluster Dashboard Tab, page 4-25
- Cluster Firewall Dashboard Tab, page 4-26
- Content Security Tab, page 4-27
- Intrusion Prevention Tab, page 4-28
- ASA CX Status Tab, page 4-30

Device Dashboard Tab

The Device Dashboard tab lets you view, at a glance, important information about your ASA, such as the status of your interfaces, the version you are running, licensing information, and performance.

Figure 4-2 shows the elements of the Device Dashboard tab.

Figure 4-2 Device Dashboard Tab

Legend

GUI Element	Description
1	Device Information Pane, page 4-19
2	Interface Status Pane, page 4-20
3	VPN Sessions Pane, page 4-20
4	Traffic Status Pane, page 4-20
5	System Resources Status Pane, page 4-20
6	Traffic Status Pane, page 4-20
See Figure 4-3	Latest ASDM Syslog Messages Pane, page 4-20

Device Information Pane

The Device Information pane includes two tabs that show device information: General tab and License tab. Under the General tab you have access to the Environment Status button, which provides an at-a-glance view of the system health:

- General Tab, page 4-19
- License Tab, page 4-19

General Tab

This tab shows basic information about the ASA:

- Host name—Shows the hostname of the device.
- ASA version—Lists the version of ASA software that is running on the device.
- ASDM version—Lists the version of ASDM software that is running on the device.
- Firewall mode—Shows the firewall mode in which the device is running.
- Total flash—Displays the total RAM that is currently being used.
- ASA Cluster Role—When you enable clustering, shows the role of this unit, either Master or Slave.
- Device uptime—Shows the time in which the device has been operational since the latest software upload.
- Context mode—Shows the context mode in which the device is running.
- Total Memory—Shows the DRAM installed on the ASA.
- Environment status—Shows the system health. The ASA 5580 and 5585 chassis models provide a set of hardware statistics that is available by clicking the plus sign (+) to the right of the Environment Status label in the General tab. You can see how many power supplies are installed, track the operational status of the fan and power supply modules, and track the temperatures of the CPUs and the ambient temperature of the system.

  In general, the Environment Status button provides an at-a-glance view of the system health. If all monitored hardware components within the system are operating within normal ranges, the plus sign (+) button shows OK in green. Conversely, if any one component within the hardware system is operating outside of normal ranges, the plus sign (+) button turns into a red circle to show Critical status and to indicate that a hardware component requires immediate attention.

  For more information about specific hardware statistics, see the hardware guide for your particular device.

Note If you do not have enough memory to upgrade to the most current release of the ASA, the Memory Insufficient Warning dialog box appears. Follow the directions that appear in this dialog box to continue using the ASA and ASDM in a supported manner. Click **OK** to close this dialog box.

License Tab

This tab shows a subset of licensed features. To view detailed license information, or to enter a new activation key, click **More Licenses**; the Configuration > Device Management > Licensing > Activation Key pane appears. See Chapter 5, “Managing Feature Licenses.”

Interface Status Pane

This pane shows the status of each interface. If you select an interface row, the input and output throughput in Kbps displays below the table.

VPN Sessions Pane

This pane shows the VPN tunnel status. Click **Details** to go to the Monitoring > VPN > VPN Statistics > Sessions pane.

Failover Status Pane

This pane shows the failover status.

Click **Configure** to start the High Availability and Scalability Wizard. After you have completed the wizard, the failover configuration status (either Active/Active or Active/Standby) appears.

If failover is configured, click **Details** to open the Monitoring > Properties > Failover > Status pane.

System Resources Status Pane

This pane shows CPU and memory usage statistics.

Traffic Status Pane

This pane shows graphs for connections per second for all interfaces and for the traffic throughput of the lowest security interface.

When your configuration contains multiple lowest security level interfaces, and any one of them is named "outside," then that interface is used for the traffic throughput graphs. Otherwise, ASDM picks the first interface from the alphabetical list of lowest security level interfaces.

Latest ASDM Syslog Messages Pane

This pane shows the most recent system messages generated by the ASA, up to a maximum of 100 messages. If logging is disabled, click **Enable Logging** to enable logging.

Figure 4-3 shows the elements of the Latest ASDM Syslog Messages pane.

Figure 4-3 Latest ASDM Syslog Messages Pane

Legend

GUI Element	Description
1	To resize the pane, drag the divider up or down.
2	Expands the pane. To return the pane to the default size, click the double-square icon.
3	Makes a floating pane. To dock the pane, click the docked pane icon.
4	Enables or disables Auto-hide. When Auto-hide is enabled, move your cursor over the Latest ASDM Syslog Messages button in the left, bottom corner and the pane displays. Move your cursor away from the pane, and it disappears.
5	Closes the pane. To show the pane, choose **View Latest ASDM Syslog Messages.**
6	To continue updating the display of syslog messages, click the green icon on the right-hand side.
7	To stop updating the display of syslog messages, click the red icon on the right-hand side.
8	To open the Logging Filters pane, click the filters icon on the right-hand side.

- To clear the current messages, right-click an event and click **Clear Content**.
- To save the current messages to a file on your PC, right-click an event and click **Save Content**.
- To copy the current content, right-click an event and click **Copy**.
- To change the background and foreground colors of syslog messages according to their severity, right-click an event and click **Color Settings**.

Firewall Dashboard Tab

The Firewall Dashboard tab lets you view important information about the traffic passing through your ASA. This dashboard differs depending on whether you are in single context mode or multiple context mode. In multiple context mode, the Firewall Dashboard is viewable within each context.

Figure 4-4 shows some of the elements of the Firewall Dashboard tab.

Figure 4-4 Firewall Dashboard Tab

Legend

GUI Element	Description
1	Traffic Overview Pane, page 4-22
2	Top 10 Access Rules Pane, page 4-23
3	Top Usage Status Pane, page 4-23
(not shown)	Top Ten Protected Servers Under SYN Attack Pane, page 4-24
(not shown)	Top 200 Hosts Pane, page 4-24
(not shown)	Top Botnet Traffic Filter Hits Pane, page 4-24

Traffic Overview Pane

Enabled by default. If you disable basic threat detection (see the "Configuring Basic Threat Detection Statistics" section on page 77-4), then this area includes an Enable button that lets you enable basic threat detection. The runtime statistics include the following information, which is *display-only*:

- The number of connections and NAT translations.
- The rate of dropped packets per second caused by access list denials and application inspections.
- The rate of dropped packets per second that are identified as part of a scanning attack, or that are incomplete sessions detected, such as TCP SYN attack detected or no data UDP session attack detected.

Top 10 Access Rules Pane

Enabled by default. If you disable threat detection statistics for access rules (see the "Configuring Advanced Threat Detection Statistics" section on page 77-5), then this area includes an Enable button that lets you enable statistics for access rules.

In the Table view, you can select a rule in the list and right-click the rule to display a popup menu item, **Show Rule**. Choose this item to go to the Access Rules table and select that rule in this table.

Top Usage Status Pane

Disabled by default. This pane contains the following four tabs:

- Top 10 Services—Threat Detection feature
- Top 10 Sources—Threat Detection feature
- Top 10 Destinations—Threat Detection feature
- Top 10 Users—Identity Firewall feature

The first three tabs—Top 10 Services, Top 10 Sources, and Top 10 Destinations—provide statistics for threat detection features. Each tab includes an Enable button that let you enable each threat detection feature. You can enable them according to the "Configuring Basic Threat Detection Statistics" section on page 77-4.

The Top 10 Services Enable button enables statistics for both ports and protocols (both must be enabled for the display). The Top 10 Sources and Top 10 Destinations Enable buttons enable statistics for hosts. The top usage status statistics for hosts (sources and destinations), and ports and protocols are displayed.

The fourth tab for Top 10 Users provides statistics for the Identity Firewall feature. The Identity Firewall feature provides access control based on users' identities. You can configure access rules and security policies based on user names and user groups name rather than through source IP addresses. The ASA provides this feature by accessing an IP-user mapping database.

The Top 10 Users tab displays data only when you have configured the Identity Firewall feature in the ASA, which includes configuring these additional components—Microsoft Active Directory and Cisco Active Directory (AD) Agent. See the Configuring the Identity Firewall, page 47-9 for information.

Depending on which option you choose, the Top 10 Users tab shows statistics for received EPS packets, sent EPS packets, and sent attacks for the top 10 users. For each user (displayed as *domain\user_name*), the tab displays the average EPS packet, the current EPS packet, the trigger, and total events for that user.

Caution Enabling statistics can affect the ASA performance, depending on the type of statistics enabled. Enabling statistics for hosts affects performance in a significant way; if you have a high traffic load, you might consider enabling this type of statistics temporarily. Enabling statistics for ports, however, has a modest effect.

Top Ten Protected Servers Under SYN Attack Pane

Disabled by default. This area includes an Enable button that lets you enable the feature, or you can enable it according to the "Configuring Basic Threat Detection Statistics" section on page 77-4. Statistics for the top ten protected servers under attack are displayed.

For the average rate of attack, the ASA samples the data every 30 seconds over the rate interval (by default 30 minutes).

If there is more than one attacker, then "<various>" displays, followed by the last attacker IP address.

Click **Detail** to view statistics for all servers (up to 1000) instead of just 10 servers. You can also view history sampling data. The ASA samples the number of attacks 60 times during the rate interval, so for the default 30-minute period, statistics are collected every 60 seconds.

Top 200 Hosts Pane

Disabled by default. Shows the top 200 hosts connected through the ASA. Each entry of a host contains the IP address of the host and the number of connections initiated by the host, and is updated every 120 seconds. To enable this display, enter the **hpm topnenable** command.

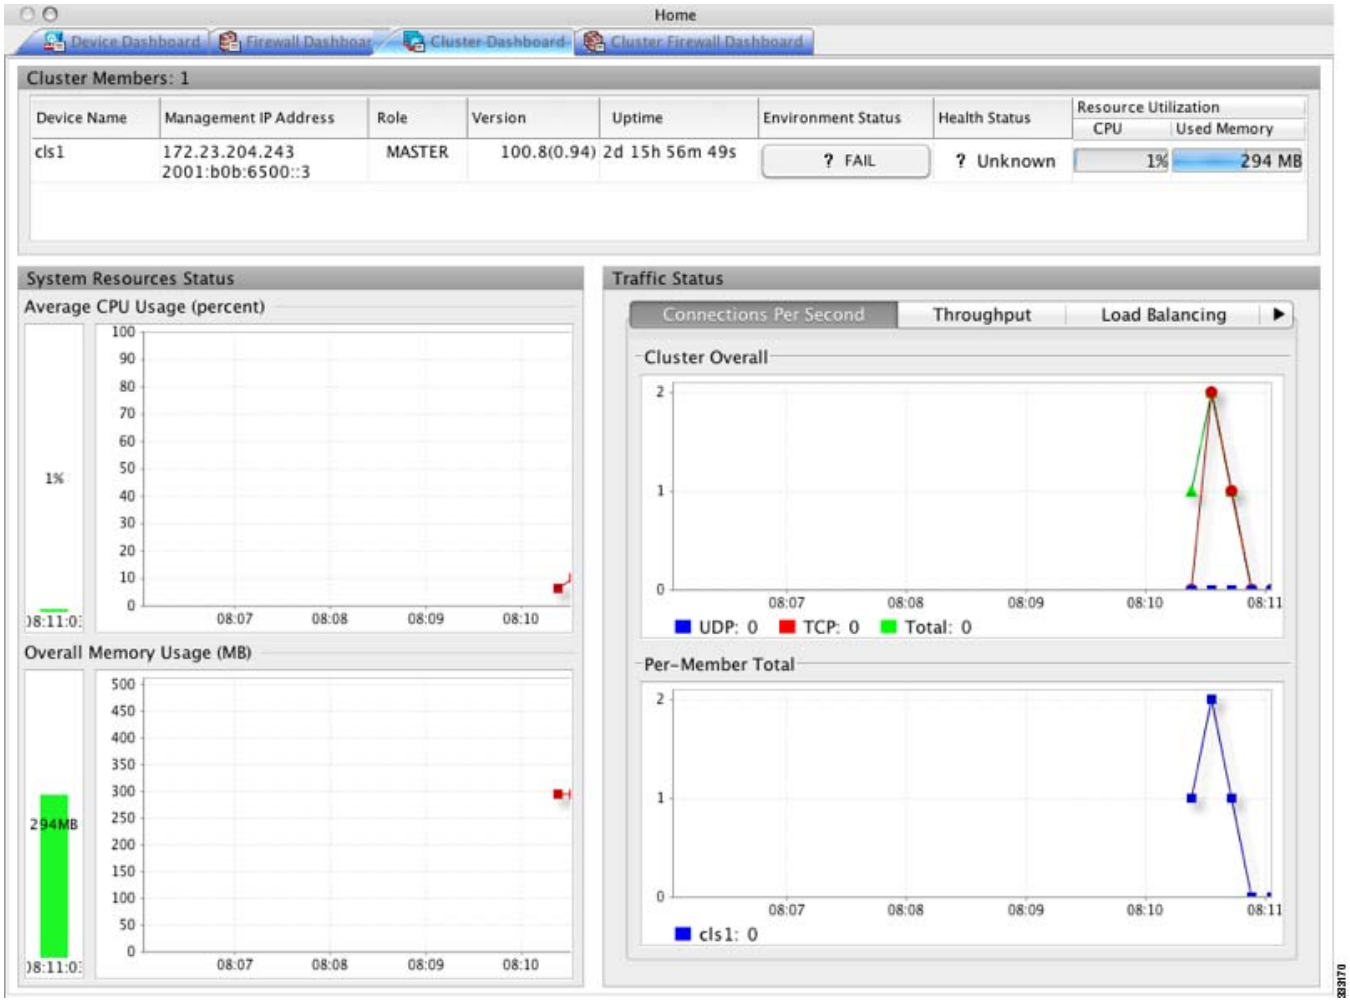
Top Botnet Traffic Filter Hits Pane

Disabled by default. This area includes links to configure the Botnet Traffic Filter. Reports of the top ten botnet sites, ports, and infected hosts provide a snapshot of the data, and may not match the top ten items since statistics started to be collected. If you right-click an IP address, you can invoke the whois tool to learn more about the botnet site.

For more information, see Configuring the Botnet Traffic Filter.

Cluster Dashboard Tab

The Cluster Dashboard tab shows a summary of cluster membership and resource utilization.



- Cluster Members—Shows the names and basic information about the members comprising the cluster (their management IP address, version, role in the cluster, etc.) and their health status (environment status, Health Status, and resource utilization meters).

  Note In multiple context mode, if you connect ASDM to the admin context, and then change to a different context, the Management IP Address listed does not change to show the current context management IP addresses; it continues to show the admin context management IP addresses, including the main cluster IP address to which ASDM is currently connected.

- System Resource Status—Shows resource utilization (CPU and memory) across the cluster and traffic graphs, both cluster-wide and per-device.
- Traffic Status—Each tab has the following graphs.
  - Connections Per Second tab:

    Cluster Overall—Shows the connections per second throughout the cluster.

Per-Member Total—Shows the average connections per second for each member.

- Throughput tab:

  Cluster Overall—Shows the aggregated egress throughput throughout the cluster.

  Per-Member Throughput—Shows the member throughput, one line per member.

- Load Balacing tab:

  Per-Member Percentage of Total Traffic—For each member, shows the percentage of total cluster traffic that the member receives.

  Per-Member Locally Processed Traffic—For each member, shows the percentage of traffic that was processed locally.

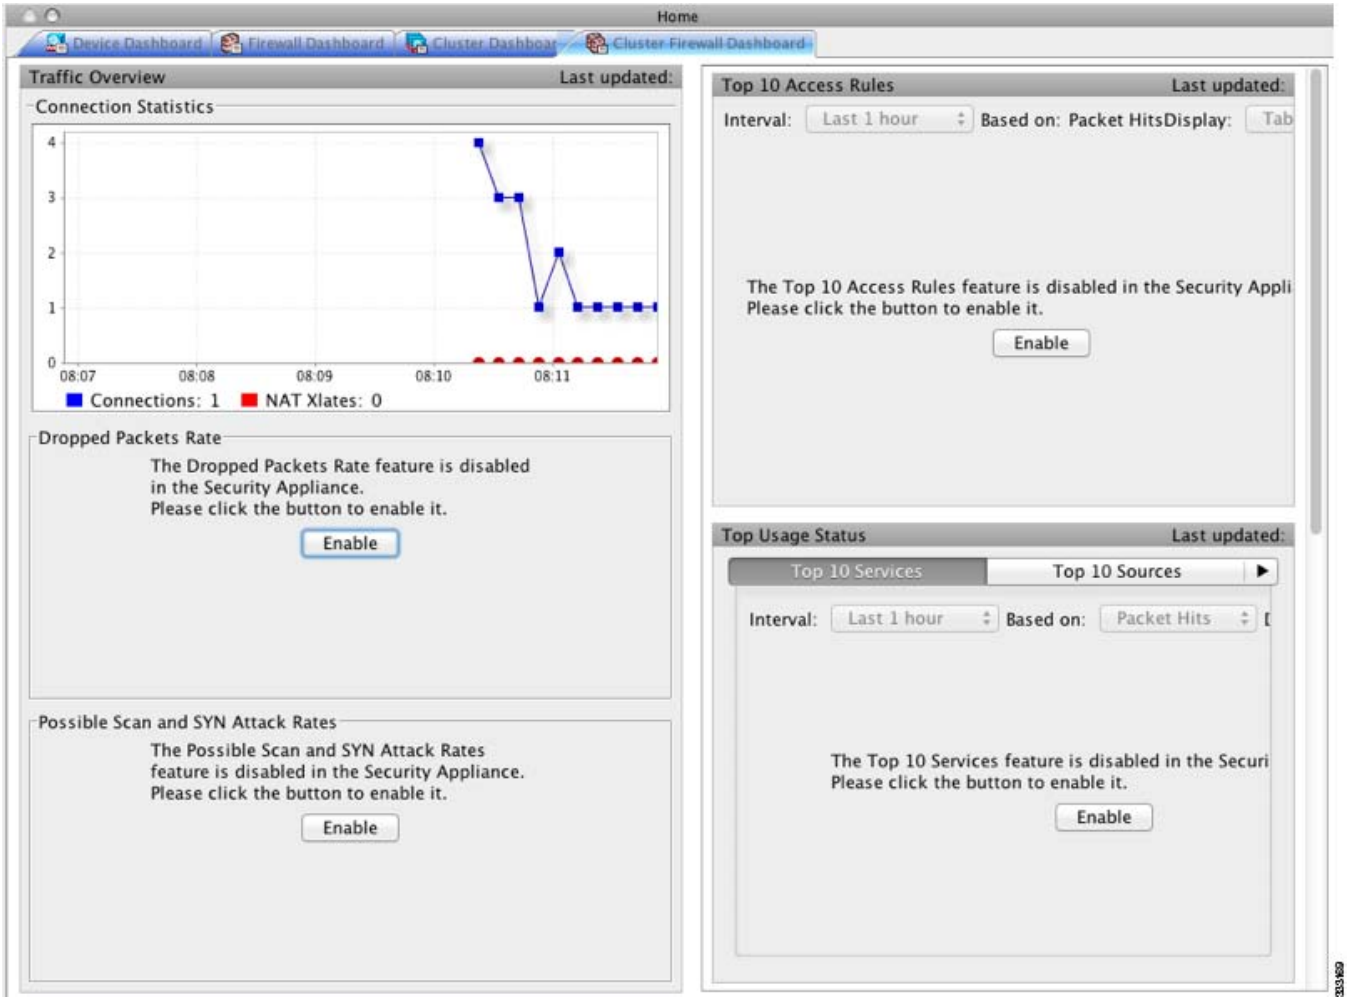
- Control Link Usage tab:

  Per-Member Receival Capacity Utilization—For each member, shows the usage of the transmittal capacity.

  Per-Member Transmittal Capacity Utilization—For each member, shows the usage of the receival capacity.

Cluster Firewall Dashboard Tab

The Cluster Firewall Dashboard tab shows Traffic Overview and the “top N” statistics, similar to those shown in the Firewall Dashboard, but aggregated across the whole cluster.



Content Security Tab

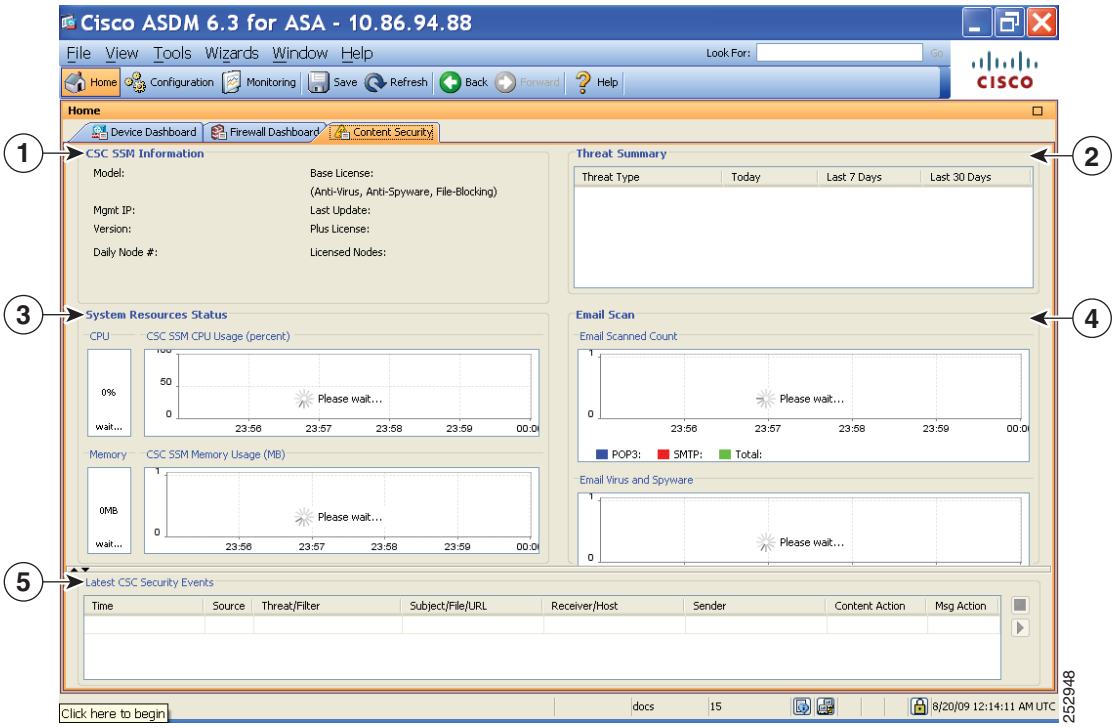
The Content Security tab lets you view important information about the Content Security and Control (CSC) SSM. This pane appears only if CSC software running on the CSC SSM is installed in the ASA.

For an introduction to the CSC SSM, see the "Information About the CSC SSM" section on page 83-1.

Note If you have not completed the CSC Setup Wizard by choosing **Configuration > Trend Micro Content Security > CSC Setup**, you cannot access the panes under Home > Content Security. Instead, a dialog box appears and lets you access the CSC Setup Wizard directly from this location.

Figure 4-5 shows the elements of the Content Security tab.

Figure 4-5 Content Security Tab



Legend

GUI Element	Description
1	CSC SSM Information pane.
2	Threat Summary pane. Shows aggregated data about threats detected by the CSC SSM, including the following threat types: Virus, Spyware, URL Filtered or Blocked, Spam. Blocked, Files Blocked, and Damage Control Services.
3	System Resources Status pane.
4	Email Scan pane. The graphs display data in ten-second intervals.
5	Latest CSC Security Events pane.

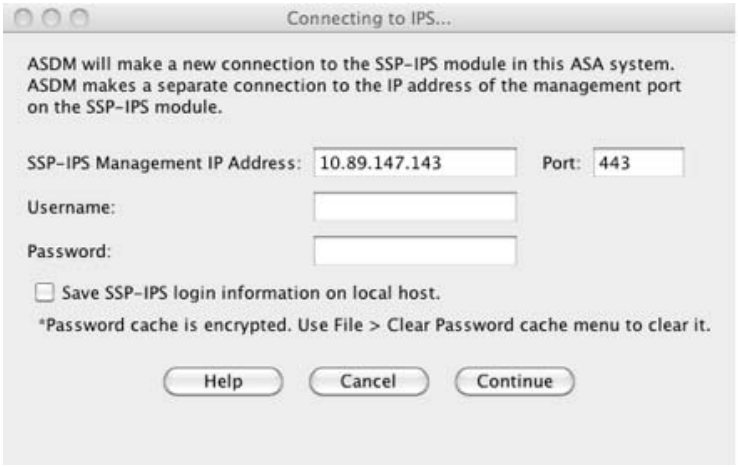
Intrusion Prevention Tab

The Intrusion Prevention tab lets you view important information about IPS. This tab appears only when you have an IPS module installed on the ASA.

To connect to the IPS module, perform the following steps:

Step 1 In the main ASDM application window, click the **Intrusion Prevention** tab.

The Connecting to IPS dialog box appears.



Step 2 Enter the IP address, port, username and password.The default IP address and port is 192.168.1.2:443. The default username and password is **cisco** and **cisco**

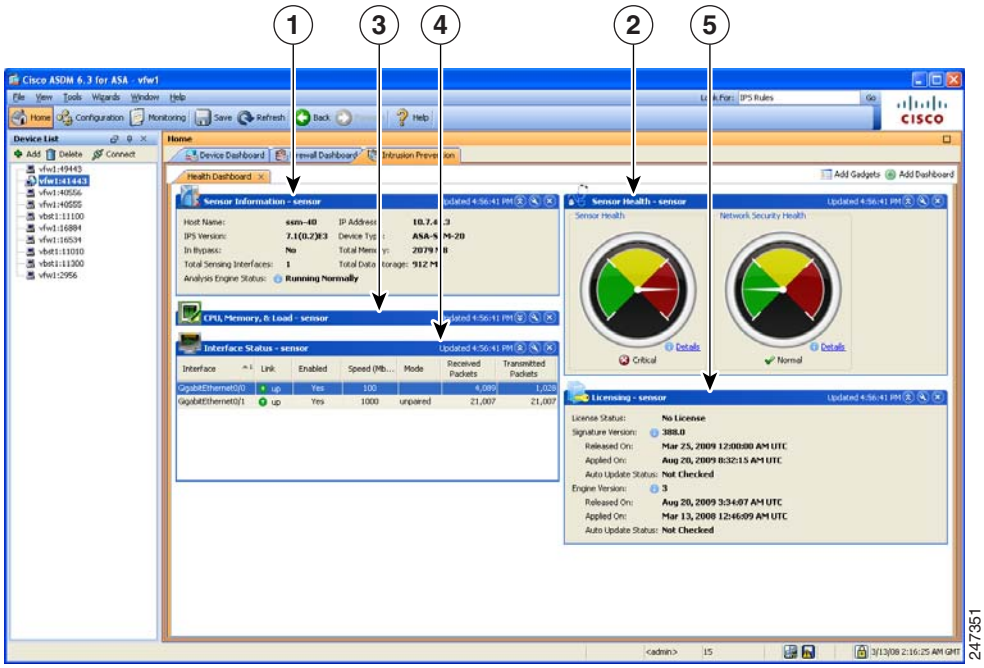
Step 3 To save the login information on your local PC, check the **Save IPS login** information on local host check box.

Step 4 Click **Continue**.

For more information about intrusion prevention, see Chapter 81, "Configuring the ASA IPS Module.".

Figure 4-6 shows the elements of the Health Dashboard tab, located on the Intrusion Prevention tab.

Figure 4-6 Intrusion Prevention Tab (Health Dashboard)

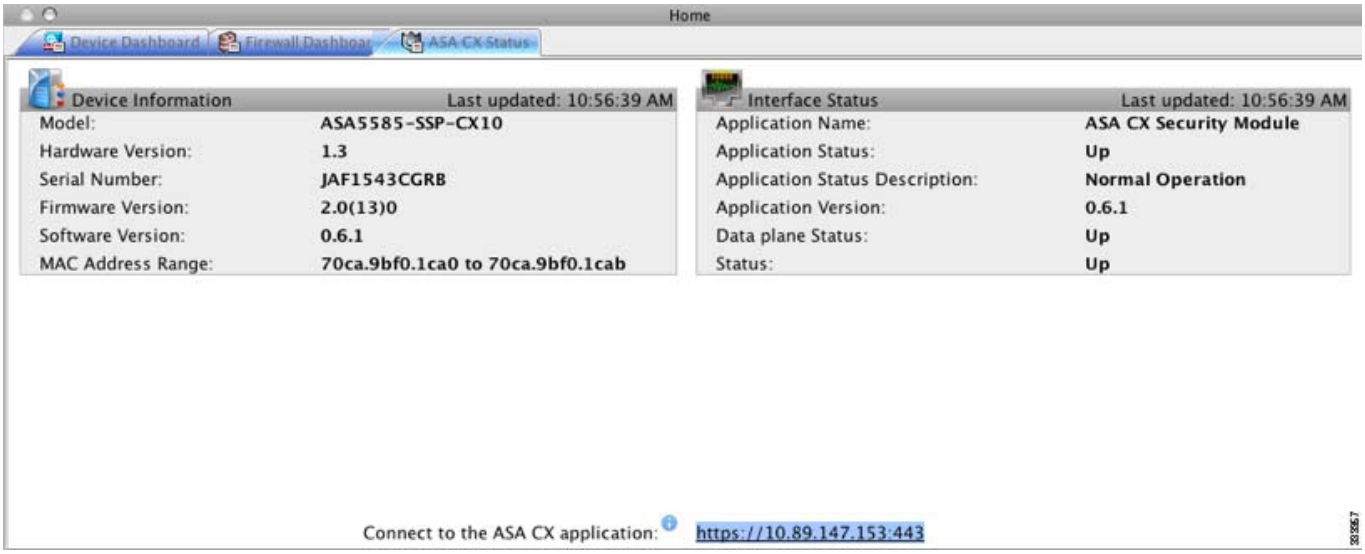


Legend

GUI Element	Description
1	Sensor Information pane.
2	Sensor Health pane.
3	CPU, Memory, and Load pane.
4	Interface Status pane.
5	Licensing pane.

ASA CX Status Tab

The ASA CX Status tab lets you view important information about the ASA CX module. This tab appears only when you have an ASA CX module installed on the ASA.

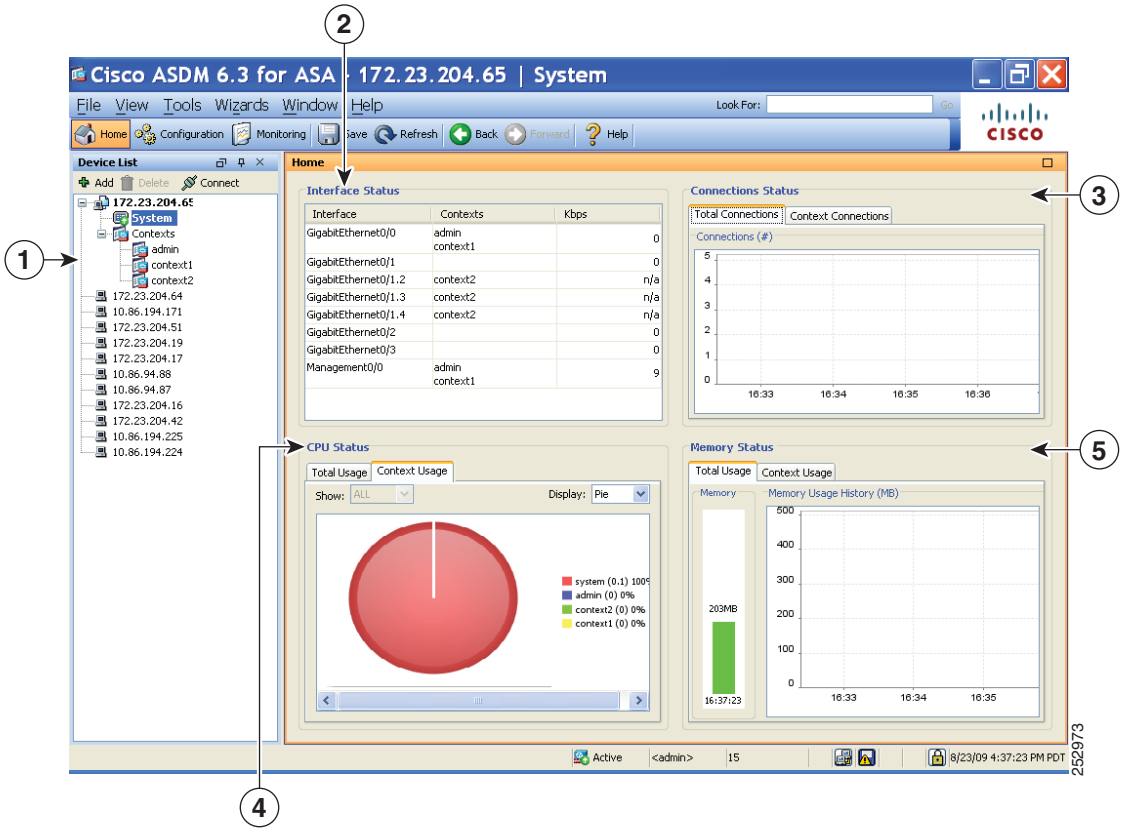


Home Pane (System)

The ASDM System Home pane lets you view important status information about your ASA. Many of the details available in the ASDM System Home pane are available elsewhere in ASDM, but this pane shows at-a-glance how your ASA is running. Status information in the System Home pane is updated every ten seconds.

Figure 4-7 on page 4-31 shows the elements of the System Home pane.

Figure 4-7 System Home Pane



Legend

GUI Element	Description
1	System vs. Context selection.
2	Interface Status pane. Choose an interface to view the total amount of traffic through the interface.
3	Connection Status pane.
4	CPU Status pane.
5	Memory Status pane.

Defining ASDM Preferences

This feature lets you define the behavior of certain ASDM settings.

To change various settings in ASDM, perform the following steps:

Step 1 In the main ASDM application window, choose **Tools > Preferences**.

The Preferences dialog box appears, with three tabs: General, Rules Table, and Syslog.

Step 2 To define your settings, click one of these tabs: the **General** tab to specify general preferences; the **Rules Table** tab to specify preferences for the Rules table; and the **Syslog** tab to specify the appearance of syslog messages displayed in the Home pane and to enable the display of a warning message for NetFlow-related syslog messages.

Step 3 On the General tab, specify the following:

a. Check the **Warn that configuration in ASDM is out of sync with the configuration in ASA** check box to be notified when the startup configuration and the running configuration are no longer in sync with each other.

b. Check the **Show configuration restriction message to read-only user** check box to display the following message to a read-only user at startup. This option is checked by default.

```
"You are not allowed to modify the ASA configuration, because you do not have
sufficient privileges."
```

c. Check the **Confirm before exiting ASDM** check box to display a prompt when you try to close ASDM to confirm that you want to exit. This option is checked by default.

d. Check the **Enable screen reader support (requires ASDM restart)** check box to enable screen readers to work. You must restart ASDM to enable this option.

e. Check the **Warn of insufficient ASA memory when ASDM loads** check box to receive notification when the minimum amount of ASA memory is insufficient to run complete functionality in the ASDM application. ASDM displays the memory warning in a text banner message at bootup, displays a message in the title bar text in ASDM, and sends a syslog alert once every 24 hours.

f. Check the **Preview commands before sending them to the device** check box to view CLI commands generated by ASDM.

g. Check the **Enable cumulative (batch) CLI delivery** check box to send multiple commands in a single group to the ASA.

h. Enter the minimum amount of time in seconds for a configuration to send a timeout message. The default is 60 seconds.

i. To allow the Packet Capture Wizard to display captured packets, enter the name of the network sniffer application or click **Browse** to find it in the file system.

Step 4 On the Rules Table tab, specify the following:

a. Display settings let you change the way rules appear in the Rules table.

- Check the **Auto-expand network and service object groups with specified prefix** check box to display the network and service object groups automatically expanded based on the Auto-Expand Prefix setting.
- In the Auto-Expand Prefix field, enter the prefix of the network and service object groups to expand automatically when displayed.

- Check the **Show members of network and service object groups** check box to display members of network and service object groups and the group name in the Rules table. If the check box is not checked, only the group name is displayed.
- In the Limit Members To field, enter the number of network and service object groups to display. When the object group members are displayed, then only the first *n* members are displayed.
- Check the **Show all actions for service policy rules** check box to display all actions in the Rules table. When unchecked, a summary appears.

b. Deployment settings let you configure the behavior of the ASA when deploying changes to the Rules table.

- Check the **Issue "clear xlate" command when deploying access lists** check box to clear the NAT table when deploying new access lists. This setting ensures the access lists that are configured on the ASA are applied to all translated addresses.

c. Access Rule Hit Count Settings let you configure the frequency for which the hit counts are updated in the Access Rules table. Hit counts are applicable for explicit rules only. No hit count will be displayed for implicit rules in the Access Rules table.

- Check the **Update access rule hit counts automatically** check box to have the hit counts automatically updated in the Access Rules table.
- In the Update Frequency field, specify the frequency in seconds in which the hit count column is updated in the Access Rules table. Valid values are 10 - 86400 seconds.

Step 5 On the Syslog tab, specify the following:

- In the Syslog Colors area, you can customize the message display by configuring background or foreground colors for messages at each severity level. The Severity column lists each severity level by name and number. To change the background color or foreground color for messages at a specified severity level, click the corresponding column. The Pick a Color dialog box appears. Click one of the following tabs:
  - On the Swatches tab, choose a color from the palette, and click **OK**.
  - On the HSB tab, specify the H, S, and B settings, and click **OK**.
  - On the RGB tab, specify the Red, Green, and Blue settings, and click **OK**.
- In the NetFlow area, to enable the display of a warning message to disable redundant syslog messages, check the **Warn to disable redundant syslog messages when NetFlow action is first applied to the global service policy rule** check box.

Step 6 After you have specified settings on these three tabs, click **OK** to save your settings and close the Preferences dialog box.

Note Each time that you check or uncheck a preferences setting, the change is saved to the .conf file and becomes available to all the other ASDM sessions running on the workstation at the time. You must restart ASDM for all changes to take effect.

Using the ASDM Assistant

The ASDM Assistant tool lets you search and view useful ASDM procedural help about certain tasks.

To access information, choose **View > ASDM Assistant > How Do I?** or enter a search request from the Look For field in the menu bar. From the Find drop-down list, choose **How Do I?** to begin the search.

Note This feature is not available on the PIX security appliance.

To view the ASDM Assistant, perform the following steps:

Step 1 In the main ASDM application window, choose **View > ASDM Assistant**.

The ASDM Assistant pane appears.

Step 2 In the Search field, enter the information that you want to find, and click **Go**.

The requested information appears in the Search Results pane.

Step 3 Click any links that appear in the Search Results and Features sections to obtain more details.

Enabling History Metrics

The Configuration > Device Management > Advanced > History Metrics pane lets you configure the adaptive ASA to keep a history of various statistics, which ASDM can display on any Graph/Table. If you do not enable history metrics, you can only monitor statistics in real time. Enabling history metrics lets you view statistics graphs from the last 10 minutes, 60 minutes, 12 hours, and 5 days.

To configure history metrics, perform the following steps:

Step 1 Choose **Configuration > Device Management > Advanced > History Metrics**.

The History Metrics pane appears.

Step 2 Check the **ASDM History Metrics** check box to enable history metrics, and then click **Apply**.

Unsupported Commands

ASDM supports almost all commands available for the adaptive ASA, but ASDM ignores some commands in an existing configuration. Most of these commands can remain in your configuration; see Tools > Show Commands Ignored by ASDM on Device for more information.

This section includes the following topics:

- Ignored and View-Only Commands, page 4-35
- Effects of Unsupported Commands, page 4-35
- Discontinuous Subnet Masks Not Supported, page 4-36
- Interactive User Commands Not Supported by the ASDM CLI Tool, page 4-36

Ignored and View-Only Commands

Table 4-5 lists commands that ASDM supports in the configuration when added through the CLI, but that cannot be added or edited in ASDM. If ASDM ignores the command, it does not appear in the ASDM GUI at all. If the command is view-only, then it appears in the GUI, but you cannot edit it.

Table 4-5 List of Unsupported Commands

Unsupported Commands	ASDM Behavior
capture	Ignored.
coredump	Ignored. This can be configured only using the CLI.
crypto engine large-mod-accel	Ignored.
dhcp-server (tunnel-group name general-attributes)	ASDM only allows one setting for all DHCP servers.
eject	Unsupported.
established	Ignored.
failover timeout	Ignored.
fips	Ignored.
nat-assigned-to-public-ip	Ignored.
pager	Ignored.
pim accept-register route-map	Ignored. You can configure only the **list** option using ASDM.

service-policy global	Ignored if it uses a **match access-list** class. For example:
	`access-list myacl extended permit ip any any`
	`class-map mycm`
	`  match access-list myacl`
	`policy-map mypm`
	`  class mycm`
	`    inspect ftp`
	`service-policy mypm global`

set metric	Ignored.
sysopt nodnsalias	Ignored.
sysopt uauth allow-http-cache	Ignored.
terminal	Ignored.
threat-detection rate	Ignored.

Effects of Unsupported Commands

If ASDM loads an existing running configuration and finds other unsupported commands, ASDM operation is unaffected. To view the unsupported commands, choose **Tools > Show Commands Ignored by ASDM on Device**.

Discontinuous Subnet Masks Not Supported

ASDM does not support discontinuous subnet masks such as 255.255.0.255. For example, you cannot use the following:

```
ip address inside 192.168.2.1 255.255.0.255
```

Interactive User Commands Not Supported by the ASDM CLI Tool

The ASDM CLI tool does not support interactive user commands. If you enter a CLI command that requires interactive confirmation, ASDM prompts you to enter "[yes/no]" but does not recognize your input. ASDM then times out waiting for your response.

For example:

1. Choose **Tools > Command Line Interface**.
2. Enter the **crypto key generate rsa** command.

   ASDM generates the default 1024-bit RSA key.
3. Enter the **crypto key generate rsa** command again.

   Instead of regenerating the RSA keys by overwriting the previous one, ASDM displays the following error:

```
Do you really want to replace them? [yes/no]:WARNING: You already have RSA
ke0000000000000$A key
Input line must be less than 16 characters in length.

%Please answer 'yes' or 'no'.
Do you really want to replace them [yes/no]:

%ERROR: Timed out waiting for a response.
ERROR: Failed to create new RSA keys names <Default-RSA-key>
```

Workaround:

- You can configure most commands that require user interaction by means of the ASDM panes.
- For CLI commands that have a **noconfirm** option, use this option when entering the CLI command. For example:

  crypto key generate rsa noconfirm

Managing Feature Licenses

A license specifies the options that are enabled on a given ASA. This document describes how to obtain a license activation key and how to activate it. It also describes the available licenses for each model.

Note This chapter describes licensing for Version 7.0; for other versions, see the licensing documentation that applies to your version:

http://www.cisco.com/en/US/products/ps6120/products_licensing_information_listing.html

This chapter includes the following sections:

- Supported Feature Licenses Per Model, page 5-1
- Information About Feature Licenses, page 5-23
- Guidelines and Limitations, page 5-34
- Configuring Licenses, page 5-36
- Monitoring Licenses, page 5-40
- Feature History for Licensing, page 5-41

Supported Feature Licenses Per Model

This section describes the licenses available for each model as well as important notes about licenses. This section includes the following topics:

- Licenses Per Model, page 5-1
- License Notes, page 5-18
- VPN License and Feature Compatibility, page 5-23

Licenses Per Model

This section lists the feature licenses available for each model:

- ASA 5505, page 5-2
- ASA 5510, page 5-3
- ASA 5520, page 5-4

- ASA 5540, page 5-5
- ASA 5550, page 5-6
- ASA 5580, page 5-7
- ASA 5512-X, page 5-8
- ASA 5515-X, page 5-9
- ASA 5525-X, page 5-10
- ASA 5545-X, page 5-11
- ASA 5555-X, page 5-12
- ASA 5585-X with SSP-10, page 5-13
- ASA 5585-X with SSP-20, page 5-14
- ASA 5585-X with SSP-40 and -60, page 5-15
- ASA Services Module, page 5-16

Items that are in italics are separate, optional licenses with which that you can replace the Base or Security Plus license. You can mix and match licenses, for example, the 24 Unified Communications license plus the Strong Encryption license; or the 500 AnyConnect Premium license plus the GTP/GPRS license; or all four licenses together.

For detailed information about licenses, see the "License Notes" section on page 5-18.

ASA 5505

Table 5-1 ASA 5505 License Features

Licenses	Description (Base License in Plain Text)	Description (Security Plus Lic. in Plain Text)
Firewall Licenses		
Botnet Traffic Filter	Disabled	*Opt. Time-based lic: Available*	Disabled	*Opt. Time-based lic: Available*
Firewall Conns, Concurrent	10,000	25,000
GTP/GPRS	No support	No support
Intercompany Media Eng.	Disabled	*Optional license: Available*	Disabled	*Optional license: Available*
UC Phone Proxy Sessions	2	*Optional license: 24*	2	*Optional license: 24*
VPN Licenses		
Adv. Endpoint Assessment	Disabled	*Optional license: Available*	Disabled	*Optional license: Available*
AnyConnect for Cisco VPN Phone	Disabled	*Optional license: Available*	Disabled	*Optional license: Available*
AnyConnect Essentials	Disabled	*Optional license: Available (25 sessions)*	Disabled	*Optional license: Available (25 sessions)*
AnyConnect for Mobile	Disabled	*Optional license: Available*	Disabled	*Optional license: Available*
AnyConnect Premium (sessions)	2	*Optional Permanent or Time-based licenses:* *10* *25*	2	*Optional Permanent or Time-based licenses:* *10* *25*
Other VPN (sessions)	10	25
Total VPN (sessions), combined all types	up to 25[1]	up to 25
VPN Load Balancing	No support	No support

Table 5-1 ASA 5505 License Features (continued)

Licenses	Description (Base License in Plain Text)				Description (Security Plus Lic. in Plain Text)			
General Licenses								
Encryption	Base (DES)	*Opt. lic.: Strong (3DES/AES)*			Base (DES)	*Opt. lic.: Strong (3DES/AES)*		
Failover	No support				Active/Standby (no stateful failover)			
Interfaces of all types, Max.	52				120			
Security Contexts	No support				No support			
Clustering	No support				No support			
Inside Hosts, concurrent[2]	10[3]	*Opt. licenses:*	*50*	*Unlimited*	10[3]	*Opt. licenses:*	*50*	*Unlimited*
VLANs, maximum	Routed mode: 3 (2 regular and 1 restricted) Transparent mode: 2				Routed mode: 20 Transparent mode: 3 (2 regular and 1 failover)			
VLAN Trunks, maximum	No support				8 trunks			

1. The total number of VPN sessions depends on your licenses. If you enable AnyConnect Essentials, then the total is the model maximum of 25. If you enable AnyConnect Premium, then the total is the AnyConnect Premium value plus the Other VPN value, not to exceed 25 sessions.
2. In routed mode, hosts on the inside (Business and Home VLANs) count toward the limit when they communicate with the outside (Internet VLAN), including when the inside initiates a connection to the outside as well as when the outside initiates a connection to the inside. Note that even when the outside initiates a connection to the inside, outside hosts are *not* counted toward the limit; only the inside hosts count. Hosts that initiate traffic between Business and Home are also not counted toward the limit. The interface associated with the default route is considered to be the outside Internet interface. If there is no default route, hosts on all interfaces are counted toward the limit. In transparent mode, the interface with the lowest number of hosts is counted toward the host limit. Use the **show local-host** command to view host limits.
3. For a 10-user license, the max. DHCP clients is 32. For 50 users, the max. is 128. For unlimited users, the max. is 250, which is the max. for other models.

ASA 5510

Table 5-2 ASA 5510 License Features

Licenses	Description (Base License in Plain Text)				Description (Security Plus Lic. in Plain Text)			
Firewall Licenses								
Botnet Traffic Filter	Disabled	*Optional Time-based license: Available*			Disabled	*Optional Time-based license: Available*		
Firewall Conns, Concurrent	50,000				130,000

		20	*50*	*100*	250			*20*	*50*	*100*	250	
Clustering	Disabled	*Optional license: Available*										
VLANs, Maximum	1024						1024					

1. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

ASA 5585-X with SSP-40 and -60

If you have a No Payload Encryption model, then some of the features below are not supported. See the "No Payload Encryption Models" section on page 5-33 for a list of unsupported features.

Note For SSP-40 and SSP-60, you can use two SSPs of the same level in the same chassis. Mixed-level SSPs are not supported (for example, an SSP-40 with an SSP-60 is not supported). Each SSP acts as an independent device, with separate configurations and management. You can use the two SSPs as a failover pair if desired. When using two SSPs in the chassis, VPN is not supported; note, however, that VPN has not been disabled.

Table 5-14 ASA 5585-X with SSP-40 and -60 License Features

Licenses	Description (Base License in Plain Text)										
Firewall Licenses											
Botnet Traffic Filter	Disabled	*Optional Time-based license: Available*

Total VPN (sessions), combined all types	10,000										
Other VPN (sessions)	10,000										
VPN Load Balancing	Supported										
General Licenses											
Encryption	Base (DES)	*Optional license: Strong (3DES/AES)*									
Failover	Active/Standby or Active/Active										
Interfaces of all types, Max.	4224										
Security Contexts	2	*Optional licenses:*									
		5	*10*	*20*	*50*	*100*	*250*				
Clustering	No support										
VLANs, Maximum	1024										

1. With the 10,000-session UC license, the total combined sessions can be 10,000, but the maximum number of Phone Proxy sessions is 5000.

License Notes

Table 5-16 includes common footnotes shared by multiple tables in the "Licenses Per Model" section on page 5-1.

Table 5-16 License Notes

License	Notes
AnyConnect Essentials	AnyConnect Essentials sessions include the following VPN types: • SSL VPN • IPsec remote access VPN using IKEv2 This license does not support browser-based (clientless) SSL VPN access or Cisco Secure Desktop. For these features, activate an AnyConnect Premium license instead of the AnyConnect Essentials license. **Note** With the AnyConnect Essentials license, VPN users can use a web browser to log in, and download and start (WebLaunch) the AnyConnect client. The AnyConnect client software offers the same set of client features, whether it is enabled by this license or an AnyConnect Premium license. The AnyConnect Essentials license cannot be active at the same time as the following licenses on a given ASA: AnyConnect Premium license (all types) or the Advanced Endpoint Assessment license. You can, however, run AnyConnect Essentials and AnyConnect Premium licenses on different ASAs in the same network. By default, the ASA uses the AnyConnect Essentials license, but you can disable it to use other licenses by using the **no anyconnect-essentials** command or in ASDM, using the **Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Essentials** pane. See also the "VPN License and Feature Compatibility" section on page 5-23.
AnyConnect for Cisco VPN Phone	In conjunction with an AnyConnect Premium license, this license enables access from hardware IP phones that have built in AnyConnect compatibility.

Table 5-16 License Notes (continued)

License	Notes
AnyConnect for Mobile	This license provides access to the AnyConnect Client for touch-screen mobile devices running Windows Mobile 5.0, 6.0, and 6.1. We recommend using this license if you want to support mobile access to AnyConnect 2.3 and later versions. This license requires activation of one of the following licenses to specify the total number of SSL VPN sessions permitted: AnyConnect Essentials or AnyConnect Premium. **Mobile Posture Support** Enforcing remote access controls and gathering posture data from mobile devices requires an AnyConnect Mobile license and either an AnyConnect Essentials or AnyConnect Premium license to be installed on the ASA. Here is the functionality you receive based on the license you install. • AnyConnect Premium License Functionality – Enforce DAP policies on supported mobile devices based on DAP attributes and any other existing endpoint attributes. This includes allowing or denying remote access from a mobile device. • AnyConnect Essentials License Functionality – Enable or disable mobile device access on a per group basis and to configure that feature using ASDM. – Display information about connected mobile devices via CLI or ASDM without having the ability to enforce DAP policies or deny or allow remote access to those mobile devices.
AnyConnect Premium	AnyConnect Premium sessions include the following VPN types: • SSL VPN • Clientless SSL VPN • IPsec remote access VPN using IKEv2
AnyConnect Premium Shared	A shared license lets the ASA act as a shared license server for multiple client ASAs. The shared license pool is large, but the maximum number of sessions used by each individual ASA cannot exceed the maximum number listed for permanent licenses.
Botnet Traffic Filter	Requires a Strong Encryption (3DES/AES) License to download the dynamic database.
Encryption	The DES license cannot be disabled. If you have the 3DES license installed, DES is still available. To prevent the use of DES when you want to only use strong encryption, be sure to configure any relevant commands to use only string encryption.
Failover, Active/Active	You cannot use Active/Active failover and VPN; if you want to use VPN, use Active/Standby failover.

Table 5-16 License Notes (continued)

License	Notes
Intercompany Media Engine	When you enable the Intercompany Media Engine (IME) license, you can use TLS proxy sessions up to the configured TLS proxy limit. If you also have a Unified Communications (UC) license installed that is higher than the default TLS proxy limit, then the ASA sets the limit to be the UC license limit plus an additional number of sessions depending on your model. You can manually configure the TLS proxy limit using the **tls-proxy maximum-sessions** command or in ASDM, using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. To view the limits of your model, enter the **tls-proxy maximum-sessions ?** command. If you also install the UC license, then the TLS proxy sessions available for UC are also available for IME sessions. For example, if the configured limit is 1000 TLS proxy sessions, and you purchase a 750-session UC license, then the first 250 IME sessions do not affect the sessions available for UC. If you need more than 250 sessions for IME, then the remaining 750 sessions of the platform limit are used on a first-come, first-served basis by UC and IME. • For a license part number ending in "K8", TLS proxy sessions are limited to 1000. • For a license part number ending in "K9", the TLS proxy limit depends on your configuration and the platform model. **Note** K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted. You might also use SRTP encryption sessions for your connections: • For a K8 license, SRTP sessions are limited to 250. • For a K9 license, there is no limit. **Note** Only calls that require encryption/decryption for media are counted toward the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count toward the limit.
Interfaces of all types, Max.	The maximum number of combined interfaces; for example, VLANs, physical, redundant, bridge group, and EtherChannel interfaces.
IPS module	The IPS module license lets you run the IPS software module on the ASA. You must also purchase a separate IPS signature subscription; for failover, purchase a subscription for each unit. To obtain IPS signature support, you must purchase the ASA with IPS pre-installed (the part number must include "IPS"). The combined failover cluster license does not let you pair non-IPS and IPS units. For example, if you buy the IPS version of the ASA 5515-X (part number ASA5515-IPS-K9) and try to make a failover pair with a non-IPS version (part number ASA5515-K9), then Cisco will not let you obtain IPS signature updates for the ASA5515-K9 unit, even though it has an IPS module license inherited from the other unit.
Other VPN	Other VPN sessions include the following VPN types: • IPsec remote access VPN using IKEv1 • IPsec site-to-site VPN using IKEv1 • IPsec site-to-site VPN using IKEv2 This license is included in the Base license.

Table 5-16 License Notes (continued)

License	Notes
Total VPN (sessions), combined all types	• Although the maximum VPN sessions add up to more than the maximum VPN AnyConnect and Other VPN sessions, the combined sessions should not exceed the VPN session limit. If you exceed the maximum VPN sessions, you can overload the ASA, so be sure to size your network appropriately. • If you start a clientless SSL VPN session and then start an AnyConnect client session from the portal, 1 session is used in total. However, if you start the AnyConnect client first (from a standalone client, for example) and then log into the clientless SSL VPN portal, then 2 sessions are used.

Table 5-16 License Notes (continued)

License	Notes
UC Phone Proxy sessions	The following applications use TLS proxy sessions for their connections. Each TLS proxy session used by these applications (and only these applications) is counted against the UC license limit: • Phone Proxy • Presence Federation Proxy • Encrypted Voice Inspection Other applications that use TLS proxy sessions do not count toward the UC limit, for example, Mobility Advantage Proxy (which does not require a license) and IME (which requires a separate IME license). Some UC applications might use multiple sessions for a connection. For example, if you configure a phone with a primary and backup Cisco Unified Communications Manager, there are 2 TLS proxy connections, so 2 UC Proxy sessions are used. You independently set the TLS proxy limit using the **tls-proxy maximum-sessions** command or in ASDM, using the **Configuration > Firewall > Unified Communications > TLS Proxy** pane. To view the limits of your model, enter the **tls-proxy maximum-sessions ?** command. When you apply a UC license that is higher than the default TLS proxy limit, the ASA automatically sets the TLS proxy limit to match the UC limit. The TLS proxy limit takes precedence over the UC license limit; if you set the TLS proxy limit to be less than the UC license, then you cannot use all of the sessions in your UC license. **Note** For license part numbers ending in "K8" (for example, licenses under 250 users), TLS proxy sessions are limited to 1000. For license part numbers ending in "K9" (for example, licenses 250 users or larger), the TLS proxy limit depends on the configuration, up to the model limit. K8 and K9 refer to whether the license is restricted for export: K8 is unrestricted, and K9 is restricted. If you clear the configuration (using the **clear configure all** command, for example), then the TLS proxy limit is set to the default for your model; if this default is lower than the UC license limit, then you see an error message to use the **tls-proxy maximum-sessions** command to raise the limit again (in ASDM, use the **TLS Proxy** pane). If you use failover and enter the **write standby** command or in ASDM, use **File > Save Running Configuration to Standby Unit** on the primary unit to force a configuration synchronization, the **clear configure all** command is generated on the secondary unit automatically, so you may see the warning message on the secondary unit. Because the configuration synchronization restores the TLS proxy limit set on the primary unit, you can ignore the warning. You might also use SRTP encryption sessions for your connections: • For K8 licenses, SRTP sessions are limited to 250. • For K9 licenses, there is not limit. **Note** Only calls that require encryption/decryption for media are counted toward the SRTP limit; if passthrough is set for the call, even if both legs are SRTP, they do not count toward the limit.
VPN Load Balancing	VPN load balancing requires a Strong Encryption (3DES/AES) License.

VPN License and Feature Compatibility

Table 5-17 shows how the VPN licenses and features can combine.

For a detailed list of the features supported by the AnyConnect Essentials license and AnyConnect Premium license, see *AnyConnect Secure Mobility Client Features, Licenses, and OSs*:

- Version 3.1: http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect31/feature/guide/anyconnect31features.html
- Version 3.0: http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect30/feature/guide/anyconnect30features.html
- Version 2.5: http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect25/feature/guide/anyconnect25features.html

Table 5-17 VPN License and Feature Compatibility

	Enable one of the following licenses:[1]	
Supported with:	**AnyConnect Essentials**	**AnyConnect Premium**
AnyConnect for Cisco VPN Phone	**No**	**Yes**
AnyConnect for Mobile[2]	**Yes**	**Yes**
Advanced Endpoint Assessment	**No**	**Yes**
AnyConnect Premium Shared	**No**	**Yes**
Client-based SSL VPN	**Yes**	**Yes**
Browser-based (clientless) SSL VPN	**No**	**Yes**
IPsec VPN	**Yes**	**Yes**
VPN Load Balancing	**Yes**	**Yes**
Cisco Secure Desktop	**No**	**Yes**

1. You can only have one license type active, either the AnyConnect Essentials license or the AnyConnect Premium license. By default, the ASA includes an AnyConnect Premium license for 2 sessions. If you install the AnyConnect Essentials license, then it is used by default. See the Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Essentials pane to enable the Premium license instead.
2. Mobile Posture support is different for the AnyConnect Essentials vs. the AnyConnect Premium license. See Table 5-16 on page 5-18 for details.

Information About Feature Licenses

A license specifies the options that are enabled on a given ASA. It is represented by an activation key that is a 160-bit (5 32-bit words or 20 bytes) value. This value encodes the serial number (an 11 character string) and the enabled features.

This section includes the following topics:

- Preinstalled License, page 5-24
- Permanent License, page 5-24
- Time-Based Licenses, page 5-24

- Shared AnyConnect Premium Licenses, page 5-27
- Failover or ASA Cluster Licenses, page 5-31
- No Payload Encryption Models, page 5-33
- Licenses FAQ, page 5-33

Preinstalled License

By default, your ASA ships with a license already installed. This license might be the Base License, to which you want to add more licenses, or it might already have all of your licenses installed, depending on what you ordered and what your vendor installed for you. See the "Monitoring Licenses" section on page 5-40 section to determine which licenses you have installed.

Permanent License

You can have one permanent activation key installed. The permanent activation key includes all licensed features in a single key. If you also install time-based licenses, the ASA combines the permanent and time-based licenses into a running license. See the "How Permanent and Time-Based Licenses Combine" section on page 5-25 for more information about how the ASA combines the licenses.

Time-Based Licenses

In addition to permanent licenses, you can purchase time-based licenses or receive an evaluation license that has a time-limit. For example, you might buy a time-based AnyConnect Premium license to handle short-term surges in the number of concurrent SSL VPN users, or you might order a Botnet Traffic Filter time-based license that is valid for 1 year.

This section includes the following topics:

- Time-Based License Activation Guidelines, page 5-24
- How the Time-Based License Timer Works, page 5-25
- How Permanent and Time-Based Licenses Combine, page 5-25
- Stacking Time-Based Licenses, page 5-26
- Time-Based License Expiration, page 5-26

Time-Based License Activation Guidelines

- You can install multiple time-based licenses, including multiple licenses for the same feature. However, only one time-based license per feature can be *active* at a time. The inactive license remains installed, and ready for use. For example, if you install a 1000-session AnyConnect Premium license, and a 2500-session AnyConnect Premium license, then only one of these licenses can be active.
- If you activate an evaluation license that has multiple features in the key, then you cannot also activate another time-based license for one of the included features. For example, if an evaluation license includes the Botnet Traffic Filter and a 1000-session AnyConnect Premium license, you cannot also activate a standalone time-based 2500-session AnyConnect Premium license.

How the Time-Based License Timer Works

- The timer for the time-based license starts counting down when you activate it on the ASA.
- If you stop using the time-based license before it times out, then the timer halts. The timer only starts again when you reactivate the time-based license.
- If the time-based license is active, and you shut down the ASA, then the timer continues to count down. If you intend to leave the ASA in a shut down state for an extended period of time, then you should deactivate the time-based license before you shut down.

Note We suggest you do not change the system clock after you install the time-based license. If you set the clock to be a later date, then if you reload, the ASA checks the system clock against the original installation time, and assumes that more time has passed than has actually been used. If you set the clock back, and the actual running time is greater than the time between the original installation time and the system clock, then the license immediately expires after a reload.

How Permanent and Time-Based Licenses Combine

When you activate a time-based license, then features from both permanent and time-based licenses combine to form the running license. How the permanent and time-based licenses combine depends on the type of license. Table 5-18 lists the combination rules for each feature license.

Note Even when the permanent license is used, if the time-based license is active, it continues to count down.

Table 5-18 Time-Based License Combination Rules

Time-Based Feature	Combined License Rule
AnyConnect Premium Sessions	The higher value is used, either time-based or permanent. For example, if the permanent license is 1000 sessions, and the time-based license is 2500 sessions, then 2500 sessions are enabled. Typically, you will not install a time-based license that has less capability than the permanent license, but if you do so, then the permanent license is used.
Unified Communications Proxy Sessions	The time-based license sessions are added to the permanent sessions, up to the platform limit. For example, if the permanent license is 2500 sessions, and the time-based license is 1000 sessions, then 3500 sessions are enabled for as long as the time-based license is active.
Security Contexts	The time-based license contexts are added to the permanent contexts, up to the platform limit. For example, if the permanent license is 10 contexts, and the time-based license is 20 contexts, then 30 contexts are enabled for as long as the time-based license is active.
Botnet Traffic Filter	There is no permanent Botnet Traffic Filter license available; the time-based license is used.
All Others	The higher value is used, either time-based or permanent. For licenses that have a status of enabled or disabled, then the license with the enabled status is used. For licenses with numerical tiers, the higher value is used. Typically, you will not install a time-based license that has less capability than the permanent license, but if you do so, then the permanent license is used.

To view the combined license, see the "Monitoring Licenses" section on page 5-40.

Stacking Time-Based Licenses

In many cases, you might need to renew your time-based license and have a seamless transition from the old license to the new one. For features that are only available with a time-based license, it is especially important that the license not expire before you can apply the new license. The ASA allows you to *stack* time-based licenses so you do not have to worry about the license expiring or about losing time on your licenses because you installed the new one early.

When you install an identical time-based license as one already installed, then the licenses are combined, and the duration equals the combined duration.

For example:

1. You install a 52-week Botnet Traffic Filter license, and use the license for 25 weeks (27 weeks remain).
2. You then purchase another 52-week Botnet Traffic Filter license. When you install the second license, the licenses combine to have a duration of 79 weeks (52 weeks plus 27 weeks).

Similarly:

1. You install an 8-week 1000-session AnyConnect Premium license, and use it for 2 weeks (6 weeks remain).
2. You then install another 8-week 1000-session license, and the licenses combine to be 1000-sessions for 14 weeks (8 weeks plus 6 weeks).

If the licenses are not identical (for example, a 1000-session AnyConnect Premium license vs. a 2500-session license), then the licenses are *not* combined. Because only one time-based license per feature can be active, only one of the licenses can be active. See the "Activating or Deactivating Keys" section on page 5-37 for more information about activating licenses.

Although non-identical licenses do not combine, when the current license expires, the ASA automatically activates an installed license of the same feature if available. See the "Time-Based License Expiration" section on page 5-26 for more information.

Time-Based License Expiration

When the current license for a feature expires, the ASA automatically activates an installed license of the same feature if available. If there are no other time-based licenses available for the feature, then the permanent license is used.

If you have more than one additional time-based license installed for a feature, then the ASA uses the first license it finds; which license is used is not user-configurable and depends on internal operations. If you prefer to use a different time-based license than the one the ASA activated, then you must manually activate the license you prefer. See the "Activating or Deactivating Keys" section on page 5-37.

For example, you have a time-based 2500-session AnyConnect Premium license (active), a time-based 1000-session AnyConnect Premium license (inactive), and a permanent 500-session AnyConnect Premium license. While the 2500-session license expires, the ASA activates the 1000-session license. After the 1000-session license expires, the ASA uses the 500-session permanent license.

Shared AnyConnect Premium Licenses

A shared license lets you purchase a large number of AnyConnect Premium sessions and share the sessions as needed among a group of ASAs by configuring one of the ASAs as a shared licensing server, and the rest as shared licensing participants. This section describes how a shared license works and includes the following topics:

- Information About the Shared Licensing Server and Participants, page 5-27
- Communication Issues Between Participant and Server, page 5-28
- Information About the Shared Licensing Backup Server, page 5-28
- Failover and Shared Licenses, page 5-29
- Maximum Number of Participants, page 5-30

Information About the Shared Licensing Server and Participants

The following steps describe how shared licenses operate:

1. Decide which ASA should be the shared licensing server, and purchase the shared licensing server license using that device serial number.
2. Decide which ASAs should be shared licensing participants, including the shared licensing backup server, and obtain a shared licensing participant license for each device, using each device serial number.
3. (Optional) Designate a second ASA as a shared licensing backup server. You can only specify one backup server.

   Note The shared licensing backup server only needs a participant license.

4. Configure a shared secret on the shared licensing server; any participants with the shared secret can use the shared license.
5. When you configure the ASA as a participant, it registers with the shared licensing server by sending information about itself, including the local license and model information.

   Note The participant needs to be able to communicate with the server over the IP network; it does not have to be on the same subnet.

6. The shared licensing server responds with information about how often the participant should poll the server.
7. When a participant uses up the sessions of the local license, it sends a request to the shared licensing server for additional sessions in 50-session increments.
8. The shared licensing server responds with a shared license. The total sessions used by a participant cannot exceed the maximum sessions for the platform model.

   Note The shared licensing server can also participate in the shared license pool. It does not need a participant license as well as the server license to participate.

a. If there are not enough sessions left in the shared license pool for the participant, then the server responds with as many sessions as available.

b. The participant continues to send refresh messages requesting more sessions until the server can adequately fulfill the request.

9. When the load is reduced on a participant, it sends a message to the server to release the shared sessions.

Note The ASA uses SSL between the server and participant to encrypt all communications.

Communication Issues Between Participant and Server

See the following guidelines for communication issues between the participant and server:

- If a participant fails to send a refresh after 3 times the refresh interval, then the server releases the sessions back into the shared license pool.
- If the participant cannot reach the license server to send the refresh, then the participant can continue to use the shared license it received from the server for up to 24 hours.
- If the participant is still not able to communicate with a license server after 24 hours, then the participant releases the shared license, even if it still needs the sessions. The participant leaves existing connections established, but cannot accept new connections beyond the license limit.
- If a participant reconnects with the server before 24 hours expires, but after the server expired the participant sessions, then the participant needs to send a new request for the sessions; the server responds with as many sessions as can be reassigned to that participant.

Information About the Shared Licensing Backup Server

The shared licensing backup server must register successfully with the main shared licensing server before it can take on the backup role. When it registers, the main shared licensing server syncs server settings as well as the shared license information with the backup, including a list of registered participants and the current license usage. The main server and backup server sync the data at 10 second intervals. After the initial sync, the backup server can successfully perform backup duties, even after a reload.

When the main server goes down, the backup server takes over server operation. The backup server can operate for up to 30 continuous days, after which the backup server stops issuing sessions to participants, and existing sessions time out. Be sure to reinstate the main server within that 30-day period. Critical-level syslog messages are sent at 15 days, and again at 30 days.

When the main server comes back up, it syncs with the backup server, and then takes over server operation.

When the backup server is not active, it acts as a regular participant of the main shared licensing server.

Note When you first launch the main shared licensing server, the backup server can only operate independently for 5 days. The operational limit increases day-by-day, until 30 days is reached. Also, if the main server later goes down for any length of time, the backup server operational limit decrements day-by-day. When the main server comes back up, the backup server starts to increment again day-by-day. For example, if the main server is down for 20 days, with the backup server active during

that time, then the backup server will only have a 10-day limit left over. The backup server "recharges" up to the maximum 30 days after 20 more days as an inactive backup. This recharging function is implemented to discourage misuse of the shared license.

Failover and Shared Licenses

This section describes how shared licenses interact with failover and includes the following topics:

- "Failover and Shared License Servers" section on page 5-29
- "Failover and Shared License Participants" section on page 5-30

Failover and Shared License Servers

This section describes how the main server and backup server interact with failover. Because the shared licensing server is also performing normal duties as the ASA, including performing functions such as being a VPN gateway and firewall, then you might need to configure failover for the main and backup shared licensing servers for increased reliability.

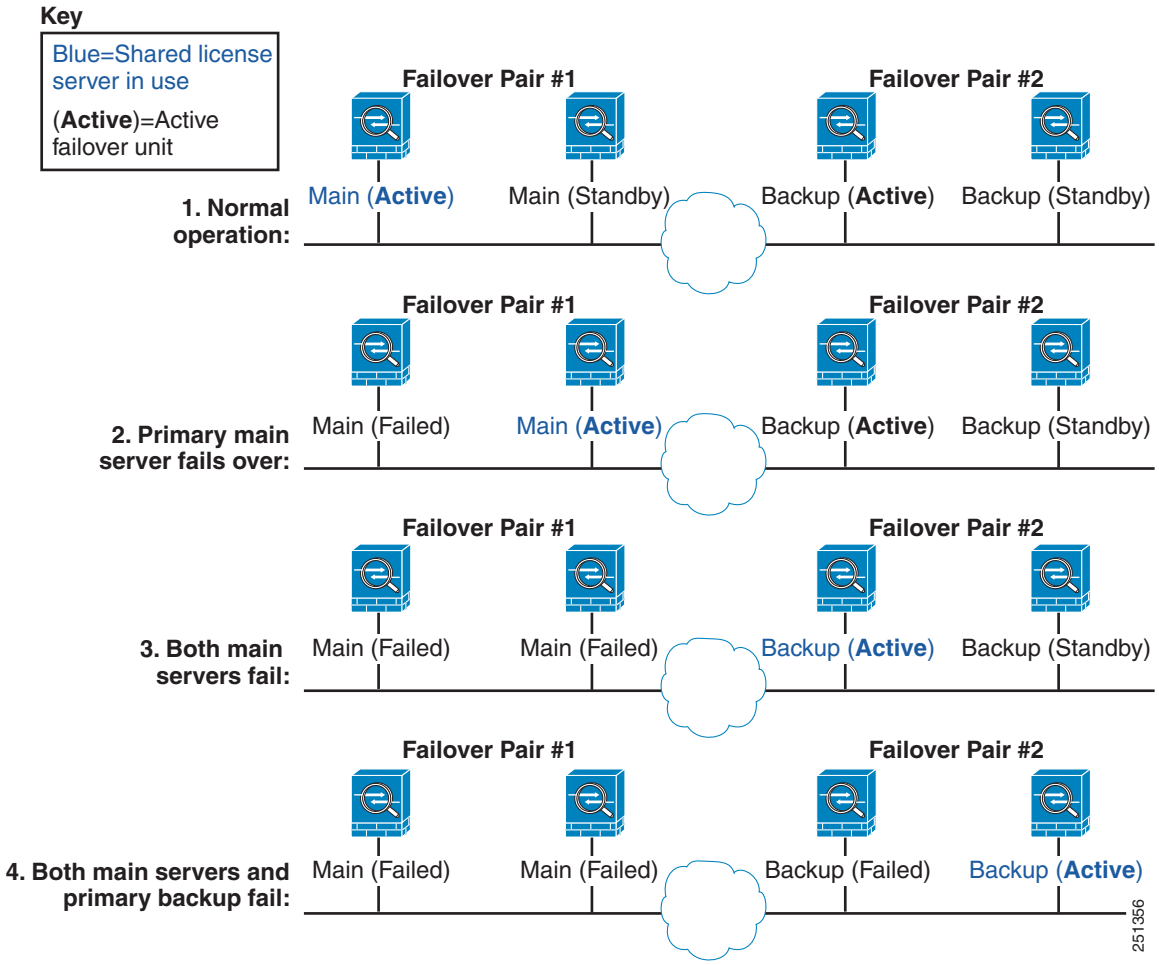
Note The backup server mechanism is separate from, but compatible with, failover.

Shared licenses are supported only in single context mode, so Active/Active failover is not supported.

For Active/Standby failover, the primary unit acts as the main shared licensing server, and the standby unit acts as the main shared licensing server after failover. The standby unit does *not* act as the backup shared licensing server. Instead, you can have a second pair of units acting as the backup server, if desired.

For example, you have a network with 2 failover pairs. Pair #1 includes the main licensing server. Pair #2 includes the backup server. When the primary unit from Pair #1 goes down, the standby unit immediately becomes the new main licensing server. The backup server from Pair #2 never gets used. Only if both units in Pair #1 go down does the backup server in Pair #2 come into use as the shared licensing server. If Pair #1 remains down, and the primary unit in Pair #2 goes down, then the standby unit in Pair #2 comes into use as the shared licensing server (see Figure 5-1).

Figure 5-1 Failover and Shared License Servers



The standby backup server shares the same operating limits as the primary backup server; if the standby unit becomes active, it continues counting down where the primary unit left off. See the "Information About the Shared Licensing Backup Server" section on page 5-28 for more information.

Failover and Shared License Participants

For participant pairs, both units register with the shared licensing server using separate participant IDs. The active unit syncs its participant ID with the standby unit. The standby unit uses this ID to generate a transfer request when it switches to the active role. This transfer request is used to move the shared sessions from the previously active unit to the new active unit.

Maximum Number of Participants

The ASA does not limit the number of participants for the shared license; however, a very large shared network could potentially affect the performance on the licensing server. In this case, you can increase the delay between participant refreshes, or you can create two shared networks.

Failover or ASA Cluster Licenses

With some exceptions, failover and cluster units do not require the same license on each unit. For earlier versions, see the licensing document for your version.

This section includes the following topics:

- Failover License Requirements and Exceptions, page 5-31
- ASA Cluster License Requirements and Exceptions, page 5-31
- How Failover or ASA Cluster Licenses Combine, page 5-32
- Loss of Communication Between Failover or ASA Cluster Units, page 5-32
- Upgrading Failover Pairs, page 5-33

Failover License Requirements and Exceptions

Failover units do not require the same license on each unit.

Older versions of ASA software required that the licenses match on each unit. Starting with Version 8.3(1), you no longer need to install identical licenses. Typically, you buy a license only for the primary unit; for Active/Standby failover, the secondary unit inherits the primary license when it becomes active. If you have licenses on both units, they combine into a single running failover cluster license.

The exceptions to this rule include:

- Security Plus license for the ASA 5505, 5510, and 5512-X—The Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.
- Encryption license—Both units must have the same encryption license.
- IPS module license for the ASA 5512-X through ASA 5555-X—The IPS module license lets you run the IPS software module on the ASA. You must also purchase a separate IPS signature subscription for each unit. To obtain IPS signature support, you must purchase the ASA with IPS pre-installed (the part number must include “IPS”). The combined failover cluster license does not let you pair non-IPS and IPS units. For example, if you buy the IPS version of the ASA 5515-X (part number ASA5515-IPS-K9) and try to make a failover pair with a non-IPS version (part number ASA5515-K9), then you will not be able to obtain IPS signature updates for the ASA5515-K9 unit, even though it has an IPS module license inherited from the other unit.

Note A valid permanent key is required; in rare instances, your authentication key can be removed. If your key consists of all 0’s, then you need to reinstall a valid authentication key before failover can be enabled.

ASA Cluster License Requirements and Exceptions

Cluster units do not require the same license on each unit. Typically, you buy a license only for the master unit; slave units inherit the master license. If you have licenses on multiple units, they combine into a single running ASA cluster license.

The exceptions to this rule include:

- Clustering license—Each unit must have a clustering license.
- Encryption license—Each unit must have the same encryption license.

How Failover or ASA Cluster Licenses Combine

For failover pairs or ASA clusters, the licenses on each unit are combined into a single running cluster license. If you buy separate licenses for each unit, then the combined license uses the following rules:

- For licenses that have numerical tiers, such as the number of sessions, the values from each unit's licenses are combined up to the platform limit. If all licenses in use are time-based, then the licenses count down simultaneously.

  For example, for failover:

  – You have two ASAs with 10 AnyConnect Premium sessions installed on each; the licenses will be combined for a total of 20 AnyConnect Premium sessions.

  – You have two ASA 5520 ASAs with 500 AnyConnect Premium sessions each; because the platform limit is 750, the combined license allows 750 AnyConnect Premium sessions.

  Note In the above example, if the AnyConnect Premium licenses are time-based, you might want to disable one of the licenses so you do not "waste" a 500 session license from which you can only use 250 sessions because of the platform limit.

  – You have two ASA 5540 ASAs, one with 20 contexts and the other with 10 contexts; the combined license allows 30 contexts. For Active/Active failover, the contexts are divided between the two units. One unit can use 18 contexts and the other unit can use 12 contexts, for example, for a total of 30.

  For example, for ASA clustering:

  – You have three units with 50 contexts each, and one unit with the default 2 contexts. The combined license allows 152 contexts to be divided up amongst the four cluster members. Therefore, you can configure up to 38 contexts on the master unit; each slave unit will also have 38 contexts through configuration replication.

- For licenses that have a status of enabled or disabled, then the license with the enabled status is used.
- For time-based licenses that are enabled or disabled (and do not have numerical tiers), the duration is the combined duration of all licenses. The primary/master unit counts down its license first, and when it expires, the secondary/slave unit(s) start counting down its license, and so on. This rule also applies to Active/Active failover and ASA clustering, even though all units are actively operating.

  For example, if you have 48 weeks left on the Botnet Traffic Filter license on two units, then the combined duration is 96 weeks.

To view the combined license, see the "Monitoring Licenses" section on page 5-40.

Loss of Communication Between Failover or ASA Cluster Units

If the units lose communication for more than 30 days, then each unit reverts to the license installed locally. During the 30-day grace period, the combined running license continues to be used by all units.

If you restore communication during the 30-day grace period, then for time-based licenses, the time elapsed is subtracted from the primary/master license; if the primary/master license becomes expired, only then does the secondary/slave license start to count down.

If you do not restore communication during the 30-day period, then for time-based licenses, time is subtracted from all unit licenses, if installed. They are treated as separate licenses and do not benefit from the combined license. The time elapsed includes the 30-day grace period.

For example:

1. You have a 52-week Botnet Traffic Filter license installed on two units. The combined running license allows a total duration of 104 weeks.
2. The units operate as a failover unit/ASA cluster for 10 weeks, leaving 94 weeks on the combined license (42 weeks on the primary/master, and 52 weeks on the secondary/slave).
3. If the units lose communication (for example the primary/master unit fails), the secondary/slave unit continues to use the combined license, and continues to count down from 94 weeks.
4. The time-based license behavior depends on when communication is restored:

- Within 30 days—The time elapsed is subtracted from the primary/master unit license. In this case, communication is restored after 4 weeks. Therefore, 4 weeks are subtracted from the primary/master license leaving 90 weeks combined (38 weeks on the primary, and 52 weeks on the secondary).
- After 30 days—The time elapsed is subtracted from both units. In this case, communication is restored after 6 weeks. Therefore, 6 weeks are subtracted from both the primary/master and secondary/slave licenses, leaving 84 weeks combined (36 weeks on the primary/master, and 46 weeks on the secondary/slave).

Upgrading Failover Pairs

Because failover pairs do not require the same license on both units, you can apply new licenses to each unit without any downtime. If you apply a permanent license that requires a reload (see Table 5-19 on page 5-37), then you can fail over to the other unit while you reload. If both units require reloading, then you can reload them separately so you have no downtime.

No Payload Encryption Models

You can purchase some models with No Payload Encryption. For export to some countries, payload encryption cannot be enabled on the Cisco ASA series. The ASA software senses a No Payload Encryption model, and disables the following features:

- Unified Communications
- VPN

You can still install the Strong Encryption (3DES/AES) license for use with management connections. For example, you can use ASDM HTTPS/SSL, SSHv2, Telnet and SNMPv3. You can also download the dynamic database for the Botnet Traffic Filer (which uses SSL).

When you view the license (see the "Monitoring Licenses" section on page 5-40), VPN and Unified Communications licenses will not be listed.

Licenses FAQ

Q. Can I activate multiple time-based licenses, for example, AnyConnect Premium and Botnet Traffic Filter?

A. Yes. You can use one time-based license per feature at a time.

Q. Can I "stack" time-based licenses so that when the time limit runs out, it will automatically use the next license?

A. Yes. For identical licenses, the time limit is combined when you install multiple time-based licenses. For non-identical licenses (for example, a 1000-session AnyConnect Premium license and a 2500-session license), the ASA automatically activates the next time-based license it finds for the feature.

Q. Can I install a new permanent license while maintaining an active time-based license?

A. Yes. Activating a permanent license does not affect time-based licenses.

Q. For failover, can I use a shared licensing server as the primary unit, and the shared licensing backup server as the secondary unit?

A. No. The secondary unit has the same running license as the primary unit; in the case of the shared licensing server, they require a server license. The backup server requires a participant license. The backup server can be in a separate failover pair of two backup servers.

Q. Do I need to buy the same licenses for the secondary unit in a failover pair?

A. No. Starting with Version 8.3(1), you do not have to have matching licenses on both units. Typically, you buy a license only for the primary unit; the secondary unit inherits the primary license when it becomes active. In the case where you also have a separate license on the secondary unit (for example, if you purchased matching licenses for pre-8.3 software), the licenses are combined into a running failover cluster license, up to the model limits.

Q. Can I use a time-based or permanent AnyConnect Premium license in addition to a shared AnyConnect Premium license?

A. Yes. The shared license is used only after the sessions from the locally installed license (time-based or permanent) are used up. **Note**: On the shared licensing server, the permanent AnyConnect Premium license is not used; you can however use a time-based license at the same time as the shared licensing server license. In this case, the time-based license sessions are available for local AnyConnect Premium sessions only; they cannot be added to the shared licensing pool for use by participants.

Guidelines and Limitations

See the following guidelines for activation keys.

Context Mode Guidelines

- In multiple context mode, apply the activation key in the system execution space.
- Shared licenses are not supported in multiple context mode.

Firewall Mode Guidelines

All license types are available in both routed and transparent mode.

Failover Guidelines

- Shared licenses are not supported in Active/Active mode. See the "Failover and Shared Licenses" section on page 5-29 for more information.
- Failover units do not require the same license on each unit.

Older versions of ASA software required that the licenses match on each unit. Starting with Version 8.3(1), you no longer need to install identical licenses. Typically, you buy a license only for the primary unit; for Active/Standby failover, the secondary unit inherits the primary license when it becomes active. If you have licenses on both units, they combine into a single running failover cluster license.

Note Failover units do require the same RAM on both units.

- For the ASA 5505 and 5510, both units require the Security Plus license; the Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.

Upgrade and Downgrade Guidelines

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier—After you upgrade, if you activate additional feature licenses that were introduced *before 8.2*, then the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in *8.2 or later*, then the activation key is not backwards compatible. If you have an incompatible license key, then see the following guidelines:
  - If you previously entered an activation key in an earlier version, then the ASA uses that key (without any of the new licenses you activated in Version 8.2 or later).
  - If you have a new system and do not have an earlier activation key, then you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier—Version 8.3 introduced more robust time-based key usage as well as failover license changes:
  - If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive. If the last time-based license is for a feature introduced in 8.3, then that license still remains the active license even though it cannot be used in earlier versions. Reenter the permanent key or a valid time-based key.
  - If you have mismatched licenses on a failover pair, then downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.
  - If you have one time-based license installed, but it is for a feature introduced in 8.3, then after you downgrade, that time-based license remains active. You need to reenter the permanent key to disable the time-based license.

Additional Guidelines and Limitations

- The activation key is not stored in your configuration file; it is stored as a hidden file in flash memory.
- The activation key is tied to the serial number of the device. Feature licenses cannot be transferred between devices (except in the case of a hardware failure). If you have to replace your device due to a hardware failure, and it is covered by Cisco TAC, contact the Cisco Licensing Team to have your existing license transferred to the new serial number. The Cisco Licensing Team will ask for the Product Authorization Key reference number and existing serial number.
- Once purchased, you cannot return a license for a refund or for an upgraded license.

- On a single unit, you cannot add two separate licenses for the same feature together; for example, if you purchase a 25-session SSL VPN license, and later purchase a 50-session license, you cannot use 75 sessions; you can use a maximum of 50 sessions. (You may be able to purchase a larger license at an upgrade price, for example from 25 sessions to 75 sessions; this kind of upgrade should be distinguished from adding two separate licenses together).
- Although you can activate all license types, some features are incompatible with each other. In the case of the AnyConnect Essentials license, the license is incompatible with the following licenses: AnyConnect Premium license, shared AnyConnect Premium license, and Advanced Endpoint Assessment license. By default, the AnyConnect Essentials license is used instead of the above licenses, but you can disable the AnyConnect Essentials license in the configuration to restore use of the other licenses using the Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Essentials pane.

Configuring Licenses

This section includes the following topics:

- Obtaining an Activation Key, page 5-36
- Activating or Deactivating Keys, page 5-37
- Configuring a Shared License, page 5-38

Obtaining an Activation Key

To obtain an activation key, you need a Product Authorization Key, which you can purchase from your Cisco account representative. You need to purchase a separate Product Activation Key for each feature license. For example, if you have the Base License, you can purchase separate keys for Advanced Endpoint Assessment and for additional AnyConnect Premium sessions.

After obtaining the Product Authorization Keys, register them on Cisco.com by performing the following steps.

Detailed Steps

Step 1 Obtain the serial number for your ASA by choosing **Configuration > Device Management > Licensing > Activation Key** (in multiple context mode, view the serial number in the System execution space).

Step 2 If you are not already registered with Cisco.com, create an account.

Step 3 Go to the following licensing website:

`http://www.cisco.com/go/license`

Step 4 Enter the following information, when prompted:

- Product Authorization Key (if you have multiple keys, enter one of the keys first. You have to enter each key as a separate process.)
- The serial number of your ASA
- Your e-mail address

An activation key is automatically generated and sent to the e-mail address that you provide. This key includes all features you have registered so far for permanent licenses. For time-based licenses, each license has a separate activation key.

Step 5 If you have additional Product Authorization Keys, repeat Step 4 for each Product Authorization Key. After you enter all of the Product Authorization Keys, the final activation key provided includes all of the permanent features you registered.

Activating or Deactivating Keys

This section describes how to enter a new activation key, and how to activate and deactivate time-based keys.

Prerequisites

- If you are already in multiple context mode, enter the activation key in the system execution space.
- Some permanent licenses require you to reload the ASA after you activate them. Table 5-19 lists the licenses that require reloading.

Table 5-19 Permanent License Reloading Requirements

Model	License Action Requiring Reload
ASA 5505, 5510	Changing between the Base and Security Plus license.
All models	Changing the Encryption license.
All models	Downgrading any permanent license (for example, going from 10 contexts to 2 contexts).

Limitations and Restrictions

Your activation key remains compatible if you upgrade to the latest version from any previous version. However, you might have issues if you want to maintain downgrade capability:

- Downgrading to Version 8.1 or earlier—After you upgrade, if you activate additional feature licenses that were introduced *before 8.2*, then the activation key continues to be compatible with earlier versions if you downgrade. However if you activate feature licenses that were introduced in *8.2 or later*, then the activation key is not backwards compatible. If you have an incompatible license key, then see the following guidelines:
  - If you previously entered an activation key in an earlier version, then the ASA uses that key (without any of the new licenses you activated in Version 8.2 or later).
  - If you have a new system and do not have an earlier activation key, then you need to request a new activation key compatible with the earlier version.
- Downgrading to Version 8.2 or earlier—Version 8.3 introduced more robust time-based key usage as well as failover license changes:
  - If you have more than one time-based activation key active, when you downgrade, only the most recently activated time-based key can be active. Any other keys are made inactive.
  - If you have mismatched licenses on a failover pair, then downgrading will disable failover. Even if the keys are matching, the license used will no longer be a combined license.

Detailed Steps

Step 1 Choose **Configuration > Device Management**, and then choose the **Licensing > Activation Key** or **Licensing Activation Key** pane, depending on your model.

Step 2 To enter a new activation key, either permanent or time-based, enter the new activation key in the New Activation Key field.

The key is a five-element hexadecimal string with one space between each element. The leading 0x specifier is optional; all values are assumed to be hexadecimal. For example:

```
0xd11b3d48 0xa80a4c0a 0x48e0fd1c 0xb0443480 0x843fc490
```

You can install one permanent key, and multiple time-based keys. If you enter a new permanent key, it overwrites the already installed one. If you enter a new time-based key, then it is active by default and displays in the Time-based License Keys Installed table. The last time-based key that you activate for a given feature is the active one.

Step 3 To activate or deactivate an installed time-based key, choose the key in the Time-based License Keys Installed table, and click either **Activate** or **Deactivate**.

You can only have one time-based key active for each feature. See the "Time-Based Licenses" section on page 5-24 for more information.

Step 4 Click **Update Activation Key**.

Some permanent licenses require you to reload the ASA after entering the new activation key. See Table 5-19 on page 5-37 for a list of licenses that need reloading. You will be prompted to reload if it is required.

Configuring a Shared License

This section describes how to configure the shared licensing server and participants. For more information about shared licenses, see the "Shared AnyConnect Premium Licenses" section on page 5-27.

This section includes the following topics:

- Configuring the Shared Licensing Server, page 5-38
- Configuring the Shared Licensing Participant and the Optional Backup Server, page 5-39

Configuring the Shared Licensing Server

This section describes how to configure the ASA to be a shared licensing server.

Prerequisites

The server must have a shared licensing server key.

Detailed Steps

Step 1 Choose the **Configuration > Device Management > Licenses > Shared SSL VPN Licenses** pane.

Step 2 In the Shared Secret field, enter the shared secret as a string between 4 and 128 ASCII characters.

Any participant with this secret can use the license server.

Step 3 (Optional) In the TCP IP Port field, enter the port on which the server listens for SSL connections from participants, between 1 and 65535.

The default is TCP port 50554.

Step 4 (Optional) In the Refresh interval field, enter the refresh interval between 10 and 300 seconds.

This value is provided to participants to set how often they should communicate with the server. The default is 30 seconds.

Step 5 In the Interfaces that serve shared licenses area, check the **Shares Licenses** check box for any interfaces on which participants contact the server.

Step 6 (Optional) To identify a backup server, in the Optional backup shared SSL VPN license server area:

a. In the Backup server IP address field, enter the backup server IP address.

b. In the Primary backup server serial number field, enter the backup server serial number.

c. If the backup server is part of a failover pair, identify the standby unit serial number in the Secondary backup server serial number field.

You can only identify 1 backup server and its optional standby unit.

Step 7 Click **Apply**.

What to Do Next

See the "Configuring the Shared Licensing Participant and the Optional Backup Server" section on page 5-39.

Configuring the Shared Licensing Participant and the Optional Backup Server

This section configures a shared licensing participant to communicate with the shared licensing server; this section also describes how you can optionally configure the participant as the backup server.

Prerequisites

The participant must have a shared licensing participant key.

Detailed Steps

Step 1 Choose the **Configuration > Device Management > Licenses > Shared SSL VPN Licenses** pane.

Step 2 In the Shared Secret field, enter the shared secret as a string between 4 and 128 ASCII characters.

Step 3 (Optional) In the TCP IP Port field, enter the port on which to communicate with the server using SSL, between 1 and 65535.

The default is TCP port 50554.

Step 4 (Optional) To identify the participant as the backup server, in the Select backup role of participant area:

a. Click the **Backup Server** radio button.

b. Check the **Shares Licenses** check box for any interfaces on which participants contact the backup server.

Step 5 Click **Apply**.

Monitoring Licenses

This section includes the following topics:

- Viewing Your Current License, page 5-40
- Monitoring the Shared License, page 5-41

Viewing Your Current License

This section describes how to view your current license, and for time-based activation keys, how much time the license has left.

Guidelines

If you have a No Payload Encryption model, then you view the license, VPN and Unified Communications licenses will not be listed. See the "No Payload Encryption Models" section on page 5-33 for more information.

Detailed Steps

Step 1 To view the running license, which is a combination of the permanent license and any active time-based licenses, choose the **Configuration > Device Management > Licensing > Activation Key** pane and view the Running Licenses area.

In multiple context mode, view the activation key in the System execution space by choosing the **Configuration > Device Management > Activation Key** pane.

For a failover pair, the running license shown is the combined license from the primary and secondary units. See the "How Failover or ASA Cluster Licenses Combine" section on page 5-32 for more information. For time-based licenses with numerical values (the duration is not combined), the License Duration column displays the shortest time-based license from either the primary or secondary unit; when that license expires, the license duration from the other unit displays.

Step 2 (Optional) To view time-based license details, such as the features included in the license and the duration, in the Time-Based License Keys Installed area, choose a license key, and then click **Show License Details**.

Step 3 (Optional) For a failover unit, to view the license installed on this unit (and not the combined license from both primary and secondary units), in the Running Licenses area, click **Show information of license specifically purchased for this device alone**.

Monitoring the Shared License

To monitor the shared license, choose **Monitoring > VPN > Clientless SSL VPN > Shared Licenses**.

Feature History for Licensing

Table 5-20 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 5-20 Feature History for Licensing

Feature Name	Platform Releases	Feature Information
Increased Connections and VLANs	7.0(5)	Increased the following limits: • ASA5510 Base license connections from 32000 to 5000; VLANs from 0 to 10. • ASA5510 Security Plus license connections from 64000 to 130000; VLANs from 10 to 25. • ASA5520 connections from 130000 to 280000; VLANs from 25 to 100. • ASA5540 connections from 280000 to 400000; VLANs from 100 to 200.
SSL VPN Licenses	7.1(1)	SSL VPN licenses were introduced.
Increased SSL VPN Licenses	7.2(1)	A 5000-user SSL VPN license was introduced for the ASA 5550 and above.
Increased interfaces for the Base license on the ASA 5510	7.2(2)	For the Base license on the ASA 5510, the maximum number of interfaces was increased from 3 plus a management interface to unlimited interfaces.
Increased VLANs	7.2(2)	The maximum number of VLANs for the Security Plus license on the ASA 5505 was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully functional interface for it. The backup interface command is still useful for an Easy VPN configuration. VLAN limits were also increased for the ASA 5510 (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 (from 100 to 150), the ASA 5550 (from 200 to 250).

Table 5-20 Feature History for Licensing (continued)

Feature Name	Platform Releases	Feature Information
Gigabit Ethernet Support for the ASA 5510 Security Plus License	7.2(3)	The ASA 5510 now supports Gigabit Ethernet (1000 Mbps) for the Ethernet 0/0 and 0/1 ports with the Security Plus license. In the Base license, they continue to be used as Fast Ethernet (100 Mbps) ports. Ethernet 0/2, 0/3, and 0/4 remain as Fast Ethernet ports for both licenses. **Note** The interface names remain Ethernet 0/0 and Ethernet 0/1.
Advanced Endpoint Assessment License	8.0(2)	The Advanced Endpoint Assessment license was introduced. As a condition for the completion of a Cisco AnyConnect or clientless SSL VPN connections, the remote computer scans for a greatly expanded collection of antivirus and antispyware applications, firewalls, operating systems, and associated updates. It also scans for any registry entries, filenames, and process names that you specify. It sends the scan results to the ASA. The ASA uses both the user login credentials and the computer scan results to assign a Dynamic Access Policy (DAP). With an Advanced Endpoint Assessment License, you can enhance Host Scan by configuring an attempt to update noncompliant computers to meet version requirements. Cisco can provide timely updates to the list of applications and versions that Host Scan supports in a package that is separate from Cisco Secure Desktop.
VPN Load Balancing for the ASA 5510	8.0(2)	VPN load balancing is now supported on the ASA 5510 Security Plus license.
AnyConnect for Mobile License	8.0(3)	The AnyConnect for Mobile license was introduced. It lets Windows mobile devices connect to the ASA using the AnyConnect client.
Time-based Licenses	8.0(4)/8.1(2)	Support for time-based licenses was introduced.
Increased VLANs for the ASA 5580	8.1(2)	The number of VLANs supported on the ASA 5580 are increased from 100 to 250.
Unified Communications Proxy Sessions license	8.0(4)	The UC Proxy sessions license was introduced. Phone Proxy, Presence Federation Proxy, and Encrypted Voice Inspection applications use TLS proxy sessions for their connections. Each TLS proxy session is counted against the UC license limit. All of these applications are licensed under the UC Proxy umbrella, and can be mixed and matched. This feature is not available in Version 8.1.

Table 5-20 Feature History for Licensing (continued)

Feature Name	Platform Releases	Feature Information
Botnet Traffic Filter License	8.2(1)	The Botnet Traffic Filter license was introduced. The Botnet Traffic Filter protects against malware network activity by tracking connections to known bad domains and IP addresses.
AnyConnect Essentials License	8.2(1)	The AnyConnect Essentials License was introduced. This license enables AnyConnect VPN client access to the ASA. This license does not support browser-based SSL VPN access or Cisco Secure Desktop. For these features, activate an AnyConnect Premium license instead of the AnyConnect Essentials license. **Note** With the AnyConnect Essentials license, VPN users can use a Web browser to log in, and download and start (WebLaunch) the AnyConnect client. The AnyConnect client software offers the same set of client features, whether it is enabled by this license or an AnyConnect Premium license. The AnyConnect Essentials license cannot be active at the same time as the following licenses on a given ASA: AnyConnect Premium license (all types) or the Advanced Endpoint Assessment license. You can, however, run AnyConnect Essentials and AnyConnect Premium licenses on different ASAs in the same network. By default, the ASA uses the AnyConnect Essentials license, but you can disable it to use other licenses by using the Configuration > Remote Access VPN > Network (Client) Access > Advanced > AnyConnect Essentials pane.
SSL VPN license changed to AnyConnect Premium SSL VPN Edition license	8.2(1)	The SSL VPN license name was changed to the AnyConnect Premium SSL VPN Edition license.
Shared Licenses for SSL VPN	8.2(1)	Shared licenses for SSL VPN were introduced. Multiple ASAs can share a pool of SSL VPN sessions on an as-needed basis.
Mobility Proxy application no longer requires Unified Communications Proxy license	8.2(2)	The Mobility Proxy no longer requires the UC Proxy license.
10 GE I/O license for the ASA 5585-X with SSP-20	8.2(3)	We introduced the 10 GE I/O license for the ASA 5585-X with SSP-20 to enable 10-Gigabit Ethernet speeds for the fiber ports. The SSP-60 supports 10-Gigabit Ethernet speeds by default. **Note** The ASA 5585-X is not supported in 8.3(x).
10 GE I/O license for the ASA 5585-X with SSP-10	8.2(4)	We introduced the 10 GE I/O license for the ASA 5585-X with SSP-10 to enable 10-Gigabit Ethernet speeds for the fiber ports. The SSP-40 supports 10-Gigabit Ethernet speeds by default. **Note** The ASA 5585-X is not supported in 8.3(x).

Table 5-20 Feature History for Licensing (continued)

Feature Name	Platform Releases	Feature Information
Non-identical failover licenses	8.3(1)	Failover licenses no longer need to be identical on each unit. The license used for both units is the combined license from the primary and secondary units. We modified the following screen: Configuration > Device Management > Licensing > Activation Key.
Stackable time-based licenses	8.3(1)	Time-based licenses are now stackable. In many cases, you might need to renew your time-based license and have a seamless transition from the old license to the new one. For features that are only available with a time-based license, it is especially important that the license not expire before you can apply the new license. The ASA allows you to *stack* time-based licenses so you do not have to worry about the license expiring or about losing time on your licenses because you installed the new one early.
Intercompany Media Engine License	8.3(1)	The IME license was introduced.
Multiple time-based licenses active at the same time	8.3(1)	You can now install multiple time-based licenses, and have one license per feature active at a time. The following screen was modified: Configuration > Device Management > Licensing > Activation Key.
Discrete activation and deactivation of time-based licenses.	8.3(1)	You can now activate or deactivate time-based licenses using a command. The following screen was modified: Configuration > Device Management > Licensing > Activation Key.
AnyConnect Premium SSL VPN Edition license changed to AnyConnect Premium SSL VPN license	8.3(1)	The AnyConnect Premium SSL VPN Edition license name was changed to the AnyConnect Premium SSL VPN license.
No Payload Encryption image for export	8.3(2)	If you install the No Payload Encryption software on the ASA 5505 through 5550, then you disable Unified Communications, strong encryption VPN, and strong encryption management protocols. **Note** This special image is only supported in 8.3(x); for No Payload Encryption support in 8.4(1) and later, you need to purchase a special hardware version of the ASA.
Increased contexts for the ASA 5550, 5580, and 5585-X	8.4(1)	For the ASA 5550 and ASA 5585-X with SSP-10, the maximum contexts was increased from 50 to 100. For the ASA 5580 and 5585-X with SSP-20 and higher, the maximum was increased from 50 to 250.
Increased VLANs for the ASA 5580 and 5585-X	8.4(1)	For the ASA 5580 and 5585-X, the maximum VLANs was increased from 250 to 1024.

Table 5-20 Feature History for Licensing (continued)

Feature Name	Platform Releases	Feature Information
Increased connections for the ASA 5580 and 5585-X	8.4(1)	We increased the firewall connection limits: • ASA 5580-20—1,000,000 to 2,000,000. • ASA 5580-40—2,000,000 to 4,000,000. • ASA 5585-X with SSP-10: 750,000 to 1,000,000. • ASA 5585-X with SSP-20: 1,000,000 to 2,000,000. • ASA 5585-X with SSP-40: 2,000,000 to 4,000,000. • ASA 5585-X with SSP-60: 2,000,000 to 10,000,000.
AnyConnect Premium SSL VPN license changed to AnyConnect Premium license	8.4(1)	The AnyConnect Premium SSL VPN license name was changed to the AnyConnect Premium license. The license information display was changed from "SSL VPN Peers" to "AnyConnect Premium Peers."
Increased AnyConnect VPN sessions for the ASA 5580	8.4(1)	The AnyConnect VPN session limit was increased from 5,000 to 10,000.
Increased Other VPN sessions for the ASA 5580	8.4(1)	The other VPN session limit was increased from 5,000 to 10,000.
IPsec remote access VPN using IKEv2	8.4(1)	IPsec remote access VPN using IKEv2 was added to the AnyConnect Essentials and AnyConnect Premium licenses. IKEv2 site-to-site sessions were added to the Other VPN license (formerly IPsec VPN). The Other VPN license is included in the Base license.
No Payload Encryption hardware for export	8.4(1)	For models available with No Payload Encryption (for example, the ASA 5585-X), the ASA software disables Unified Communications and VPN features, making the ASA available for export to certain countries.
Dual SSPs for SSP-20 and SSP-40	8.4(2)	For SSP-40 and SSP-60, you can use two SSPs of the same level in the same chassis. Mixed-level SSPs are not supported (for example, an SSP-40 with an SSP-60 is not supported). Each SSP acts as an independent device, with separate configurations and management. You can use the two SSPs as a failover pair if desired. When using two SSPs in the chassis, VPN is not supported; note, however, that VPN has not been disabled.
IPS Module license for the ASA 5512-X through ASA 5555-X	8.6(1)	The IPS SSP software module on the ASA 5512-X, ASA 5515-X, ASA 5525-X, ASA 5545-X, and ASA 5555-X requires the IPS module license.
Clustering license for the ASA 5580 and ASA 5585-X.	9.0(1)	A clustering license was added for the ASA 5580 and ASA 5585-X.
Support for VPN on the ASASM	9.0(1)	The ASASM now supports all VPN features.
Unified communications support on the ASASM	9.0(1)	The ASASM now supports all Unified Communications features.

Configuring the Transparent or Routed Firewall

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode. This chapter also includes information about customizing the transparent firewall operation.

You can set the firewall mode independently for each context in multiple context mode.

This chapter includes the following sections:

- Configuring the Firewall Mode, page 6-1
- Configuring ARP Inspection for the Transparent Firewall, page 6-10
- Customizing the MAC Address Table for the Transparent Firewall, page 6-14
- Firewall Mode Examples, page 6-17

Configuring the Firewall Mode

This section describes routed and transparent firewall mode, and how to set the mode. This section includes the following topics:

- Information About the Firewall Mode, page 6-1
- Licensing Requirements for the Firewall Mode, page 6-6
- Default Settings, page 6-6
- Guidelines and Limitations, page 6-6
- Setting the Firewall Mode (Single Mode), page 6-8
- Feature History for Firewall Mode, page 6-9

Information About the Firewall Mode

This section describes routed and transparent firewall mode and includes the following topics:

- Information About Routed Firewall Mode, page 6-2
- Information About Transparent Firewall Mode, page 6-2

Information About Routed Firewall Mode

In routed mode, the ASA is considered to be a router hop in the network. Routed mode supports many interfaces. Each interface is on a different subnet. You can share interfaces between contexts.

The ASA acts as a router between connected networks, and each interface requires an IP address on a different subnet. The ASA supports multiple dynamic routing protocols. However, we recommend using the advanced routing capabilities of the upstream and downstream routers instead of relying on the ASA for extensive routing needs.

Information About Transparent Firewall Mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

This section describes transparent firewall mode and includes the following topics:

- Transparent Firewall Network, page 6-2
- Bridge Groups, page 6-2
- Management Interface (ASA 5510 and Higher), page 6-3
- Allowing Layer 3 Traffic, page 6-3
- Allowed MAC Addresses, page 6-3
- Passing Traffic Not Allowed in Routed Mode, page 6-3
- BPDU Handling, page 6-4
- MAC Address vs. Route Lookups, page 6-4
- Using the Transparent Firewall in Your Network, page 6-5

Transparent Firewall Network

The ASA connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

Bridge Groups

If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the ASA, and traffic must exit the ASA before it is routed by an external router back to another bridge group in the ASA. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context.

Note Each bridge group requires a management IP address. The ASA uses this IP address as the source address for packets originating from the bridge group. The management IP address must be on the same subnet as the connected network. For another method of management, see the "Management Interface (ASA 5510 and Higher)" section on page 6-3.

The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported.

Management Interface (ASA 5510 and Higher)

In addition to each bridge group management IP address, you can add a separate Management *slot*/*port* interface that is not part of any bridge group, and that allows only management traffic to the ASA. For more information, see the "Management Interface" section on page 15-2.

Allowing Layer 3 Traffic

- IPv4 and IPv6 traffic is allowed through the transparent firewall automatically from a higher security interface to a lower security interface, without an access list.
- ARPs are allowed through the transparent firewall in both directions without an access list. ARP traffic can be controlled by ARP inspection.
- For Layer 3 traffic travelling from a low to a high security interface, an extended access list is required on the low security interface. See Chapter 51, "Configuring Access Rules," for more information.

Allowed MAC Addresses

The following destination MAC addresses are allowed through the transparent firewall. Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD
- AppleTalk multicast MAC addresses from 0900.0700.0000 to 0900.07FF.FFFF

Passing Traffic Not Allowed in Routed Mode

In routed mode, some types of traffic cannot pass through the ASA even if you allow it in an access list. The transparent firewall, however, can allow almost any traffic through using either an extended access list (for IP traffic) or an EtherType access list (for non-IP traffic).

Non-IP traffic (for example AppleTalk, IPX, BPDUs, and MPLS) can be configured to go through using an EtherType access list.

Note The transparent mode ASA does not pass CDP packets packets, or any packets that do not have a valid EtherType greater than or equal to 0x600. For example, you cannot pass IS-IS packets. An exception is made for BPDUs, which are supported.

Passing Traffic For Routed-Mode Features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality. For example, by using an extended access list, you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or

multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an extended access list. Likewise, protocols like HSRP or VRRP can pass through the ASA.

BPDU Handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default. To block BPDUs, you need to configure an EtherType access list to deny them. If you are using failover, you might want to block BPDUs to prevent the switch port from going into a blocking state when the topology changes. See the "Transparent Firewall Mode Requirements" section on page 11-15 for more information.

MAC Address vs. Route Lookups

When the ASA runs in transparent mode, the outgoing interface of a packet is determined by performing a MAC address lookup instead of a route lookup.

Route lookups, however, are necessary for the following traffic types:

- Traffic originating on the ASA—For example, if your syslog server is located on a remote network, you must use a static route so the ASA can reach that subnet.
- Traffic that is at least one hop away from the ASA with NAT enabled—The ASA needs to perform a route lookup; you need to add a static route on the ASA for the real host address.
- Voice over IP (VoIP) traffic with inspection enabled, and the endpoint is at least one hop away from the ASA—For example, if you use the transparent firewall between a CCM and an H.323 gateway, and there is a router between the transparent firewall and the H.323 gateway, then you need to add a static route on the ASA for the H.323 gateway for successful call completion.
- VoIP or DNS traffic with inspection enabled, with NAT enabled, and the embedded address is at least one hop away from the ASA—To successfully translate the IP address inside VoIP and DNS packets, the ASA needs to perform a route lookup; you need to add a static route on the ASA for the real host address that is embedded in the packet.

Using the Transparent Firewall in Your Network

Figure 6-1 shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 6-1 Transparent Firewall Network

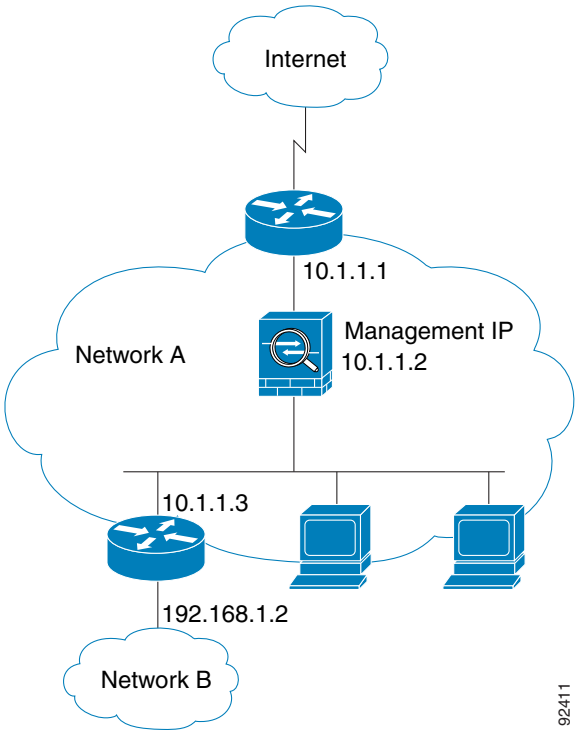


Figure 6-2 shows two networks connected to the ASA, which has two bridge groups.

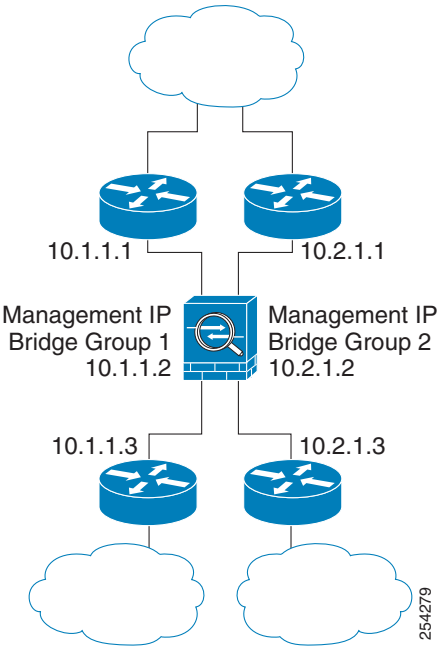
Figure 6-2 Transparent Firewall Network with Two Bridge Groups



Licensing Requirements for the Firewall Mode

The following table shows the licensing requirements for this feature.

Model	License Requirement
All models	Base License.

Default Settings

The default mode is routed mode.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Set the firewall mode per context.

Transparent Firewall Guidelines

Follow these guidelines when planning your transparent firewall network:

- In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the ASA updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the ASA will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.
- Each directly-connected network must be on the same subnet.
- Do not specify the bridge group management IP address as the default gateway for connected devices; devices need to specify the router on the other side of the ASA as the default gateway.
- The default route for the transparent firewall, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a static route that identifies the network from which you expect management traffic.

See the "Guidelines and Limitations" section on page 18-5 for more guidelines.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines and Limitations

- When you change firewall modes, the ASA clears the running configuration because many commands are not supported for both modes. The startup configuration remains unchanged. If you reload without saving, then the startup configuration is loaded, and the mode reverts back to the original setting. See the "Setting the Firewall Mode (Single Mode)" section on page 6-8 for information about backing up your configuration file.
- If you download a text configuration to the ASA that changes the mode with the **firewall transparent** command, be sure to put the command at the top of the configuration; the ASA changes the mode as soon as it reads the command and then continues reading the configuration you downloaded. If the command appears later in the configuration, the ASA clears all the preceding lines in the configuration.

Unsupported Features in Transparent Mode

Table 6-1 lists the features are not supported in transparent mode.

Table 6-1 Unsupported Features in Transparent Mode

Feature	Description
Dynamic DNS	—
DHCP relay	The transparent firewall can act as a DHCP server, but it does not support the DHCP relay commands. DHCP relay is not required because you can allow DHCP traffic to pass through using two extended access lists: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
Dynamic routing protocols	You can, however, add static routes for traffic originating on the ASA. You can also allow dynamic routing protocols through the ASA using an extended access list.
Multicast IP routing	You can allow multicast traffic through the ASA by allowing it in an extended access list.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the ASA. You can pass VPN traffic through the ASA using an extended access list, but it does not terminate non-management connections. SSL VPN is also not supported.
Unified Communications	—

Setting the Firewall Mode (Single Mode)

This section describes how to change the firewall mode using the CLI. For single mode, you cannot change the mode in ASDM. For multiple mode, see the "Configuring a Security Context" section on page 9-20.

Note We recommend that you set the firewall mode before you perform any other configuration because changing the firewall mode clears the running configuration.

Prerequisites

When you change modes, the ASA clears the running configuration (see the "Guidelines and Limitations" section on page 6-6 for more information).

- If you already have a populated configuration, be sure to back up your configuration before changing the mode; you can use this backup for reference when creating your new configuration.
- Use the CLI at the console port to change the mode. If you use any other type of session, including the ASDM Command Line Interface tool or SSH, you will be disconnected when the configuration is cleared, and you will have to reconnect to the ASA using the console port in any case.
- Set the mode within the context.

Detailed Steps

Command	Purpose

`firewall transparent`
 	
Example:
`hostname(config)# firewall transparent`
	Sets the firewall mode to transparent. To change the mode to routed, enter the **no firewall transparent** command.
	
	Note You are not prompted to confirm the firewall mode change; the change occurs immediately.

Feature History for Firewall Mode

Table 6-2 lists the release history for this feature.

Table 6-2 Feature History for Firewall Mode

Feature Name	Releases	Feature Information
Transparent firewall mode	7.0(1)	A transparent firewall is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices. We introduced the following commands: **firewall transparent**, **show firewall**. You cannot set the firewall mode in ASDM; you must use the command-line interface.

Table 6-2 Feature History for Firewall Mode (continued)

Feature Name	Releases	Feature Information
Transparent firewall bridge groups	8.4(1)	If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups. You can configure up to 8 bridge groups in single mode or per context in multiple mode, with 4 interfaces maximum per bridge group. **Note** Although you can configure multiple bridge groups on the ASA 5505, the restriction of 2 data interfaces in transparent mode on the ASA 5505 means you can only effectively use 1 bridge group. We modified or introduced the following screens: Configuration > Device Setup > Interfaces Configuration > Device Setup > Interfaces > Add/Edit Bridge Group Interface Configuration > Device Setup > Interfaces > Add/Edit Interface
Mixed firewall mode support in multiple context mode	8.5(1)/9.0(1)	You can set the firewall mode independently for each security context in multiple context mode, so some can run in transparent mode while others run in routed mode. We modified the following command: **firewall transparent**. For single mode, you cannot set the firewall mode in ASDM; you must use the command-line interface. For multiple mode, we modified the following screen: Configuration > Context Management > Security Contexts.

Configuring ARP Inspection for the Transparent Firewall

This section describes ARP inspection and how to enable it and includes the following topics:

- Information About ARP Inspection, page 6-11
- Licensing Requirements for ARP Inspection, page 6-11
- Default Settings, page 6-11
- Guidelines and Limitations, page 6-11
- Configuring ARP Inspection, page 6-12
- Feature History for ARP Inspection, page 6-14

Information About ARP Inspection

By default, all ARP packets are allowed through the ASA. You can control the flow of ARP packets by enabling ARP inspection.

When you enable ARP inspection, the ASA compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the ASA drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the ASA to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated management interface, if present, never floods packets even if this parameter is set to flood.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a "man-in-the-middle" attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

Licensing Requirements for ARP Inspection

The following table shows the licensing requirements for this feature.

Model	License Requirement
All models	Base License.

Default Settings

By default, all ARP packets are allowed through the ASA.

If you enable ARP inspection, the default setting is to flood non-matching packets.

Guidelines and Limitations

Context Mode Guidelines

- Supported in single and multiple context mode.
- In multiple context mode, configure ARP inspection within each context.

Firewall Mode Guidelines

Supported only in transparent firewall mode. Routed mode is not supported.

Configuring ARP Inspection

This section describes how to configure ARP inspection and includes the following topics:

- Task Flow for Configuring ARP Inspection, page 6-12
- Adding a Static ARP Entry, page 6-12
- Enabling ARP Inspection, page 6-13

Task Flow for Configuring ARP Inspection

To configure ARP Inspection, perform the following steps:

Step 1 Add static ARP entries according to the "Adding a Static ARP Entry" section on page 6-12. ARP inspection compares ARP packets with static ARP entries in the ARP table, so static ARP entries are required for this feature.

Step 2 Enable ARP inspection according to the "Enabling ARP Inspection" section on page 6-13.

Adding a Static ARP Entry

ARP inspection compares ARP packets with static ARP entries in the ARP table. Although hosts identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry times out before it can be updated.

Note The transparent firewall uses dynamic ARP entries in the ARP table for traffic to and from the ASA, such as management traffic.

Detailed Steps

Step 1 Choose the **Configuration > Device Management > Advanced > ARP > ARP Static Table** pane.

Step 2 (Optional) To set the ARP timeout for *dynamic* ARP entries, enter a value in the ARP Timeout field.

This field sets the amount of time before the ASA rebuilds the ARP table, between 60 to 4294967 seconds. The default is 14400 seconds. Rebuilding the ARP table automatically updates new host information and removes old host information. You might want to reduce the timeout because the host information changes frequently.

Step 3 (Optional; 8.4(5) only) To allow non-connected subnets, check the **Allow non-connected subnets** check box. The ASA ARP cache only contains entries from directly-connected subnets by default. You can enable the ARP cache to also include non-directly-connected subnets. We do not recommend enabling this feature unless you know the security risks. This feature could facilitate denial of service (DoS) attack against the ASA; a user on any interface could send out many ARP replies and overload the ASA ARP table with false entries.

You may want to use this feature if you use:

- Secondary subnets.
- Proxy ARP on adjacent routes for traffic forwarding.

Step 4 Click **Add**.

The Add ARP Static Configuration dialog box appears.

Step 5 From the Interface drop-down list, choose the interface attached to the host network.

Step 6 In the IP Address field, enter the IP address of the host.

Step 7 In the MAC Address field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.

Step 8 To perform proxy ARP for this address, check the **Proxy ARP** check box.

If the ASA receives an ARP request for the specified IP address, then it responds with the specified MAC address.

Step 9 Click **OK**, and then **Apply**.

What to Do Next

Enable ARP inspection according to the "Enabling ARP Inspection" section on page 6-13.

Enabling ARP Inspection

This section describes how to enable ARP inspection.

Detailed Steps

Step 1 Choose the **Configuration > Device Management > Advanced > ARP > ARP Inspection** pane.

Step 2 Choose the interface row on which you want to enable ARP inspection, and click **Edit**.

The Edit ARP Inspection dialog box appears.

Step 3 To enable ARP inspection, check the **Enable ARP Inspection** check box.

Step 4 (Optional) To flood non-matching ARP packets, check the **Flood ARP Packets** check box.

By default, packets that do not match any element of a static ARP entry are flooded out all interfaces except the originating interface. If there is a mismatch between the MAC address, the IP address, or the interface, then the ASA drops the packet.

If you uncheck this check box, all non-matching packets are dropped, which restricts ARP through the ASA to only static entries.

Note The Management 0/0 or 0/1 interface or subinterface, if present, never floods packets even if this parameter is set to flood.

Step 5 Click **OK**, and then **Apply**.

Feature History for ARP Inspection

Table 6-2 lists the release history for this feature.

Table 6-3 Feature History for ARP Inspection

Feature Name	Releases	Feature Information
ARP inspection	7.0(1)	ARP inspection compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table. We introduced the following commands: **arp**, **arp-inspection**, and **show arp-inspection**.
ARP cache additions for non-connected subnets	8.4(5)	The ASA ARP cache only contains entries from directly-connected subnets by default. You can now enable the ARP cache to also include non-directly-connected subnets. We do not recommend enabling this feature unless you know the security risks. This feature could facilitate denial of service (DoS) attack against the ASA; a user on any interface could send out many ARP replies and overload the ASA ARP table with false entries. You may want to use this feature if you use: • Secondary subnets. • Proxy ARP on adjacent routes for traffic forwarding. We modified the following screen: Configuration > Device Management > Advanced > ARP > ARP Static Table. *This feature is not available in 8.5(1), 8.6(1), or 9.0(1).*

Customizing the MAC Address Table for the Transparent Firewall

This section describes the MAC address table and includes the following topics:

- Information About the MAC Address Table, page 6-15
- Licensing Requirements for the MAC Address Table, page 6-15
- Default Settings, page 6-15
- Guidelines and Limitations, page 6-15
- Configuring the MAC Address Table, page 6-16
- Feature History for the MAC Address Table, page 6-17

Information About the MAC Address Table

The ASA learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the ASA, the ASA adds the MAC address to its table. The table associates the MAC address with the source interface so that the ASA knows to send any packets addressed to the device out the correct interface.

The ASA 5505 includes a built-in switch; the switch MAC address table maintains the MAC address-to-switch port mapping for traffic within each VLAN. This section only discusses the *bridge* MAC address table, which maintains the MAC address-to-VLAN interface mapping for traffic that passes between VLANs.

Because the ASA is a firewall, if the destination MAC address of a packet is not in the table, the ASA does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly connected devices or for remote devices:

- Packets for directly connected devices—The ASA generates an ARP request for the destination IP address, so that the ASA can learn which interface receives the ARP response.
- Packets for remote devices—The ASA generates a ping to the destination IP address so that the ASA can learn which interface receives the ping reply.

The original packet is dropped.

Licensing Requirements for the MAC Address Table

The following table shows the licensing requirements for this feature.

Model	License Requirement
All models	Base License.

Default Settings

The default timeout value for dynamic MAC address table entries is 5 minutes.

By default, each interface automatically learns the MAC addresses of entering traffic, and the ASA adds corresponding entries to the MAC address table.

Guidelines and Limitations

Context Mode Guidelines

- Supported in single and multiple context mode.
- In multiple context mode, configure the MAC address table within each context.

Firewall Mode Guidelines

Supported only in transparent firewall mode. Routed mode is not supported.

Additional Guidelines

In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the ASA updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the ASA will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.

Configuring the MAC Address Table

This section describes how you can customize the MAC address table and includes the following sections:

- Adding a Static MAC Address, page 6-16
- Disabling MAC Address Learning, page 6-16

Adding a Static MAC Address

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can add static MAC addresses to the MAC address table if desired. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the ASA drops the traffic and generates a system message. When you add a static ARP entry (see the "Adding a Static ARP Entry" section on page 6-12), a static MAC address entry is automatically added to the MAC address table.

To add a static MAC address to the MAC address table, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Bridging > MAC Address Table** pane.

Step 2 (Optional) To set the time a MAC address entry stays in the MAC address table before timing out, enter a value in the Dynamic Entry Timeout field.

This value is between 5 and 720 minutes (12 hours). 5 minutes is the default.

Step 3 Click **Add**.

The Add MAC Address Entry dialog box appears.

Step 4 From the Interface Name drop-down list, choose the source interface associated with the MAC address.

Step 5 In the MAC Address field, enter the MAC address.

Step 6 Click **OK**, and then **Apply**.

Disabling MAC Address Learning

By default, each interface automatically learns the MAC addresses of entering traffic, and the ASA adds corresponding entries to the MAC address table. You can disable MAC address learning if desired, however, unless you statically add MAC addresses to the table, no traffic can pass through the ASA.

To disable MAC address learning, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Bridging > MAC Learning** pane.

Step 2 To disable MAC learning, choose an interface row, and click **Disable**.

Step 3 To reenable MAC learning, click **Enable**.

Step 4 Click **Apply**.

Feature History for the MAC Address Table

Table 6-2 lists the release history for this feature.

Table 6-4 Feature History for the MAC Address Table

Feature Name	Releases	Feature Information
MAC address table	7.0(1)	Transparent firewall mode uses a MAC address table. We introduced the following commands: **mac-address-table static**, **mac-address-table aging-time**, **mac-learn disable**, and **show mac-address-table**.

Firewall Mode Examples

This section includes examples of how traffic moves through the ASA and includes the following topics:

- How Data Moves Through the ASA in Routed Firewall Mode, page 6-17
- How Data Moves Through the Transparent Firewall, page 6-23

How Data Moves Through the ASA in Routed Firewall Mode

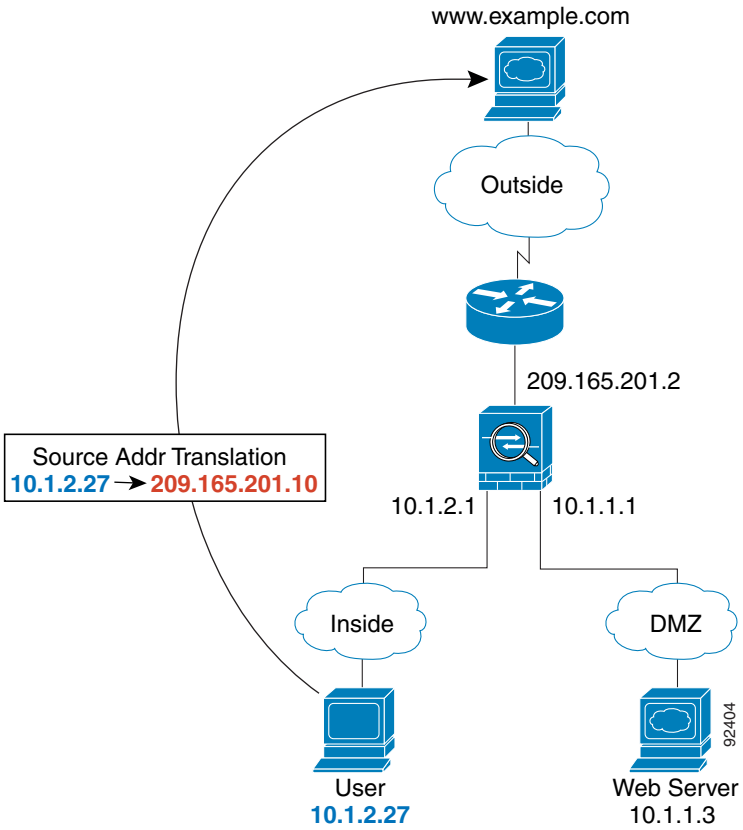
This section describes how data moves through the ASA in routed firewall mode and includes the following topics:

- An Inside User Visits a Web Server, page 6-18
- An Outside User Visits a Web Server on the DMZ, page 6-19
- An Inside User Visits a Web Server on the DMZ, page 6-20
- An Outside User Attempts to Access an Inside Host, page 6-20
- A DMZ User Attempts to Access an Inside Host, page 6-22

An Inside User Visits a Web Server

Figure 6-3 shows an inside user accessing an outside web server.

Figure 6-3 Inside to Outside



The following steps describe how data moves through the ASA (see Figure 6-3):

1. The user on the inside network requests a web page from www.example.com.
2. The ASA receives the packet and because it is a new session, the ASA verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

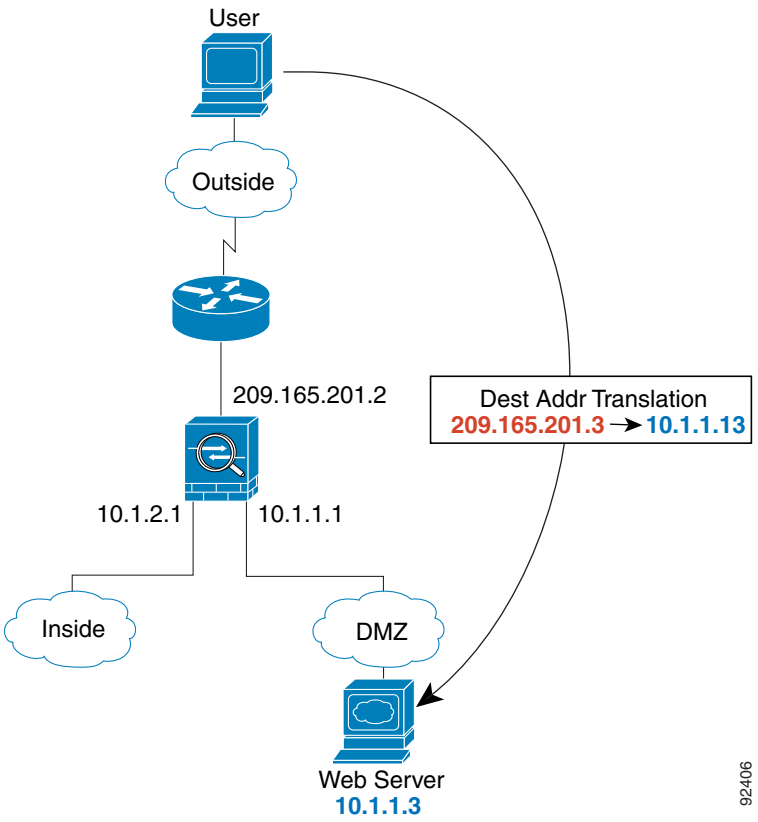
   For multiple context mode, the ASA first classifies the packet to a context.
3. The ASA translates the local source address (10.1.2.27) to the global address 209.165.201.10, which is on the outside interface subnet.

   The global address could be on any subnet, but routing is simplified when it is on the outside interface subnet.
4. The ASA then records that a session is established and forwards the packet from the outside interface.
5. When www.example.com responds to the request, the packet goes through the ASA, and because the session is already established, the packet bypasses the many lookups associated with a new connection. The ASA performs NAT by untranslating the global destination address to the local user address, 10.1.2.27.
6. The ASA forwards the packet to the inside user.

An Outside User Visits a Web Server on the DMZ

Figure 6-4 shows an outside user accessing the DMZ web server.

Figure 6-4 Outside to DMZ



The following steps describe how data moves through the ASA (see Figure 6-4):

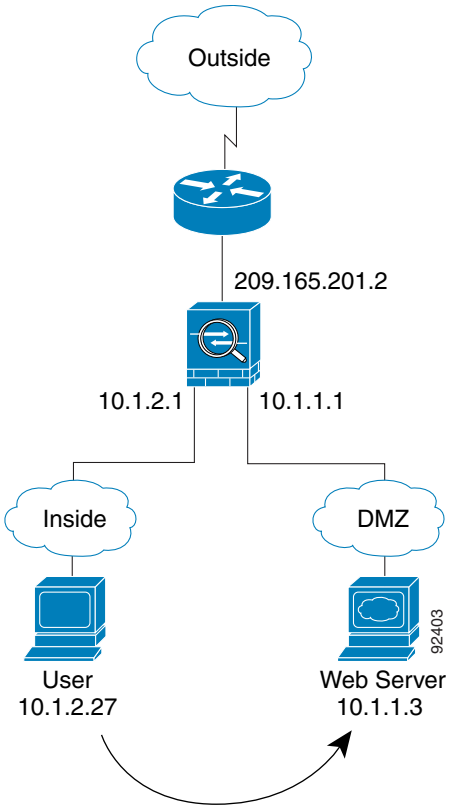
1. A user on the outside network requests a web page from the DMZ web server using the global destination address of 209.165.201.3, which is on the outside interface subnet.
2. The ASA receives the packet and untranslates the destination address to the local address 10.1.1.3.
3. Because it is a new session, the ASA verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

   For multiple context mode, the ASA first classifies the packet to a context.
4. The ASA then adds a session entry to the fast path and forwards the packet from the DMZ interface.
5. When the DMZ web server responds to the request, the packet goes through the ASA and because the session is already established, the packet bypasses the many lookups associated with a new connection. The ASA performs NAT by translating the local source address to 209.165.201.3.
6. The ASA forwards the packet to the outside user.

An Inside User Visits a Web Server on the DMZ

Figure 6-5 shows an inside user accessing the DMZ web server.

Figure 6-5 Inside to DMZ



The following steps describe how data moves through the ASA (see Figure 6-5):

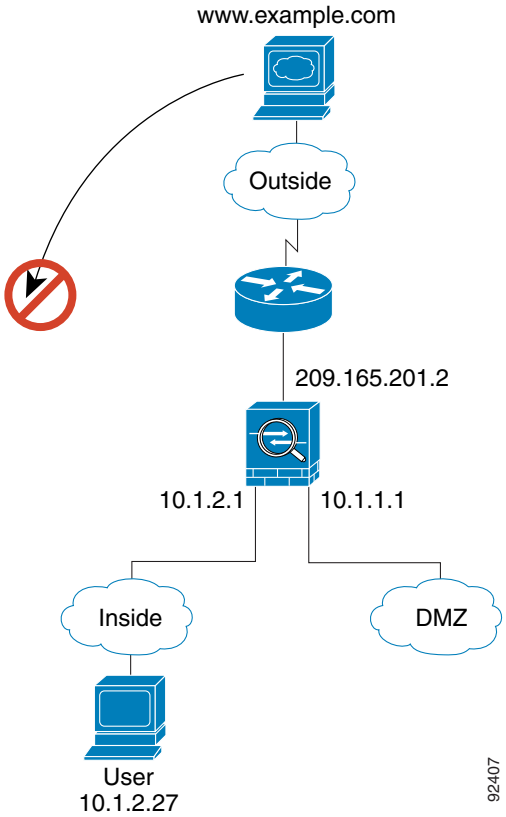
1. A user on the inside network requests a web page from the DMZ web server using the destination address of 10.1.1.3.
2. The ASA receives the packet and because it is a new session, the ASA verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

   For multiple context mode, the ASA first classifies the packet to a context.
3. The ASA then records that a session is established and forwards the packet out of the DMZ interface.
4. When the DMZ web server responds to the request, the packet goes through the fast path, which lets the packet bypass the many lookups associated with a new connection.
5. The ASA forwards the packet to the inside user.

An Outside User Attempts to Access an Inside Host

Figure 6-6 shows an outside user attempting to access the inside network.

Figure 6-6 Outside to Inside



The following steps describe how data moves through the ASA (see Figure 6-6):

1. A user on the outside network attempts to reach an inside host (assuming the host has a routable IP address).

   If the inside network uses private addresses, no outside user can reach the inside network without NAT. The outside user might attempt to reach an inside user by using an existing NAT session.

2. The ASA receives the packet and because it is a new session, the ASA verifies if the packet is allowed according to the security policy (access lists, filters, AAA).

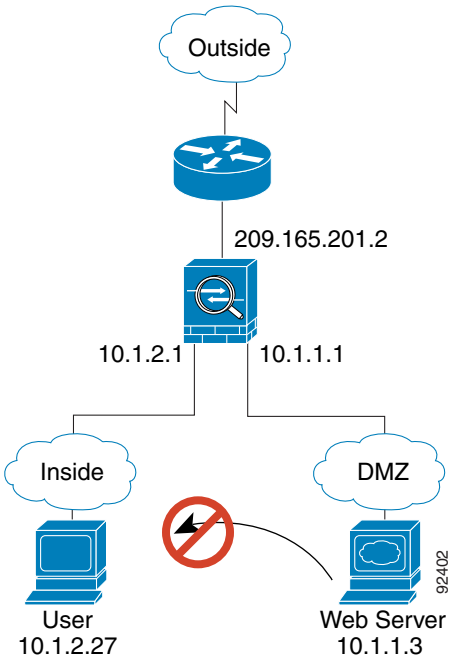
3. The packet is denied, and the ASA drops the packet and logs the connection attempt.

   If the outside user is attempting to attack the inside network, the ASA employs many technologies to determine if a packet is valid for an already established session.

A DMZ User Attempts to Access an Inside Host

Figure 6-7 shows a user in the DMZ attempting to access the inside network.

Figure 6-7 DMZ to Inside



The following steps describe how data moves through the ASA (see Figure 6-7):

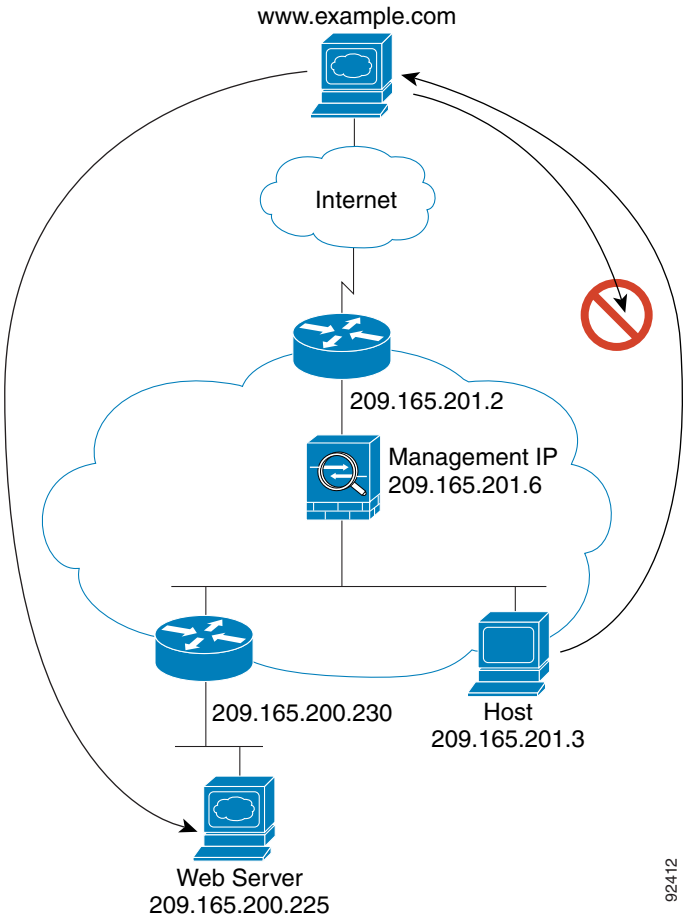
1. A user on the DMZ network attempts to reach an inside host. Because the DMZ does not have to route the traffic on the Internet, the private addressing scheme does not prevent routing.
2. The ASA receives the packet and because it is a new session, the ASA verifies if the packet is allowed according to the security policy (access lists, filters, AAA).

   The packet is denied, and the ASA drops the packet and logs the connection attempt.

How Data Moves Through the Transparent Firewall

Figure 6-8 shows a typical transparent firewall implementation with an inside network that contains a public web server. The ASA has an access list so that the inside users can access Internet resources. Another access list lets the outside users access only the web server on the inside network.

Figure 6-8 Typical Transparent Firewall Data Path



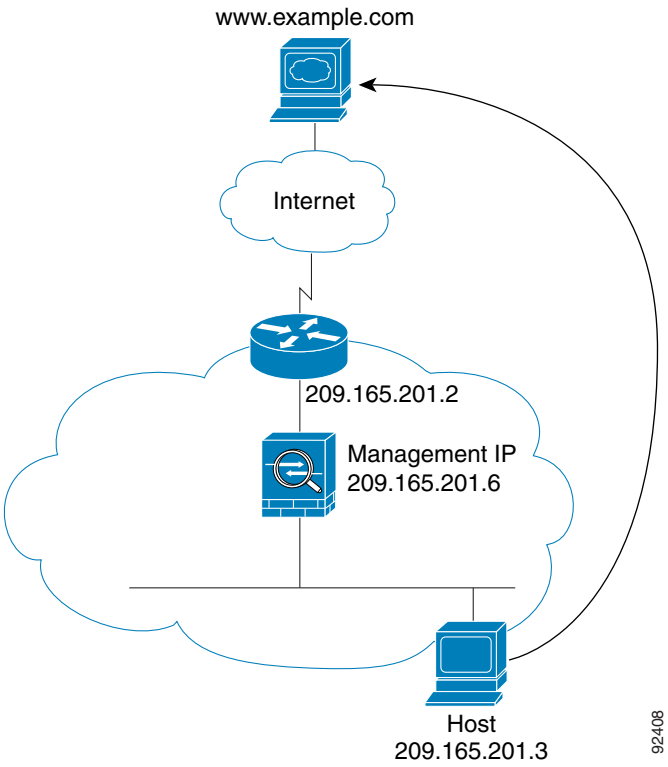
This section describes how data moves through the ASA and includes the following topics:

- An Inside User Visits a Web Server, page 6-24
- An Inside User Visits a Web Server Using NAT, page 6-25
- An Outside User Visits a Web Server on the Inside Network, page 6-26
- An Outside User Attempts to Access an Inside Host, page 6-27

An Inside User Visits a Web Server

Figure 6-9 shows an inside user accessing an outside web server.

Figure 6-9 Inside to Outside



The following steps describe how data moves through the ASA (see Figure 6-9):

1. The user on the inside network requests a web page from www.example.com.
2. The ASA receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

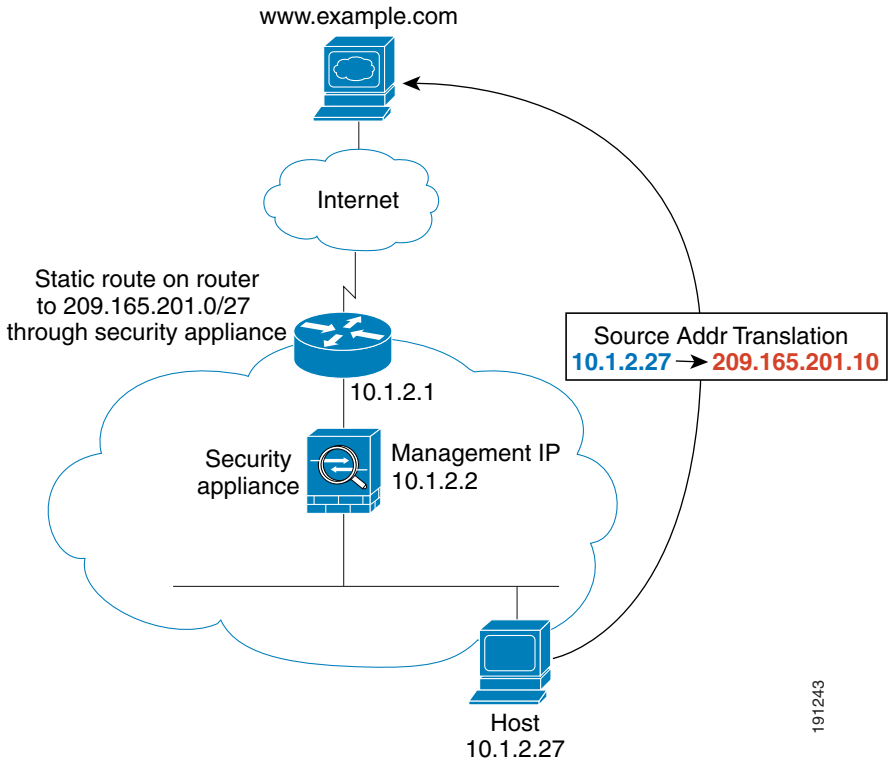
   For multiple context mode, the ASA first classifies the packet to a context.
3. The ASA records that a session is established.
4. If the destination MAC address is in its table, the ASA forwards the packet out of the outside interface. The destination MAC address is that of the upstream router, 209.165.201.2.

   If the destination MAC address is not in the ASA table, the ASA attempts to discover the MAC address by sending an ARP request or a ping. The first packet is dropped.
5. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
6. The ASA forwards the packet to the inside user.

An Inside User Visits a Web Server Using NAT

Figure 6-10 shows an inside user accessing an outside web server.

Figure 6-10 Inside to Outside with NAT



The following steps describe how data moves through the ASA (see Figure 6-10):

1. The user on the inside network requests a web page from www.example.com.
2. The ASA receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

   For multiple context mode, the ASA first classifies the packet according to a unique interface.
3. The ASA translates the real address (10.1.2.27) to the mapped address 209.165.201.10.

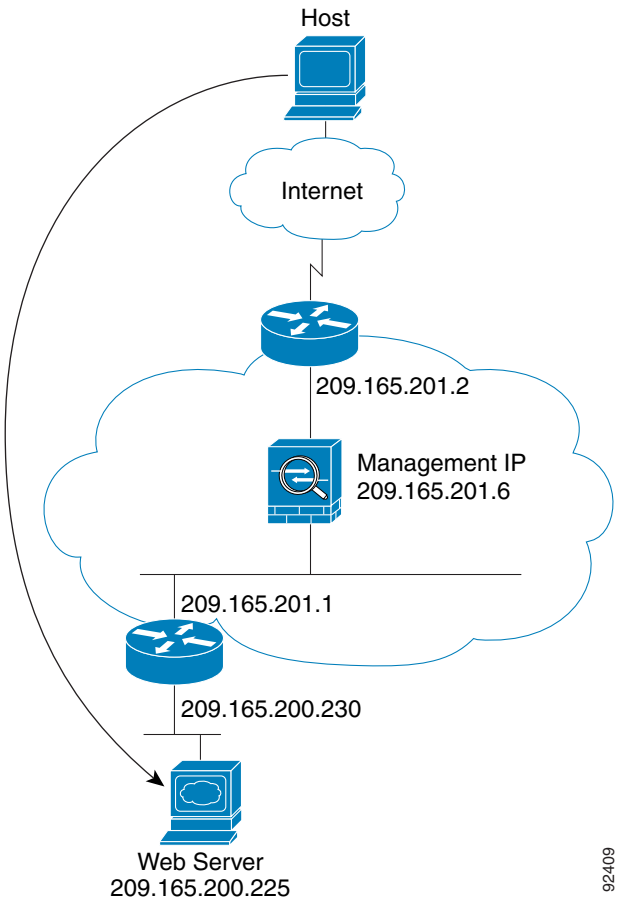
   Because the mapped address is not on the same network as the outside interface, then be sure the upstream router has a static route to the mapped network that points to the ASA.
4. The ASA then records that a session is established and forwards the packet from the outside interface.
5. If the destination MAC address is in its table, the ASA forwards the packet out of the outside interface. The destination MAC address is that of the upstream router, 10.1.2.1.

   If the destination MAC address is not in the ASA table, the ASA attempts to discover the MAC address by sending an ARP request and a ping. The first packet is dropped.
6. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
7. The ASA performs NAT by untranslating the mapped address to the real address, 10.1.2.27.

An Outside User Visits a Web Server on the Inside Network

Figure 6-11 shows an outside user accessing the inside web server.

Figure 6-11 Outside to Inside



The following steps describe how data moves through the ASA (see Figure 6-11):

1. A user on the outside network requests a web page from the inside web server.
2. The ASA receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies that the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

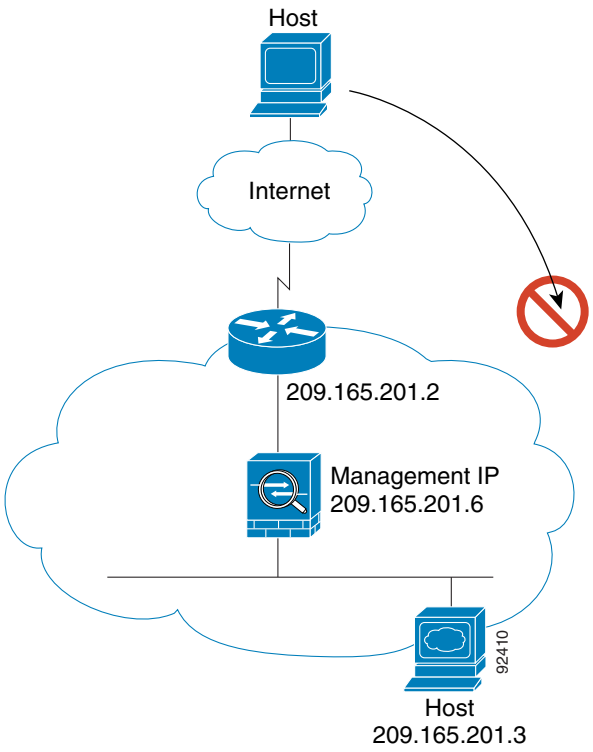
   For multiple context mode, the ASA first classifies the packet to a context.
3. The ASA records that a session is established.
4. If the destination MAC address is in its table, the ASA forwards the packet out of the inside interface. The destination MAC address is that of the downstream router, 209.165.201.1.

   If the destination MAC address is not in the ASA table, the ASA attempts to discover the MAC address by sending an ARP request and a ping. The first packet is dropped.
5. The web server responds to the request; because the session is already established, the packet bypasses the many lookups associated with a new connection.
6. The ASA forwards the packet to the outside user.

An Outside User Attempts to Access an Inside Host

Figure 6-12 shows an outside user attempting to access a host on the inside network.

Figure 6-12 Outside to Inside



The following steps describe how data moves through the ASA (see Figure 6-12):

1. A user on the outside network attempts to reach an inside host.
2. The ASA receives the packet and adds the source MAC address to the MAC address table, if required. Because it is a new session, it verifies if the packet is allowed according to the terms of the security policy (access lists, filters, AAA).

   For multiple context mode, the ASA first classifies the packet to a context.
3. The packet is denied because there is no access list permitting the outside host, and the ASA drops the packet.
4. If the outside user is attempting to attack the inside network, the ASA employs many technologies to determine if a packet is valid for an already established session.

Using the Startup Wizard

The ASDM Startup Wizard guides you through the initial configuration of the ASA, and helps you define basic settings.

This chapter includes the following sections:

- Accessing the Startup Wizard, page 7-1
- Licensing Requirements for the Startup Wizard, page 7-1
- Guidelines and Limitations, page 7-1
- Startup Wizard Screens, page 7-2
- Feature History for the Startup Wizard, page 7-6

Accessing the Startup Wizard

To access this feature in the main ASDM application window, choose one of the following:

- **Wizards > Startup Wizard**.
- **Configuration > Device Setup > Startup Wizard,** and then click **Launch Startup Wizard**.

Licensing Requirements for the Startup Wizard

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single mode and within a context in multiple context mode. This wizard is not supported in the System.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

IPv6 Guidelines

Supports IPv6.

Startup Wizard Screens

The actual sequence of screens is determined by your specified configuration selections. Each screen is available for all modes or models unless otherwise noted. This section includes the following topics:

- Starting Point or Welcome, page 7-2
- Basic Configuration, page 7-3
- Interface Screens, page 7-3
- Static Routes, page 7-4
- Easy VPN Remote Configuration (ASA 5505, Single Mode, Routed Mode), page 7-4
- DHCP Server, page 7-4
- Address Translation (NAT/PAT), page 7-5
- Administrative Access, page 7-5
- IPS Basic Configuration, page 7-5
- Time Zone and Clock Configuration, page 7-5
- Auto Update Server (Single Mode), page 7-5
- Startup Wizard Summary, page 7-6

Starting Point or Welcome

- To change the existing configuration, click the **Modify existing configuration** radio button.
- To set the configuration to the factory default values, click the **Reset configuration to factory defaults** radio button.
  - To configure the IP address and subnet mask of the Management 0/0 (ASA 5510 and higher) or VLAN 1 (ASA 5505) interface to be different from the default value (192.168.1.1), check the **Configure the IP address of the management interface** check box.

Note If you reset the configuration to factory defaults, you cannot undo these changes by clicking **Cancel** or by closing this screen.

In multiple context mode, this screen does not contain any parameters.

Basic Configuration

- (ASA 5505) To specify a group of configuration settings for a remote worker, check the **Configure the device for Teleworker usage** check box. See the "Easy VPN Remote Configuration (ASA 5505, Single Mode, Routed Mode)" section on page 7-4 for more information.
- For information about the hostname, domain name, and enable password, see the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1.

Interface Screens

The interface screens depend on the mode and model. This section includes the following topics:

- Interface Selection (ASA 5505), page 7-3
- Switch Port Allocation (ASA 5505), page 7-3
- Interface IP Address Configuration (ASA 5505, Routed Mode), page 7-3
- Interface Configuration - PPPoE (ASA 5505, Routed Mode, Single Mode), page 7-3
- Outside Interface Configuration - PPPoE (ASA 5510 and Higher, Routed Mode, Single Mode), page 7-4
- Management IP Address Configuration (Transparent Mode), page 7-4
- Other Interfaces Configuration (ASA 5510 and Higher), page 7-4

Interface Selection (ASA 5505)

This screen lets you group the eight, Fast Ethernet switch ports on the ASA 5505 into three VLANs. These VLANs function as separate, Layer 3 networks. You can then choose or create the VLANs that define your network—one for each interface: Outside, Inside, or DMZ (DMZ is available in routed mode only). A DMZ is a separate network located in the neutral zone between a private (inside) network and a public (outside) network.

See the "Configuring VLAN Interfaces" section on page 16-6 for more information.

Switch Port Allocation (ASA 5505)

This screen lets you allocate switch ports to Outside, Inside, or DMZ interfaces (DMZ is only available in routed mode). By default, all switch ports are assigned to VLAN 1 (Inside).

See the "Configuring VLAN Interfaces" section on page 16-6 for more information.

Interface IP Address Configuration (ASA 5505, Routed Mode)

Configure the IP address of each VLAN interface. See the "Configuring General Interface Parameters" section on page 17-7 for more information..

Interface Configuration - PPPoE (ASA 5505, Routed Mode, Single Mode)

Configure the PPoE settings for each interface. See the "PPPoE IP Address and Route Settings" section on page 17-11 for more information.

Outside Interface Configuration (ASA 5510 and Higher, Routed Mode)

- Configure the IP address of the outside interface (the interface with the lowest security level). See the "Configuring General Interface Parameters" section on page 17-7 for more information..
- To configure the IPv6 address, see the "Configuring IPv6 Addressing" section on page 17-15.

Outside Interface Configuration - PPPoE (ASA 5510 and Higher, Routed Mode, Single Mode)

Configure the PPoE settings for the outside interface. See the "PPPoE IP Address and Route Settings" section on page 17-11 for more information.

Management IP Address Configuration (Transparent Mode)

For IPv4, a management IP address is required for each bridge group for both management traffic and for traffic to pass through the ASA. This screen sets the IP address for BVI 1.

See the "Configuring Bridge Groups" section on page 18-8 for more information.

Other Interfaces Configuration (ASA 5510 and Higher)

- You can configure parameters for other interfaces. See the "Configuring General Interface Parameters" section on page 17-7 for more information.
- See the "Allowing Same Security Level Communication" section on page 17-20 for information about the Enable traffic between... check boxes.

Static Routes

Configure static routes. See Chapter 31, "Configuring Static and Default Routes," for more information.

Note For the ASA 5505, to access this screen, you must have checked the **Configure the device for Teleworker usage** check box in Basic Configuration.

Easy VPN Remote Configuration (ASA 5505, Single Mode, Routed Mode)

The ASA can act as an Easy VPN remote device to enable deployment of VPNs to remote locations. See the "Easy VPN Remote" section on page 87-105.

Note To access this screen, you must have checked the **Configure the device for Teleworker usage** check box in Basic Configuration and unchecked the **Enable Auto Update** check box in Auto Update Server (Single Mode).

DHCP Server

Configure the DHCP server. See the "Configuring a DHCP Server" section on page 23-3 for more information.

Address Translation (NAT/PAT)

Configures NAT or PAT for inside addresses (the interface with the highest security level) when accessing the outside (the interface with the lowest security level). See the "Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool" section on page 40-4 or the "Configuring Dynamic PAT (Hide)" section on page 40-8 for more information.

Administrative Access

- Configures ASDM, Telnet, or SSH access. See the "Configuring Management Access" section on page 52-3 for more information.
- To enable a secure connection to an HTTP server to access ASDM, check the **Enable HTTP server for HTTPS/ASDM access** check box. See the "Configuring Management Access" section on page 52-3 for more information.
- To allow ASDM to collect and display statistics, check the **Enable ASDM history metrics** check box. See the "Enabling History Metrics" section on page 4-34 for more information.

IPS Basic Configuration

In single context mode, you can use the Startup Wizard in ASDM to configure basic IPS network configuration. These settings are saved to the IPS configuration, not the ASA configuration. See the "Configuring Basic IPS Module Network Settings" section on page 81-12.

Time Zone and Clock Configuration

Configure the clock parameters. See the "Setting the Date and Time" section on page 21-2 for more information.

Auto Update Server (Single Mode)

- Configure an auto update server by checking the **Enable Auto Update Server for ASA** check box. See the "Configuring Auto Update" section on page 101-30 for more information.
- If you have an IPS module, you can check the **Enable Signature and Engine Updates from Cisco.com** check box. Set the following additional parameters:
  - Enter your Cisco.com username and password, and then confirm the password.
  - Enter the start time in hh:mm:ss format, using a 24-hour clock.

Note For the ASA 5505, to access this screen, you must have checked the **Configure the device for Teleworker usage** check box in Basic Configuration.

Startup Wizard Summary

This screen summarizes all of the configuration settings that you have made for the ASA.

- To change any of the settings in previous screens, click **Back**.
- Choose one of the following:
  - If you ran the Startup Wizard directly from a browser, when you click **Finish**, the configuration settings that you created through the wizard are sent to the ASA and saved in flash memory automatically.
  - If you ran the Startup Wizard from within ASDM, you must explicitly save the configuration in flash memory by choosing **File > Save Running Configuration to Flash**.

Feature History for the Startup Wizard

Table 7-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 7-1 Feature History for the Startup Wizard

Feature Name	Platform Releases	Feature Information
Startup Wizard	7.0(1)	This feature was introduced. We introduced the Wizards > Startup Wizard screen.
IPS Configuration	8.4(1)	For the IPS module, the IPS Basic Configuration screen was added to the startup wizard. Signature updates for the IPS module were also added to the Auto Update screen. The Time Zone and Clock Configuration screen was added to ensure the clock is set on the ASA; the IPS module gets its clock from the ASA. We introduced or modified the following screens: Wizards > Startup Wizard > IPS Basic Configuration Wizards > Startup Wizard > Auto Update Wizards > Startup Wizard > Time Zone and Clock Configuration

PART 1

Configuring High Availability and Scalability

Configuring Multiple Context Mode

This chapter describes how to configure multiple security contexts on the ASA and includes the following sections:

- Information About Security Contexts, page 9-1
- Licensing Requirements for Multiple Context Mode, page 9-13
- Guidelines and Limitations, page 9-14
- Default Settings, page 9-15
- Configuring Multiple Contexts, page 9-15
- Changing Between Contexts and the System Execution Space, page 9-25
- Managing Security Contexts, page 9-26
- Monitoring Security Contexts, page 9-30
- Feature History for Multiple Context Mode, page 9-33

Information About Security Contexts

You can partition a single ASA into multiple virtual devices, known as security contexts. Each context acts as an independent device, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple standalone devices. For unsupported features in multiple context mode, see the "Guidelines and Limitations" section on page 9-14.

This section provides an overview of security contexts and includes the following topics:

- Common Uses for Security Contexts, page 9-2
- Context Configuration Files, page 9-2
- How the ASA Classifies Packets, page 9-3
- Cascading Security Contexts, page 9-6
- Management Access to Security Contexts, page 9-7
- Information About Resource Management, page 9-8
- Information About MAC Addresses, page 9-11

Common Uses for Security Contexts

You might want to use multiple security contexts in the following situations:

- You are a service provider and want to sell security services to many customers. By enabling multiple security contexts on the ASA, you can implement a cost-effective, space-saving solution that keeps all customer traffic separate and secure, and also eases configuration.
- You are a large enterprise or a college campus and want to keep departments completely separate.
- You are an enterprise that wants to provide distinct security policies to different departments.
- You have any network that requires more than one ASA.

Context Configuration Files

This section describes how the ASA implements multiple context mode configurations and includes the following topics:

- Context Configurations, page 9-2
- System Configuration, page 9-2
- Admin Context Configuration, page 9-2

Context Configurations

For each context, the ASA includes a configuration that identifies the security policy, interfaces, and all the options you can configure on a standalone device. You can store context configurations in flash memory, or you can download them from a TFTP, FTP, or HTTP(S) server.

System Configuration

The system administrator adds and manages contexts by configuring each context configuration location, allocated interfaces, and other context operating parameters in the system configuration, which, like a single mode configuration, is the startup configuration. The system configuration identifies basic settings for the ASA. The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the *admin context*. The system configuration does include a specialized failover interface for failover traffic only.

Admin Context Configuration

The admin context is just like any other context, except that when a user logs in to the admin context, then that user has system administrator rights and can access the system and all other contexts. The admin context is not restricted in any way, and can be used as a regular context. However, because logging into the admin context grants you administrator privileges over all contexts, you might need to restrict access to the admin context to appropriate users. The admin context must reside on flash memory, and not remotely.

If your system is already in multiple context mode, or if you convert from single mode, the admin context is created automatically as a file on the internal flash memory called admin.cfg. This context is named “admin.” If you do not want to use admin.cfg as the admin context, you can change the admin context.

How the ASA Classifies Packets

Each packet that enters the ASA must be classified, so that the ASA can determine to which context to send a packet. This section includes the following topics:

- Valid Classifier Criteria, page 9-3
- Classification Examples, page 9-4

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each context.

Valid Classifier Criteria

This section describes the criteria used by the classifier and includes the following topics:

- Unique Interfaces, page 9-3
- Unique MAC Addresses, page 9-3
- NAT Configuration, page 9-3

Note For management traffic destined for an interface, the interface IP address is used for classification.

The routing table is not used for packet classification.

Unique Interfaces

If only one context is associated with the ingress interface, the ASA classifies the packet into that context. In transparent firewall mode, unique interfaces for contexts are required, so this method is used to classify packets at all times.

Unique MAC Addresses

If multiple contexts share an interface, then the classifier uses unique MAC addresses assigned to the interface in each context. An upstream router cannot route directly to a context without unique MAC addresses. By default, auto-generation of MAC addresses is enabled. You can also set the MAC addresses manually when you configure each interface.

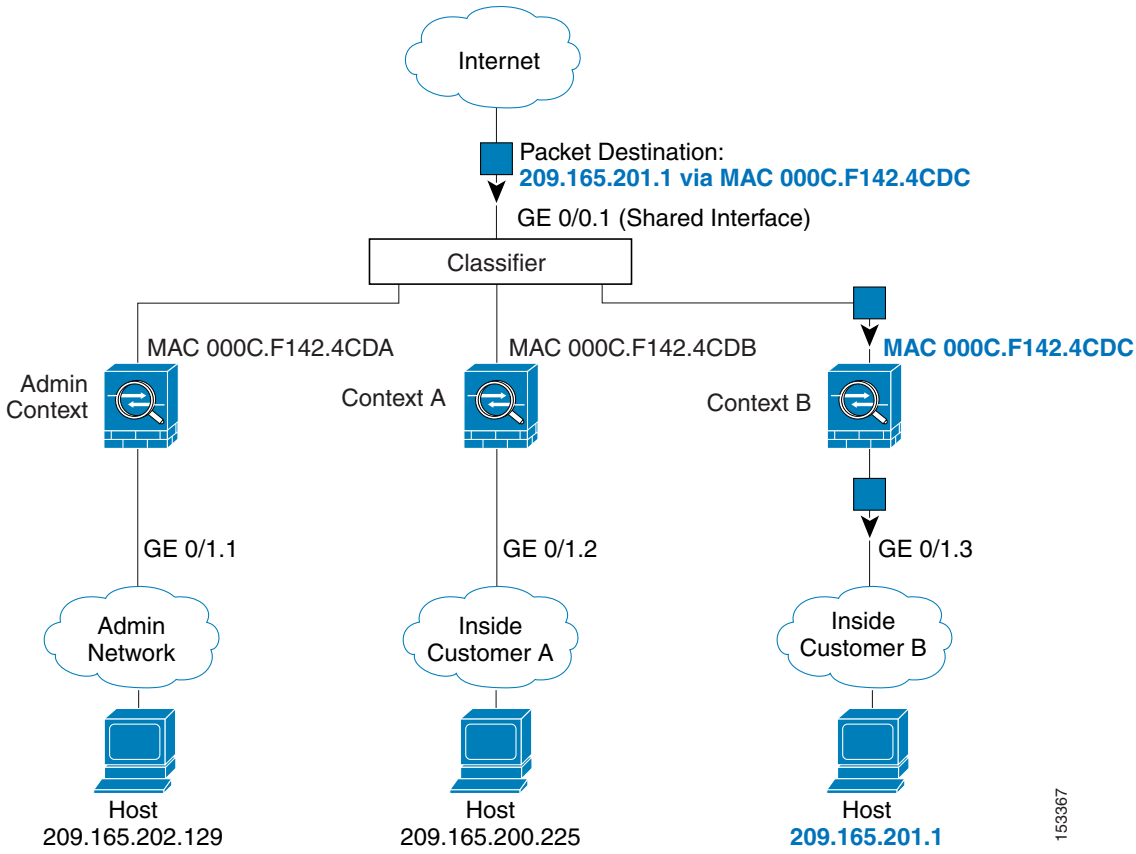
NAT Configuration

If you disable use of unique MAC addresses, then the ASA uses the mapped addresses in your NAT configuration to classify packets. We recommend using MAC addresses instead of NAT, so that traffic classification can occur regardless of the completeness of the NAT configuration.

Classification Examples

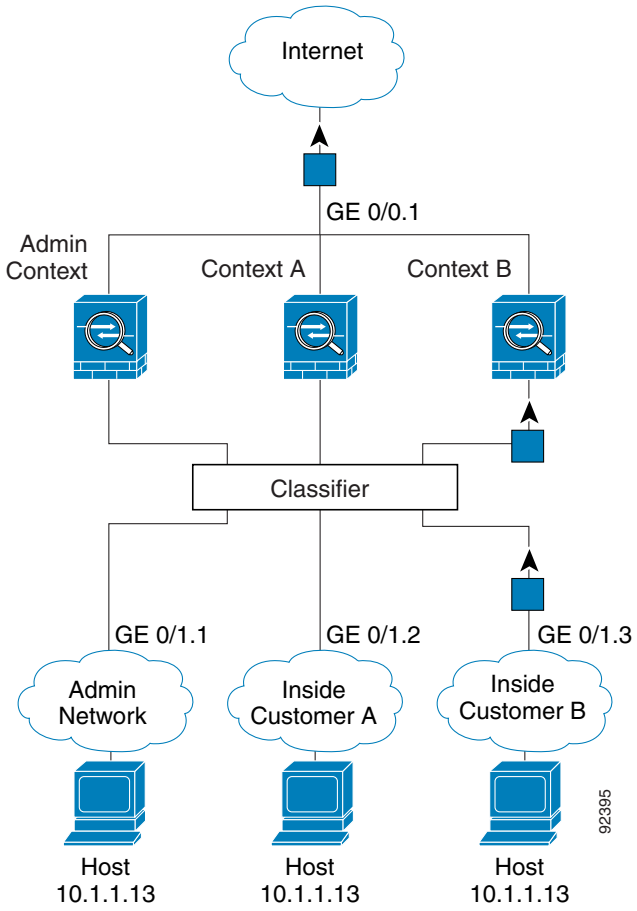
Figure 9-1 shows multiple contexts sharing an outside interface. The classifier assigns the packet to Context B because Context B includes the MAC address to which the router sends the packet.

Figure 9-1 Packet Classification with a Shared Interface Using MAC Addresses



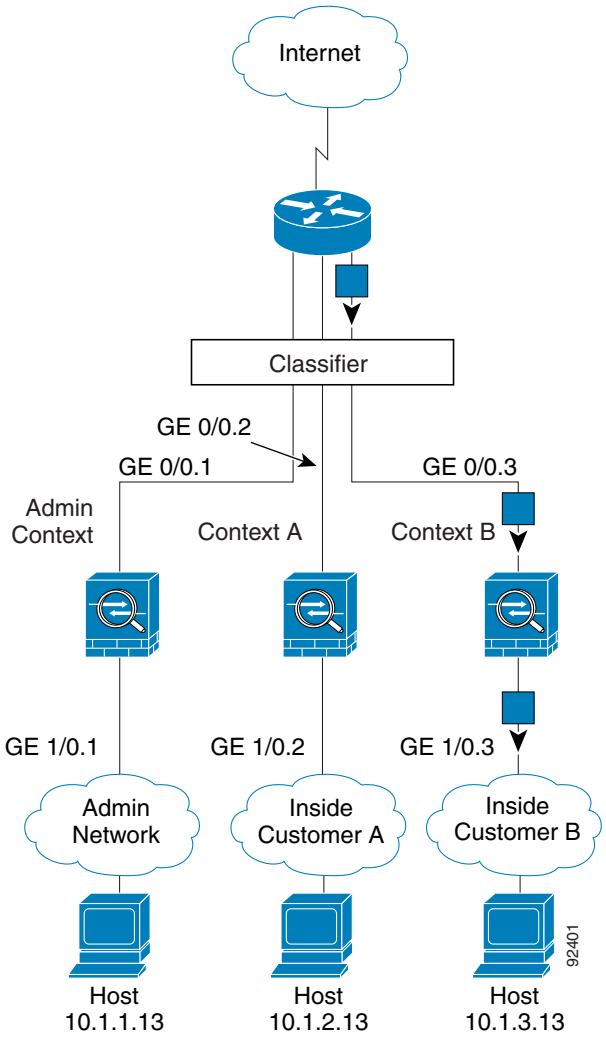
Note that all new incoming traffic must be classified, even from inside networks. Figure 9-2 shows a host on the Context B inside network accessing the Internet. The classifier assigns the packet to Context B because the ingress interface is Gigabit Ethernet 0/1.3, which is assigned to Context B.

Figure 9-2 Incoming Traffic from Inside Networks



For transparent firewalls, you must use unique interfaces. Figure 9-3 shows a packet destined to a host on the Context B inside network from the Internet. The classifier assigns the packet to Context B because the ingress interface is Gigabit Ethernet 1/0.3, which is assigned to Context B.

Figure 9-3 Transparent Firewall Contexts



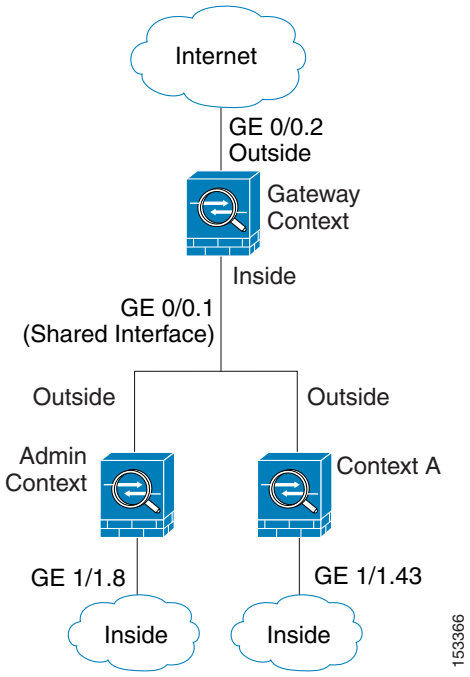
Cascading Security Contexts

Placing a context directly in front of another context is called *cascading contexts*; the outside interface of one context is the same interface as the inside interface of another context. You might want to cascade contexts if you want to simplify the configuration of some contexts by configuring shared parameters in the top context.

Note Cascading contexts requires unique MAC addresses for each context interface (the default setting). Because of the limitations of classifying packets on shared interfaces without MAC addresses, we do not recommend using cascading contexts without unique MAC addresses.

Figure 9-4 shows a gateway context with two contexts behind the gateway.

Figure 9-4 Cascading Contexts



Management Access to Security Contexts

The ASA provides system administrator access in multiple context mode as well as access for individual context administrators. The following sections describe logging in as a system administrator or as a context administrator:

- System Administrator Access, page 9-7
- Context Administrator Access, page 9-8

System Administrator Access

You can access the ASA as a system administrator in two ways:

- Access the ASA console.

  From the console, you access the *system execution space*, which means that any commands you enter affect only the system configuration or the running of the system (for run-time commands).

- Access the admin context using Telnet, SSH, or ASDM.

  See Chapter 52, "Configuring Management Access," to enable Telnet, SSH, and ASDM access.

As the system administrator, you can access all contexts.

When you change to a context from admin or the system, your username changes to the default "enable_15" username. If you configured command authorization in that context, you need to either configure authorization privileges for the "enable_15" user, or you can log in as a different name for which you provide sufficient privileges. To log in with a new username, enter the **login** command. For

example, you log in to the admin context with the username "admin." The admin context does not have any command authorization configuration, but all other contexts include command authorization. For convenience, each context configuration includes a user "admin" with maximum privileges. When you change from the admin context to context A, your username is altered to enable_15, so you must log in again as "admin" by entering the **login** command. When you change to context B, you must again enter the **login** command to log in as "admin."

The system execution space does not support any AAA commands, but you can configure its own enable password, as well as usernames in the local database to provide individual logins.

Context Administrator Access

You can access a context using Telnet, SSH, or ASDM. If you log in to a non-admin context, you can only access the configuration for that context. You can provide individual logins to the context. See Chapter 52, "Configuring Management Access," to enable Telnet, SSH, and ASDM access and to configure management authentication.

Information About Resource Management

By default, all security contexts have unlimited access to the resources of the ASA, except where maximum limits per context are enforced; the only exception is VPN resources, which are disabled by default. If you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context. For VPN resources, you must configure resource management to allow any VPN tunnels.

This section includes the following topics:

- Resource Classes, page 9-8
- Resource Limits, page 9-8
- Default Class, page 9-9
- Using Oversubscribed Resources, page 9-10
- Using Unlimited Resources, page 9-11

Resource Classes

The ASA manages resources by assigning contexts to resource classes. Each context uses the resource limits set by the class. To use the settings of a class, assign the context to the class when you define the context. All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to default. You can only assign a context to one resource class. The exception to this rule is that limits that are undefined in the member class are inherited from the default class; so in effect, a context could be a member of default plus another class.

Resource Limits

You can set the limit for individual resources as a percentage (if there is a hard system limit) or as an absolute value.

For most resources, the ASA does not set aside a portion of the resources for each context assigned to the class; rather, the ASA sets the maximum limit for a context. If you oversubscribe resources, or allow some resources to be unlimited, a few contexts can "use up" those resources, potentially affecting service

to other contexts. The exception is VPN resource types, which you cannot oversubscribe, so the resources assigned to each context are guaranteed. To accommodate temporary bursts of VPN sessions beyond the amount assigned, the ASA supports a "burst" VPN resource type, which is equal to the remaining unassigned VPN sessions. The burst sessions *can* be oversubscribed, and are available to contexts on a first-come, first-served basis.

Default Class

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

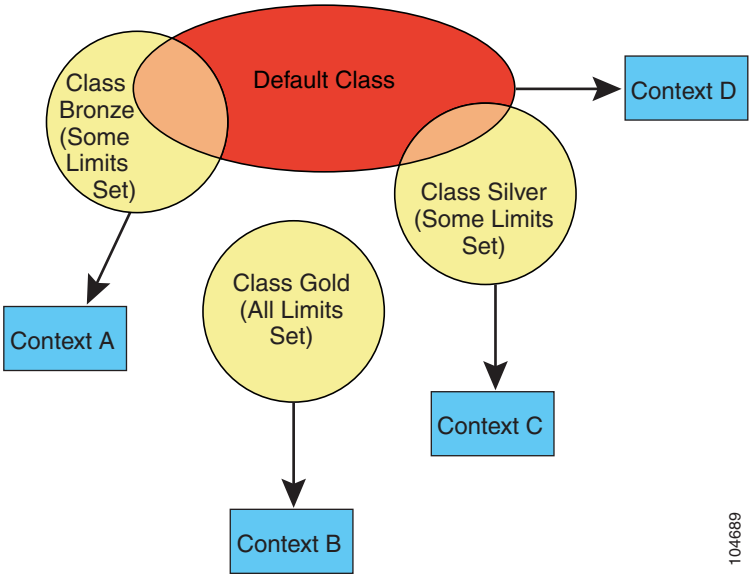
If a context belongs to a class other than the default class, those class settings always override the default class settings. However, if the other class has any settings that are not defined, then the member context uses the default class for those limits. For example, if you create a class with a 2 percent limit for all concurrent connections, but no other limits, then all other limits are inherited from the default class. Conversely, if you create a class with a limit for all resources, the class uses no settings from the default class.

For most resources, the default class provides unlimited access to resources for all contexts, except for the following limits:

- Telnet sessions—5 sessions. (The maximum per context.)
- SSH sessions—5 sessions. (The maximum per context.)
- IPsec sessions—5 sessions. (The maximum per context.)
- MAC addresses—65,535 entries. (The maximum per context.)
- VPN site-to-site tunnels—0 sessions. (You must manually configure the class to allow any VPN sessions.)

Figure 9-5 shows the relationship between the default class and other classes. Contexts A and C belong to classes with some limits set; other limits are inherited from the default class. Context B inherits no limits from default because all limits are set in its class, the Gold class. Context D was not assigned to a class, and is by default a member of the default class.

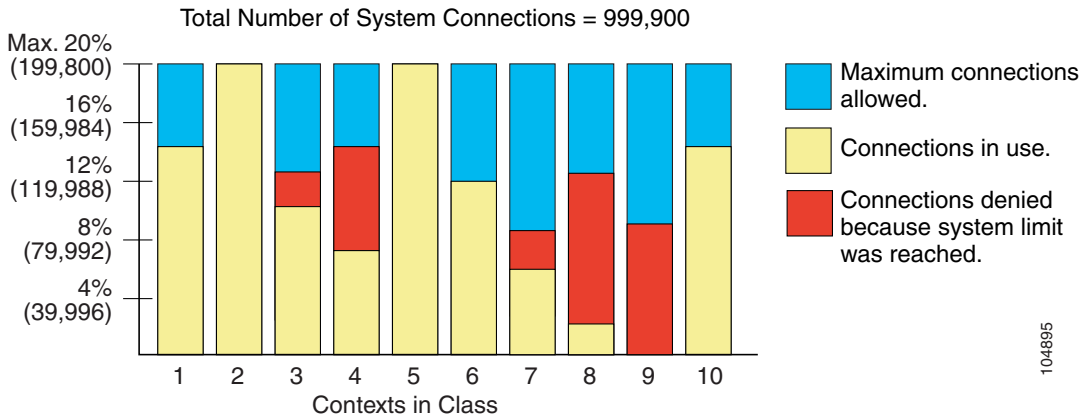
Figure 9-5 Resource Classes



Using Oversubscribed Resources

You can oversubscribe the ASA by assigning more than 100 percent of a resource across all contexts (with the exception of non-burst VPN resources). For example, you can set the Bronze class to limit connections to 20 percent per context, and then assign 10 contexts to the class for a total of 200 percent. If contexts concurrently use more than the system limit, then each context gets less than the 20 percent you intended. (See Figure 9-6.)

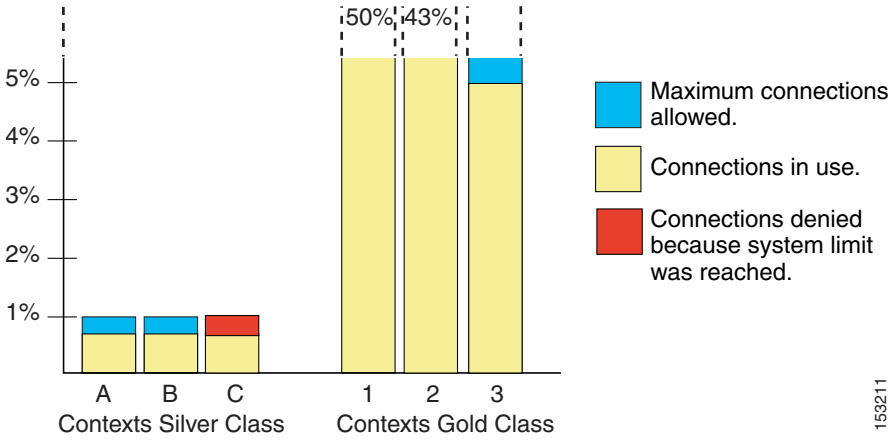
Figure 9-6 Resource Oversubscription



Using Unlimited Resources

The ASA lets you assign unlimited access to one or more resources in a class, instead of a percentage or absolute number. When a resource is unlimited, contexts can use as much of the resource as the system has available. For example, Context A, B, and C are in the Silver Class, which limits each class member to 1 percent of the connections, for a total of 3 percent; but the three contexts are currently only using 2 percent combined. Gold Class has unlimited access to connections. The contexts in the Gold Class can use more than the 97 percent of "unassigned" connections; they can also use the 1 percent of connections not currently in use by Context A, B, and C, even if that means that Context A, B, and C are unable to reach their 3 percent combined limit. (See Figure 9-7.) Setting unlimited access is similar to oversubscribing the ASA, except that you have less control over how much you oversubscribe the system.

Figure 9-7 Unlimited Resources



Information About MAC Addresses

To allow contexts to share interfaces, you should assign unique MAC addresses to each shared context interface.

The MAC address is used to classify packets within a context. If you share an interface, but do not have unique MAC addresses for the interface in each context, then other classification methods are attempted that might not provide full coverage. See the "How the ASA Classifies Packets" section on page 9-3 for information about classifying packets.

In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, you can manually set the MAC address for the interface within the context. See the "Configuring the MAC Address and MTU" section on page 17-13 to manually set the MAC address.

This section includes the following topics:

- Default MAC Address, page 9-12
- Interaction with Manual MAC Addresses, page 9-12
- Failover MAC Addresses, page 9-12
- MAC Address Format, page 9-12

Default MAC Address

If you disable MAC address generation, see the following default MAC addresses:

- For the ASA 5500 series appliances—The physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.
- For the ASASM—All VLAN interfaces use the same MAC address, derived from the backplane MAC address.

See the following sections for your release for additional information about automatic MAC address generation. See also the "MAC Address Format" section on page 9-12.

8.6(1) and Later

Automatic MAC address generation is enabled—Uses an autogenerated prefix. The ASA autogenerates the prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address. You cannot use the legacy auto-generation method (without a prefix).

Note To maintain hitless upgrade for failover pairs, the ASA does not convert an existing auto-generation configuration upon a reload if failover is enabled. However, we strongly recommend that you manually change to the prefix method of generation when using failover, especially for the ASASM. Without the prefix method, ASASMs installed in different slot numbers experience a MAC address change upon failover, and can experience traffic interruption. After upgrading, to use the prefix method of MAC address generation, reenable MAC address autogeneration to use a prefix.

8.5(1) (ASASM only)

Automatic MAC address generation is enabled—Uses the legacy auto-generation method (without a prefix).

Earlier Releases

Automatic MAC address generation is disabled.

Interaction with Manual MAC Addresses

If you manually assign a MAC address and also enable auto-generation, then the manually assigned MAC address is used. If you later remove the manual MAC address, the auto-generated address is used.

Because auto-generated addresses (when using a prefix) start with A2, you cannot start manual MAC addresses with A2 if you also want to use auto-generation.

Failover MAC Addresses

For use with failover, the ASA generates both an active and standby MAC address for each interface. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption. See the "MAC Address Format" section on page 9-12 section for more information.

MAC Address Format

The MAC address format without a prefix is a legacy version not supported on newer ASA versions.

MAC Address Format Using a Prefix

The ASA generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or an autogenerated prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address, and *zz.zzzz* is an internal counter generated by the ASA. For the standby MAC address, the address is identical except that the internal counter is increased by 1.

For an example of how the prefix is used, if you set a prefix of 77, then the ASA converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the ASA native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

MAC Address Format Without a Prefix (Legacy Method; Not Available in 8.6(1) and Later)

Without a prefix, the MAC address is generated using the following format:

- Active unit MAC address: 12*_slot.port_subid.contextid*.
- Standby unit MAC address: 02*_slot.port_subid.contextid*.

For platforms with no interface slots, the slot is always 0. The *port* is the interface port. The *subid* is an internal ID for the subinterface, which is not viewable. The *contextid* is an internal ID for the context, viewable with the **show context detail** command. For example, the interface GigabitEthernet 0/1.200 in the context with the ID 1 has the following generated MAC addresses, where the internal ID for subinterface 200 is 31:

- Active: 1200.0131.0001
- Standby: 0200.0131.0001

This MAC address generation method does not allow for persistent MAC addresses across reloads, does not allow for multiple ASAs on the same network segment (because unique MAC addresses are not guaranteed), and does not prevent overlapping MAC addresses with manually assigned MAC addresses. We recommend using a prefix with the MAC address generation to avoid these issues.

Licensing Requirements for Multiple Context Mode

Model	License Requirement
ASA 5505	No support.
ASA 5510	Security Plus License: 2 contexts. *Optional license: 5 contexts.*
ASA 5520	Base License: 2 contexts. *Optional licenses: 5, 10, or 20 contexts.*
ASA 5540	Base License: 2 contexts. *Optional licenses: 5, 10, 20, or 50 contexts.*

Model	License Requirement
ASA 5550	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, or 100 contexts.*
ASA 5580	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, 100, or 250 contexts.*
ASA 5512-X	No support.
ASA 5515-X	Security Plus License: 2 contexts. *Optional license: 5 contexts.*
ASA 5525-X	Base License: 2 contexts. *Optional licenses: 5, 10, or 20 contexts.*
ASA 5545-X	Base License: 2 contexts. *Optional licenses: 5, 10, 20, or 50 contexts.*
ASA 5555-X	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, or 100 contexts.*
ASA 5585-X with SSP-10	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, or 100 contexts.*
ASA 5585-X with SSP-20, -40, and -60	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, 100, or 250 contexts.*
ASASM	Base License: 2 contexts. *Optional licenses: 5, 10, 20, 50, 100, or 250 contexts.*

Prerequisites

After you are in multiple context mode, connect tothe admin context to access the system configuration. You cannot configure the system from a non-admin context. By default, after you enable multiple context mode, you can connect to the admin context by using the default management IP address. See Chapter 3, "Getting Started," for more information about connecting to the ASA.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode; set the firewall mode per context.

Failover Guidelines

Active/Active mode failover is only supported in multiple context mode.

IPv6 Guidelines

Supports IPv6.

Model Guidelines

Does not support the ASA 5505 and 5512-X.

Unsupported Features

Multiple context mode does not support the following features:

- RIP
- OSPFv3. (OSPFv2 is supported.)
- Multicast routing
- Threat Detection
- Unified Communications
- QoS
- Remote access VPN. (Site-to-site VPN is supported.)

Additional Guidelines

The context mode (single or multiple) is not stored in the configuration file, even though it does endure reboots. If you need to copy your configuration to another device, set the mode on the new device to match.

Default Settings

- By default, the ASA is in single context mode.
- See the "Default Class" section on page 9-9.
- See the "Default MAC Address" section on page 9-12.

Configuring Multiple Contexts

This section describes how to configure multiple context mode and includes the following topics:

- Task Flow for Configuring Multiple Context Mode, page 9-15
- Enabling or Disabling Multiple Context Mode, page 9-16
- Configuring a Class for Resource Management, page 9-17
- Configuring a Security Context, page 9-20
- Automatically Assigning MAC Addresses to Context Interfaces, page 9-24

Task Flow for Configuring Multiple Context Mode

To configure multiple context mode, perform the following steps:

Step 1 Enable multiple context mode. See the "Enabling or Disabling Multiple Context Mode" section on page 9-16.

Step 2 (Optional) Configure classes for resource management. See the "Configuring a Class for Resource Management" section on page 9-17.

Step 3 Configure interfaces in the system execution space.

- ASA 5500—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
- ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

Step 4 Configure security contexts. See the "Configuring a Security Context" section on page 9-20.

Step 5 (Optional) Customize MAC address assignments. See the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24.

Step 6 Complete interface configuration in the context. See Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Enabling or Disabling Multiple Context Mode

Your ASA might already be configured for multiple security contexts depending on how you ordered it from Cisco. If you need to convert from single mode to multiple mode, follow the procedures in this section.

ASDM supports changing modes from single to multiple mode if you use the High Availability and Scalability Wizard and you enable Active/Active failover. See Chapter 13, "Configuring Active/Active Failover," for more information. If you do not want to use Active/Active failover or want to change back to single mode, you must change modes using the CLI; because changing modes requires confirmation, you cannot use the Command Line Interface tool. This section describes changing modes at the CLI.

This section includes the following topics:

- Enabling Multiple Context Mode, page 9-16
- Restoring Single Context Mode, page 9-17

Enabling Multiple Context Mode

When you convert from single mode to multiple mode, the ASA converts the running configuration into two files: a new startup configuration that comprises the system configuration, and admin.cfg that comprises the admin context (in the root directory of the internal flash memory). The original running configuration is saved as old_running.cfg (in the root directory of the internal flash memory). The original startup configuration is not saved. The ASA automatically adds an entry for the admin context to the system configuration with the name "admin."

Prerequisites

Back up your startup configuration. When you convert from single mode to multiple mode, the ASA converts the running configuration into two files. The original startup configuration is not saved. See the "Managing Files" section on page 101-14.

Detailed Steps

Command	Purpose
mode multiple **Example:** `hostname(config)# mode multiple`	Changes to multiple context mode. You are prompted to reboot the ASA.

Restoring Single Context Mode

To copy the old running configuration to the startup configuration and to change the mode to single mode, perform the following steps.

Prerequisites

Perform this procedure in the system execution space.

Detailed Steps

	Command	Purpose
Step 1	**copy disk0:old_running.cfg startup-config** **Example:** `hostname(config)# copy disk0:old_running.cfg startup-config`	Copies the backup version of your original running configuration to the current startup configuration.
Step 2	**mode single** **Example:** `hostname(config)# mode single`	Sets the mode to single mode. You are prompted to reboot the ASA.

Configuring a Class for Resource Management

To configure a class in the system configuration, perform the following steps. You can change the value of a particular resource limit by reentering the command with a new value.

Prerequisites

Perform this procedure in the system execution space.

Guidelines

Table 9-1 lists the resource types and the limits.

Table 9-1 Resource Names and Limits

Resource Name	Rate or Concurrent	Minimum and Maximum Number per Context	System Limit[1]	Description
ASDM Sessions	Concurrent	1 minimum 5 maximum	32	ASDM management sessions. **Note** ASDM sessions use two HTTPS connections: one for monitoring that is always present, and one for making configuration changes that is present only when you make changes. For example, the system limit of 32 ASDM sessions represents a limit of 64 HTTPS sessions.
Connections Conns/sec	Concurrent or Rate	N/A	Concurrent connections: See the "Supported Feature Licenses Per Model" section on page 5-1 for the connection limit available for your model. Rate: N/A	TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts.
Hosts	Concurrent	N/A	N/A	Hosts that can connect through the ASA.
Inspects/sec	Rate	N/A	N/A	Application inspections per second.
MAC Entries	Concurrent	N/A	65,535	For transparent firewall mode, the number of MAC addresses allowed in the MAC address table.
Routes	Concurrent	N/A	N/A	Dynamic routes.
Site-to-Site VPN Burst	Concurrent	N/A	The Other VPN session amount for your model minus the sum of the sessions assigned to all contexts for Site-to-Site VPN.	The number of site-to-site VPN sessions allowed beyond the amount assigned to a context with Site-to-Site VPN. For example, if your model supports 5000 sessions, and you assign 4000 sessions across all contexts with Site-to-Site VPN, then the remaining 1000 sessions are available for Site-to-Site VPN Burst. Unlike Site-to-Site VPN, which guarantees the sessions to the context, Site-to-Site VPN Burst can be oversubscribed; the burst pool is available to all contexts on a first-come, first-served basis.
Site-to-Site VPN	Concurrent	N/A	See the "Supported Feature Licenses Per Model" section on page 5-1 for the Other VPN sessions available for your model.	Site-to-site VPN sessions. You cannot oversubscribe this resource; all context assignments combined cannot exceed the model limit. The sessions you assign for this resource are guaranteed to the context.
SSH	Concurrent	1 minimum 5 maximum	100	SSH sessions.

Table 9-1 Resource Names and Limits (continued)

Resource Name	Rate or Concurrent	Minimum and Maximum Number per Context	System Limit[1]	Description
Syslogs/sec	Rate	N/A	N/A	Syslog messages per second.
Telnet	Concurrent	1 minimum 5 maximum	100	Telnet sessions.
xlates	Concurrent	N/A	N/A	Network address translations.

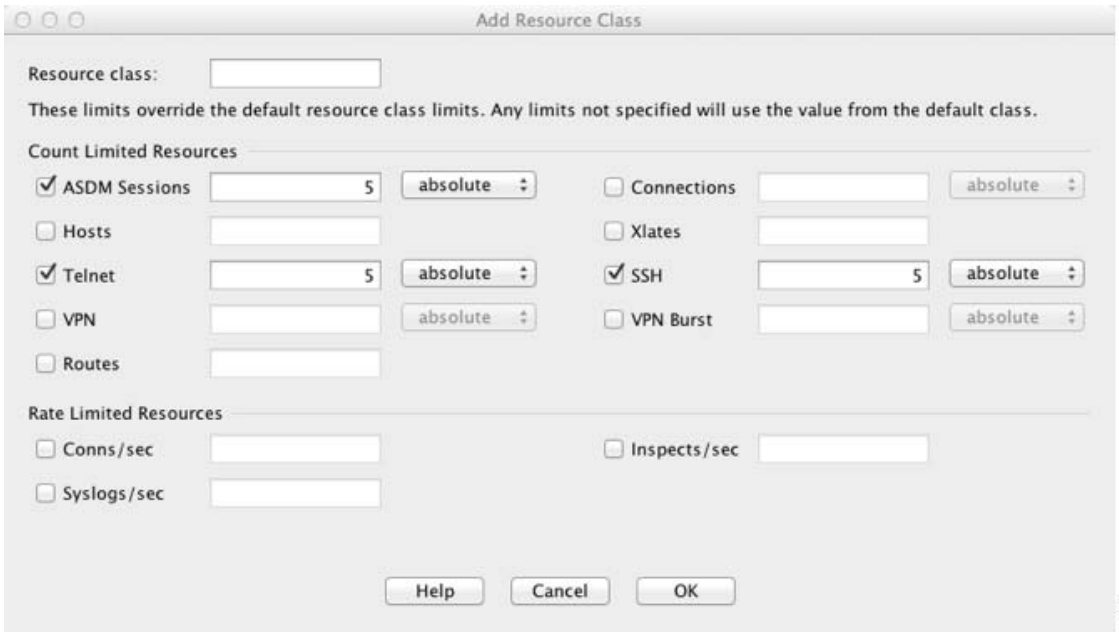
1. If this column value is N/A, then you cannot set a percentage of the resource because there is no hard system limit for the resource.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Resource Class**, and click **Add**.

The Add Resource Class dialog box appears.



Step 3 In the Resource Class field, enter a class name up to 20 characters in length.

Step 4 In the Count Limited Resources area, set the concurrent limits for resources.

See the Table 9-1 on page 9-18 for a description of each resource type.

For resources that do not have a system limit, you cannot set the percentage; you can only set an absolute value. If you do not set a limit, the limit is inherited from the default class. If the default class does not set a limit, then the resource is unlimited, or the system limit if available. For most resources, 0 sets the limit to unlimited. For VPN types, 0 sets the limit none.

Step 5 In the Rate Limited Resources area, set the rate limit for resources.

See the Table 9-1 on page 9-18 for a description of each resource type.

If you do not set a limit, the limit is inherited from the default class. If the default class does not set a limit, then it is unlimited by default. 0 sets the limit to unlimited

Step 6 Click **OK**.

Configuring a Security Context

The security context definition in the system configuration identifies the context name, configuration file URL, interfaces that a context can use, and other settings.

Prerequisites

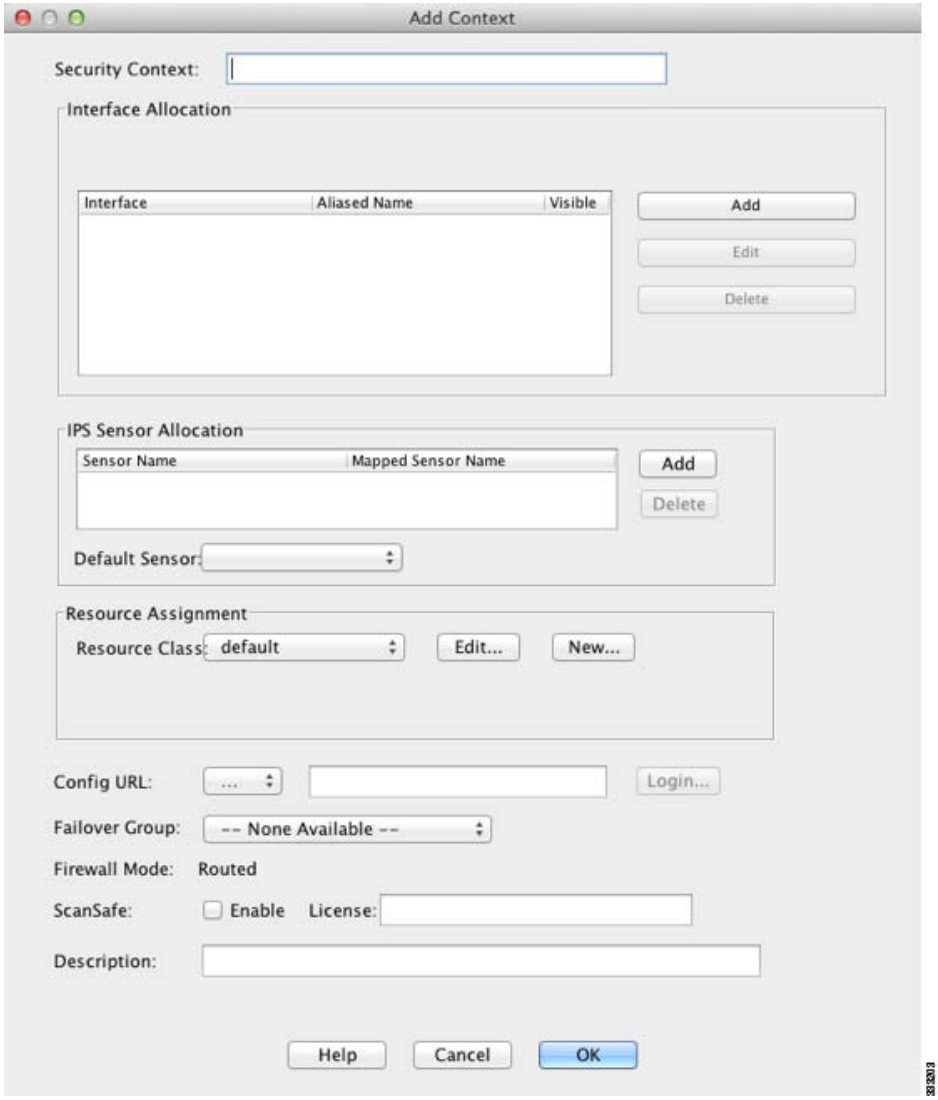
- Perform this procedure in the system execution space.
- For the ASASM, assign VLANs to the ASASM on the switch according to Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- For the ASA 5500, configure physical interface parameters, VLAN subinterfaces, EtherChannels, and redundant interfaces according to Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Security Contexts**, and click **Add**.

The Add Context dialog box appears.



Step 3 In the Security Context field, enter the context name as a string up to 32 characters long.

This name is case sensitive, so you can have two contexts named “customerA” and “CustomerA,” for example. “System” or “Null” (in upper or lower case letters) are reserved names, and cannot be used.

Step 4 In the Interface Allocation area, click the **Add** button to assign an interface to the context.

a. From the Interfaces > Physical Interface drop-down list, choose an interface.

   You can assign the main interface, in which case you leave the subinterface ID blank, or you can assign a subinterface or a range of subinterfaces associated with this interface. In transparent firewall mode, only interfaces that have not been allocated to other contexts are shown. If the main interface was already assigned to another context, then you must choose a subinterface.

b. (Optional) In the Interfaces > Subinterface Range (optional) drop-down list, choose a subinterface ID.

   For a range of subinterface IDs, choose the ending ID in the second drop-down list, if available.

   In transparent firewall mode, only subinterfaces that have not been allocated to other contexts are shown.

a. (Optional) In the Aliased Names area, check **Use Aliased Name in Context** to set an aliased name for this interface to be used in the context configuration instead of the interface ID.

   – In the Name field, sets the aliased name.

     An aliased name must start with a letter, end with a letter, and have as interior characters only letters, digits, or an underscore. This field lets you specify a name that ends with a letter or underscore; to add an optional digit after the name, set the digit in the Range field.

   – (Optional) In the Range field, set the numeric suffix for the aliased name.

     If you have a range of subinterfaces, you can enter a range of digits to be appended to the name.

b. (Optional) To enable context users to see physical interface properties even if you set an aliased name, check **Show Hardware Properties in Context**.

c. Click **OK** to return to the Add Context dialog box.

Step 5 (Optional) If you use IPS virtual sensors, then assign a sensor to the context in the IPS Sensor Allocation area.

For detailed information about IPS and virtual sensors, see Chapter 81, “Configuring the ASA IPS Module.”

Step 6 (Optional) To assign this context to a resource class, choose a class name from the Resource Assignment > Resource Class drop-down list.

You can add or edit a resource class directly from this area. See the "Configuring a Class for Resource Management" section on page 9-17 for more information.

Step 7 To set the context configuration location, identify the URL by choosing a file system type from the Config URL drop-down list and entering a path in the field.

For example, the combined URL for FTP has the following format:

ftp://server.example.com/configs/admin.cfg

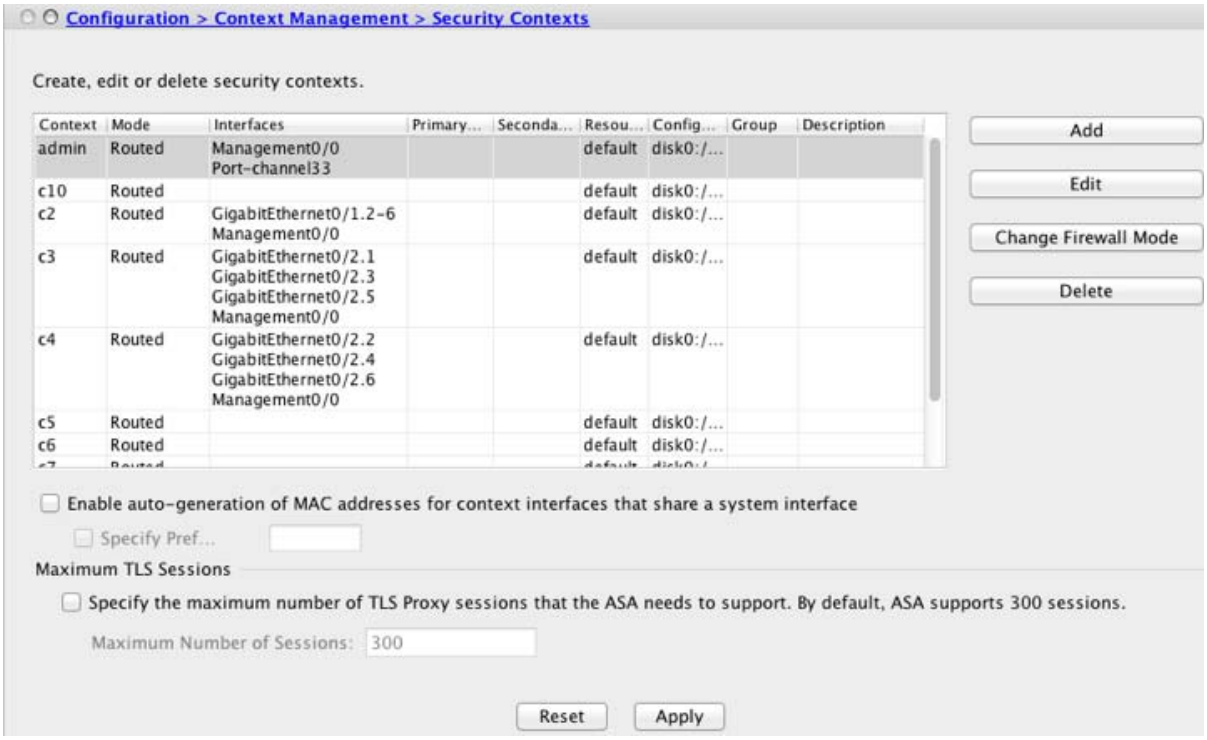
a. (Optional) For external file systems, set the username and password by clicking **Login**.

Step 8 (Optional) To set the failover group for Active/Active failover, choose the group name in the Failover Group drop-down list.

Step 9 (Optional) To enable ScanSafe inspection in this context, click **Enable**. To override the license set in the system configuration, enter a license in the License field.

Step 10 (Optional) Add a description in the Description field.

Step 11 Click **OK** to return to the Security Contexts pane.



Step 12 (Optional) To set the firewall mode to transparent, select the context and click **Change Firewall Mode**.

You see the following confirmation dialog box:

If this is a new context, there is no configuration to erase. Click **Change Mode** to change to transparent firewall mode.

If this is an existing context, then be sure to back up the configuration before you change the mode.

Step 13 To customize auto-generation of MAC addresses, see the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24.

Step 14 To specify the maximum TLS Proxy sessions for the device, check the **Specify the maximum number of TLS Proxy sessions that the ASA needs to support** check box. For more information about TLS proxy, see Chapter 66, "Configuring the TLS Proxy for Encrypted Voice Inspection."

Automatically Assigning MAC Addresses to Context Interfaces

This section describes how to configure auto-generation of MAC addresses.

The MAC address is used to classify packets within a context. See the "Information About MAC Addresses" section on page 9-11 for more information, especially if you are upgrading from an earlier ASA version. See also the "Viewing Assigned MAC Addresses" section on page 9-32.

Guidelines

- When you configure a name for the interface in a context, the new MAC address is generated immediately. If you enable this feature after you configure context interfaces, then MAC addresses are generated for all interfaces immediately after you enable it. If you disable this feature, the MAC address for each interface reverts to the default MAC address. For example, subinterfaces of GigabitEthernet 0/1 revert to using the MAC address of GigabitEthernet 0/1.
- In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, you can manually set the MAC address for the interface within the context. See the "Configuring the MAC Address and MTU" section on page 17-13 to manually set the MAC address.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Security Contexts**, and check **Mac-Address auto**. If you do not enter a prefix, then the ASA autogenerates the prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address.

Step 3 (Optional) Check the **Prefix** check box, and in the field, enter a decimal value between 0 and 65535.

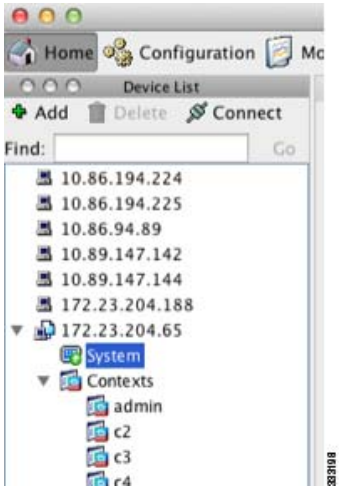
This prefix is converted to a four-digit hexadecimal number, and used as part of the MAC address. See the "MAC Address Format" section on page 9-12 section for more information about how the prefix is used.

Changing Between Contexts and the System Execution Space

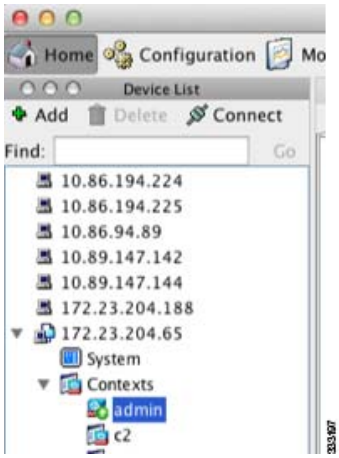
If you log in to the system execution space (or the admin context), you can change between contexts and perform configuration and monitoring tasks within each context. The running configuration that you edit in a configuration mode depends on your location. When you are in the system execution space, the running configuration consists only of the system configuration; when you are in a context, the running configuration consists only of that context.

Detailed Steps

Step 1 To configure the System, in the Device List pane, double-click **System** under the active device IP address.



Step 2 To configure a context, in the Device List pane, double-click the context name under the active device IP address.



Managing Security Contexts

This section describes how to manage security contexts and includes the following topics:

- Removing a Security Context, page 9-26
- Changing the Admin Context, page 9-27
- Changing the Security Context URL, page 9-28
- Reloading a Security Context, page 9-29

Removing a Security Context

You cannot remove the current admin context.

Note If you use failover, there is a delay between when you remove the context on the active unit and when the context is removed on the standby unit.

Prerequisites

Perform this procedure in the system execution space.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Security Contexts**.

Step 3 Select the context you want to delete, and click **Delete**.

The Delete Context dialog box appears.

Step 4 If you might want to re-add this context later, and want to keep the configuration file for future use, uncheck the **Also delete config URL file from the disk** check box.

If you want to delete the configuration file, then leave the check box checked.

Step 5 Click **Yes**.

Changing the Admin Context

The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the admin context.

The admin context is just like any other context, except that when a user logs in to the admin context, then that user has system administrator rights and can access the system and all other contexts. The admin context is not restricted in any way, and can be used as a regular context. However, because logging into the admin context grants you administrator privileges over all contexts, you might need to restrict access to the admin context to appropriate users.

Note For ASDM, you cannot change the admin context within ASDM because your ASDM session would disconnect. You can perform this procedure using the Command Line Interface tool noting that you will have to reconnect to the new admin context.

Guidelines

You can set any context to be the admin context, as long as the configuration file is stored in the internal flash memory.

Prerequisites

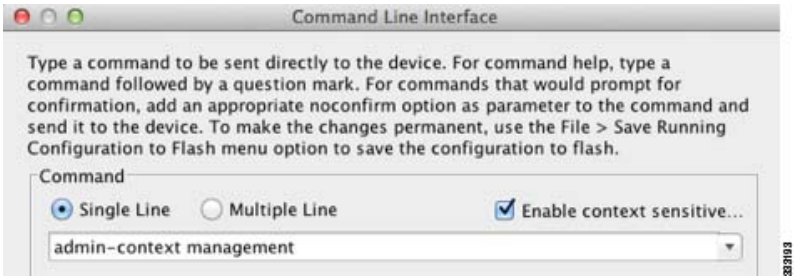
Perform this procedure in the system execution space.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Tools > Command Line Interface**.

The Command Line Interface dialog box appears.



Step 3 Enter the following command:

admin-context *context_name*

Step 4 Click **Send**.

Any remote management sessions, such as Telnet, SSH, or HTTPS (ASDM), that are connected to the admin context are terminated. You must reconnect to the new admin context.

Note A few system configuration commands, including **ntp server**, identify an interface name that belongs to the admin context. If you change the admin context, and that interface name does not exist in the new admin context, be sure to update any system commands that refer to the interface.

Changing the Security Context URL

This section describes how to change the context URL.

Guidelines

- You cannot change the security context URL without reloading the configuration from the new URL. The ASA merges the new configuration with the current running configuration.
- Reentering the same URL also merges the saved configuration with the running configuration.
- A merge adds any new commands from the new configuration to the running configuration.
  - If the configurations are the same, no changes occur.
  - If commands conflict or if commands affect the running of the context, then the effect of the merge depends on the command. You might get errors, or you might have unexpected results. If the running configuration is blank (for example, if the server was unavailable and the configuration was never downloaded), then the new configuration is used.
- If you do not want to merge the configurations, you can clear the running configuration, which disrupts any communications through the context, and then reload the configuration from the new URL.

Prerequisites

Perform this procedure in the system execution space.

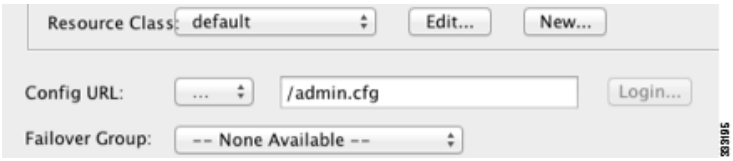
Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Security Contexts**.

Step 3 Select the context you want to edit, and click **Edit**.

The Edit Context dialog box appears.



Step 4 Enter a new URL in the Config URL field, and click **OK**.

The system immediately loads the context so that it is running.

Reloading a Security Context

You can reload the context in two ways:

- Clear the running configuration and then import the startup configuration.

  This action clears most attributes associated with the context, such as connections and NAT tables.

- Remove the context from the system configuration.

  This action clears additional attributes, such as memory allocation, which might be useful for troubleshooting. However, to add the context back to the system requires you to respecify the URL and interfaces.

This section includes the following topics:

- Reloading by Clearing the Configuration, page 9-29
- Reloading by Removing and Re-adding the Context, page 9-30

Reloading by Clearing the Configuration

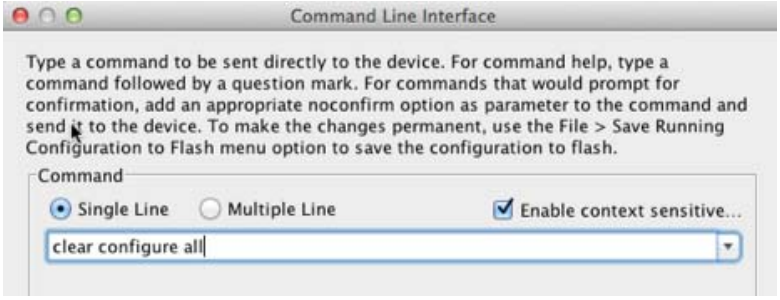
To reload the context by clearing the context configuration and reloading the configuration from the URL, perform the following steps.

Detailed Steps

Step 1 In the Device List pane, double-click the context name under the active device IP address.

Step 2 Choose **Tools > Command Line Interface**.

The Command Line Interface dialog box appears.



Step 3 Enter the following command:

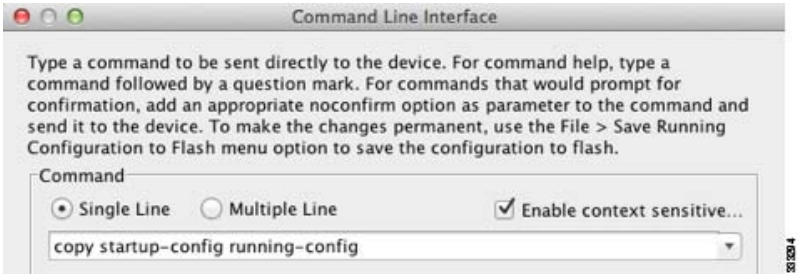
```
clear configure all
```

Step 4 Click **Send**.

The context configuration is cleared.

Step 5 Choose **Tools > Command Line Interface** again.

The Command Line Interface dialog box appears.



Step 6 Enter the following command:

```
copy startup-config running-config
```

Step 7 Click **Send**.

The ASA reloads the configuration. The ASA copies the configuration from the URL specified in the system configuration. You cannot change the URL from within a context.

Reloading by Removing and Re-adding the Context

To reload the context by removing the context and then re-adding it, perform the steps in the following sections:

1. "Removing a Security Context" section on page 9-26. Be sure to uncheck the **Also delete config URL file from the disk** check box.
2. "Configuring a Security Context" section on page 9-20

Monitoring Security Contexts

This section describes how to view and monitor context information and includes the following topics:

- Monitoring Context Resource Usage, page 9-31
- Viewing Assigned MAC Addresses, page 9-32

Monitoring Context Resource Usage

To monitor resource usage of all contexts from the system execution space, perform the following steps:

Step 1 If you are not already in the System mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Click the **Monitoring** button on the toolbar.

Step 3 Click **Context Resource Usage**.

Click each resource type to view the resource usage for all contexts:

- **ASDM/Telnet/SSH**—Shows the usage of ASDM, Telnet, and SSH connections.
  - Context—Shows the name of each context.

  For each access method, see the following usage statistics:
  - Existing Connections (#)—Shows the number of existing connections.
  - Existing Connections (%)—Shows the connections used by this context as a percentage of the total number of connections used by all contexts.
  - Peak Connections (#)—Shows the peak number of connections since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.
- **Routes**—Shows the usage of dynamic routes.
  - Context—Shows the name of each context.
  - Existing Connections (#)—Shows the number of existing connections.
  - Existing Connections (%)—Shows the connections used by this context as a percentage of the total number of connections used by all contexts.
  - Peak Connections (#)—Shows the peak number of connections since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.
- **Xlates**—Shows the usage of network address translations.
  - Context—Shows the name of each context.
  - Xlates (#)—Shows the number of current xlates.
  - Xlates (%)—Shows the xlates used by this context as a percentage of the total number of xlates used by all contexts.
  - Peak (#)—Shows the peak number of xlates since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.
- **NATs**—Shows the number of NAT rules.
  - Context—Shows the name of each context.
  - NATs (#)—Shows the current number of NAT rules.
  - NATs (%)—Shows the NAT rules used by this context as a percentage of the total number of NAT rules used by all contexts.
  - Peak NATs (#)—Shows the peak number of NAT rules since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.

- **Syslogs**—Shows the rate of system log messages.
  - Context—Shows the name of each context.
  - Syslog Rate (#/sec)—Shows the current rate of system log messages.
  - Syslog Rate (%)—Shows the system log messages generated by this context as a percentage of the total number of system log messages generated by all contexts.
  - Peak Syslog Rate (#/sec)—Shows the peak rate of system log messages since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.
- VPN—Shows the usage of VPN site-to-site tunnels.
  - Context—Shows the name of each context.
  - VPN Connections—Shows usage of guaranteed VPN sessions.
  - VPN Burst Connections—Shows usage of burst VPN sessions.

    Existing (#)—Shows the number of existing tunnels.

    Peak (#)—Shows the peak number of tunnels since the statistics were last cleared, either using the **clear resource usage** command or because the device rebooted.

Step 4 Click **Refresh** to refresh the view.

Viewing Assigned MAC Addresses

You can view auto-generated MAC addresses within the system configuration or within the context. This section includes the following topics:

- Viewing MAC Addresses in the System Configuration, page 9-32
- Viewing MAC Addresses Within a Context, page 9-33

Viewing MAC Addresses in the System Configuration

This section describes how to view MAC addresses in the system configuration.

Guidelines

If you manually assign a MAC address to an interface, but also have auto-generation enabled, the auto-generated address continues to show in the configuration even though the manual MAC address is the one that is in use. If you later remove the manual MAC address, the auto-generated one shown will be used.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Context Management > Security Contexts**, and view the Primary MAC and Secondary MAC columns.

Viewing MAC Addresses Within a Context

This section describes how to view MAC addresses within a context.

Detailed Steps

Step 1 If you are not already in the System configuration mode, in the Device List pane, double-click **System** under the active device IP address.

Step 2 Choose **Configuration > Interfaces**, and view the MAC Address address column.

This table shows the MAC address in use; if you manually assign a MAC address and also have auto-generation enabled, then you can only view the unused auto-generated address from within the system configuration.

Feature History for Multiple Context Mode

Table 9-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 9-2 Feature History for Multiple Context Mode

Feature Name	Platform Releases	Feature Information
Multiple security contexts	7.0(1)	Multiple context mode was introduced. We introduced the following screens: Configuration > Context Management.
Automatic MAC address assignment	7.2(1)	Automatic assignment of MAC address to context interfaces was introduced. We modified the following screen: Configuration > Context Management > Security Contexts.
Resource management	7.2(1)	Resource management was introduced. We introduced the following screen: Configuration > Context Management > Resource Management.

Table 9-2 Feature History for Multiple Context Mode (continued)

Feature Name	Platform Releases	Feature Information
Virtual sensors for IPS	8.0(2)	The AIP SSM running IPS software Version 6.0 and above can run multiple virtual sensors, which means you can configure multiple security policies on the AIP SSM. You can assign each context or single mode ASA to one or more virtual sensors, or you can assign multiple security contexts to the same virtual sensor. We modified the following screen: Configuration > Context Management > Security Contexts.
Automatic MAC address assignment enhancements	8.0(5)/8.2(2)	The MAC address format was changed to use a prefix, to use a fixed starting value (A2), and to use a different scheme for the primary and secondary unit MAC addresses in a failover pair. The MAC addresses are also now persistent across reloads. The command parser now checks if auto-generation is enabled; if you want to also manually assign a MAC address, you cannot start the manual MAC address with A2. We modified the following screen: Configuration > Context Management > Security Contexts.
Maximum contexts increased for the ASA 5550 and 5580	8.4(1)	The maximum security contexts for the ASA 5550 was increased from 50 to 100. The maximum for the ASA 5580 was increased from 50 to 250.
Automatic MAC address assignment enabled by default	8.5(1)	Automatic MAC address assignment is now enabled by default. We modified the following screen: Configuration > Context Management > Security Contexts.

Table 9-2 Feature History for Multiple Context Mode (continued)

Feature Name	Platform Releases	Feature Information
Automatic generation of a MAC address prefix	8.6(1)	In multiple context mode, the ASA now converts the automatic MAC address generation configuration to use a default prefix. The ASA auto-generates the prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address. This conversion happens automatically when you reload, or if you reenable MAC address generation. The prefix method of generation provides many benefits, including a better guarantee of unique MAC addresses on a segment. If you want to change the prefix, you can reconfigure the feature with a custom prefix. The legacy method of MAC address generation is no longer available. **Note** To maintain hitless upgrade for failover pairs, the ASA does *not* convert the MAC address method in an existing configuration upon a reload if failover is enabled. However, we strongly recommend that you manually change to the prefix method of generation when using failover, especially for the ASASM. Without the prefix method, ASASMs installed in different slot numbers experience a MAC address change upon failover, and can experience traffic interruption. After upgrading, to use the prefix method of MAC address generation, reenable MAC address generation to use the default prefix. We modified the following screen: Configuration > Context Management > Security Contexts
Dynamic routing in Security Contexts	9.0(1)	EIGRP and OSPFv2 dynamic routing protocols are now supported in multiple context mode. OSPFv3, RIP, and multicast routing are not supported.
New resource type for routing table entries	9.0(1)	A new resource type, routes, was created to set the maximum number of routing table entries in each context. We modified the following screen: Configuration > Context Management > Resource Class > Add Resource Class
Site-to-Site VPN in multiple context mode	9.0(1)	Site-to-site VPN tunnels are now supported in multiple context mode.
New resource type for site-to-site VPN tunnels	9.0(1)	New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context. We modified the following screen: Configuration > Context Management > Resource Class > Add Resource Class

Configuring a Cluster of ASAs

Clustering lets you group multiple ASAs together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

This chapter includes the following sections:

- Information About ASA Clustering, page 10-1
- Licensing Requirements for ASA Clustering, page 10-21
- Prerequisites for ASA Clustering, page 10-21
- Guidelines and Limitations, page 10-23
- Default Settings, page 10-24
- Configuring ASA Clustering, page 10-24
- Managing ASA Cluster Members, page 10-50
- Monitoring the ASA Cluster, page 10-63
- Configuration Examples for ASA Clustering, page 10-66
- Feature History for ASA Clustering, page 10-71

Information About ASA Clustering

This section includes the following topics:

- How the ASA Cluster Fits into Your Network, page 10-2
- Performance Scaling Factor, page 10-2
- Cluster Members, page 10-2
- ASA Cluster Interfaces, page 10-4
- Cluster Control Link, page 10-6
- High Availability within the ASA Cluster, page 10-7
- Configuration Replication, page 10-8
- ASA Cluster Management, page 10-9
- Load Balancing Methods, page 10-10
- How the ASA Cluster Manages Connections, page 10-13

- ASA Features and Clustering, page 10-14

How the ASA Cluster Fits into Your Network

The cluster consists of up to 8 ASAs acting as a single unit. To act as a cluster, the ASAs need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*. See the "Cluster Control Link" section on page 10-6.
- Management access to each ASA for configuration and monitoring. See the "ASA Cluster Management" section on page 10-9.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using one of the following methods:

- Spanned EtherChannel (Recommended)—Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units. See the "Spanned EtherChannel (Recommended)" section on page 10-10.
- Policy-Based Routing (Routed mode only)—The upstream and downstream routers perform load balancing between units using route maps and ACLs. See the "Policy-Based Routing (Routed Mode Only)" section on page 10-12.
- Equal-Cost Multi-Path Routing (Routed mode only)—The upstream and downstream routers perform load balancing between units using equal cost static or dynamic routes. See the "Equal-Cost Multi-Path Routing (Routed Mode Only)" section on page 10-13.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect a performance of approximately:

- 70% of the combined throughput
- 60% of maximum connections
- 50% of connections per second

For example, for throughput, the ASA 5585-X with SSP-40 can handle approximately 10 Gbps of real world firewall traffic when running alone. For a cluster of 8 units, the maximum combined throughput will be approximately 70% of 80 Gbps (8 units x 10 Gbps): 56 Gbps.

Cluster Members

- Bootstrap Configuration, page 10-3
- Master and Slave Unit Roles, page 10-3
- Master Unit Election, page 10-3
- New Connection Ownership, page 10-3

Bootstrap Configuration

On each device, you configure a minimal bootstrap configuration including the cluster name, cluster control link interface, and other cluster settings. The first unit on which you enable clustering typically becomes the *master* unit. When you enable clustering on subsequent units, they join the cluster as *slaves*.

Master and Slave Unit Roles

One member of the cluster is the master unit. The master unit is determined by the priority setting in the bootstrap configuration; the priority is set between 1 and 100, where 1 is the highest priority. All other members are slave units. Typically, when you first create a cluster, the first unit you add becomes the master unit simply because it is the only unit in the cluster so far.

You must perform all configuration (aside from the bootstrap configuration) on the master unit only; the configuration is then replicated to the slave units. In the case of physical assets, such as interfaces, the configuration of the master unit is mirrored on all slave units. For example, if you configure GigabitEthernet 0/1 as the inside interface and GigabitEthernet 0/0 as the outside interface, then these interfaces are also used on the slave units as inside and outside interfaces.

Some features do not scale in a cluster, and the master unit handles all traffic for those features. See the "Centralized Features" section on page 10-15.

Master Unit Election

Members of the cluster communicate over the cluster control link to elect a master unit, as follows:

1. When you enable clustering for a unit (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other units with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes master.

   Note If multiple units tie for the highest priority, the cluster unit name, and then the serial number is used to determine the master.

4. If a unit later joins the cluster with a higher priority, it does not automatically become the master unit; the existing master unit always remains as the master unless it stops responding, at which point a new master unit is elected.

Note You can manually force a unit to become the master. For centralized features, if you force a master unit change, then all connections are dropped, and you have to re-establish the connections on the new master unit. See the "Centralized Features" section on page 10-15 for a list of centralized features.

New Connection Ownership

When a new connection is directed to a member of the cluster, that unit owns both directions of the connection. If any connection packets arrive at a different unit, they are forwarded to the owner unit over the cluster control link. For best performance, proper external load balancing is required for both

directions of a flow to arrive at the same unit, and for flows to be distributed evenly between units. If a reverse flow arrives at a different unit, it is redirected back to the original unit. For more information, see the "Load Balancing Methods" section on page 10-10.

ASA Cluster Interfaces

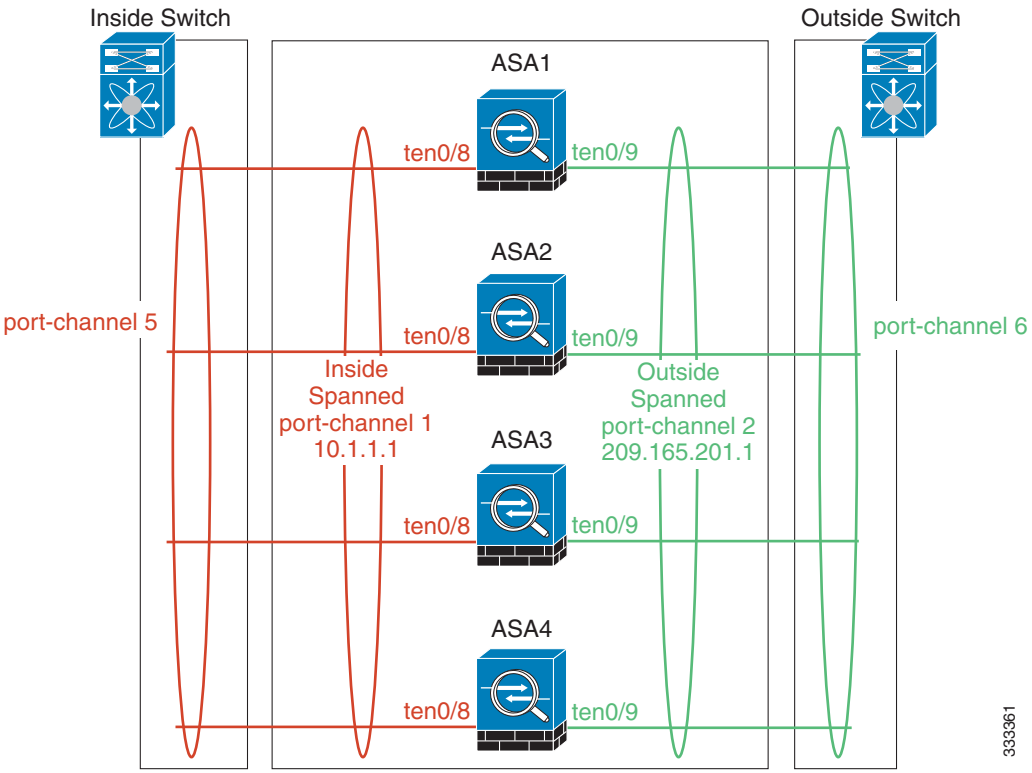
You can configure data For example, if you have the ASA 5585-X with SSP-60interfaces as either spanned EtherChannels or as individual interfaces. All data interfaces in the cluster must be one type only.

- Interface Types, page 10-4
- Interface Type Mode, page 10-5

Interface Types

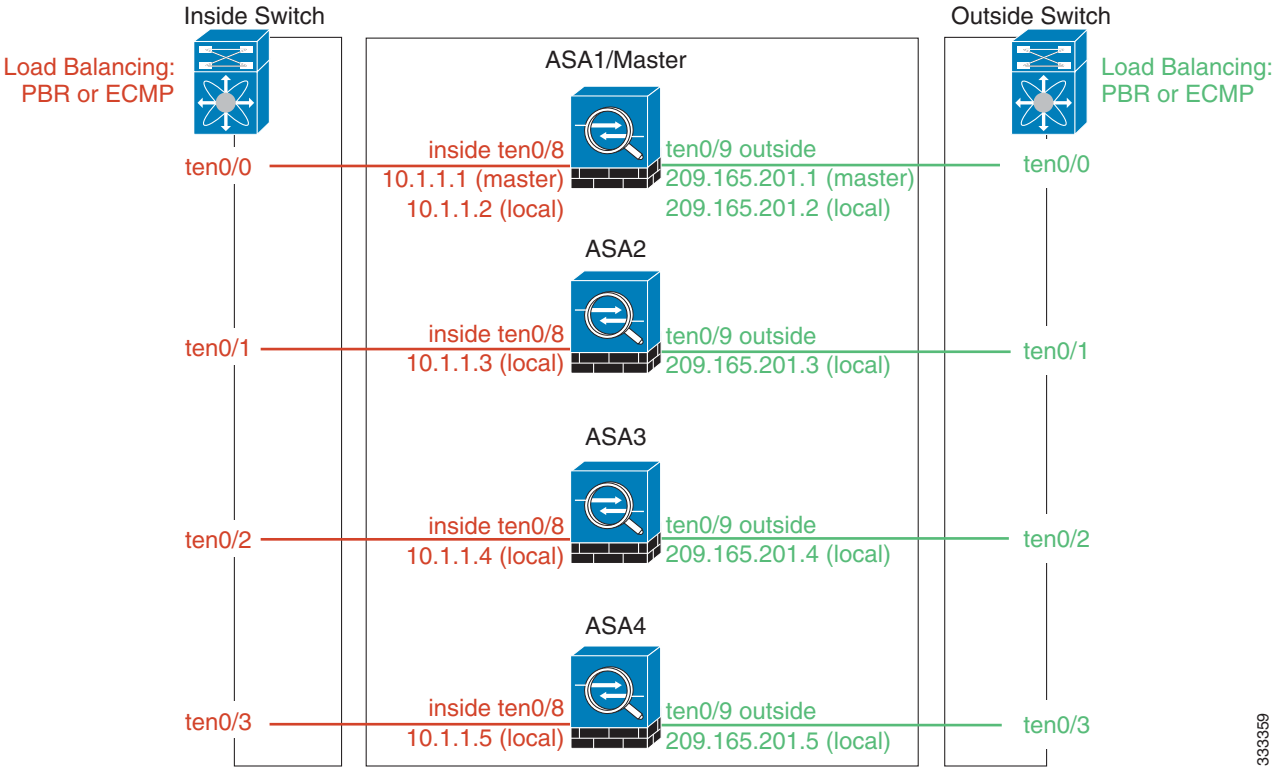
- Spanned EtherChannel

  You can group one or more interfaces per unit into an EtherChannel that spans all units in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel. A spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the bridge group, not to the interface. The EtherChannel inherently provides load balancing as part of basic operation. See also the "Spanned EtherChannel (Recommended)" section on page 10-10.



- Individual interfaces (Routed mode only)

Individual interfaces are normal routed interfaces, each with their own local IP address. Because interface configuration must be configured only on the master unit, the interface configuration lets you set a pool of IP addresses to be used for a given interface on the cluster members, including the master. The main cluster IP address is a fixed address for the cluster that always belongs to the current master unit. The main cluster IP address is a secondary IP address for the master unit; the local IP address is always the primary address for routing. The main cluster IP address provides consistent management access to an address; when a master unit changes, the main cluster IP address moves to the new master unit, so management of the cluster continues seamlessly. Load balancing, however, must be configured separately on the upstream switch in this case. For information about load balancing, see the "Load Balancing Methods" section on page 10-10.



Interface Type Mode

You must choose the interface type before you configure your devices. See the following guidelines for the interface type mode:

- You can always configure the management-only interface as an individual interface (recommended), even in spanned EtherChannel mode. The management interface can be an individual interface even in transparent firewall mode.
- In spanned EtherChannel mode, if you configure the management interface as an individual interface, you cannot enable dynamic routing for the management interface. You must use a static route.
- In multiple context mode, you must choose one interface type for all contexts. For example, if you have a mix of transparent and routed mode contexts, you must use spanned EtherChannel mode for all contexts because that is the only interface type allowed for transparent mode.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link.

- Cluster Control Link Traffic Overview, page 10-6
- Cluster Control Link Network, page 10-6
- Sizing the Cluster Control Link, page 10-6
- Cluster Control Link Redundancy, page 10-7
- Cluster Control Link Failure, page 10-7

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Master election. (See the "Cluster Members" section on page 10-2.)
- Configuration replication. (See the "Configuration Replication" section on page 10-8.)
- Health monitoring. (See the "Unit Health Monitoring" section on page 10-7.)

Data traffic includes:

- State replication. (See the "Data Path Connection State Replication" section on page 10-8.)
- Connection ownership queries and data packet forwarding. (See the "Rebalancing New TCP Connections Across the Cluster" section on page 10-14.)

Cluster Control Link Network

Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the ASA cluster control link interfaces.

Sizing the Cluster Control Link

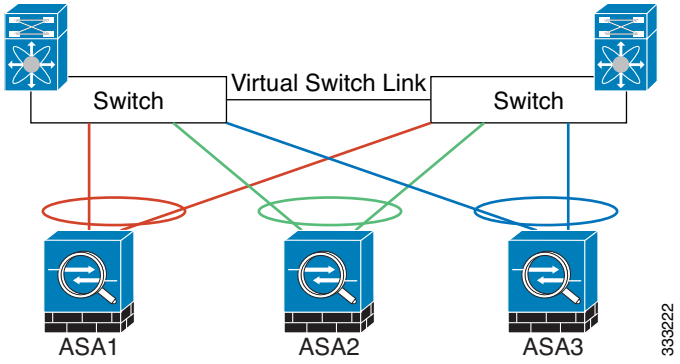
You should assign an equal amount of bandwidth to the cluster control link as you assign for through traffic. We recommend that you use Ten Gigabit Ethernet interface(s) for the cluster control link. For example, if you have the ASA 5585-X with SSP-60, which can pass 14 Gbps per unit maximum in a cluster, then you should also assign interfaces to the cluster control link that can pass approximately 14 Gbps. In this case, you could use 2 Ten Gigabit Ethernet interfaces in an EtherChannel for the cluster control link, and use the rest of the interfaces as desired for data links.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. For example, state updates could consume up to 10% of the through traffic amount if through traffic consists exclusively of short-lived TCP connections. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features; for example, NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units; AAA for network access is a centralized features, so all traffic is forwarded to the master unit. When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth. A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Cluster Control Link Redundancy

If you have enough Ten Gigabit Ethernet interfaces, we recommend using an EtherChannel for the cluster control link, so you can pass traffic on multiple links in the EtherChannel while still achieving redundancy.

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS) or Virtual Port Channel (vPC) environment. All links in the EtherChannel are active. When the switch is part of a VSS or vPC, then you can connect ASA interfaces within the same EtherChannel to separate switches in the VSS or vPC. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a spanned EtherChannel.



Cluster Control Link Failure

If the cluster control link line protocol goes down for a unit, then clustering is disabled; data interfaces are shut down until you manually re-enable clustering on each affected unit (after you fix the cluster control link.)

High Availability within the ASA Cluster

- Unit Health Monitoring, page 10-7
- Interface monitoring, page 10-7
- Unit Health Monitoring, page 10-7
- Data Path Connection State Replication, page 10-8

Unit Health Monitoring

The master unit monitors every slave unit by sending keepalive messages over the cluster control link periodically (the period is configurable). Each slave unit monitors the master unit using the same mechanism.

Interface monitoring

Each unit monitors the link status of all hardware interfaces in use, and reports status changes to the master unit.

- Spanned EtherChannel—Uses cluster Link Aggregation Control Protocol (cLACP). Each unit monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the master unit.
- Individual interfaces (Routed mode only)—Each unit self-monitors its interfaces and reports interface status to the master unit.

Unit or Interface Failure

When health monitoring is enabled, a unit is removed from the cluster if it fails or if its interfaces fail. If an interface fails on a particular unit, but the same interface is active on other units, then the unit is removed from the cluster.

When a unit in the cluster fails, the connections hosted by that unit are seamlessly transferred to other units; state information for traffic flows is shared over the control cluster link.

If the master unit fails, then another member of the cluster with the highest priority (lowest number) becomes the master.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure.

If the owner becomes unavailable, the first unit to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

Some traffic requires state information above the TCP or UDP layer. See Table 10-1 for clustering support or lack of support for this traffic.

Table 10-1 ASA Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	Transparent mode only.
MAC address table	Yes	Transparent mode only.
User Identity	Yes	Includes AAA rules (uauth) and identify firewall.
IPv6 Neighbor database	Yes	
Dynamic routing	Yes	
Multi-site licensing	No	
SNMP Engine ID	No	
VPN	No	VPN sessions will be disconnected if the master unit fails.

Configuration Replication

All units in the cluster share a single configuration. Except for the initial bootstrap configuration, you can only make configuration changes on the master unit, and changes are automatically replicated to all other units in the cluster.

ASA Cluster Management

- Management Network, page 10-9
- Management Interface, page 10-9
- Master Unit Management Vs. Slave Unit Management, page 10-10
- RSA Key Replication, page 10-10
- ASDM Connection Certificate IP Address Mismatch, page 10-10

Management Network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

Management Interface

For the management interface, we recommend using one of the dedicated management interfaces. You can configure the management interfaces as individual interfaces (for both routed and transparent modes) or as a spanned EtherChannel interface.

We recommend using individual interfaces for management, even if you use spanned EtherChannels for your data interfaces. Individual interfaces let you connect directly to each unit if necessary, while a spanned EtherChannel interface only allows remote connection to the current master unit.

Note If you use spanned EtherChannel interface mode, and configure the management interface as an individual interface, you cannot enable dynamic routing for the management interface. You must use a static route.

For an individual interface, the main cluster IP address is a fixed address for the cluster that always belongs to the current master unit. For each interface, you also configure a range of addresses so that each unit, including the current master, can use a local address from the range. The main cluster IP address provides consistent management access to an address; when a master unit changes, the main cluster IP address moves to the new master unit, so management of the cluster continues seamlessly. The local IP address is used for routing, and is also useful for troubleshooting.

For example, you can manage the cluster by connecting to the main cluster IP address, which is always attached to the current master unit. To manage an individual member, you can connect to the local IP address.

For outbound management traffic, such as TFTP or syslog, each unit uses the local IP address to connect to the server, including the master unit.

For a spanned EtherChannel interface, you can only configure one IP address, and that IP address is always attached to the master unit. You cannot connect directly to a slave unit using the EtherChannel interface; we recommend configuring the management interface as an individual interface so you can connect to each unit. You can use a device-local EtherChannel for management.

Master Unit Management Vs. Slave Unit Management

Aside from the bootstrap configuration, all management and monitoring can take place on the master unit. From the master unit, you can check runtime statistics, resource usage, or other monitoring information of all units. You can also issue a command to all units in the cluster, and replicate the console messages from slave units to the master unit.

You can monitor slave units directly if desired. Although also available from the master unit, you can perform file management on slave units (including backing up the configuration and updating images). The following functions are not available from the master unit:

- Monitoring per-unit cluster-specific statistics.
- Syslog monitoring per unit.

RSA Key Replication

When you create an RSA key on the master unit, the key is replicated to all slave units. If you have an SSH session to the main cluster IP address, you will be disconnected if the master unit fails. The new master unit uses the same key for SSH connections, so you do not need to update the cached SSH host key when you reconnect to the new master unit.

ASDM Connection Certificate IP Address Mismatch

By default, a self-signed certificate is used for the ASDM connection based on the local IP address. If you connect to the main cluster IP address using ASDM, then a warning message about a mismatched IP address appears because the certificate uses the local IP address, and not the main cluster IP address. You can ignore the message and establish the ASDM connection. However, to avoid this type of warning, you can enroll a certificate that contains the main cluster IP address and all the local IP addresses from the IP address pool. You can then use this certificate for each cluster member. For more information, see Chapter 49, “Configuring Digital Certificates.”

Load Balancing Methods

See also the “ASA Cluster Interfaces” section on page 10-4.

- Spanned EtherChannel (Recommended), page 10-10
- Policy-Based Routing (Routed Mode Only), page 10-12
- Equal-Cost Multi-Path Routing (Routed Mode Only), page 10-13

Spanned EtherChannel (Recommended)

You can group one or more interfaces per unit into an EtherChannel that spans all units in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

- Spanned EtherChannel Benefits, page 10-11
- Guidelines for Maximum Throughput, page 10-11
- Load Balancing, page 10-11
- EtherChannel Redundancy, page 10-11
- Connecting to a VSS or vPC, page 10-11

Spanned EtherChannel Benefits

The EtherChannel method of load-balancing is recommended over other methods for the following benefits:

- Faster failure discovery.
- Faster convergence time.
- Ease of configuration.

For more information about EtherChannels in general (not just for clustering), see the "EtherChannels" section on page 15-5.

Guidelines for Maximum Throughput

To achieve maximum throughput, we recommend the following:

- Use a load balancing hash algorithm that is "symmetric," meaning that packets from both directions will have the same hash, and will be sent to the same ASA in the spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.
- Use the same type of line cards when connecting the ASAs to the switch so that hashing algorithms applied to all packets are the same.

Load Balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and VLAN numbers.

The number of links in the EtherChannel affects load balancing. See the "Load Balancing" section on page 15-7 for more information.

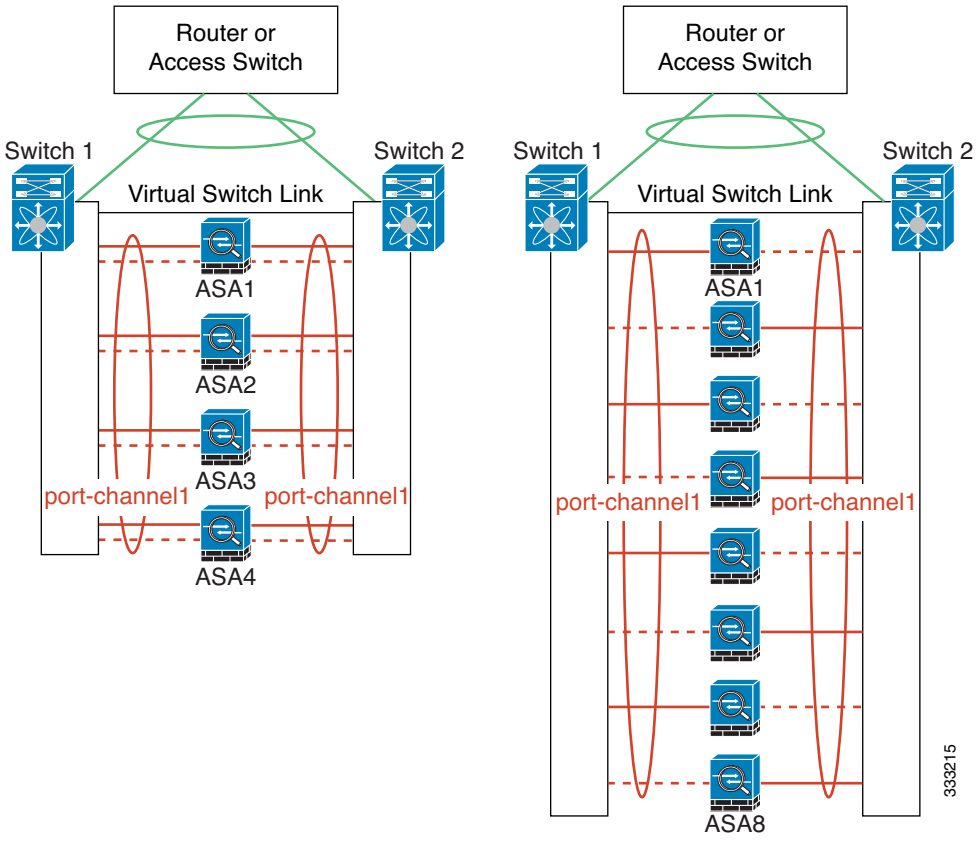
Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit. See the "NAT" section on page 10-19 for more information.

EtherChannel Redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.

Connecting to a VSS or vPC

You can include multiple interfaces per ASA in the spanned EtherChannel. Multiple interfaces per ASA are especially useful for connecting to both switches in a VSS or vPC. Keep in mind that an EtherChannel can have only 8 active interfaces out of 16 maximum; the remaining 8 interfaces are on standby in case of link failure. The following figure shows a 4-ASA cluster and an 8-ASA cluster, both with a total of 16 links in the EtherChannel. The active links are shown as solid lines, while the inactive links are dotted. cLACP load-balancing can automatically choose the best 8 links to be active in the EtherChannel. As shown, cLACP helps achieve load balancing at the link level.



Policy-Based Routing (Routed Mode Only)

When using individual interfaces, each ASA interface maintains its own IP address and MAC address. One method of load balancing in routed mode is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure. This method might offer additional tuning options vs. spanned EtherChannel as well.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all ASAs in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same physical ASA. For example, if you have a Cisco router, redundancy can be achieved by using IOS PBR with Object Tracking. IOS Object Tracking monitors each ASA using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular ASA. See the following URLs for more details:

http://www.cisco.com/en/US/products/ps6599/products_white_paper09186a00800a4409.shtml

http://www.cisco.com/en/US/docs/ios/12_3t/12_3t4/feature/guide/gtpbrtrk.html#wp1057830

Note If you use this method of load-balancing, you can use a device-local EtherChannel as an individual interface.

Equal-Cost Multi-Path Routing (Routed Mode Only)

When using individual interfaces, each ASA interface maintains its own IP address and MAC address. One method of load balancing in routed mode is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure. This method might offer additional tuning options vs. spanned EtherChannel as well.

ECMP routing can forward packets over multiple "best paths" that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then an ASA failure can cause problems; the route continues to be used, and traffic to the failed ASA will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each ASA to participate in dynamic routing.

Note If you use this method of load-balancing, you can use a device-local EtherChannel as an individual interface.

How the ASA Cluster Manages Connections

- Connection Roles, page 10-13
- Sample Data Flow, page 10-14
- Rebalancing New TCP Connections Across the Cluster, page 10-14

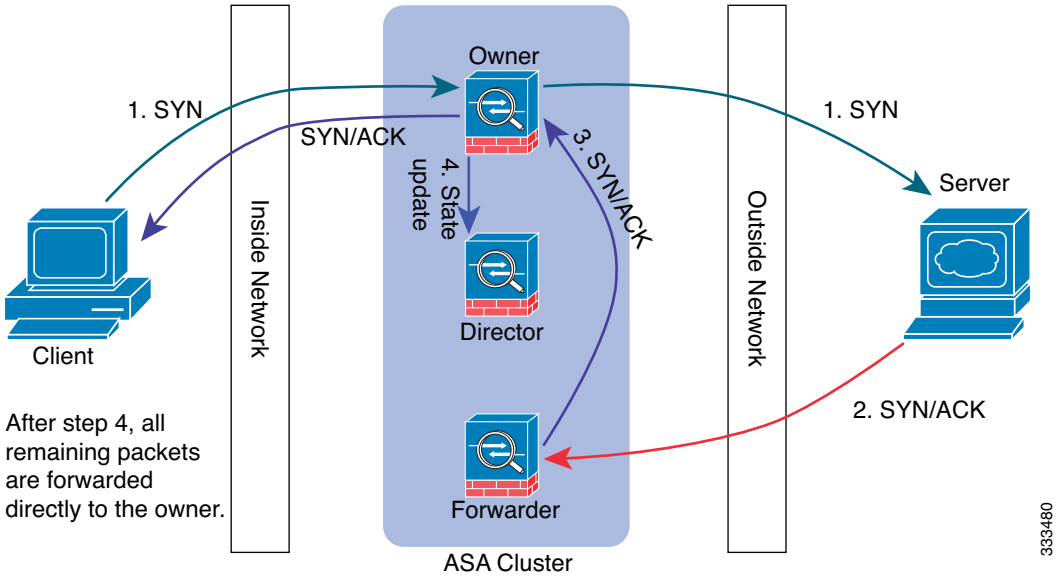
Connection Roles

There are 3 different ASA roles defined for each connection:

- Owner—The unit that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner.
- Director—The unit that handles owner lookup requests from forwarders and also maintains the connection state to serve as a backup if the owner fails. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and TCP ports, and sends a message to the director to register the new connection. If packets arrive at any unit other than the owner, the unit queries the director about which unit is the owner so it can forward the packets. A connection has only one director.
- Forwarder—A unit that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director (if you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required). For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Sample Data Flow

The following example shows the establishment of a new connection.



1. The SYN packet originates from the client and is delivered to an ASA (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different ASA (based on the load balancing method). This ASA is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional units, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Rebalancing New TCP Connections Across the Cluster

If the load balancing capabilities of the upstream or downstream routers result in unbalanced flow distribution, you can configure overloaded units to redirect new TCP flows to other units. No existing flows will be moved to other units.

ASA Features and Clustering

- Unsupported Features, page 10-15

- Centralized Features, page 10-15
- Features Applied to Individual Units, page 10-16
- Dynamic Routing, page 10-17
- NAT, page 10-19
- Syslog and Netflow, page 10-20
- SNMP, page 10-20
- VPN, page 10-20
- FTP, page 10-20
- Cisco TrustSec, page 10-20

Unsupported Features

These features cannot be configured with clustering enabled, and the commands will be rejected.

- Unified Communications
- Remote access VPN (SSL VPN and IPsec VPN)
- The following application inspections:
  - CTIQBE
  - GTP
  - H323, H225, and RAS
  - IPsec passthrough
  - MGCP
  - MMP
  - RTSP
  - SIP
  - SCCP (Skinny)
  - WAAS
  - WCCP
- Botnet Traffic Filter
- Auto Update Server
- DHCP client, server, relay, and proxy
- VPN load balancing
- Failover
- ASA CX module

Centralized Features

The following features are only supported on the master unit, and are not scaled for the cluster. For example, you have a cluster of eight units (5585-X with SSP-60). The Other VPN license allows a maximum of 10,000 IPsec tunnels for one ASA 5585-X with SSP-60. For the entire cluster of eight units, you can only use 10,000 tunnels; the feature does not scale.

Note Traffic for centralized features is forwarded from member units to the master unit over the cluster control link; see the "Sizing the Cluster Control Link" section on page 10-6 to ensure adequate bandwidth for the cluster control link.

If you use the rebalancing feature (see the "Rebalancing New TCP Connections Across the Cluster" section on page 10-14), traffic for centralized features may be rebalanced to non-master units before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the master unit.

For centralized features, if the master unit fails, all connections are dropped, and you have to re-establish the connections on the new master unit.

- Site-to-site VPN
- The following application inspections:
  - DCERPC
  - NetBios
  - PPTP
  - RADIUS
  - RSH
  - SUNRPC
  - TFTP
  - XDMCP
- Dynamic routing (spanned EtherChannel mode only)
- Multicast routing (individual interface mode only)
- Static route monitoring
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Authentication and Authorization for network access. Accounting is decentralized.
- Filtering Services

Features Applied to Individual Units

These features are applied to each ASA unit, instead of the cluster as a whole.

- QoS—The QoS policy is synced across the cluster as part of configuration replication. However, the policy is enforced on each unit independently. For example, if you configure policing on output, then the conform rate and conform burst values are enforced on traffic exiting a particular ASA. In a cluster with 8 units and with traffic evenly distributed, the conform rate actually becomes 8 times the *rate* for the cluster.
- Threat detection—Threat detection works on each unit independently; for example, the top statistics is unit-specific. Port scanning detection, for example, does not work because scanning traffic will be load-balanced between all units, and one unit will not see all traffic.

- Resource management—Resource management in multiple context mode is enforced separately on each unit based on local usage.
- IPS module—There is no configuration sync or state sharing between IPS modules. Some IPS signatures require IPS to keep the state across multiple connections. For example, the port scanning signature is used when the IPS module detects that someone is opening many connections to one server but with different ports. In clustering, those connections will be balanced between multiple ASA devices, each of which has its own IPS module. Because these IPS modules do not share state information, the cluster may not be able to detect port scanning as a result.

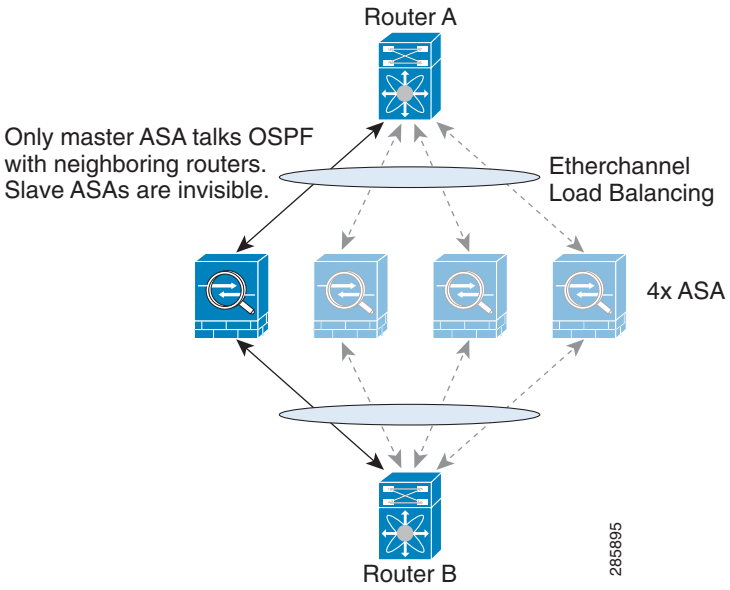
Dynamic Routing

- Dynamic Routing in Spanned EtherChannel Mode, page 10-17
- Dynamic Routing in Individual Interface Mode, page 10-18

Dynamic Routing in Spanned EtherChannel Mode

In spanned EtherChannel mode, the routing process only runs on the master unit, and routes are learned through the master unit and replicated to slaves. If a routing packet arrives at a slave, it is redirected to the master unit.

Figure 10-1 Dynamic Routing in Spanned EtherChannel Mode



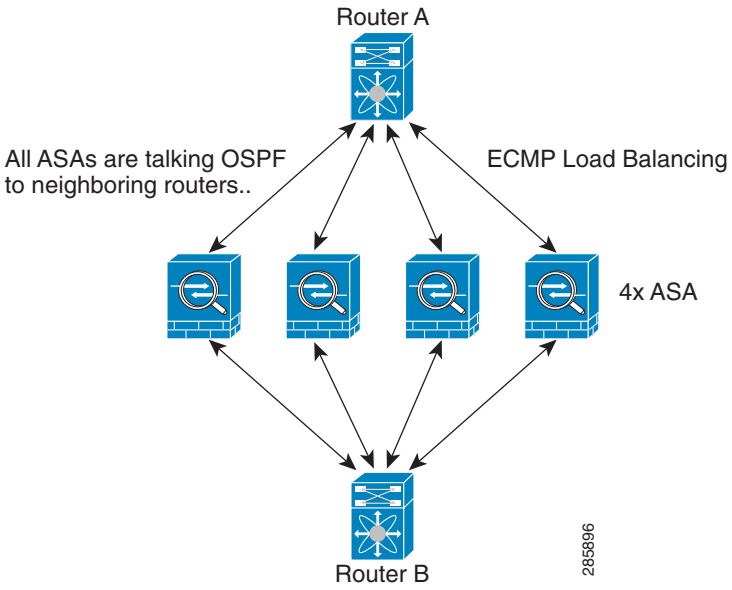
After the slave members learn the routes from the master unit, each unit makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the master unit to slave units. If there is a master unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster.

Dynamic Routing in Individual Interface Mode

In individual interface mode, each unit runs the routing protocol as a standalone router, and routes are learned by each unit independently.

Figure 10-2 Dynamic Routing in Individual Interface Mode



In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through an ASA. ECMP is used to load balance traffic between the 4 paths. Each ASA picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each unit has a separate router ID.

Multicast Routing

- Multicast Routing in Spanned EtherChannel Mode, page 10-18
- Multicast Routing in Individual Interface Mode, page 10-18

Multicast Routing in Spanned EtherChannel Mode

In spanned EtherChannel mode, the master unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each slave can forward multicast data packets.

Multicast Routing in Individual Interface Mode

In individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the master unit, thus avoiding packet replication.

NAT

NAT can impact the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different ASAs in the cluster because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at an ASA that is not the connection owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the main cluster IP address. This is not an issue for a spanned EtherChannel, because there is only one IP address associated with the cluster interface.
- No interface PAT on an individual interface—Interface PAT is not supported for individual interfaces.
- NAT pool address distribution—The master unit evenly pre-distributes addresses across the cluster. If a member receives a connection and they have no addresses left, the connection is dropped, even if other members still have addresses available. Make sure to include at least as many NAT addresses as there are units in the cluster to ensure that each unit receives an address. Use the **show nat pool cluster** command to see the address allocations.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- Dynamic NAT xlates managed by the master unit—The master unit maintains and replicates the xlate table to slave units. When a slave unit receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the master unit. The slave unit owns the connection.
- Per-session PAT feature—Although not exclusive to clustering, the per-session PAT feature improves the scalability of PAT and, for clustering, allows each slave unit to own PAT connections; by contrast, multi-session PAT connections have to be forwarded to and owned by the master unit. By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that requires multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT. For more information about per-session PAT, see the "Per-Session PAT vs. Multi-Session PAT (Version 9.0(1) and Later)" section on page 39-11.

AAA for Network Access

AAA for network access consists of three components: authentication, authorization, and accounting. Authentication and accounting are implemented as centralized features on the clustering master with replication of the data structures to the cluster slaves. If a master is elected, the new master will have all the information it needs to continue uninterrupted operation of the established authenticated users and their associated authorizations. Idle and absolute timeouts for user authentications are preserved when a master unit change occurs.

Accounting is implemented as a distributed feature in a cluster. Accounting is done on a per-flow basis, so the cluster unit owning a flow will send accounting start and stop messages to the AAA server when accounting is configured for a flow.

Syslog and Netflow

- Syslog—Each unit in the cluster generates its own syslog messages. You can configure logging so that each unit uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all units in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all units look as if they come from a single unit. If you configure logging to use the local-unit name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different units. See the "Including the Device ID in Non-EMBLEM Format Syslog Messages" section on page 96-21.
- NetFlow—Each unit in the cluster generates its own NetFlow stream. The NetFlow collector can only treat each ASA as a separate NetFlow exporter.

SNMP

An SNMP agent polls each individual ASA by its local IP address. You cannot poll consolidated data for the cluster.

You should always use the local address, and not the main cluster IP address for SNMP polling. If the SNMP agent polls the main cluster IP address, if a new master is elected, the poll to the new master unit will fail.

VPN

Site-to-site VPN is a centralized feature; only the master unit supports VPN connections. Remote access VPN is not supported with clustering. VPN functionality is limited to the master unit and does not take advantage of the cluster high availability capabilities. If the master unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new master is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a spanned EtherChannel address, connections are automatically forwarded to the master unit. For connections to an individual interface when using PBR or ECMP, you must always connect to the main cluster IP address, not a local interface address.

VPN-related keys and certificates are replicated to all units.

FTP

If FTP data channel and control channel flows are owned by different cluster members, the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Cisco TrustSec

Only the master unit learns security group tag (SGT) information. The master unit then populates the SGT to slaves, and slaves can make a match decision for SGT based on the security policy.

Licensing Requirements for ASA Clustering

Model	License Requirement
ASA 5580, ASA 5585-X	Cluster License. A Cluster license is required on each unit. For other feature licenses, cluster units do not require the same license on each unit. If you have feature licenses on multiple units, they combine into a single running ASA cluster license. **Note** Each unit must have the same encryption license.
All other models	No support.

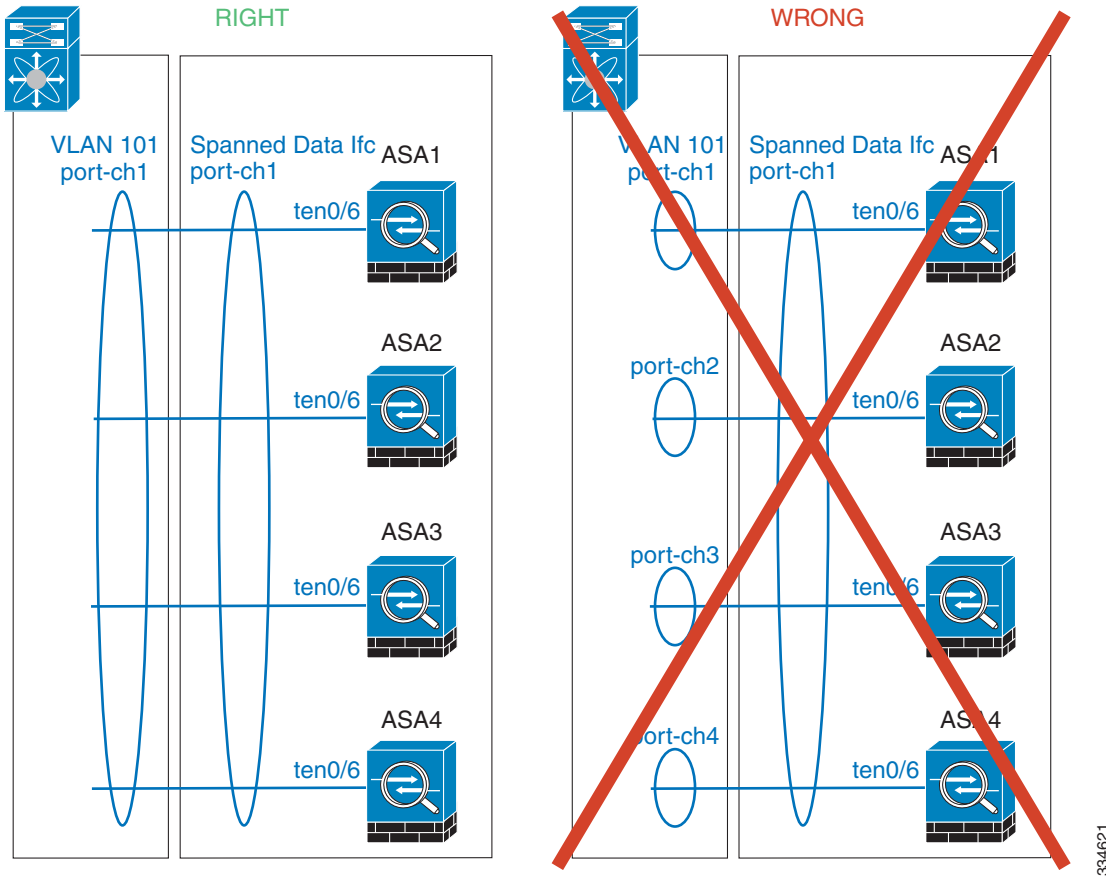
Prerequisites for ASA Clustering

- Table 10-2 lists supported external hardware and software to interoperate with ASA clustering.

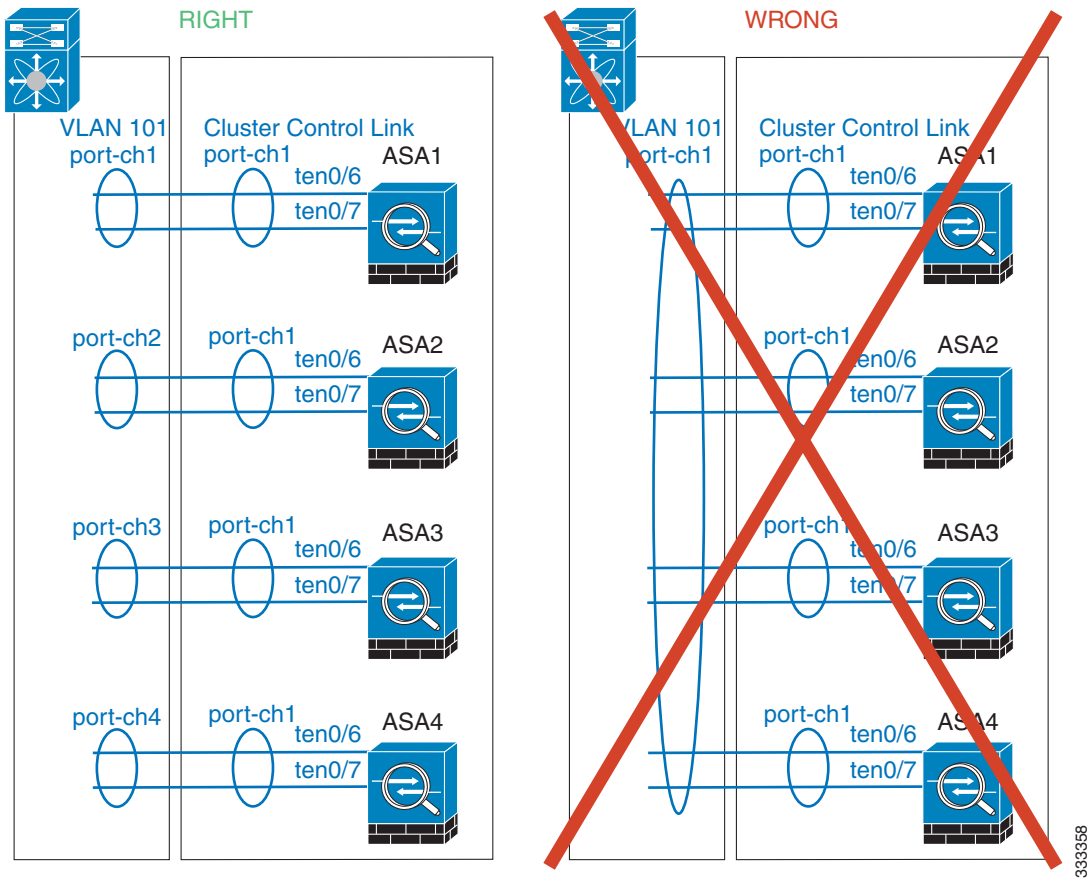
Table 10-2 External Hardware and Software Dependencies for ASA Clustering

Supported Hardware	Supported Software
Nexus 7000	NXOS 5.2(5)
Catalyst 6500 with Supervisor 32, 720, and 720-10GE	IOS 12.2(33)SXI7, SXI8, and SXI9

- On the switch for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the ASA to speed up the join process for new units.
- When you see slow bundling of a spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch.
- Spanned EtherChannels—For ASA *spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.



- Device-local EtherChannels—For ASA *device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple ASA EtherChannels into one EtherChannel on the switch.



Guidelines and Limitations

Context Mode Guidelines

Supported in single and multiple context modes. The mode must match on each member unit.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

Failover Guidelines

Failover is not supported with clustering.

IPv6 Guidelines

Supports IPv6. However, the cluster control link is only supported using IPv4.

Model Guidelines

Supported only on the ASA 5580 and the ASA 5585-X.

For the ASA 5585-X with SSP-10 and SSP-20, which includes two Ten Gigabit Ethernet interfaces, we recommend using one interface for the cluster control link, and the other for data (you can use subinterfaces for data). Although this setup does not accommodate redundancy for the cluster control link, it does satisfy the need to size the cluster control link to match the size of the data interfaces. See the "Sizing the Cluster Control Link" section on page 10-6 for more information.

Additional Guidelines

- Each cluster can include up to 8 units.
- All units in the cluster must be the same model with the same DRAM. You do not have to have the same amount of flash memory.
- All members in a cluster must run the identical software except at the time of an image upgrade. Hitless upgrade is supported between any maintenance releases within a minor release (such as 9.0(1) to 9.0(4)), adjacent minor releases (such as 9.0 to 9.1), and last minor release of previous version to the next major release (such as 8.6 to 9.0, where 8.6 is the last version available for your model previous to 9.0).
- All members of the cluster must be in the same geographical location.
- New cluster members must use the same SSL encryption setting (the **ssl encryption** command) as the master unit.
- When any topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the ASA or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.

Default Settings

- When using spanned EtherChannels, the cLACP system ID is auto-generated and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds.
- Connection rebalancing is disabled by default. If you enable connection rebalancing, the default time between load information exchanges is 5 seconds.

Configuring ASA Clustering

- Task Flow for ASA Cluster Configuration, page 10-25
- Cabling the Cluster Units and Configuring Upstream and Downstream Equipment, page 10-25
- Configuring the Cluster Interface Mode on the Master Unit, page 10-27
- Configuring the Management Interface on Each Unit, page 10-29

- Enabling the Cluster Control Link Interface on the Master Unit, page 10-29
- Backing Up Your Configurations (Recommended), page 10-32
- Configuring Interfaces on the Master Unit, page 10-32
- Adding or Joining an ASA Cluster, page 10-44

Task Flow for ASA Cluster Configuration

To configure clustering, perform the following steps:

Step 1 Cable your equipment. Before configuring clustering, cable the cluster control link network, management network, and data networks. See the "Cabling the Cluster Units and Configuring Upstream and Downstream Equipment" section on page 10-25.

Step 2 Connect to the console port. You will need to perform configuration at the console port of each unit. See the "Accessing the Appliance Command-Line Interface" section on page 3-1. After initial configuration, you can complete your configuration using ASDM.

Step 3 Configure the interface type. You can only configure one type of interface for clustering: spanned EtherChannels or individual interfaces. See the "Configuring the Cluster Interface Mode on the Master Unit" section on page 10-27.

Step 4 Configure the management interface for each unit so you can connect to each unit using ASDM. After you configure unique IP addresses, you can use ASDM to configure the rest of your configuration. See the "Configuring the Management Interface on Each Unit" section on page 10-29.

Step 5 (Recommended) Back up each unit configuration before you enable clustering. See the "Backing Up Your Configurations (Recommended)" section on page 10-32.

Step 6 Configure interfaces for clustering on the master unit. You cannot enable clustering if the interfaces are not cluster-ready. You should complete all interface configuration before enabling clustering to avoid problems. See the "Configuring Interfaces on the Master Unit" section on page 10-32.

Step 7 Join the cluster running the High Availability and Scalability wizard. See the "Adding or Joining an ASA Cluster" section on page 10-44.

Step 8 Configure the security policy on the master unit. See the chapters in this guide to configure supported features on the master unit. The configuration is replicated to the slave units. For a list of supported and unsupported features, see the "ASA Features and Clustering" section on page 10-14.

Cabling the Cluster Units and Configuring Upstream and Downstream Equipment

Before configuring clustering, cable the cluster control link network, management network, and data networks.

Note At a minimum, an active cluster control link network is required before you configure the units to join the cluster.

You should also configure the upstream and downstream equipment. For example, if you use EtherChannels, then you should configure the upstream and downstream equipment for the EtherChannels.

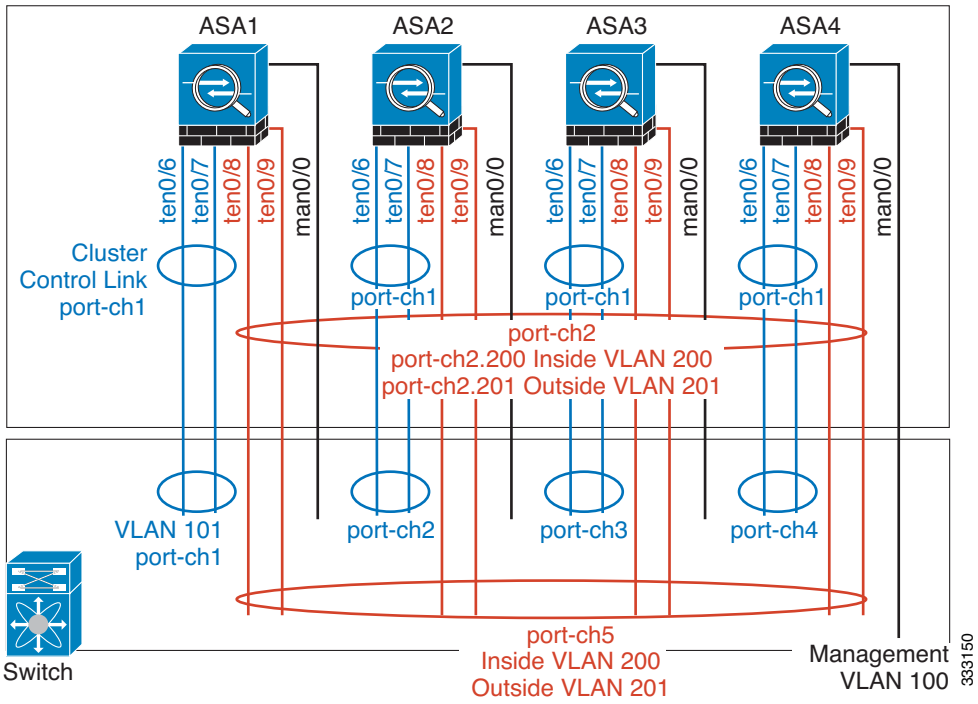
Detailed Steps

Note This example uses EtherChannels for load-balancing. If you are using PBR or ECMP, your switch configuration will differ.

For example on each of 4 ASA 5585-Xs, you want to use:

- 2 Ten Gigabit Ethernet interfaces in a device-local EtherChannel for the cluster control link.
- 2 Ten Gigabit Ethernet interfaces in a spanned EtherChannel for the inside and outside network; each interface is a VLAN subinterface of the EtherChannel. Using subinterfaces lets both inside and outside interfaces take advantage of the benefits of an EtherChannel.
- 1 Management interface.

You have one switch for both the inside and outside networks.



Purpose	Connect Interfaces on each of 4 ASAs	To Switch Ports
Cluster control link	TenGigabitEthernet 0/6 and TenGigabitEthernet 0/7	8 ports total For each TenGigabitEthernet 0/6 and TenGigabitEthernet 0/7 pair, configure 4 EtherChannels (1 EC for each ASA). These EtherChannels must all be on the same isolated cluster control VLAN, for example VLAN 101.
Inside and outside interfaces	TenGigabitEthernet 0/8 and TenGigabitEthernet 0/9	8 ports total Configure a single EtherChannel (across all ASAs). You can configure these VLANs and networks now or later; for example, a trunk including VLAN 200 for the inside and VLAN 201 for the outside.
Management interface	Management 0/0	4 ports total Place all interfaces on the same isolated management VLAN, for example VLAN 100.

What to Do Next

Configure the cluster interface mode from the master unit. See the "Configuring the Cluster Interface Mode on the Master Unit" section on page 10-27.

Configuring the Cluster Interface Mode on the Master Unit

You can only configure one type of interface for clustering: spanned EtherChannels or individual interfaces; you cannot mix interface types in a cluster. For exceptions for the management interface and other guidelines, see the "Interface Type Mode" section on page 10-5.

You cannot change the mode on the master unit within ASDM.

Note If you do not add slave units from the master unit, you must set the interface mode manually on all units according to this section, not just the master unit; if you add slaves from the master, ASDM sets the interface mode automatically on the slave.

Prerequisites

- Perform this procedure at the console port.
- Transparent firewall mode supports only spanned EtherChannel mode.

- For multiple context mode, configure this setting in the system execution space; you cannot configure the mode per context.

Limitations and Restrictions

When you set the cluster interface mode, your configuration cannot contain any features that are not supported with clustering. See the "Unsupported Features" section on page 10-15 for a list of unsupported features. Before you set the mode, you can check for any incompatible configuration.

Detailed Steps

	Command	Purpose
Step 1	**cluster interface-mode** {**individual** | **spanned**} **check-details** **Example:** `hostname(config)# cluster interface-mode spanned check-details`	The **check-details** command shows any incompatible configuration so you can decide whether to force the interface mode and fix your configuration later, or whether to clear the configuration when setting the interface mode; the mode is not changed with this command.
Step 2	**cluster interface-mode** {**individual** | **spanned**} [**force**] **Example:** `hostname(config)# cluster interface-mode spanned force`	Sets the interface mode for clustering. There is no default setting; you must explicitly choose the mode. If you have not set the mode, you cannot enable clustering. In spanned EtherChannel mode, you cannot configure a cluster IP pool for an interface. In individual interface mode, you cannot enable cluster spanning for an EtherChannel. The **force** option changes the mode without checking your configuration for incompatible settings. You need to manually fix any configuration issues after you change the mode. Because any interface configuration can only be fixed after you set the mode, we recommend using the **force** option so you can at least start from the default configuration, if present. You can re-run the **check-details** option after you set the mode for more guidance. Without the **force** option, if there is any incompatible configuration, you are prompted to clear your configuration and reload. If your configuration is compatible (rare), the mode is changed and the configuration is preserved. If you do not want to clear your configuration, you can exit the command by typing **n**. To remove the interface mode, enter the **no cluster interface-mode** command.

What to Do Next

- Configure the management interface for remote configuration. See the "Configuring the Management Interface on Each Unit" section on page 10-29.
-

Configuring the Management Interface on Each Unit

To perform configuration remotely using ASDM, configure the management interface on each unit according to this section using CLI at the console port.

Guidelines

The factory default configuration includes a pre-configured Management 0/0 interface, 192.168.1.1 (if you did not clear the configuration when you set the interface mode).

- To connect all prospective cluster members to the management network for initial configuration, you must provide a unique IP address for each unit.
- Except for the IP address used by the master unit (typically the first unit you add to the cluster), these management IP addresses are for temporary use only.
- After a slave joins the cluster, its management interface configuration is replaced by the one replicated from the master unit.

Detailed Steps

Step 1 Connect to the console port. See the "Accessing the Appliance Command-Line Interface" section on page 3-1.

Step 2 See the "Accessing ASDM Using a Non-Default Configuration (ASA 5510 and Higher)" section on page 3-9 to change the management IP address and configure ASDM access for the new address from the console port.

Step 3 Connect ASDM to the new management address. See the "Starting ASDM" section on page 3-13.

Step 4 For multiple context mode, you must also configure the cluster IP pool for the admin context management interface on the master unit only according to the "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32. You cannot later configure IP addresses within a context in the High Availability and Scalability wizard.

What to Do Next

(Optional) Configure the cluster control link. See the "Enabling the Cluster Control Link Interface on the Master Unit" section on page 10-29.

Enabling the Cluster Control Link Interface on the Master Unit

You can configure the cluster control link interface in the High Availability and Scalability wizard; if you do not use the wizard, perform the procedure in this section for the master unit; if you later add slaves from the master unit, the cluster control link interface configuration is automatically applied to the slave.

We recommend that you combine multiple cluster control link interfaces into an EtherChannel if you have enough interfaces. The EtherChannel is local to the ASA, and is not a spanned EtherChannel. We recommend that you use a Ten Gigabit Ethernet interface for the cluster control link.

Prerequisites

- Determine the size of the cluster control link by referring to the "Sizing the Cluster Control Link" section on page 10-6.
- For multiple context mode, start this procedure in the system execution space. If you are not already in the System configuration mode in the Configuration > Device List pane, double-click **System** under the active device IP address.

Restrictions

- You cannot use a VLAN subinterface as the cluster control link.
- You cannot use a Management *x*/*x* interface as the cluster control link, either alone or as an EtherChannel.
- For the ASA 5585-X with an IPS module, you cannot use the IPS module interfaces for the cluster control link.

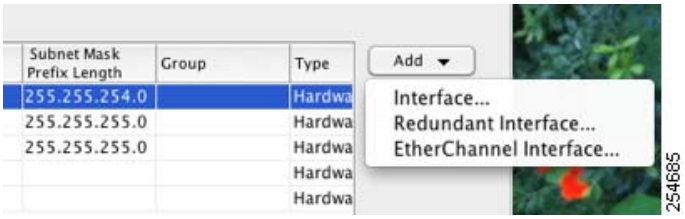
Detailed Steps

This section includes the procedure to configure an EtherChannel. To use a single interface as the cluster control link, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23. You only need to enable the interface; do not configure a name for the interface, or any other parameters.

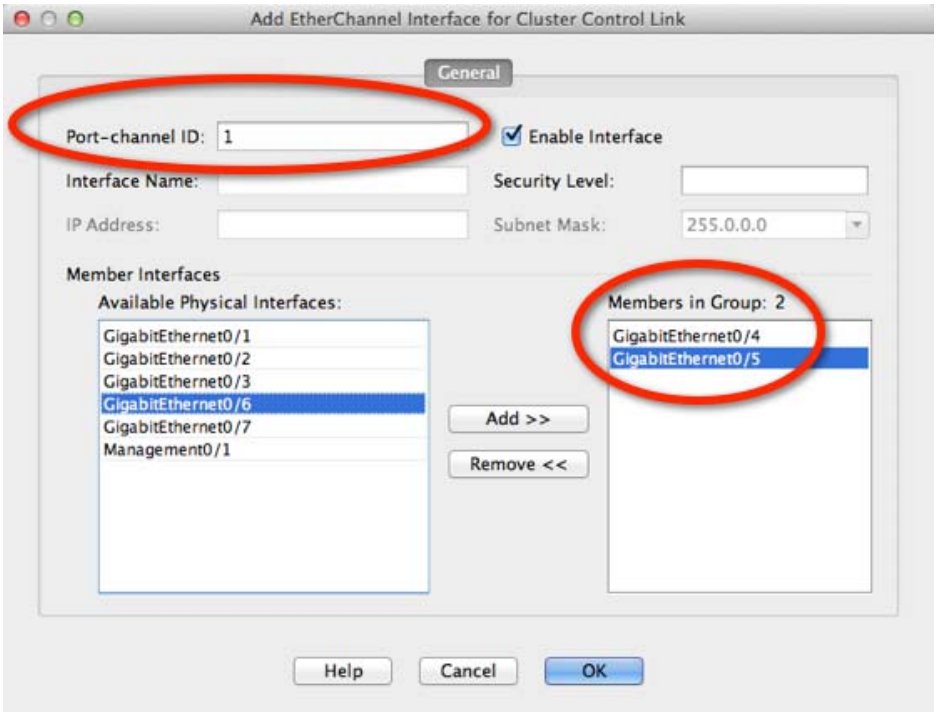
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Choose **Add > EtherChannel Interface**.



The Add EtherChannel Interface dialog box appears.



Step 3 Configure only the port channel ID and the group members. Do not configure a name for the cluster control link.

Step 4 Click **OK**.

You return to the Interfaces pane.

Step 5 Select each member interface, and click **Edit**.

The Edit Interface dialog box appears.

Step 6 Click the **Advanced** tab.

Step 7 In the EtherChannel area, from the Mode drop down list, choose **On**. We recommend using the On mode for member interfaces to reduce unnecessary traffic on the cluster control link. The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network.

Step 8 Click **OK**.

You return to the Interfaces pane.

Step 9 Click **Apply**.

What to Do Next

Back up your configuration. See the "Backing Up Your Configurations (Recommended)" section on page 10-32.

Backing Up Your Configurations (Recommended)

When you enable clustering on a slave unit, the current configuration is replaced with one synced from the master unit. If you ever want to leave the cluster entirely, it may be useful to have a backup configuration with a usable management interface configuration. See the "Leaving the Cluster" section on page 10-58 for more information.

Guidelines

Perform a backup on each unit.

Detailed Steps

Step 1 Choose **Tools > Backup Configurations**.

Step 2 Back up at least the running configuration. See the "Backing Up Configurations" section on page 101-21 for a detailed procedure.

Configuring Interfaces on the Master Unit

This section describes how to configure interfaces to be compatible with clustering. You can configure data interfaces as either spanned EtherChannels or as individual interfaces. Each method uses a different load-balancing mechanism. You cannot configure both types in the same configuration. For more information, see the "ASA Cluster Interfaces" section on page 10-4.

You cannot enable clustering if the interfaces are not cluster-ready. You should complete all interface configuration before enabling clustering to avoid problems.

- Configuring Individual Interfaces (Recommended for the Management Interface), page 10-32
- Configuring Spanned EtherChannels, page 10-37

Configuring Individual Interfaces (Recommended for the Management Interface)

Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The main cluster IP address is a fixed address for the cluster that always belongs to the current master unit.

In spanned EtherChannel mode, we recommend configuring the management interface as an individual interface. Individual management interfaces let you connect directly to each unit if necessary, while a spanned EtherChannel interface only allows connection to the current master unit. See the "Management Interface" section on page 10-9 for more information.

Prerequisites

- Except for the management-only interface, you must be in individual interface mode; see the "Configuring the Cluster Interface Mode on the Master Unit" section on page 10-27.
- For multiple context mode, perform this procedure in each context. If you are not already in the context configuration mode in the Configuration > Device List pane, double-click the context name under the active device IP address.

- Individual interfaces require you to configure load balancing on neighbor devices. External load balancing is not required for the management interface. For information about load balancing, see the "Load Balancing Methods" section on page 10-10.
- (Optional) Configure the interface as a device-local EtherChannel interface, a redundant interface, and/or configure subinterfaces.
  - For an EtherChannel, see the "Configuring an EtherChannel" section on page 15-28. This EtherChannel is local to the unit, and is not a spanned EtherChannel.
  - For a redundant interface, see the "Configuring a Redundant Interface" section on page 15-25. Management interfaces cannot be redundant interfaces.
  - For subinterfaces, see the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.
- If you are connecting remotely to the management interface using ASDM, the current IP address of prospective slave units are for temporary use.
  - Each member will be assigned an IP address from the cluster IP pool defined on the master unit.
  - The cluster IP pool cannot include addresses already in use on the network, including prospective slave IP addresses.

    For example:

  a. You configure the master unit to use 10.1.1.1.
  b. Other units use 10.1.1.2, 10.1.1.3, and 10.1.1.4.
  c. When you configure the cluster IP pool on the master unit, you cannot include the .2, .3, or .4 addresses in the pool, because they are in use.
  d. Instead, you need to use other IP addresses on the network, such as .5, .6, .7, and .8.

  Note The pool needs as many addresses as there are members of the cluster, including the master unit; the original .1 address is the main cluster IP address that belongs to the current master unit.

  e. After you join the cluster, the old, temporary addresses are relinquished and can be used elsewhere.

Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Choose the interface row, and click **Edit**. Configure the following parameters:

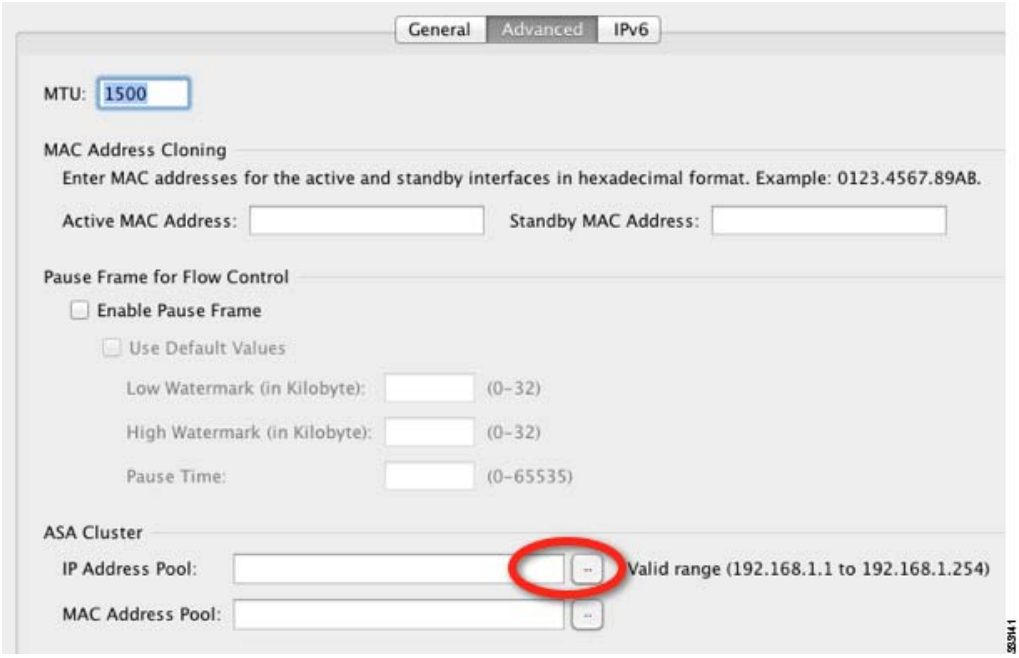
a. (Required in spanned EtherChannel mode) Dedicate this interface to management only—Sets an interface to management-only mode so that it does not pass through traffic. By default, Management type interfaces are configured as management-only. In transparent mode, this command is always enabled for a Management type interface.
b. Interface Name—Enter a name up to 48 characters in length.
c. Security Level—Enter a level between 0 (lowest) and 100 (highest). See the "Security Levels" section on page 17-1 for more information.
d. Enable Interface—If the interface is not already enabled, check this check box.
e. Use Static IP—To set the IP address, click the **Use Static IP** radio button and enter the IP address and mask. DHCP and PPPoE are not supported.

f. (Optional) Description—Enter a description for this interface. The description can be up to 240 characters on a single line, without carriage returns.

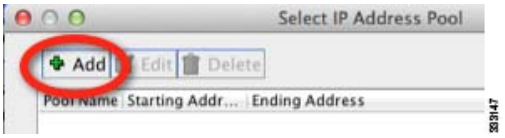
Note For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Step 3 To add the IPv4 cluster IP pool, and optionally a MAC address pool, click the **Advanced** tab.

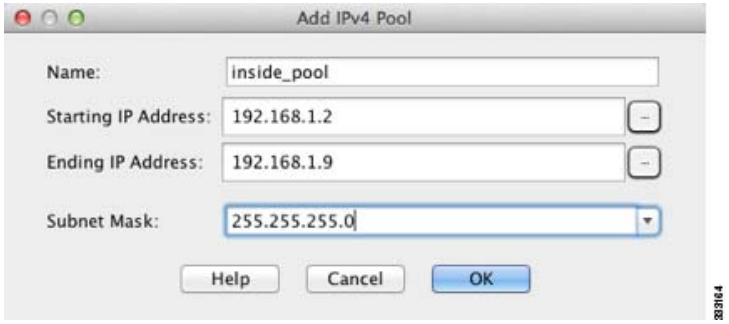
g. Under ASA Cluster, create a cluster IP pool by clicking the **...** button next to the IP Address Pool field. The valid range shown is determined by the main IP address you set on the General tab.



h. Click **Add**.

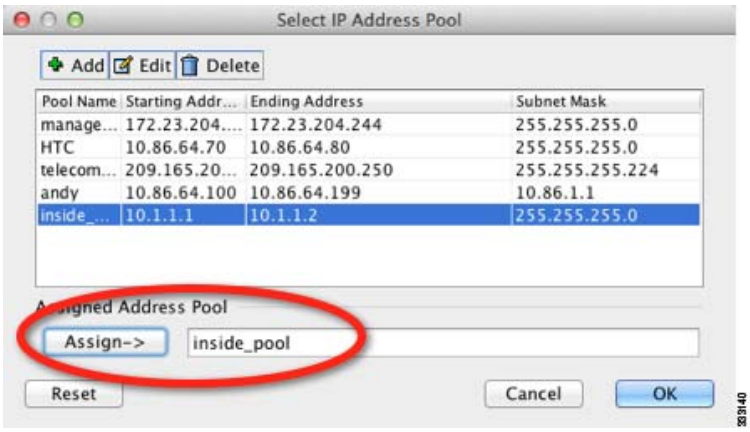


i. Configure a range of addresses that does not include the main cluster IP address, and that does not include any addresses currently in-use on your network. You should make the range large enough for the size of the cluster, for example, 8 addresses.



j. Click **OK** to create the new pool.

k. Select the new pool you created, and click **Assign**, and then click **OK**.

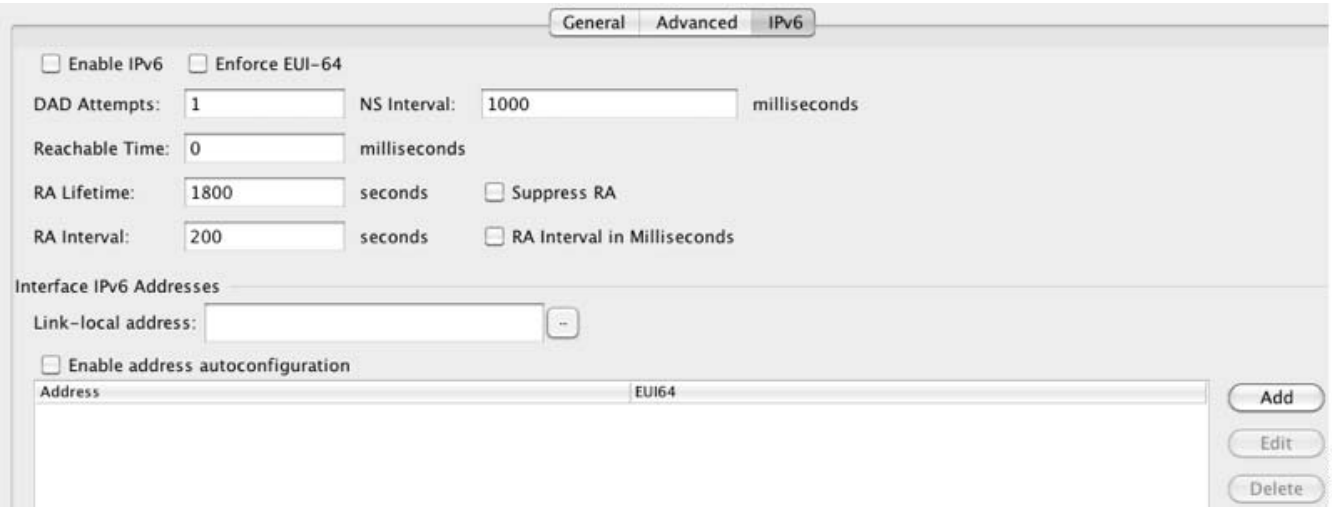


The pool name appears in the IP Address Pool field.

l. (Optional) To configure a MAC address pool, click the **...** button next to the MAC Address Pool field. Follow the screens to add a pool of MAC addresses for your interfaces. It is not common to manually configure MAC addresses for an interface, but if you have special needs to do so, then this pool is used to assign a unique MAC address to each interface.

m. For other optional parameters on the Advanced tab, see the "Configuring the MAC Address and MTU" section on page 17-13 and the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Step 4 To configure an IPv6 address, click the **IPv6** tab.



a. Check the **Enable IPv6** checkbox.

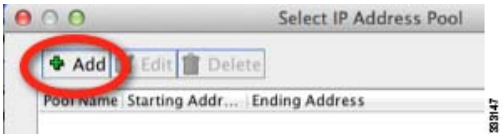
b. To manually configure a global IPv6 address, in the Interface IPv6 Addresses area, click **Add**.

   The Enable address autoconfiguration option is not supported.

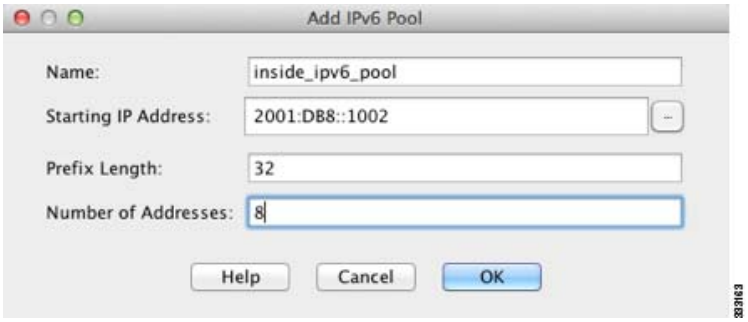
   The Add IPv6 Address for Interface dialog box appears.

c. In the Address/Prefix Length field, enter the global IPv6 address and the IPv6 prefix length. For example, 2001:0DB8::BA98:0:3210/48. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

d. Click the **...** button to configure the cluster IP pool.



e. Click **Add**.



f. Configure the starting IP address (network prefix), prefix length, and number of addresses in the pool.

g. Click **OK** to create the new pool.

h. Select the new pool you created, and click **Assign**, and then click **OK**.

The pool appears in the ASA Cluster IP Pool field.

i. Click **OK**.

j. For other optional parameters on the IPv6 tab, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 5 Click **OK** to return to the Interfaces pane.

Step 6 Click **Apply**.

What to Do Next

- For spanned interface mode, configure your data interfaces. See the "Configuring Spanned EtherChannels" section on page 10-37.
- For individual interface mode, join the cluster. See the "Adding or Joining an ASA Cluster" section on page 10-44.

Configuring Spanned EtherChannels

A spanned EtherChannel spans all ASAs in the cluster, and provides load balancing as part of the EtherChannel operation.

Prerequisites

- You must be in spanned EtherChannel interface mode; see the "Configuring the Cluster Interface Mode on the Master Unit" section on page 10-27.
- For multiple context mode, start this procedure in the system execution space. If you are not already in the System configuration mode in the Configuration > Device List pane, double-click **System** under the active device IP address.
- For transparent mode, configure the bridge group according to the "Configuring Bridge Groups" section on page 18-8.

Guidelines

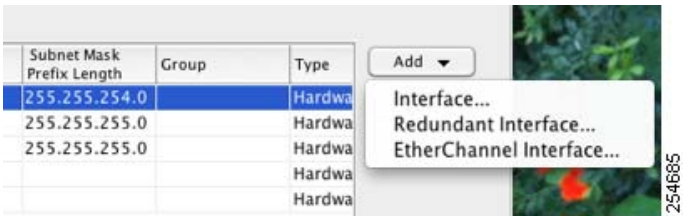
- *Do not* specify the maximum and minimum links in the EtherChannel—We recommend that you do not specify the maximum and minimum links in the EtherChannel on either the ASA or the switch. If you need to use them, note the following:
  - The maximum links set on the ASA is the total number of active ports for the whole cluster. Be sure the maximum links value configured on the switch is not larger than the ASA value.
  - The minimum links set on the ASA is the minimum active ports to bring up a port-channel interface *per unit*. On the switch, the minimum links is the minimum links across the cluster, so this value will not match the ASA value.
- For detailed EtherChannel guidelines, limitations, and prerequisites, see the "Configuring an EtherChannel" section on page 15-28.
- See also the "EtherChannel Guidelines" section on page 15-11.

Detailed Steps

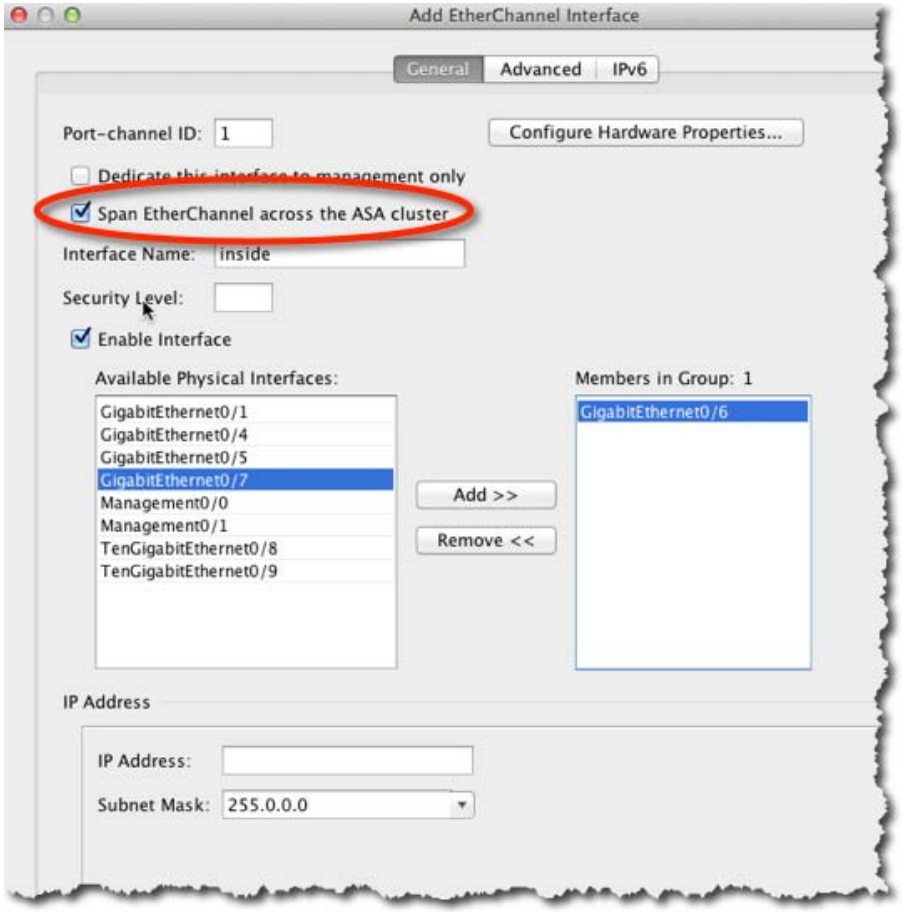
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Choose **Add > EtherChannel Interface**.



The Add EtherChannel Interface dialog box appears.



Step 3 Enable the following:

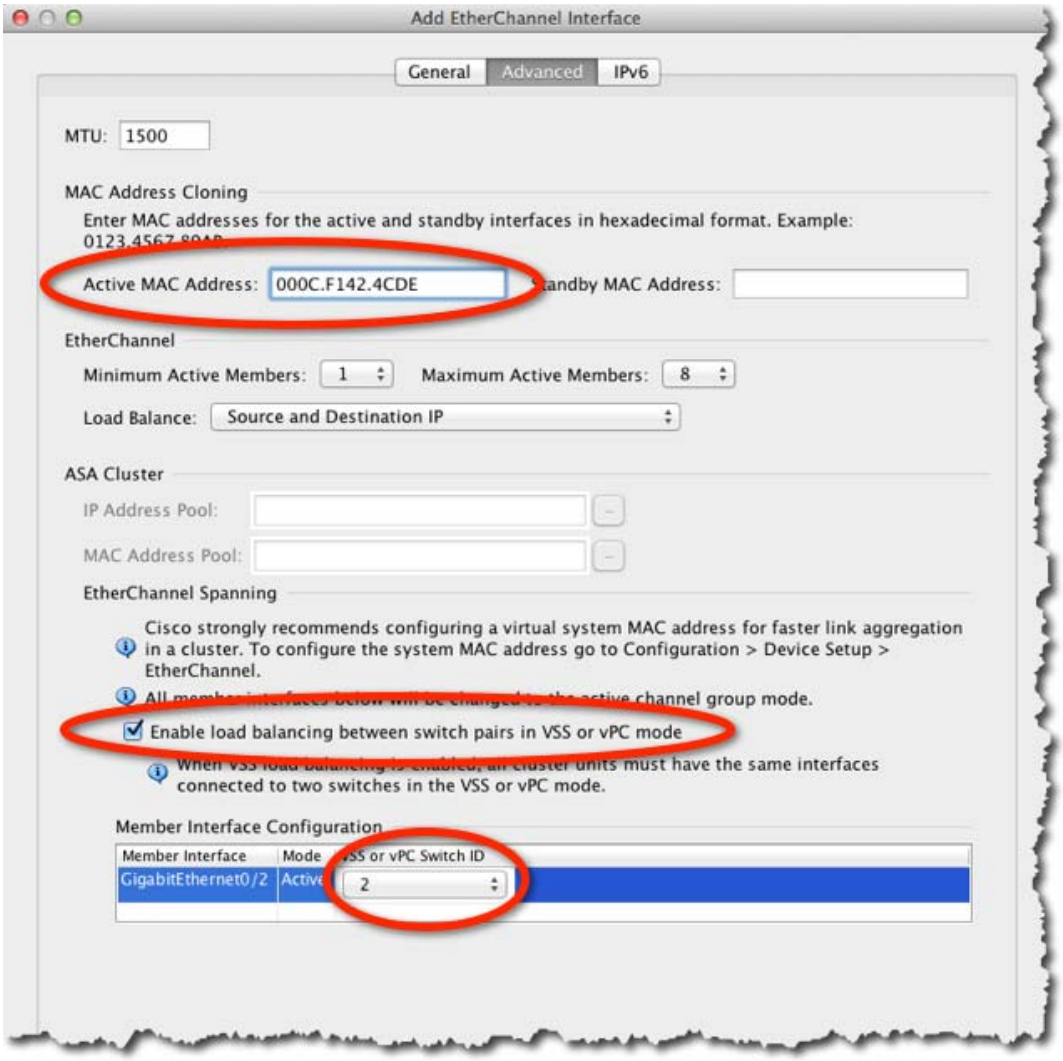
- Port Channel ID
- Span EtherChannel across the ASA cluster
- Enable Interface (checked by default)
- Members in Group—In the Members in Group box, you need to add at least one interface. Multiple interfaces in the EtherChannel per unit are useful for connecting to switches in a VSS or vPC. Keep in mind that an EtherChannel, including a spanned EtherChannel, can have only 8 active interfaces out of 16 maximum; the remaining 8 interfaces are on standby in case of link failure. For example, for a cluster of 8 ASAs, you can use a maximum of 2 interfaces on each ASA, for a total of 16 interfaces in the EtherChannel. Make sure all interfaces are the same type and speed. The first interface you add determines the type and speed of the EtherChannel. Any non-matching interfaces you add will be put into a suspended state. ASDM does not prevent you from adding non-matching interfaces.

The rest of the fields on this screen are described later in this procedure.

Step 4 (Optional) To override the media type, duplex, speed, and pause frames for flow control for all member interfaces, click **Configure Hardware Properties**. This method provides a shortcut to set these parameters because these parameters must match for all interfaces in the channel group. For more information about these settings, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Click **OK** to accept the Hardware Properties changes.

Step 5 (Optional) To configure the MAC address and optional parameters, click the **Advanced** tab.



a. In single mode, under MAC Address Cloning, set a manual MAC address for the EtherChannel. Do not set the Standby MAC Address; it is ignored. You must configure a MAC address for a spanned EtherChannel so that the MAC address does not change when the current master unit leaves the cluster; with a manually-configured MAC address, the MAC address stays with the current master unit.

   In multiple context mode, if you share an interface between contexts, auto-generation of MAC addresses is enabled by default, so you only need to set the MAC address manually for a shared interface if you disable auto-generation. The first two bytes of a manual MAC address cannot be A2 if you also want to use auto-generated MAC addresses.

b. (Optional) If you are connecting the ASA to two switches in a VSS or vPC, then you should enable VSS load balancing by checking the **Enable load balancing between switch pairs in VSS or vPC** mode check box. This feature ensures that the physical link connections between the ASAs to the VSS (or vPC) pair are balanced.

   Under Member Interface Configuration, you must then identify to which switch a given interface is connected, 1 or 2.

c. (Optional) For information about Load Balancing, see the "Configuring an EtherChannel" section on page 15-28. For information about the MTU, see the "Configuring the MAC Address and MTU" section on page 17-13.

   We recommend that you do not set the Minimum Active Members and the Maximum Active Members. See the "Guidelines" section on page 10-38 for more information.

Step 6 (Optional) If you want to configure VLAN subinterfaces on this EtherChannel, see the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34. The rest of this procedure applies to the subinterfaces.

Step 7 (Multiple context mode) Before you complete this procedure, you need to allocate interfaces to contexts.

a. Click **OK** to accept your changes.

b. To allocate interfaces, see the "Configuring a Security Context" section on page 9-20.

c. Change to the context you want to configure: in the Device List pane, double-click the context name under the active device IP address.

d. Choose the **Configuration > Device Setup > Interfaces** pane, select the port-channel interface you want to customize, and click **Edit**.

   The Edit Interface dialog box appears.

Step 8 Click the **General** tab.

Step 9 (Transparent Mode) In the Bridge Group drop-down menu, choose the bridge group to which you want to assign this interface.

Step 10 In the Interface Name field, enter a name up to 48 characters in length.

Step 11 In the Security level field, enter a level between 0 (lowest) and 100 (highest). See the "Security Levels" section on page 17-1 for more information.

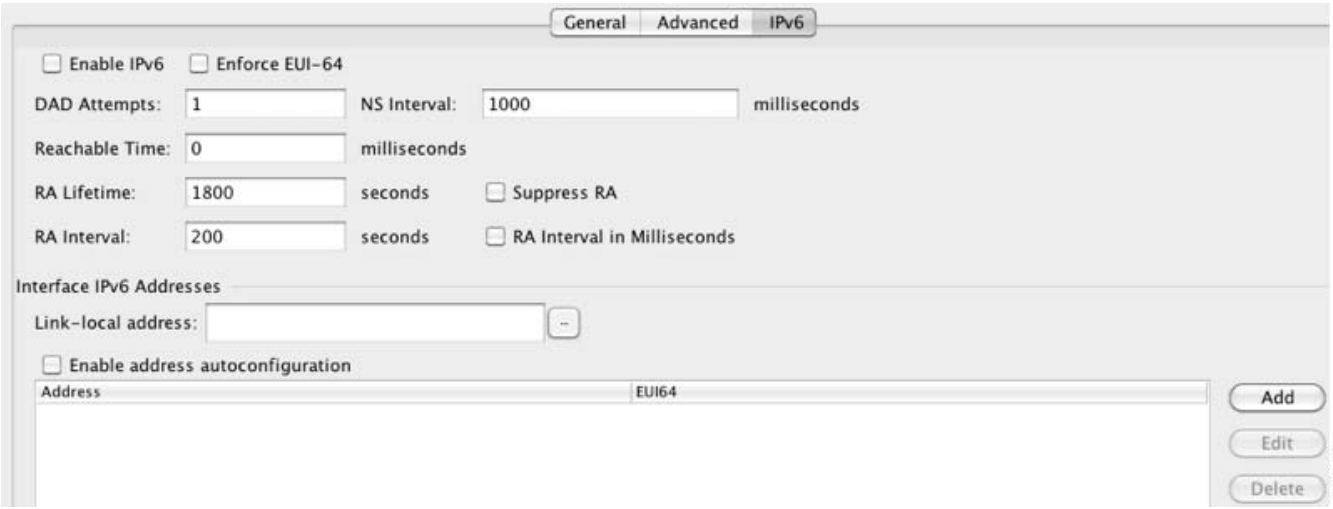
Step 12 (Routed Mode) For an IPv4 address, click the **Use Static IP** radio button and enter the IP address and mask. DHCP and PPPoE are not supported. For transparent mode, you configure the IP address for the bridge group interface, not the EtherChannel interface.

Step 13 (Optional) In the Description field, enter a description for this interface. The description can be up to 240 characters on a single line, without carriage returns.

Step 14 (Routed Mode) To configure an IPv6 address, click the **IPv6** tab.

For transparent mode, you configure the IP address for the bridge group interface, not the EtherChannel interface.

a. Check the **Enable IPv6** check box.



b. To manually configure a global IPv6 address, in the Interface IPv6 Addresses area, click **Add**.

The Enable address autoconfiguration option is not supported.

The Add IPv6 Address for Interface dialog box appears.

c. In the Address/Prefix Length field, enter the global IPv6 address and the IPv6 prefix length. For example, 2001:DB8::BA98:0:3210/64. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

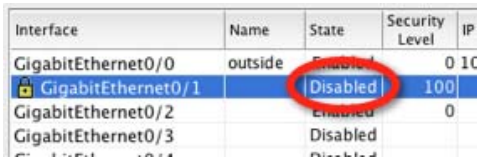
d. (Optional) To use the Modified EUI-64 interface ID as the host address, check the **EUI-64** check box. In this case, just enter the prefix in the Address/Prefix Length field.

e. Click **OK**.

f. For other optional parameters on the IPv6 tab, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 15 Click **OK** to return to the Interfaces screen.

Step 16 If a member interface is not already enabled (interfaces are disabled by default), enable it by selecting the member interface, and clicking **Edit**. Then check the **Enable Interface** check box, and click **OK**.



Step 17 Click **Apply**.

What to Do Next

Join the cluster. See the "Adding or Joining an ASA Cluster" section on page 10-44.

Adding or Joining an ASA Cluster

Each unit in the cluster requires a bootstrap configuration to join the cluster. Run the High Availability and Scalability wizard on one unit (that will become the master unit) to create the cluster, and then add slave units to it. If you do not want to use the wizard, or want to set advanced cluster parameters, see the "Configuring ASA Cluster Parameters" section on page 10-51.

Note For the master unit, if you want to change the default of the cLACP system ID and priority, you cannot use the wizard; you must configure the cluster manually according to the "Configuring ASA Cluster Parameters" section on page 10-51.

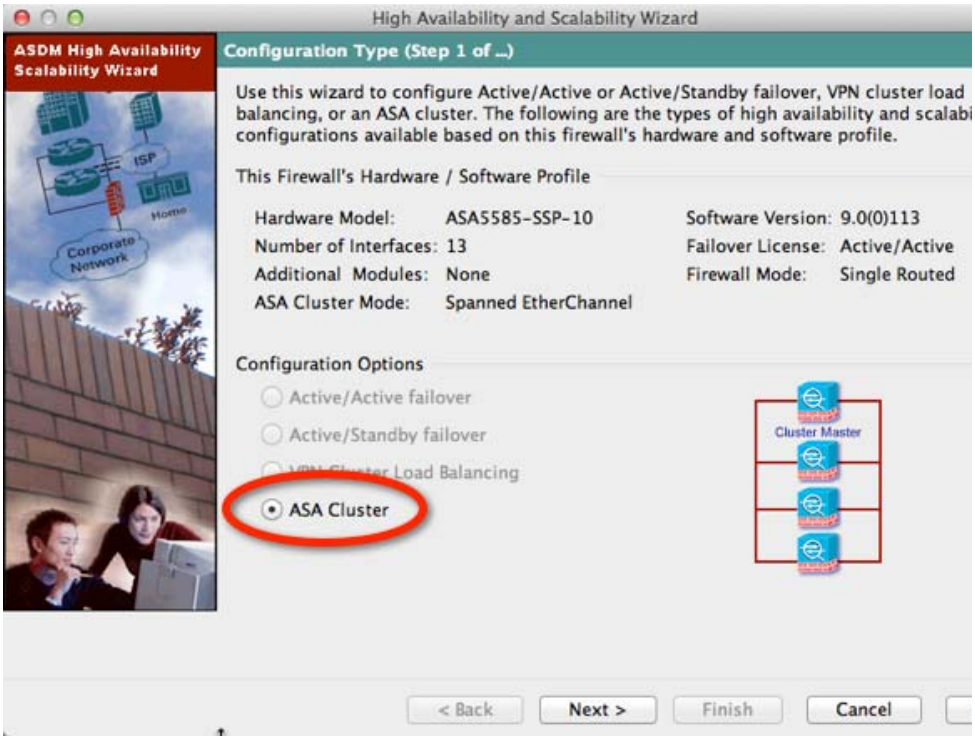
Prerequisites

- For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.
- For multiple context mode, individual interfaces within contexts must already be cluster-ready, with a cluster IP pool assigned. You can use the wizard to configure interfaces in single mode. See the "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32.
- We recommend enabling jumbo frame reservation for use with the cluster control link. See the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.
- The cluster control link interface must be in an up state.
- When you add a unit to a running cluster, you may see temporary, limited packet/connection drops; this is expected behavior.

Detailed Steps 1—Starting the Wizard

Step 1 Choose **Wizards > High Availability and Scalability Wizard**.

Step 2 **ASA Cluster** is already selected. Click **Next**.



Step 3 Click **Set up a new ASA cluster**, and click **Next**.

If you click **Join an existing ASA cluster**, you add this ASA to an existing cluster.

On a master ASA in an existing cluster, the second radio button is labeled **Add another member to the cluster**.

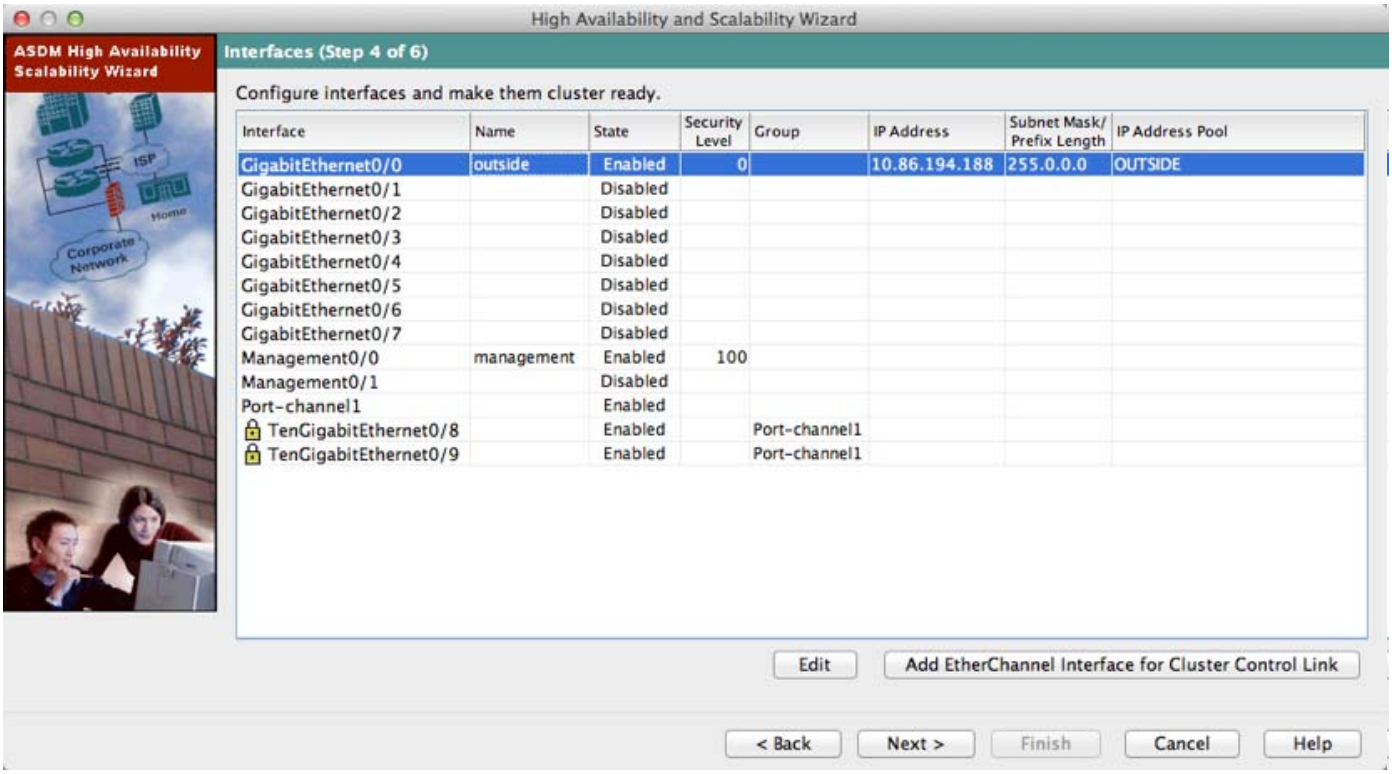
Step 4 Click **Next**. The ASA Cluster Mode screen appears.

If you have already set the cluster interface mode (see the "Configuring the Cluster Interface Mode on the Master Unit" section on page 10-27), this screen shows the currently-configured interface mode. If you have not set the interface mode, you are prompted to exit the wizard and set the mode at the CLI before continuing.

Step 5 Click **Next**. The Interfaces screen appears.

Detailed Steps 2—Configuring Interfaces

Step 1 If you did not already configure interfaces according to the "Configuring Interfaces on the Master Unit" section on page 10-32, you can use this screen to configure some interface parameters, including changing settings for any existing interface and creating an EtherChannel for the cluster control link.

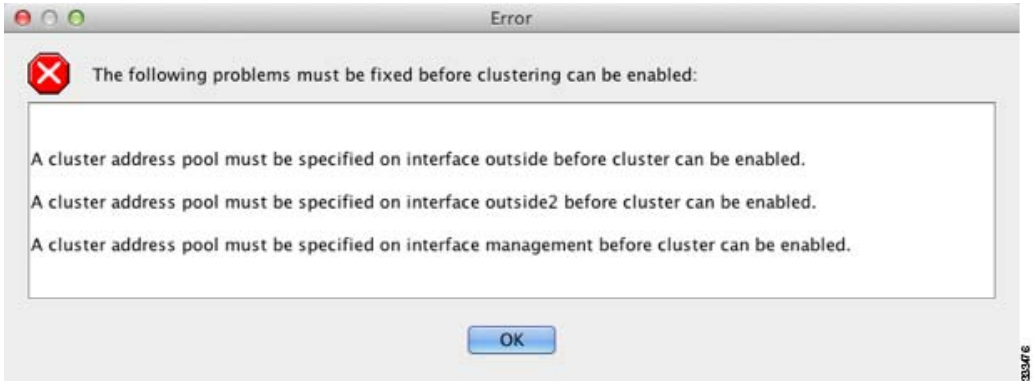


Step 2 Make any necessary interface changes; you cannot create new EtherChannels from this screen (except for the cluster control link). For more information about configuring interfaces for clustering, see the following sections:

- "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32
- "Configuring Spanned EtherChannels" section on page 10-37
- "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32

Step 3 Click **Next**.

The wizard verifies that all interfaces are cluster-ready. If you have any interfaces that are not cluster-ready, you see an error similar to the following:

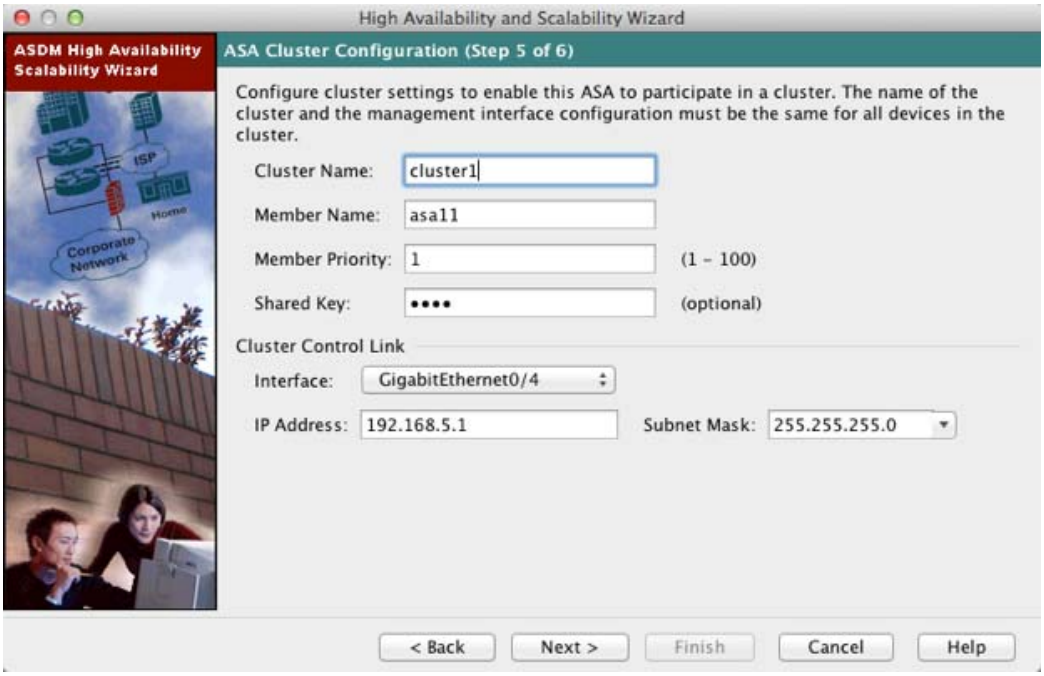


You are returned to the Interfaces screen to fix the interface configuration.

If your interface configuration passes the error checker, the ASA Cluster Configuration screen appears.

Detailed Steps 3—Configuring Bootstrap Parameters

Step 1 Configure the following bootstrap parameters:



a. Cluster Name—Names the cluster. The name must be an ASCII string from 1 to 38 characters. You can only configure one cluster per unit. All members of the cluster must use the same name.

b. Member Name—Names this member of the cluster with a unique ASCII string from 1 to 38 characters.

c. Member Priority—Sets the priority of this unit for master unit elections, between 1 and 100, where 1 is the highest priority.

d. (Optional) Shared Key—Sets an encryption key for control traffic on the cluster control link. The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the encryption key. This parameter does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear. You must configure this parameter if you also enable the password encryption service.

e. Cluster Control Link—Specifies the cluster control link interface. This interface cannot have a name configured; available interfaces are shown in the drop-down list.

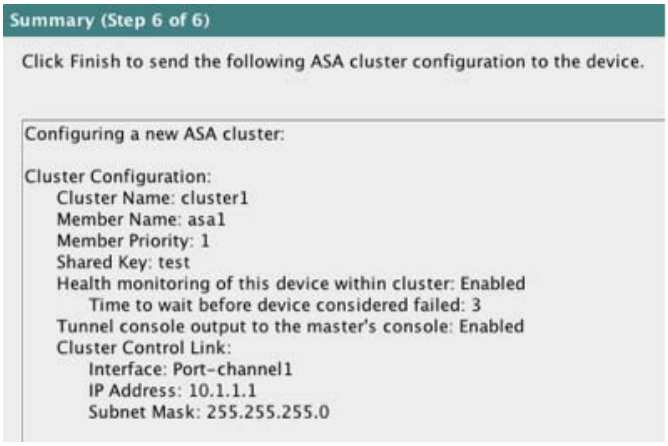
   – Interface—Specifies the interface ID, preferably an EtherChannel. Subinterfaces and Management type interfaces are not allowed.

   – IP Address—Specifies an IPv4 address for the IP address; IPv6 is not supported for this interface.

   – Subnet Mask—Specifies the subnet mask.

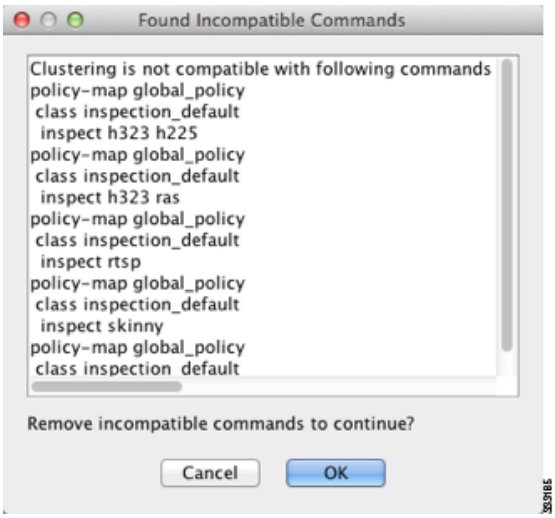
Step 2 Click **Next**.

The wizard shows the cluster configuration.

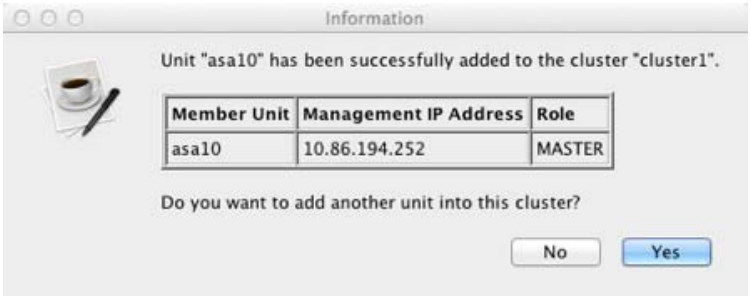


Step 3 Click **Finish**.

Step 4 The ASA scans the running configuration for incompatible commands for features that are not supported with clustering, including commands that may be present in the default configuration. Click **OK** to delete the incompatible commands. If you click **Cancel**, then clustering is not enabled.



Step 5 After a period of time while ASDM enables clustering and reconnects to the ASA, the Information screen appears confirming that the ASA was added to the cluster.

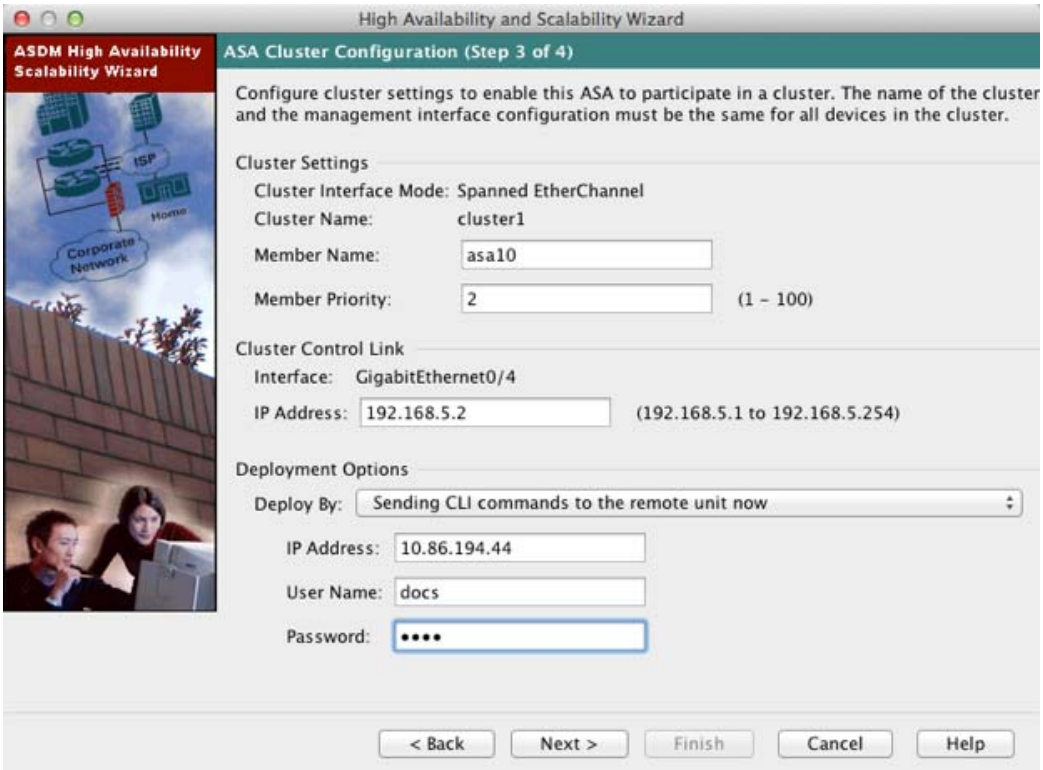


Note In some cases, there might be an error when joining the cluster after you finish the wizard. If ASDM was disconnected, ASDM will not receive any subsequent errors from the ASA. If clustering remains disabled after you reconnect ASDM, you should connect to the ASA console port to determine the exact error condition that disabled clustering; for example, the cluster control link might be down.

Detailed Steps 4—Adding Slave Units

Step 1 To add a slave unit, click **Yes**.

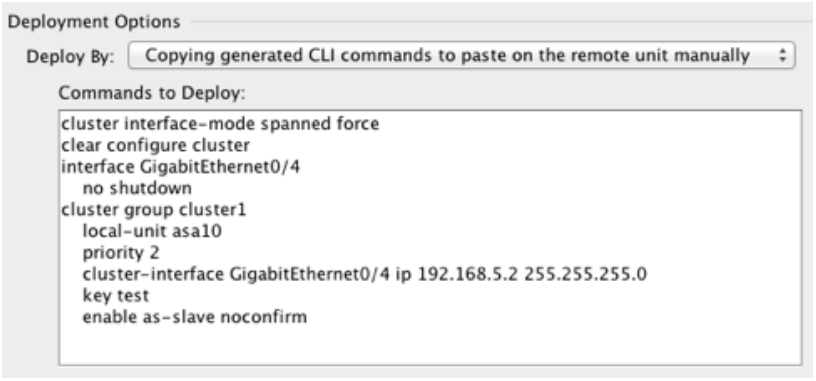
If you are re-running the wizard from the master, you can add slave units by choosing the **Add another member to the cluster** option when you first start the wizard.



Step 2 Set the new member name, priority, and cluster control link IP address (on the same network as the other units' cluster control links).

Step 3 Under Deployment Options, choose one of the following Deploy By options:

- **Sending CLI commands to the remote unit now—**Send the bootstrap configuration to the slave (temporary) management IP address. Enter the slave management IP address, username, and password.
- **Copying generated CLI commands to paste on the remote unit manually**—Generates the commands so you can cut and paste them at the slave unit CLI or using the CLI tool in ASDM. In the Commands to Deploy box, select and copy the generated commands for later use.



Step 4 Click **Next**. After a validation, the Summary screen appears. Click **Finish**.

The slave unit is added to the cluster.

What to Do Next

Configure the security policy on the master unit. See the chapters in this guide to configure supported features on the master unit. The configuration is replicated to the slave units. For a list of supported and unsupported features, see the "ASA Features and Clustering" section on page 10-14.

To configure advanced cluster parameters, see the "Configuring ASA Cluster Parameters" section on page 10-51.

Managing ASA Cluster Members

- Configuring ASA Cluster Parameters, page 10-51
- Adding a New Slave from the Master Unit, page 10-54
- Becoming an Inactive Member, page 10-56
- Inactivating a Slave Member from the Master Unit, page 10-57
- Leaving the Cluster, page 10-58
- Changing the Master Unit, page 10-61
- Executing a Command Cluster-Wide, page 10-62

Configuring ASA Cluster Parameters

If you do not use the wizard to add a unit to the cluster, you can configure the cluster parameters manually. If you already enabled clustering, you can edit some cluster parameters; others that cannot be edited while clustering is enabled are grayed out. This procedure also includes advanced parameters that are not included in the wizard.

Prerequisites

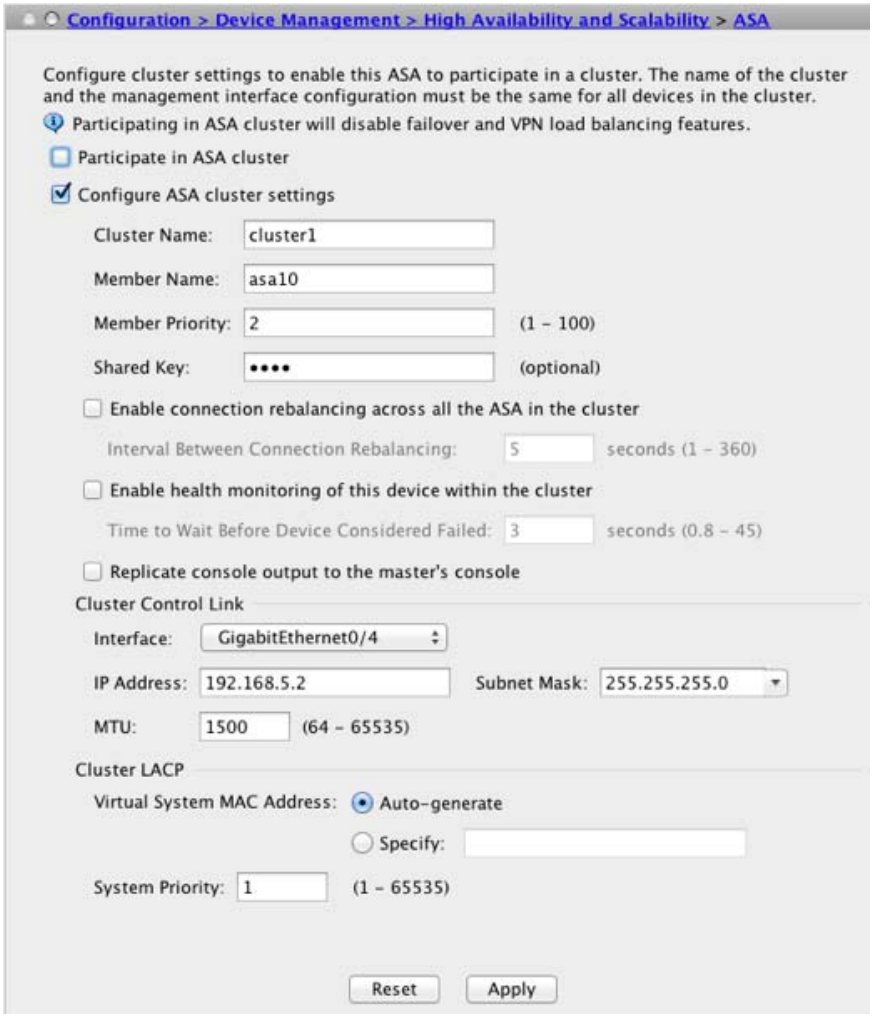
For multiple context mode, perform this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

Step 1 Choose **Configuration > Device Management > High Availability and Scalability > ASA Cluster**.

If your device is already in the cluster, and is the master unit, then this pane is on the Cluster Configuration tab.

Step 2 Check the **Configure ASA cluster settings** check box.



If you uncheck the check box, the settings are erased. Do not check Participate in ASA cluster until after you have set all your parameters.

Step 3 Configure the following bootstrap parameters:

a. Cluster Name—Names the cluster. The name must be an ASCII string from 1 to 38 characters. You can only configure one cluster per unit. All members of the cluster must use the same name.

b. Member Name—Names this member of the cluster with a unique ASCII string from 1 to 38 characters.

c. Member Priority—Sets the priority of this unit for master unit elections, between 1 and 100, where 1 is the highest priority.

d. (Optional) Shared Key—Sets an encryption key for control traffic on the cluster control link. The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the encryption key. This parameter does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear. You must configure this parameter if you also enable the password encryption service.

e. (Optional) Enable connection rebalancing for TCP traffic across all the ASAs in the cluster—Enables connection rebalancing. This parameter is disabled by default. If enabled, ASAs in a cluster exchange load information periodically, and offload new connections from more loaded

devices to less loaded devices. The frequency, between 1 and 360 seconds, specifies how often the load information is exchanged. This parameter is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

f. (Optional) Enable health monitoring of this device within the cluster—Enables the cluster health check feature, which includes unit heath monitoring and interface health monitoring. **Note**: When you are adding new units to the cluster, and making topology changes on the ASA or the switch, you should disable this feature temporarily until the cluster is complete. You can re-enable this feature after cluster and topology changes are complete. Keepalive messages between members determine member health. If a unit does not receive any keepalive message from a peer unit within the holdtime period, the peer unit is considered unresponsive or dead. Interface status messages detect link failure. Health check is enabled by default, and we recommend keeping it enabled. The holdime determines the amount of time between keepalive messages, between .8 and 45 seconds. By default, the holdtime is 3 seconds. This parameter is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

Note When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the ASA or the switch, adding an additional switch to form a VSS or vPC) you must disable the health check. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check.

g. (Optional) Replicate console output to the master's console—Enables console replication from slave units to the master unit. This feature is disabled by default. The ASA may print out some messages directly to the console for certain critical events. If you enable console replication, slave units send the console messages to the master unit so you only need to monitor one console port for the cluster. This parameter is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

h. Cluster Control Link—Specifies the cluster control link interface. This interface cannot have a name configured; available interfaces are shown in the drop-down list.

- Interface—Specifies the interface ID, preferably an EtherChannel. Subinterfaces and Management type interfaces are not allowed.
- IP Address—Specifies an IPv4 address for the IP address; IPv6 is not supported for this interface.
- Subnet Mask—Specifies the subnet mask.
- (Optional) MTU—Specifies the maximum transmission unit for the cluster control link interface, between 64 and 65,535 bytes. Data that is larger than the MTU value is fragmented before being sent. The default MTU is 1500 bytes. We suggest stting the MTU to 1600 bytes or greater, which requires you to enable jumbo frame reservation. See the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

i. (Optional) Cluster LACP—When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch. ASAs in a cluster collaborate in cLACP negotiation so that they appear as a single (virtual) device to the switch.

- Virtual System MAC Address—Sets the cLACP system ID, which is in the format of a MAC address. All ASAs use the same system ID: auto-generated by the master unit (the default) and replicated to all slaves; or manually specified in the form *H.H.H*, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE. This parameter is not part of the bootstrap configuration, and is replicated from the master unit to the slave units. However, you cannot change this value after you enable clustering.

– System Priority—Sets the system priority, between 1 and 65535. The priority is used to decide which unit is in charge of making a bundling decision. By default, the ASA uses priority 1, which is the highest priority. The priority needs to be higher than the priority on the switch. This parameter is not part of the bootstrap configuration, and is replicated from the master unit to the slave units. However, you cannot change this value after you enable clustering.

Step 4 Check the **Participate in ASA cluster** check box to join the cluster.

Step 5 Click **Apply**.

Adding a New Slave from the Master Unit

You can add additional slaves to the cluster from the master unit. You can also add slaves using the High Availability and Scalability wizard. Adding a slave from the master unit has the benefit of configuring the cluster control link and setting the cluster interface mode on each slave unit you add.

You can alternatively log into the slave unit and configure clustering on the unit according to the "Configuring ASA Cluster Parameters" section on page 10-51. However, after you enable clustering, your ASDM session will be disconnected.

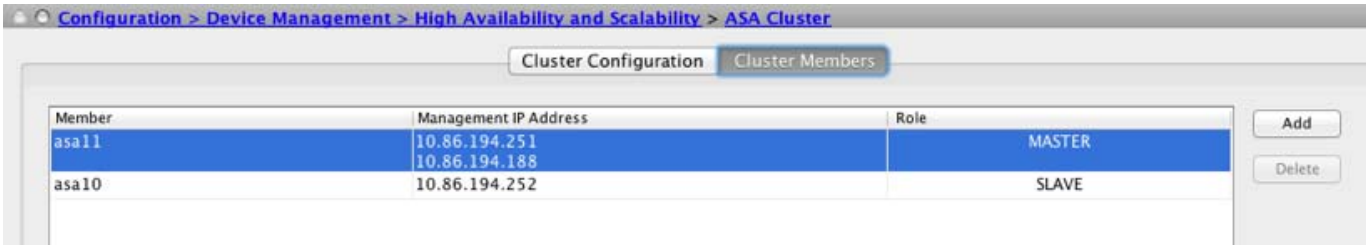
Prerequisites

- For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.
- If you want to send the bootstrap configuration over the management network, be sure the slave unit has an accessible IP address. See the "Configuring the Management Interface on Each Unit" section on page 10-29.

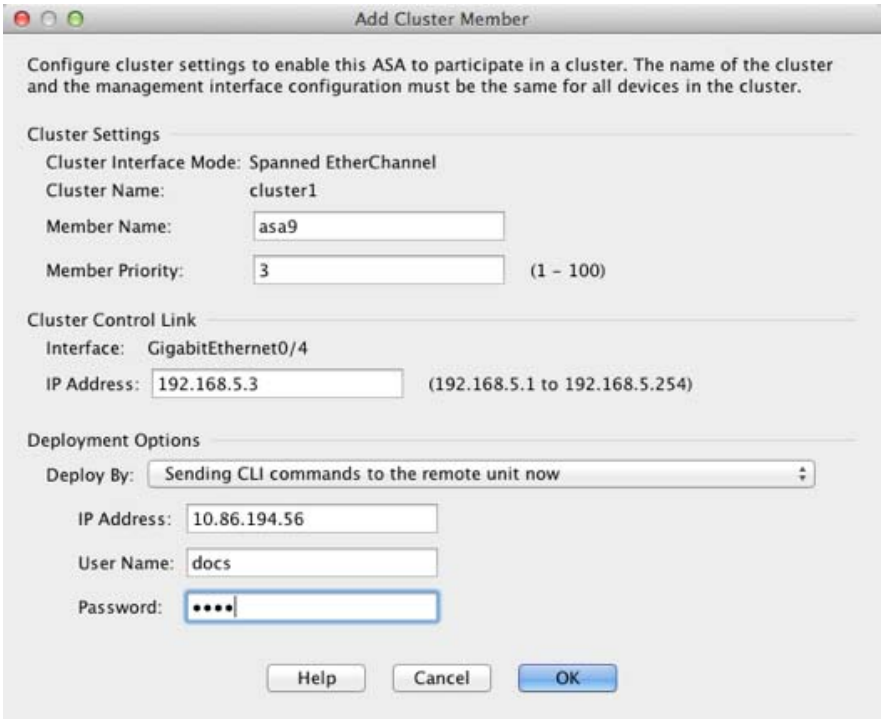
Detailed Steps

Step 1 Choose **Configuration > Device Management > High Availability and Scalability > ASA Cluster > Cluster Members**.

Step 2 Click **Add**.



Step 3 Configure the following parameters:



a. Member Name—Names this member of the cluster with a unique ASCII string from 1 to 38 characters.

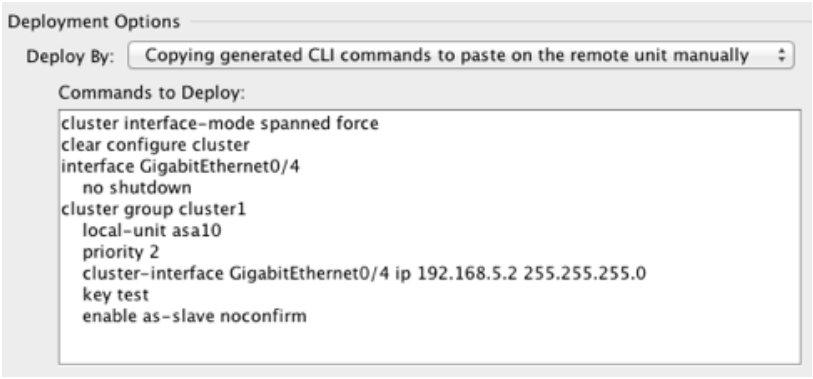
b. Member Priority—Sets the priority of this unit for master unit elections, between 1 and 100, where 1 is the highest priority.

c. Cluster Control Link > IP Address—Specifies a unique IP address for this member for the cluster control link, on the same network as the master cluster control link.

d. Under Deployment Options, choose one of the following Deploy By options:

   – **Sending CLI commands to the remote unit now**—Send the bootstrap configuration to the slave (temporary) management IP address. Enter the slave management IP address, username, and password.

   – **Copying generated CLI commands to paste on the remote unit manually**—Generates the commands so you can cut and paste them at the slave unit CLI or using the CLI tool in ASDM. In the Commands to Deploy box, select and copy the generated commands for later use.



Step 4 Click **OK**, then **Apply**.

Becoming an Inactive Member

To become an inactive member of the cluster, disable clustering on the unit while leaving the clustering configuration intact.

Note When the ASA becomes inactive, all data interfaces are shut down; only the management-only interface can send and receive traffic. To resume traffic flow, re-enable clustering; or you can remove the unit altogether from the cluster. See the "Leaving the Cluster" section on page 10-58. The management interface remains up using the IP address the unit received from the cluster IP pool. However if you reload, the management interface is not accessible (because it uses the same IP address as the master unit). You must use the console port for any further configuration.

Prerequisites

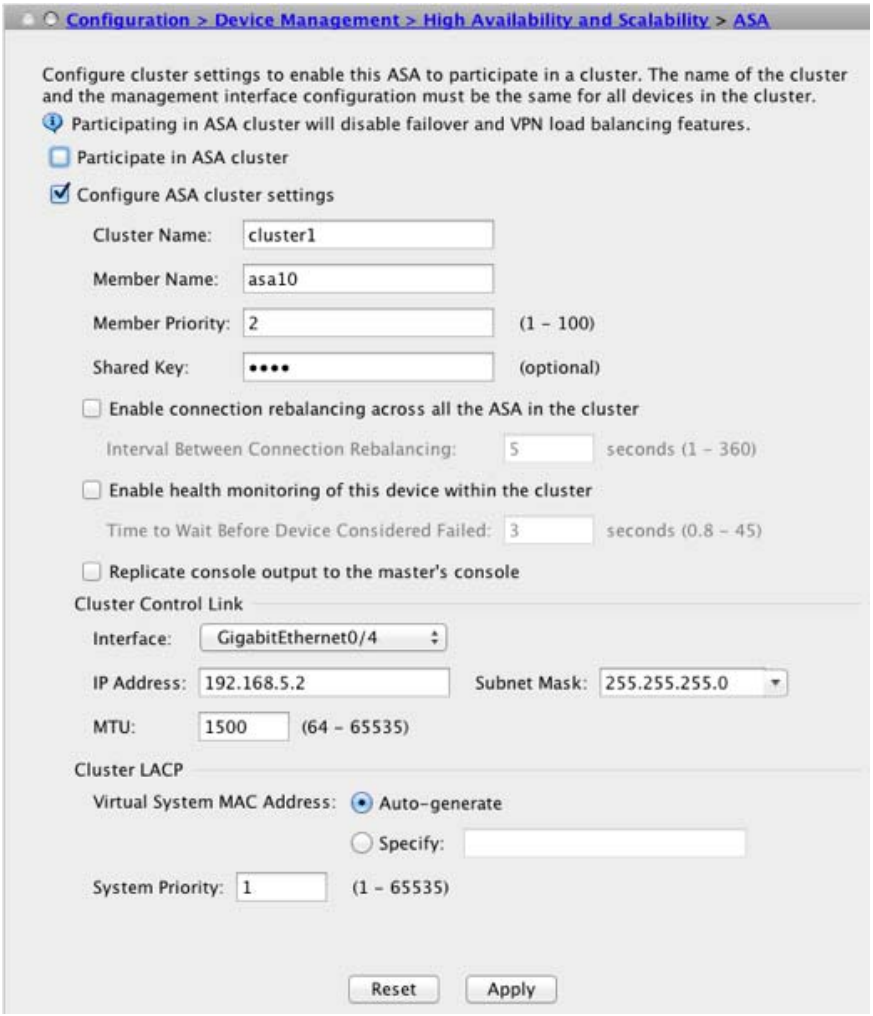
- For multiple context mode, perform this procedure in the system execution space. If you are not already in the System configuration mode in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

Step 1 Choose **Configuration > Device Management > High Availability and Scalability > ASA Cluster**.

If your device is already in the cluster, and is the master unit, then this pane is on the Cluster Configuration tab.

Step 2 Uncheck the **Participate in ASA cluster** check box.



Step 3 Click **Apply**.

If this unit was the master unit, a new master election takes place, and a different member becomes the master unit.

The cluster configuration is maintained, so you can enable clustering again later.

Inactivating a Slave Member from the Master Unit

To inactivate a slave member, perform the following steps.

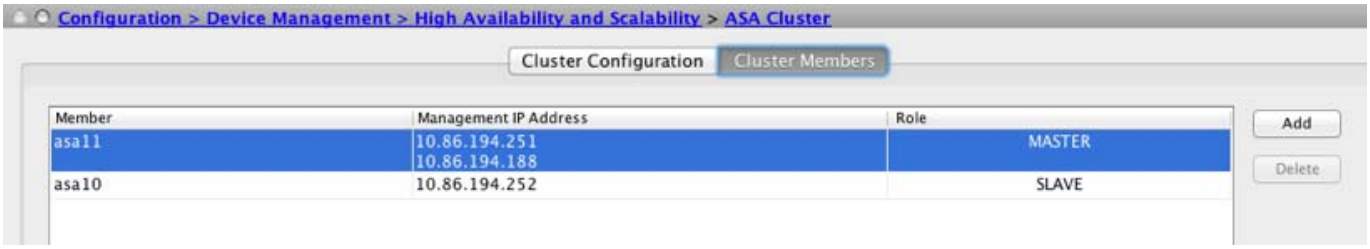
Note When the ASA becomes inactive, all data interfaces are shut down; only the management-only interface can send and receive traffic. To resume traffic flow, re-enable clustering; or you can remove the unit altogether from the cluster. See the "Leaving the Cluster" section on page 10-58. The management interface remains up using the IP address the unit received from the cluster IP pool. However if you reload, the management interface is not accessible (because it uses the same IP address as the master unit). You must use the console port for any further configuration.

Prerequisites

For multiple context mode, perform this procedure in the system execution space. If you are not already in the System configuration mode in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

Step 1 Choose **Configuration > Device Management > High Availability and Scalability > ASA Cluster**.



Step 2 Select the slave you want to remove, and click **Delete**.

The slave bootstrap configuration remains intact, so you can later re-add the slave without losing your configuration.

Step 3 Click **Apply**.

Leaving the Cluster

If you want to leave the cluster altogether, you need to remove the entire cluster bootstrap configuration. In practice, you need to clear or replace your entire configuration.

Prerequisites

Because the current configuration on each member is the same (synced from the master unit), leaving the cluster also means either restoring a pre-clustering configuration from backup, or clearing your configuration and starting over.

- Using ASDM, you can restore a backup running configuration. However, you also need to use the CLI at the console port to disable the cluster interface mode. See the "Backing Up Your Configurations (Recommended)" section on page 10-32 for more information about backing up the configuration before joining the cluster.
- If you do not have a backup configuration, you need to use the CLI to reconfigure the ASA for ASDM management access.
- Using CLI, you must use the console port; you cannot enable or disable clustering from a remote CLI connection.

Detailed Steps—CLI from the Console Port

	Command	Purpose

Step 1	For a slave unit:
	cluster group *cluster_name*
	no enable
	
	Example:
	`hostname(config)# cluster group cluster1`
	`hostname(cfg-cluster)# no enable`
		Disables clustering. You cannot make configuration changes while clustering is enabled on a slave unit.

Step 2	**clear configure all** **Example:** `hostname(config)# clear configure all`	Clears the running configuration.

Step 3	`no cluster interface-mode`
	
	Example:
	`hostname(config)# no cluster interface-mode`
		Disables cluster interface mode. The mode is not stored in the configuration and must be reset manually.

Step 4	If you have a backup configuration:
	copy *backup_cfg* **running-config**
	
	Example:
	`hostname(config)# copy backup_cluster.cfg running-config`
	
	`Source filename [backup_cluster.cfg]?`
	
	`Destination filename [running-config]?`
	`hostname(config)#`
		Copies the backup configuration to the running configuration.

Step 5	`write memory`
	
	Example:
	`hostname(config)# write memory`
		Saves the configuration to startup.

Step 6	If you do not have a backup configuration, reconfigure management access according to Chapter 3, "Getting Started."	

Detailed Steps—ASDM

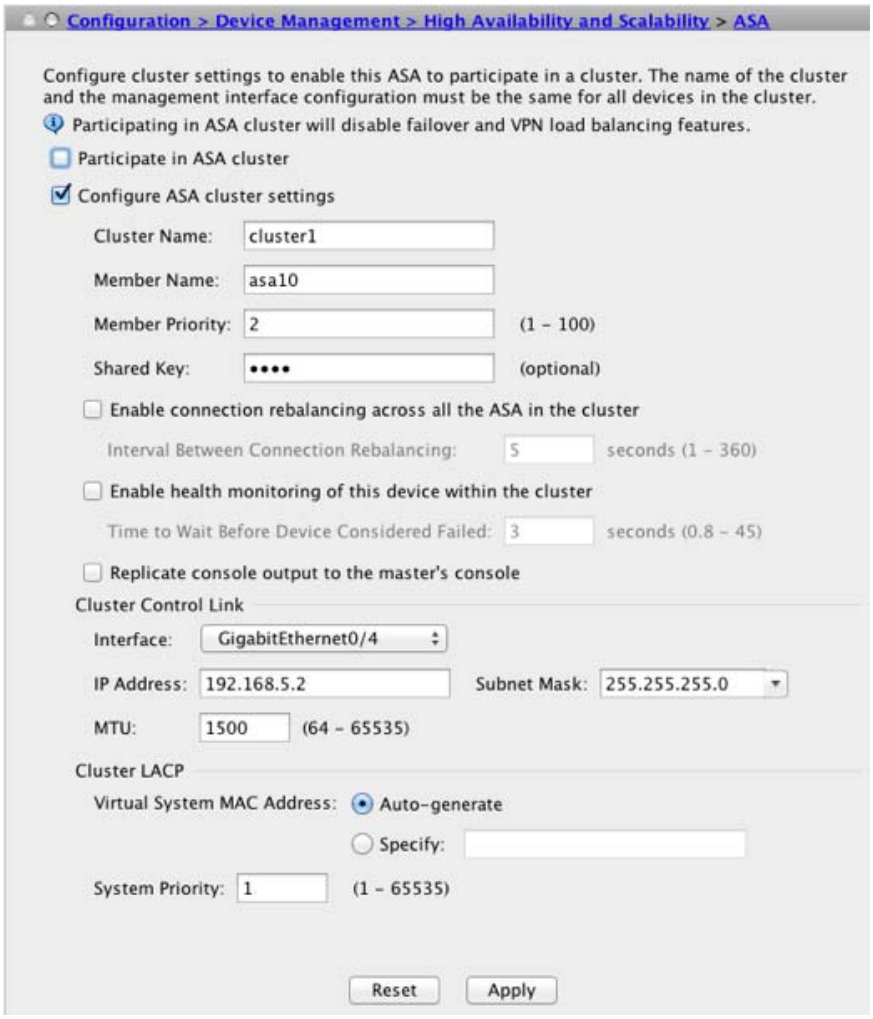
Step 1 Connect ASDM directly to the cluster member unit using the individual management IP address, not the main cluster IP address.

To view the member IP addresses from the master unit, choose **Home > Cluster Dashboard**, and view the Management IP Address column.

Step 2 Choose **Configuration > Device Management > High Availability and Scalability > ASA Cluster > Cluster Configuration**.

If your device is already in the cluster, and is the master unit, then this pane is on the Cluster Configuration tab.

Step 3 Uncheck the **Participate in ASA cluster** check box.



Step 4 Click **Apply**.

If this unit was the master unit, a new master election takes place, and a different member becomes the master unit.

Step 5 You are prompted to exit ASDM.

Step 6 Connect to the ASA console port, and enter the following command:

```
hostname(config)# no cluster interface-mode
```

Step 7 Reconnect ASDM to the same management IP address.

Step 8 Choose **Tools > Restore Configurations**.

The Restore Configurations dialog box appears.

Step 9 Browse to the backup zip file (that you created as part of the "Backing Up Your Configurations (Recommended)" section on page 10-32), and click **Next**.

Step 10 Check at a minimum the **Running Configuration** check box, and click **Restore**.

The Running Configuration Restore dialog box appears asking if you want to replace or merge with the current configuration.

Step 11 Click **Replace**.

Step 12 When completed, exit the restore dialog box, and exit ASDM.

Step 13 Reconnect ASDM to the *original* management IP in the backup running configuration.

Changing the Master Unit

To change the master unit, perform the following steps.

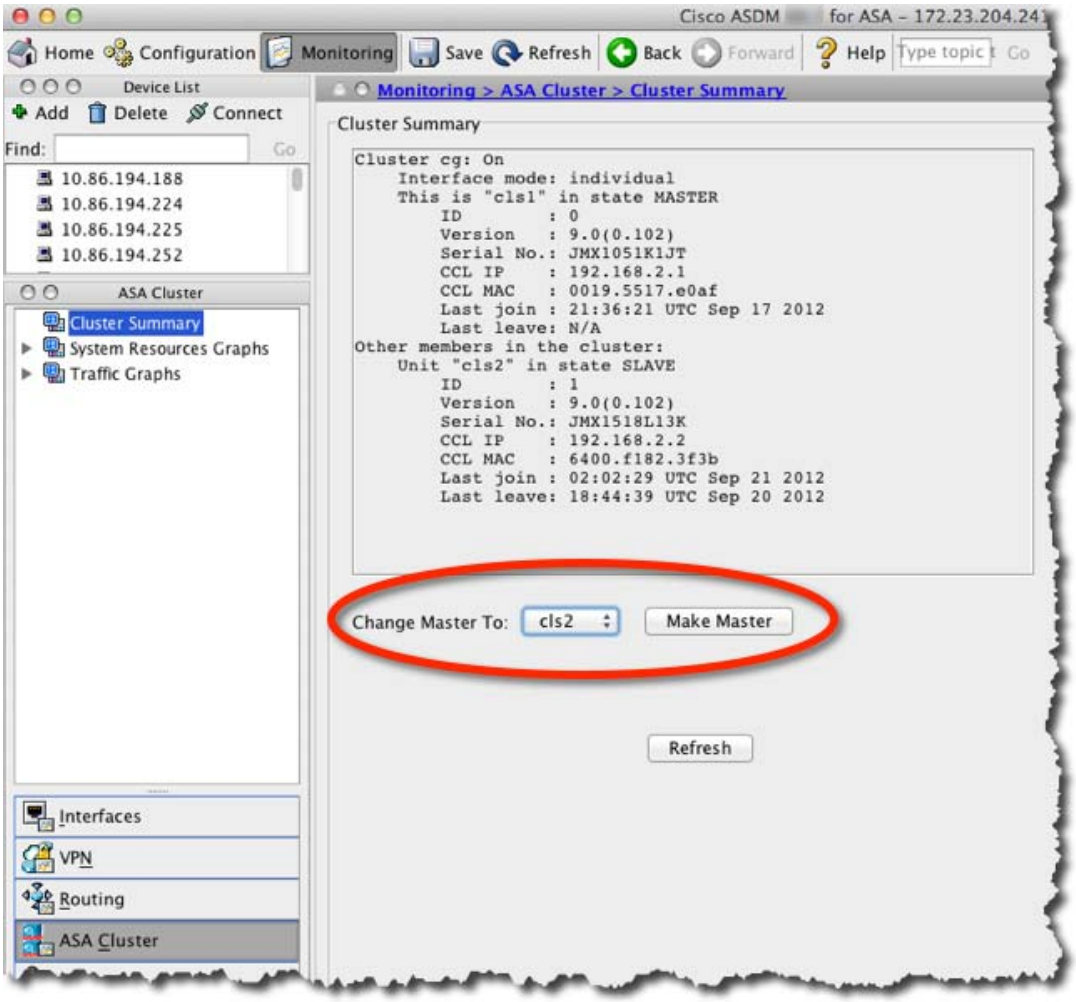
Note For centralized features, if you force a master unit change, then all connections are dropped, and you have to re-establish the connections on the new master unit. See the "Centralized Features" section on page 10-15 for a list of centralized features.

Prerequisites

For multiple context mode, perform this procedure in the system execution space. If you are not already in the System configuration mode in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

Step 1 Choose **Monitoring > ASA Cluster > Cluster Summary**.



Step 2 In the Change Master To drop-down menu, choose a slave unit to become master, and click **Make Master**.

Executing a Command Cluster-Wide

To send a command to all members in the cluster, or to a specific member, perform the following steps. Sending a **show** command to all members collects all output and displays it on the console of the current unit. Other commands, such as **capture** and **copy**, can also take advantage of cluster-wide execution.

Detailed Steps

Step 1 Choose **Tools > Command Line Interface**.

Step 2 Enter the following command:

Command	Purpose
cluster exec [**unit** *unit_name*] *command* **Example:** `hostname# cluster exec show xlate`	Sends a command to all members, or if you specify the unit name, a specific member. To view member names, enter **cluster exec unit ?** (to see all names except the current unit), or enter the **show cluster info** command.

Step 3 Click **Send**.

Examples

To copy the same capture file from all units in the cluster at the same time to a TFTP server, enter the following command on the master unit:

```
cluster exec copy /pcap capture: tftp://10.1.1.56/capture1.pcap
```

Multiple PCAP files, one from each unit, are copied to the TFTP server. The destination capture file name is automatically attached with the unit name, such as capture1_asa1.pcap, capture1_asa2.pcap, and so on. In this example, asa1 and asa2 are cluster unit names.

The following sample output for the **cluster exec show port-channel** summary command shows EtherChannel information for each member in the cluster:

```
cluster exec show port-channel summary
primary(LOCAL):*********************************************************
 Number of channel-groups in use: 2
Group  Port-channel  Protocol  Span-cluster  Ports
------+-------------+----------+-----------------------------------------------
1         Po1             LACP      Yes  Gi0/0(P)
2         Po2             LACP      Yes  Gi0/1(P)
 secondary:*****************************************************************
 Number of channel-groups in use: 2
Group  Port-channel  Protocol  Span-cluster   Ports
------+-------------+----------+-----------------------------------------------
1         Po1             LACP      Yes   Gi0/0(P)
2         Po2             LACP      Yes   Gi0/1(P)
```

Monitoring the ASA Cluster

- Cluster Dashboards, page 10-63
- Monitoring Screens, page 10-64
- Related Features, page 10-65

Cluster Dashboards

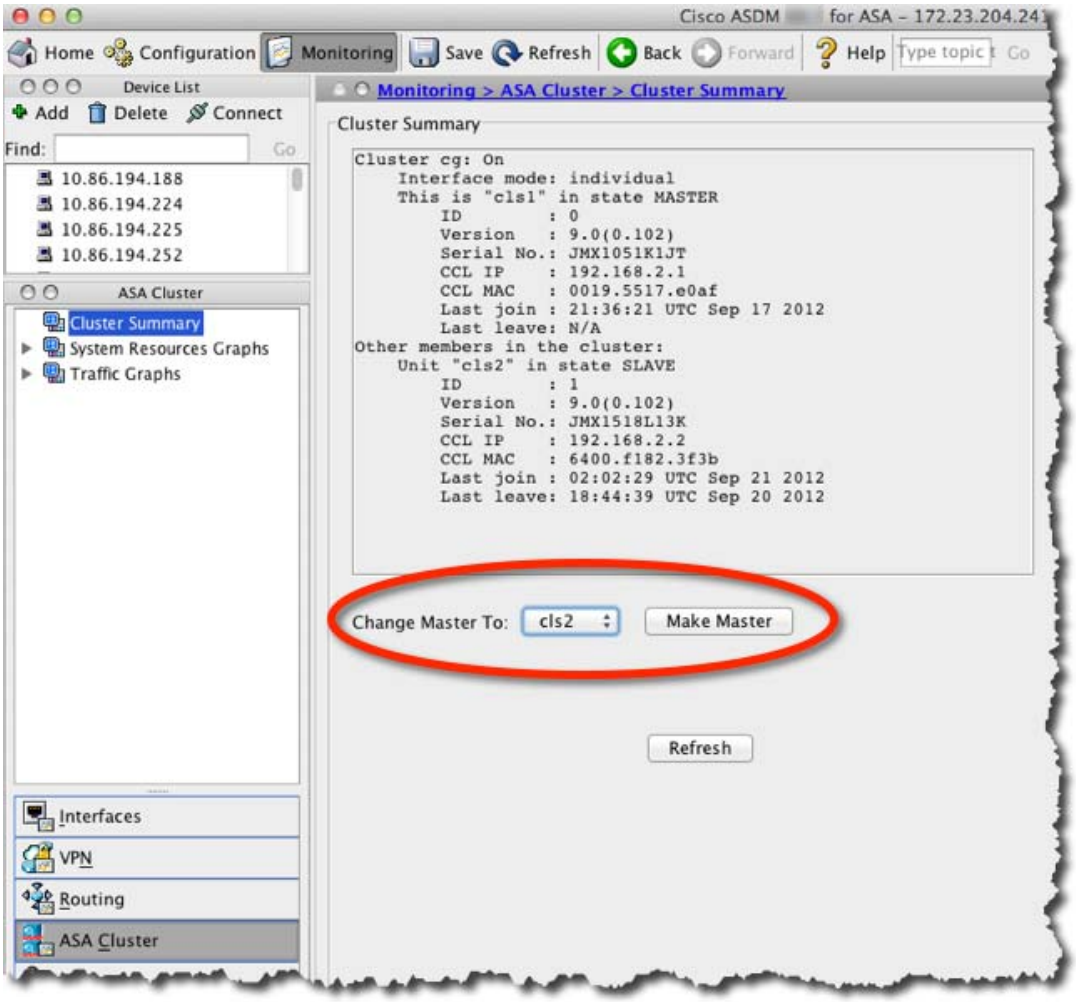
On the Home page on the master unit, you can monitor the cluster using the Cluster Dashboard and the Cluster Firewall Dashboard. For more information, see the "Cluster Dashboard Tab" section on page 4-25 and the "Cluster Firewall Dashboard Tab" section on page 4-26.

Monitoring Screens

- Viewing the Cluster Summary, page 10-64
- Monitoring Cluster Resources, page 10-65
- Monitoring Cluster Traffic, page 10-65
- Monitoring the Cluster Control Link, page 10-65

Viewing the Cluster Summary

Choose **Monitoring > ASA Cluster > Cluster Summary**. This pane shows cluster information about the unit to which you are connected, as well as other units in the cluster. You can also change the master unit from this pane.



Monitoring Cluster Resources

CPU

Choose **Monitoring > ASA Cluster > System Resources Graphs > CPU**. This pane lets you create graphs or tables showing the CPU utilization across the cluster members.

Memory

Choose **Monitoring > ASA Cluster > System Resources Graphs > Memory**. This pane lets you create graphs or tables showing the Free Memory and Used Memory across the cluster members.

Monitoring Cluster Traffic

Connections

Choose **Monitoring > ASA Cluster > Traffic Graphs > Connections**. This pane lets you create graphs or tables showing the Connections across the cluster members.

Throughput

Choose **Monitoring > ASA Cluster > Traffic Graphs > Throughput**. This pane lets you create graphs or tables showing the traffic throughput across the cluster members.

Monitoring the Cluster Control Link

Choose **Monitoring > Properties > System Resources Graphs > Cluster Control Link**. This pane lets you create graphs or tables showing the cluster control link Receival and Transmittal capacity utilization.

Related Features

Command	Purpose
Wizards > Packet Capture Wizard	To support cluster-wide troubleshooting, you can enable capture of cluster-specific traffic on the master unit, which is then automatically enabled on all of the slave units in the cluster. See the "Configuring and Running Captures with the Packet Capture Wizard" section on page 102-1.
Configuration > Device Management > Interfaces > Edit Interface > Advanced	Creates a MAC address pool for an individual inteface.

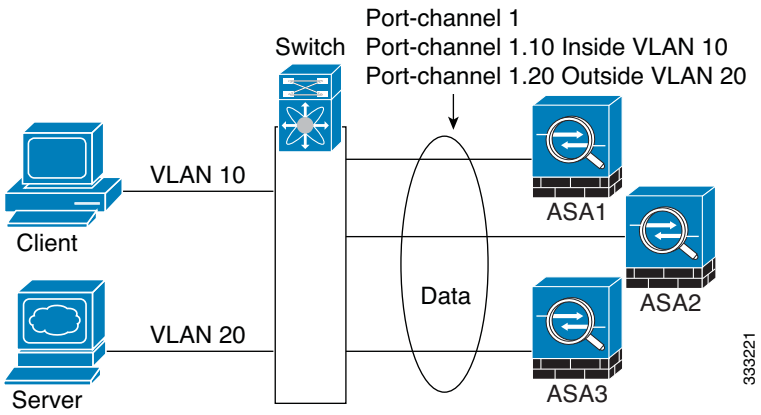
Command	Purpose
Configuration > Device Management > Management Access > Command Line (CLI) > CLI Prompt	Sets the CLI prompt to include the cluster unit name. See the "Customizing a CLI Prompt" section on page 52-6.
Configuration > Device Management > Logging > Syslog Setup	Each unit in the cluster generates syslog messages independently. You can generate syslog messages with identical or different device IDs to make messages appear to come from the same or different units in the cluster. See the "Including the Device ID in Non-EMBLEM Format Syslog Messages" section on page 96-21.

Configuration Examples for ASA Clustering

This section includes the following topics:

- Firewall on a Stick, page 10-66
- Traffic Segregation, page 10-67
- Redundant Interface (PBR or ECMP), page 10-67
- Spanned EtherChannel With Backup Links, page 10-68

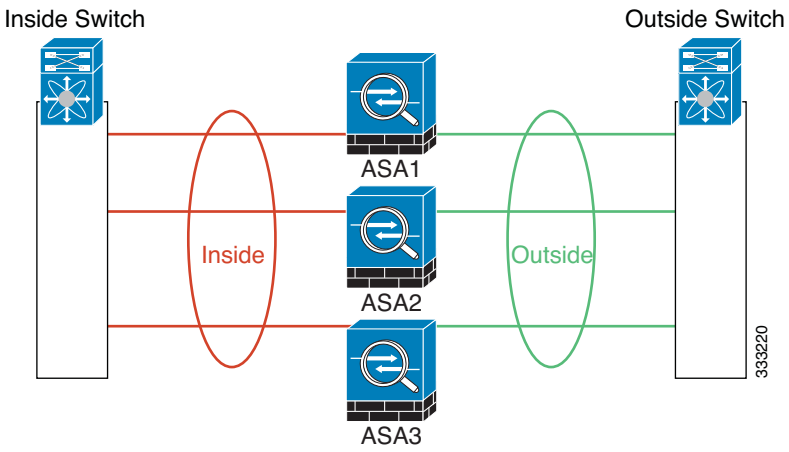
Firewall on a Stick



Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each ASA has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The ASA is the firewall between VLAN 10 and VLAN 20.

When using spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If an ASA becomes unavailable, the switch will rebalance traffic between the remaining units.

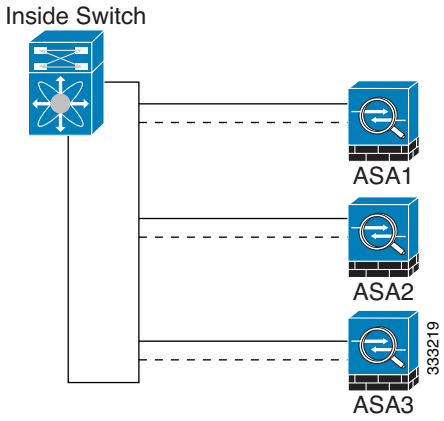
Traffic Segregation



You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Redundant Interface (PBR or ECMP)

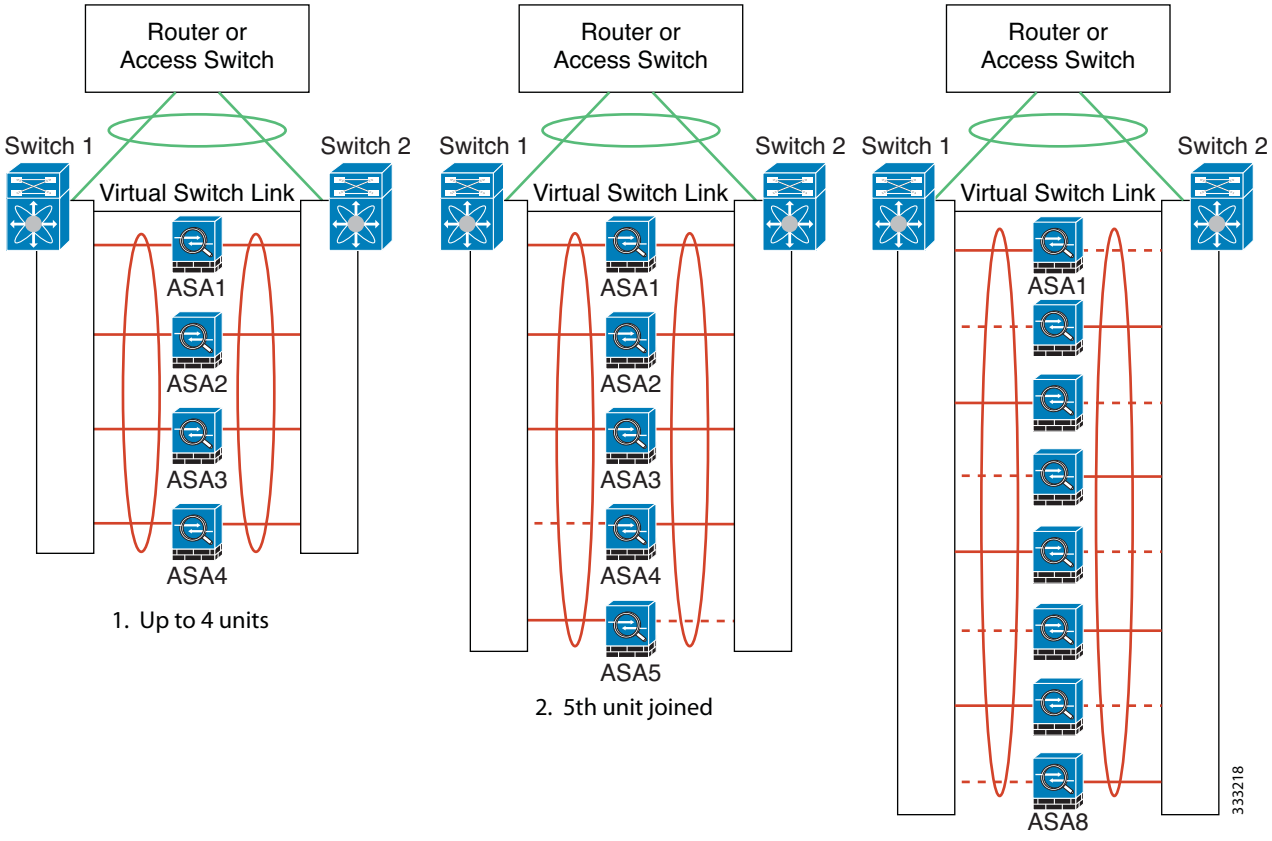


Redundant interfaces can be used to provide link-level redundancy.

When using individual interfaces, switching to a backup interface is similar to how it behaves in non-clustering mode. The ASA activates the backup link if the primary link fails. It takes time for the Spanning Tree on the switch to converge before the backup link is activated on the switch side. The backup links can be connected to a separate switch to provide inter-switch redundancy.

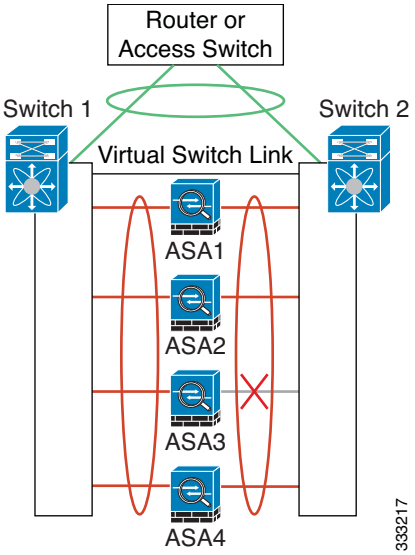
Spanned EtherChannel With Backup Links

The maximum number of active ports in an etherchannel is limited to 8 from the switch side. If you have an 8-ASA cluster, and you allocate 2 ports per unit to the EtherChannel, for a total of 16 ports total, then 8 of them have to be in standby mode. The ASA uses LACP to negotiate which links should be active or standby. If you enable multi-switch EtherChannel using VSS or vPC, you can achieve inter-switch redundancy. On the ASA, all physical ports are ordered first by the slot number then by the port number. In the following figure, the lower ordered port is the "primary" port (for example, GigabitEthernet 0/0), and the other one is the "secondary" port (for example, GigabitEthernet 0/1). You must guarantee symmetry in the hardware connection: all primary links must terminate on one switch, and all secondary links must terminate on another switch if VSS/vPC is used. The following diagram shows what happens when the total number of links grows as more units join the cluster:

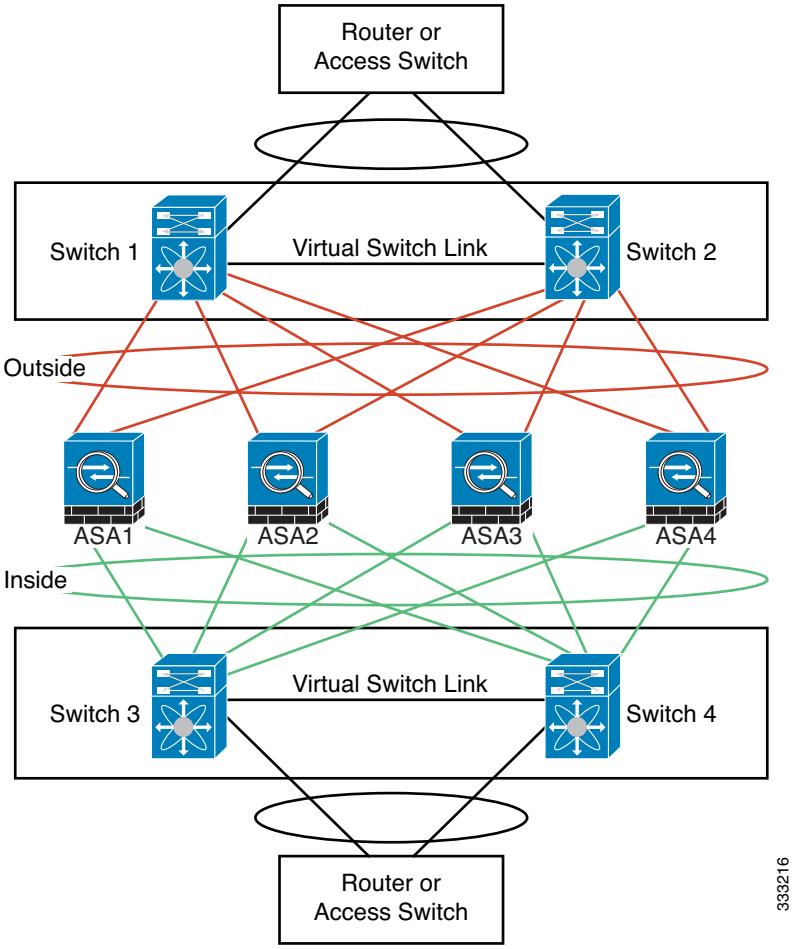


The principle is to first maximize the number of active ports in the channel, and secondly keep the number of active primary ports and the number of active secondary ports in balance. Note that when a 5th unit joins the cluster, traffic is not balanced evenly between all units.

Link or device failure is handled with the same principle. You may end up with a less-than-perfect load balancing situation. The following figure shows a 4-unit cluster with a single link failure on one of the units.



There could be multiple EtherChannels configured in the network. The following diagram shows an EtherChannel on the inside and one on the outside. An ASA is removed from the cluster if both primary and secondary links in one EtherChannel fail. This prevents the ASA from receiving traffic from the outside network when it has already lost connectivity to the inside network.



Feature History for ASA Clustering

Table 10-3 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 10-3 Feature History for Clustering

Feature Name	Platform Releases	Feature Information
ASA Clustering	9.0(1)	Clustering lets you group multiple ASAs together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. We introduced or modified the following screens: Home > Device Dashboard Home > Cluster Dashboard Home > Cluster Firewall Dashboard Configuration > Device Management > Advanced > Address Pools > MAC Address Pools Configuration > Device Management > High Availability and Scalability > ASA Cluster Configuration > Device Management > Logging > Syslog Setup > Advanced Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced Configuration > Device Setup > Interfaces > Add/Edit Interface > IPv6 Configuration > Device Setup > Interfaces > Add/Edit EtherChannel Interface > Advanced Configuration > Firewall > Advanced > Per-Session NAT Rules Monitoring > ASA Cluster Monitoring > Properties > System Resources Graphs > Cluster Control Link Tools > Preferences > General Tools > System Reload Tools > Upgrade Software from Local Computer Wizards > High Availability and Scalability Wizard Wizards > Packet Capture Wizard Wizards > Startup Wizard

Information About Failover

This chapter provides an overview of the failover features that enable you to achieve high availability on the Cisco 5500 series ASAs. For information about configuring high availability, see Chapter 13, "Configuring Active/Active Failover" or Chapter 12, "Configuring Active/Standby Failover."

This chapter includes the following sections:

- Introduction to Failover and High Availability, page 11-1
- Failover System Requirements, page 11-2
- Failover and Stateful Failover Links, page 11-3
- Active/Active and Active/Standby Failover, page 11-8
- Stateless (Regular) and Stateful Failover, page 11-9
- Intra- and Inter-Chassis Module Placement for the ASA Services Module, page 11-11
- Transparent Firewall Mode Requirements, page 11-15
- Auto Update Server Support in Failover Configurations, page 11-16
- Failover Health Monitoring, page 11-18
- Failover Times, page 11-20
- Failover Messages, page 11-20

Introduction to Failover and High Availability

Configuring high availability requires two identical ASAs connected to each other through a dedicated failover link and, optionally, a Stateful Failover link. The health of the active interfaces and units is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

The ASA supports two failover configurations, Active/Active failover and Active/Standby failover. Each failover configuration has its own method for determining and performing failover.

With Active/Active failover, both units can pass network traffic. This also lets you configure traffic sharing on your network. Active/Active failover is available only on units running in multiple context mode.

With Active/Standby failover, only one unit passes traffic while the other unit waits in a standby state. Active/Standby failover is available on units running in either single or multiple context mode.

Both failover configurations support stateful or stateless (regular) failover.

Note When the ASA is configured for Active/Active Stateful Failover, you cannot enable IPsec or SSL VPN. Therefore, these features are unavailable. VPN failover is available for Active/Standby failover configurations only.

Failover System Requirements

This section describes the hardware, software, and license requirements for ASAs in a failover configuration.

This section includes the following topics:

- Hardware Requirements, page 11-2
- Software Requirements, page 11-2
- License Requirements, page 11-2

Hardware Requirements

The two units in a failover configuration must be the same model, have the same number and types of interfaces, the same SSMs installed (if any), and the same RAM installed.

If you are using units with different flash memory sizes in your failover configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software Requirements

The two units in a failover configuration must be in the same operating modes (routed or transparent, single or multiple context). They must have the same major (first number) and minor (second number) software version. However, you can use different versions of the software during an upgrade process; for example, you can upgrade one unit from Version 8.3(1) to Version 8.3(2) and have failover remain active. We recommend upgrading both units to the same version to ensure long-term compatibility.

License Requirements

The two units in a failover configuration do not need to have identical licenses; the licenses combine to make a failover cluster license. See the "Failover or ASA Cluster Licenses" section on page 5-31 for more information.

Failover and Stateful Failover Links

This section describes the failover and the Stateful Failover links, which are dedicated connections between the two units in a failover configuration. This section includes the following topics:

- Failover Link, page 11-3
- Stateful Failover Link, page 11-4
- Avoiding Interrupted Failover Links, page 11-5

Failover Link

The two units in a failover pair constantly communicate over a failover link to determine the operating status of each unit. The following information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Caution All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If the ASA is used to terminate VPN tunnels, this information includes any usernames, passwords and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication with a failover key if you are using the ASA to terminate VPN tunnels.

You can use any unused interface on the device as the failover link; however, you cannot specify an interface that is currently configured with a name. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface should only be used for the failover link (and optionally for the Stateful Failover link).

Connect the failover link in one of the following two ways:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the ASA.
- Using a crossover Ethernet cable to connect the appliances directly, without the need for an external switch.

Note When you use a crossover cable for the failover link, if the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which interface failed and caused the link to come down.

Note The ASA supports Auto-MDI/MDIX on its copper Ethernet ports, so you can either use a crossover cable or a straight-through cable. If you use a straight-through cable, the interface automatically detects the cable and swaps one of the transmit/receive pairs to MDIX.

Although you can configure the failover and failover state links on a port channel link, this port channel cannot be shared with other firewall traffic.

Stateful Failover Link

To use Stateful Failover, you must configure a Stateful Failover link to pass all state information. You have three options for configuring a Stateful Failover link:

- You can use a dedicated Ethernet interface for the Stateful Failover link.
- You can share the failover link.
- You can share a regular data interface, such as the inside interface. However, this option is not recommended.

Connect a dedicated state link in one of the following two ways:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the ASA.
- Using a crossover Ethernet cable to connect the appliances directly, without the need for an external switch.

Note When you use a crossover cable for the state link, if the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which interface failed and caused the link to come down.

The ASA supports Auto-MDI/MDIX on its copper Ethernet ports, so you can either use a crossover cable or a straight-through cable. If you use a straight-through cable, the interface automatically detects the cable and swaps one of the transmit/receive pairs to MDIX.

Enable the PortFast option on Cisco switch ports that connect directly to the ASA.

If you use a data interface as the Stateful Failover link, you receive the following warning when you specify that interface as the Stateful Failover link:

```
******* WARNING ***** WARNING ******* WARNING ****** WARNING  *********
  Sharing Stateful failover interface with regular data interface is not
  a recommended configuration due to performance and security concerns.
******* WARNING ***** WARNING ******* WARNING ****** WARNING  *********
```

Sharing a data interface with the Stateful Failover interface can leave you vulnerable to replay attacks. Additionally, large amounts of Stateful Failover traffic may be sent on the interface, causing performance problems on that network segment.

Note Using a data interface as the Stateful Failover interface is supported in single context, routed mode only.

In multiple context mode, the Stateful Failover link resides in the system context. This interface and the failover interface are the only interfaces in the system context. All other interfaces are allocated to and configured from within security contexts.

Note The IP address and MAC address for the Stateful Failover link does not change at failover unless the Stateful Failover link is configured on a regular data interface.

Caution All information sent over the failover and Stateful Failover links is sent in clear text unless you secure the communication with a failover key. If the ASA is used to terminate VPN tunnels, this information includes any usernames, passwords, and preshared keys used for establishing the tunnels. Transmitting this sensitive data in clear text could pose a significant security risk. We recommend securing the failover communication with a failover key if you are using the ASA to terminate VPN tunnels.

Failover Interface Speed for Stateful Links

If you use the failover link as the Stateful Failover link, you should use the fastest Ethernet interface available. If you experience performance problems on that interface, consider dedicating a separate interface for the Stateful Failover interface.

Use the following failover interface speed guidelines for the ASAs:

- Cisco ASA 5510
  - Stateful link speed can be 100 Mbps, even though the data interface can operate at 1 Gigabit due to the CPU speed limitation.
- Cisco ASA 5520/5540/5550
  - Stateful link speed should match the fastest data link.
- Cisco ASA 5580/5585-X
  - Use only non-management 1 Gigabit ports for the stateful link because management ports have lower performance and cannot meet the performance requirement for Stateful Failover.

For optimum performance when using long distance failover, the latency for the failover link should be less than 10 milliseconds and no more than 250 milliseconds. If latency is more than10 milliseconds, some performance degradation occurs due to retransmission of failover messages.

The ASA supports sharing of failover heartbeat and stateful link, but we recommend using a separate heartbeat link on systems with high Stateful Failover traffic.

Avoiding Interrupted Failover Links

Because the uses failover interfaces to transport messages between primary and secondary units, if a failover interface is down (that is, the physical link is down or the switch used to connect the interface is down), then the ASA failover operation is affected until the health of the failover interface is restored.

In the event that all communication is cut off between the units in a failover pair, both units go into the active state, which is expected behavior. When communication is restored and the two active units resume communication through the failover link or through any monitored interface, the primary unit remains active, and the secondary unit immediately returns to the standby state. This relationship is established regardless of the health of the primary unit.

Because of this behavior, stateful flows that were passed properly by the secondary active unit during the network split are now interrupted. To avoid this interruption, failover links and data interfaces should travel through different paths to decrease the chance that all links fail at the same time. In the event that only one failover link is down, the ASA takes a sample of the interface health, exchanges this information with its peer through the data interface, and performs a switchover if the active unit has a greater number of down interfaces. Subsequently, the failover operation is suspended until the health of the failover link is restored.

Depending upon their network topologies, several primary/secondary failure scenarios exist in ASA failover pairs, as shown in the following scenarios.

Scenario 1—Not Recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two ASAs, then when a switch or inter-switch-link is down, both ASAs become active. Therefore, the following two connection methods shown in Figure 11-1 and Figure 11-2 are NOT recommended.

Figure 11-1 Connecting with a Single Switch—Not Recommended

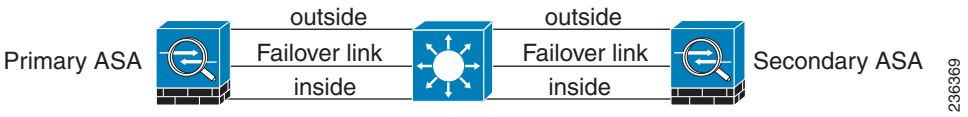


Figure 11-2 Connecting with a Double Switch—Not Recommended

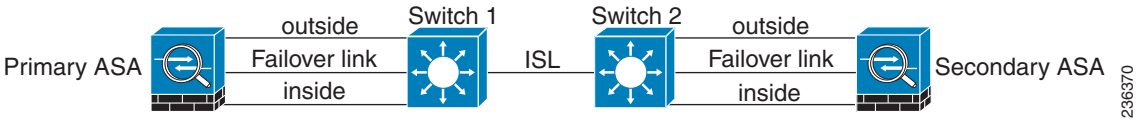

Scenario 2—Recommended

To make the ASA failover pair resistant to failover interface failure, we recommend that failover interfaces NOT use the same switch as the data interfaces, as shown in the preceding connections. Instead, use a different switch or use a direct cable to connect two ASA failover interfaces, as shown in Figure 11-3 and Figure 11-4.

Figure 11-3 Connecting with a Different Switch

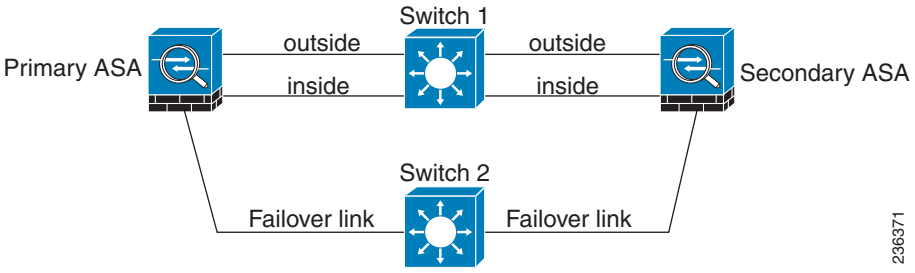

Figure 11-4 Connecting with a Cable

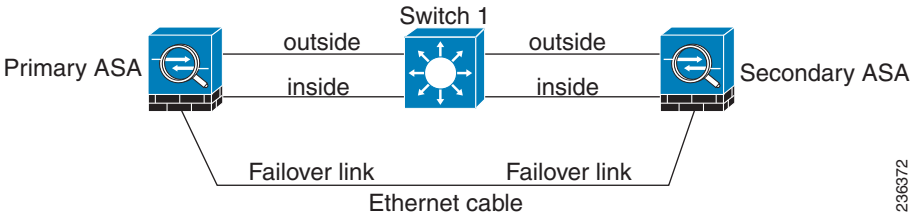
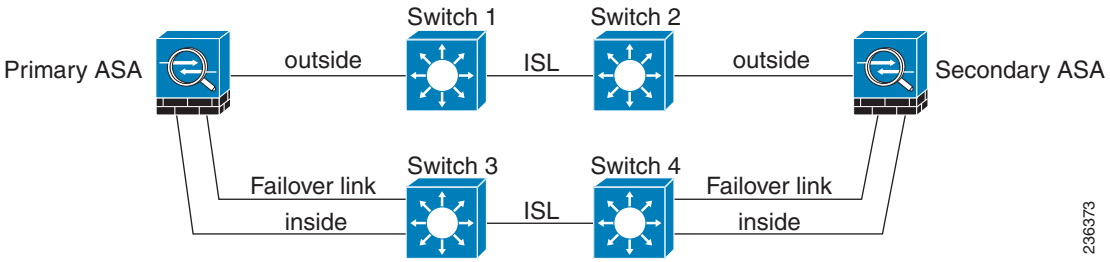


Scenario 3—Recommended

If the ASA data interfaces are connected to more than one set of switches, then a failover interface can be connected to one of the switches, preferably the switch on the secure side of network, as shown in Figure 11-5.

Figure 11-5 Connecting with a Secure Switch



Scenario 4—Recommended

The most reliable failover configurations use a redundant interface on the failover interface, as shown in Figure 11-6 and Figure 11-7.

Figure 11-6 Connecting with Redundant Interfaces

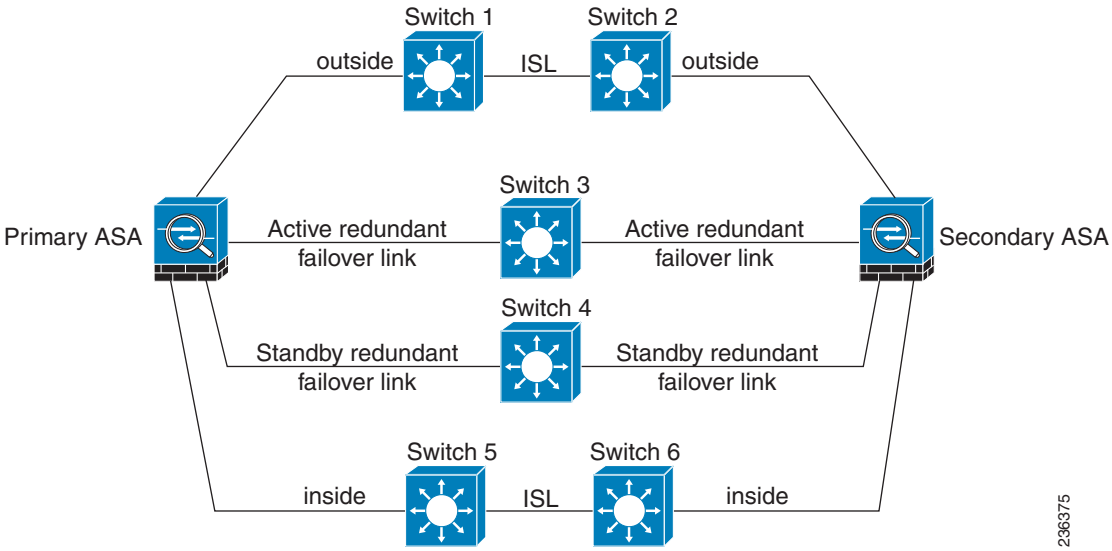


Figure 11-7 Connecting with Inter-switch Links

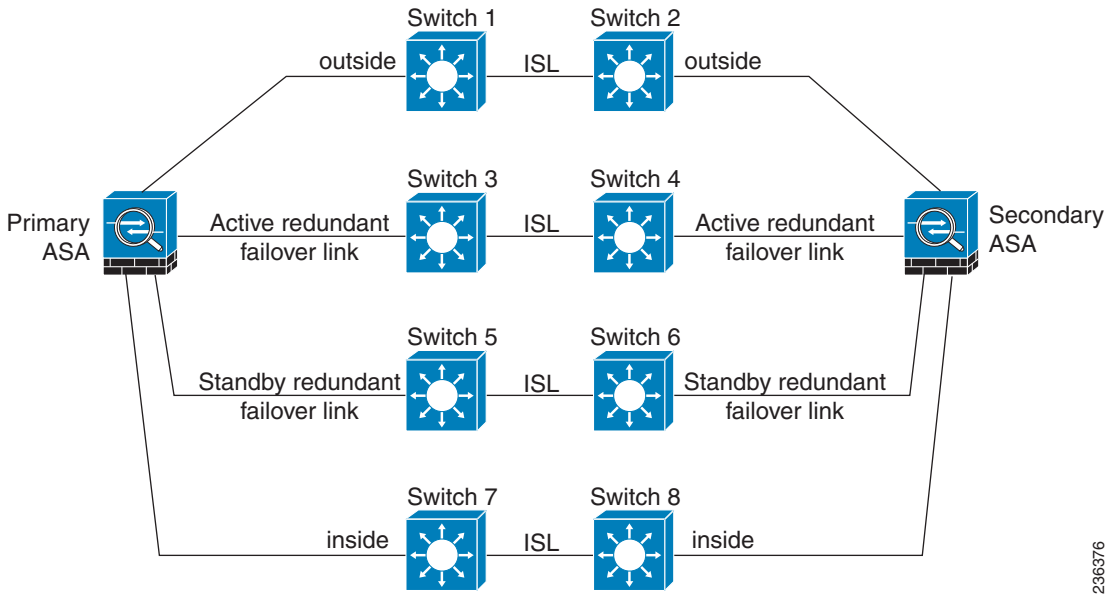


Active/Active and Active/Standby Failover

Two types of failover configurations are supported by the ASA: Active/Standby and Active/Active.

In Active/Standby failover, one unit is the active unit. It passes traffic. The standby unit does not actively pass traffic. When a failover occurs, the active unit fails over to the standby unit, which then becomes active. You can use Active/Standby failover for ASAs in single or multiple context mode, although it is most commonly used for ASAs in single context mode.

Active/Active failover is only available to ASAs in multiple context mode. In an Active/Active failover configuration, both ASAs can pass network traffic. In Active/Active failover, you divide the security contexts on the ASA into *failover groups*. A failover group is simply a logical group of one or more security contexts. Each group is assigned to be active on a specific ASA in the failover pair. When a failover occurs, it occurs at the failover group level.

For more detailed information about each type of failover, refer the following information:

- Chapter 12, “Configuring Active/Standby Failover”
- Chapter 13, “Configuring Active/Active Failover”

Determining Which Type of Failover to Use

The type of failover you choose depends upon your ASA configuration and how you plan to use the ASAs.

If you are running the ASA in single mode, then you can use only Active/Standby failover. Active/Active failover is only available to ASAs running in multiple context mode.

Note The ASA 5505 does not support multiple context mode or Active/Active failover.

VPN is not supported in multiple context mode or Active/Active failover.

If you are running the ASA in multiple context mode, then you can configure either Active/Active failover or Active/Standby failover.

- To allow both members of the failover pair to share the traffic, use Active/Active failover. Do not exceed 50% load on each device.
- If you do not want to share the traffic in this way, use Active/Standby or Active/Active failover.

Table 11-1 provides a comparison of some of the features supported by each type of failover configuration:

Table 11-1 Failover Configuration Feature Support

Feature	Active/Active	Active/Standby
Single Context Mode	No	Yes
Multiple Context Mode	Yes	Yes
Traffic Sharing Network Configurations	Yes	No
Unit Failover	Yes	Yes
Failover of Groups of Contexts	Yes	No
Failover of Individual Contexts	No	No

Stateless (Regular) and Stateful Failover

The ASA supports two types of failover, regular and stateful. This section includes the following topics:

- Stateless (Regular) Failover, page 11-9
- Stateful Failover, page 11-10

Stateless (Regular) Failover

When a failover occurs, all active connections are dropped. Clients need to reestablish connections when the new active unit takes over.

Note Some configuration elements for clientless SSL VPN (such as bookmarks and customization) use the VPN failover subsystem, which is part of Stateful Failover. You must use Stateful Failover to synchronize these elements between the members of the failover pair. Stateless (regular) failover is not recommended for clientless SSL VPN.

Stateful Failover

When Stateful Failover is enabled, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

In Version 8.4 and later, Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the Active secondary ASA initially has rules that mirror the primary ASA. Immediately after failover, the re-convergence timer starts on the newly Active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly Active unit.

The following state information is passed to the standby ASA when Stateful Failover is enabled:

- NAT translation table
- TCP connection states
- UDP connection states
- The ARP table
- The Layer 2 bridge table (when running in transparent firewall mode)
- The HTTP connection states (if HTTP replication is enabled)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signalling sessions
- ICMP connection state. ICMP connection replication is enabled only if the respective interface is assigned to an asymmetric routing group.

The following state information is *not* passed to the standby ASA when Stateful Failover is enabled:

- The HTTP connection table (unless HTTP replication is enabled).
- The user authentication (uauth) table.
- Inspected protocols are subject to advanced TCP-state tracking, and the TCP state of these connections is not automatically replicated. While these connections are replicated to the standby unit, there is a best-effort attempt to re-establish a TCP state.
- DHCP server address leases.
- State information for modules.
- Stateful Failover for phone proxy. When the active unit goes down, the call fails, media stops flowing, and the phone should unregister from the failed unit and reregister with the active unit. The call must be re-established.

The following clientless SSL VPN features are not supported with Stateful Failover:

- Smart Tunnels
- Port Forwarding
- Plugins
- Java Applets

- IPv6 clientless or Anyconnect sessions
- Citrix authentication (Citrix users must reauthenticate after failover)

Note If failover occurs during an active Cisco IP SoftPhone session, the call remains active because the call session state information is replicated to the standby unit. When the call is terminated, the IP SoftPhone client loses connection with the Cisco CallManager. This occurs because there is no session information for the CTIQBE hangup message on the standby unit. When the IP SoftPhone client does not receive a response back from the Call Manager within a certain time period, it considers the CallManager unreachable and unregisters itself.

For VPN failover, VPN end-users should not have to reauthenticate or reconnect the VPN session in the event of a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.

Intra- and Inter-Chassis Module Placement for the ASA Services Module

You can place the primary and secondary ASASMs within the same switch or in two separate switches. The following sections describe each option:

- Intra-Chassis Failover, page 11-11
- Inter-Chassis Failover, page 11-12

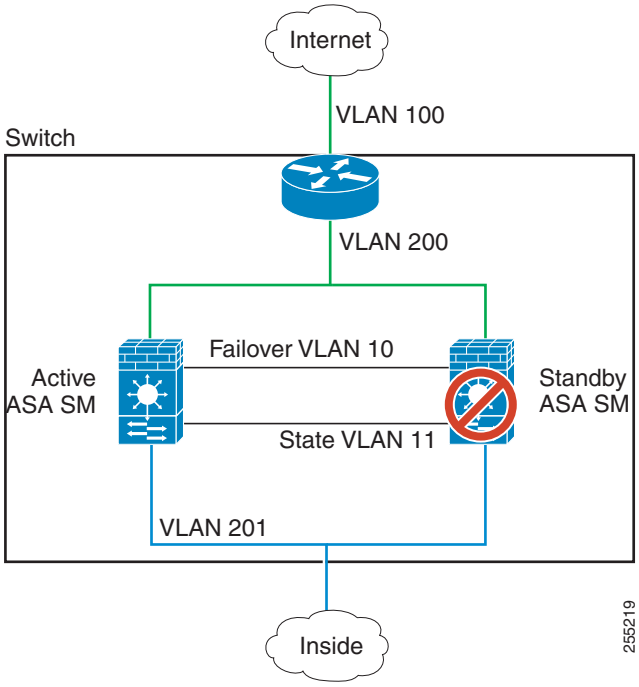
Intra-Chassis Failover

If you install the secondary ASASM in the same switch as the primary ASASM, you protect against module-level failure. To protect against switch-level failure, as well as module-level failure, see the "Inter-Chassis Failover" section on page 11-12.

Even though both ASASMs are assigned the same VLANs, only the active module takes part in networking. The standby module does not pass any traffic.

Figure 11-8 shows a typical intra-switch configuration.

Figure 11-8 Intra-Switch Failover



Inter-Chassis Failover

To protect against switch-level failure, you can install the secondary ASASM in a separate switch. The ASASM does not coordinate failover directly with the switch, but it works harmoniously with the switch failover operation. See the switch documentation to configure failover for the switch.

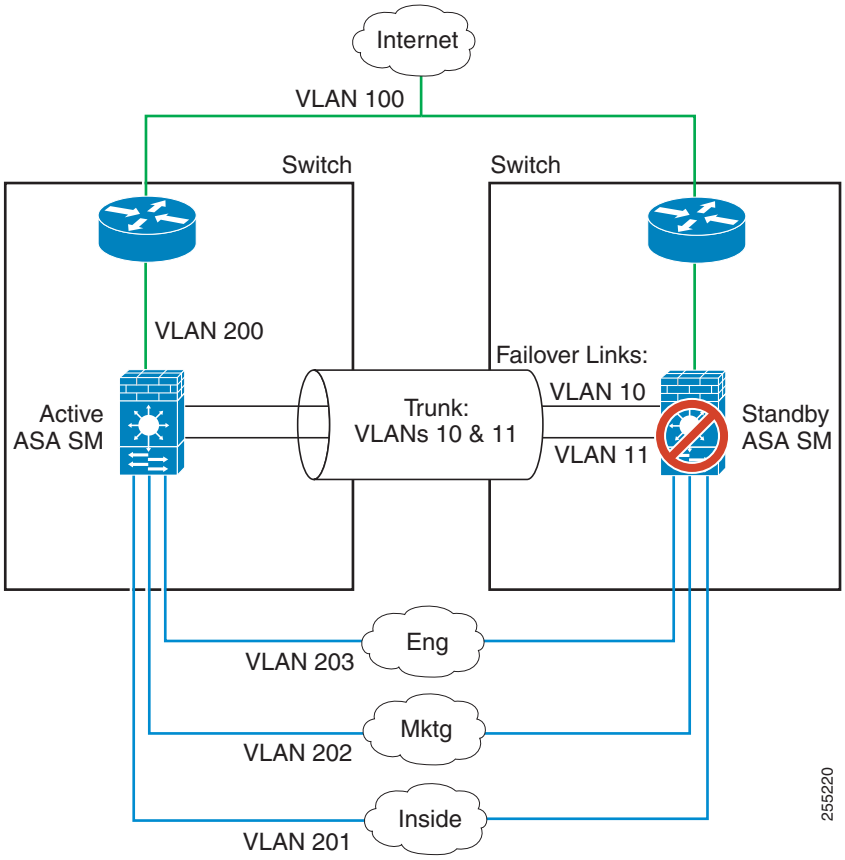
To accommodate the failover communications between ASASMs, we recommend that you configure a trunk port between the two switches that carries the failover and state VLANs. The trunk ensures that failover communication between the two units is subject to minimal failure risk.

For other VLANs, you must ensure that both switches have access to all firewall VLANs, and that monitored VLANs can successfully pass hello packets between both switches.

Figure 11-9 shows a typical switch and ASASM redundancy configuration. The trunk between the two switches carries the failover ASASM VLANs (VLANs 10 and 11).

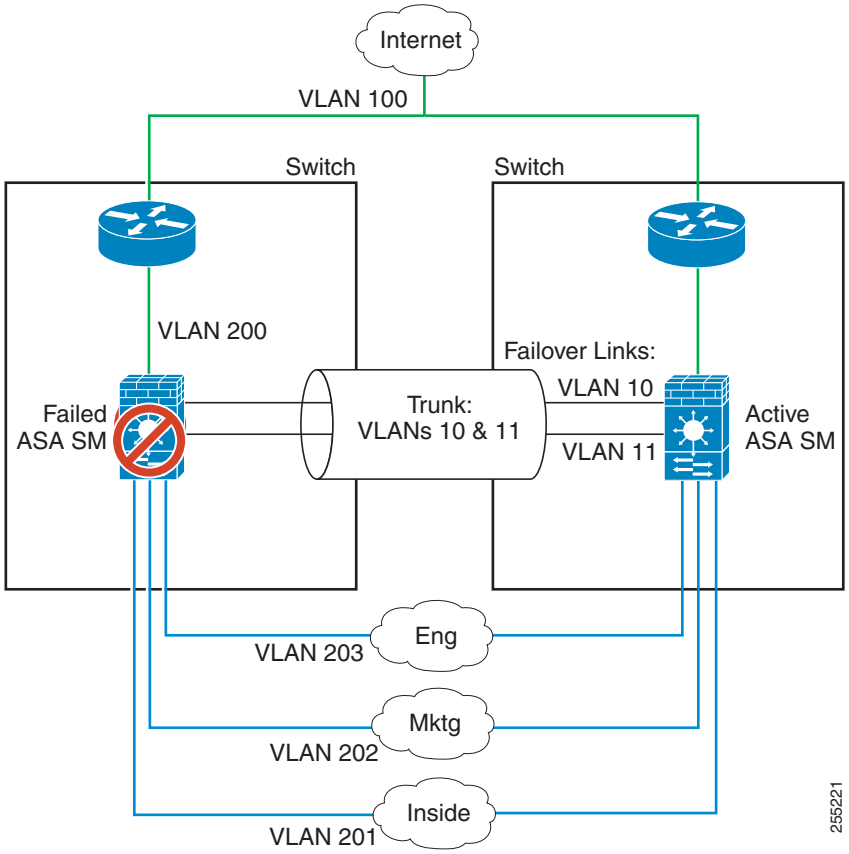
Note ASASM failover is independent of the switch failover operation; however, ASASM works in any switch failover scenario.

Figure 11-9 Normal Operation



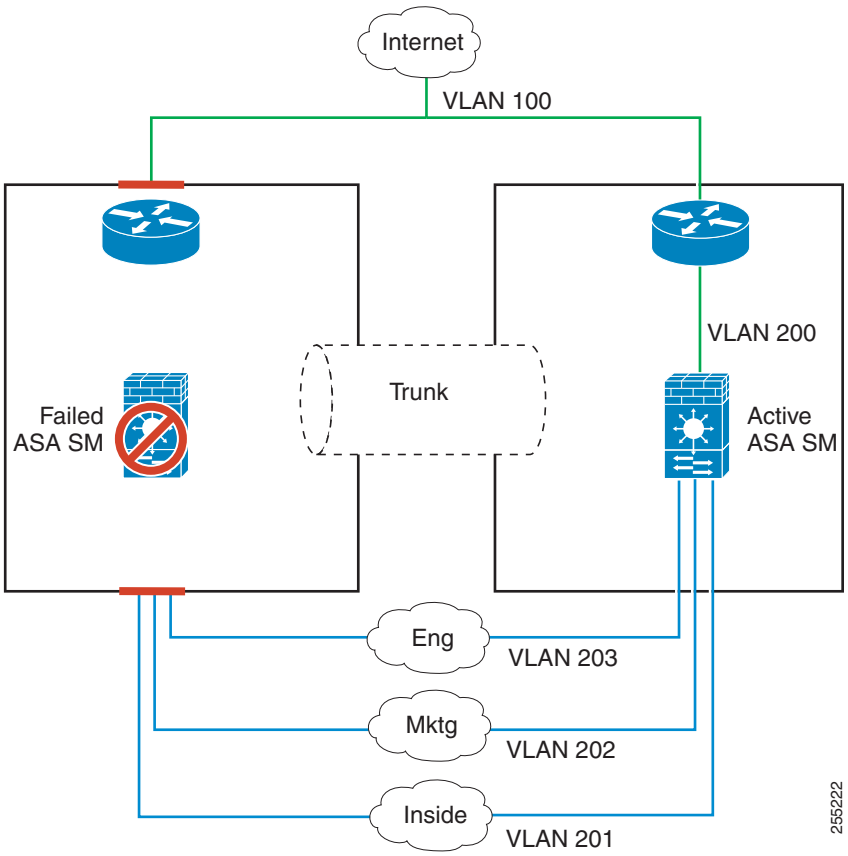
If the primary ASASM fails, then the secondary ASASM becomes active and successfully passes the firewall VLANs (Figure 11-10).

Figure 11-10 ASASM Failure



If the entire switch fails, as well as the ASASM (such as in a power failure), then both the switch and the ASASM fail over to their secondary units (Figure 11-11).

Figure 11-11 Switch Failure



Transparent Firewall Mode Requirements

When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can configure one of the following workarounds depending on the switch port mode:

- Access mode—Enable the STP PortFast feature on the switch:

  ```
  interface interface_id
  spanning-tree portfast
  ```

  The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- Trunk mode—Block BPDUs on the ASA on both the inside and outside interfaces:

  ```
  access-list id ethertype deny bpdu
  access-group id in interface inside_name
  access-group id in interface outside_name
  ```

Blocking BPDUs disables STP on the switch. Be sure not to have any loops involving the ASA in your network layout.

If neither of the above options are possible, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:

- Disable failover interface monitoring.
- Increase failover interface holdtime to a high value that will allow STP to converge before the ASAs fail over.
- Decrease STP timers to allow STP to converge faster than the failover interface holdtime.

Auto Update Server Support in Failover Configurations

You can use the Auto Update Server to deploy software images and configuration files to ASAs in an Active/Standby failover configuration. To enable Auto Update on an Active/Standby failover configuration, enter the Auto Update Server configuration on the primary unit in the failover pair.

The following restrictions and behaviors apply to Auto Update Server support in failover configurations:

- Only single mode, Active/Standby configurations are supported.
- When loading a new platform software image, the failover pair stops passing traffic.
- When using LAN-based failover, new configurations must not change the failover link configuration. If they do, communication between the units will fail.
- Only the primary unit will perform the call home to the Auto Update Server. The primary unit must be in the active state to call home. If it is not, the ASA automatically fails over to the primary unit.
- Only the primary unit downloads the software image or configuration file. The software image or configuration is then copied to the secondary unit.
- The interface MAC address and hardware-serial ID is from the primary unit.
- The configuration file stored on the Auto Update Server or HTTP server is for the primary unit only.

Auto Update Process Overview

The following is an overview of the Auto Update process in failover configurations. This process assumes that failover is enabled and operational. The Auto Update process cannot occur if the units are synchronizing configurations, if the standby unit is in the failed state for any reason other than SSM card failure, or if the failover link is down.

1. Both units exchange the platform and ASDM software checksum and version information.
2. The primary unit contacts the Auto Update Server. If the primary unit is not in the active state, the ASA first fails over to the primary unit and then contacts the Auto Update Server.
3. The Auto Update Server replies with software checksum and URL information.
4. If the primary unit determines that the platform image file needs to be updated for either the active or standby unit, the following occurs:
   a. The primary unit retrieves the appropriate files from the HTTP server using the URL from the Auto Update Server.
   b. The primary unit copies the image to the standby unit and then updates the image on itself.

c. If both units have new image, the secondary (standby) unit is reloaded first.

– If hitless upgrade can be performed when secondary unit boots, then the secondary unit becomes the active unit and the primary unit reloads. The primary unit becomes the active unit when it has finished loading.

– If hitless upgrade cannot be performed when the standby unit boots, then both units reload at the same time.

d. If only the secondary (standby) unit has new image, then only the secondary unit reloads. The primary unit waits until the secondary unit finishes reloading.

e. If only the primary (active) unit has new image, the secondary unit becomes the active unit, and the primary unit reloads.

f. The update process starts again at Step 1.

5. If the ASA determines that the ASDM file needs to be updated for either the primary or secondary unit, the following occurs:

   a. The primary unit retrieves the ASDM image file from the HTTP server using the URL provided by the Auto Update Server.

   b. The primary unit copies the ASDM image to the standby unit, if needed.

   c. The primary unit updates the ASDM image on itself.

   d. The update process starts again at Step 1.

6. If the primary unit determines that the configuration needs to be updated, the following occurs:

   a. The primary unit retrieves the configuration file from the using the specified URL.

   b. The new configuration replaces the old configuration on both units simultaneously.

   c. The update process begins again at Step 1.

7. If the checksums match for all image and configuration files, no updates are required. The process ends until the next poll time.

Monitoring the Auto Update Process

You can use the **debug auto-update client** or **debug fover cmd-exe** commands to display the actions performed during the Auto Update process. The following is sample output from the **debug auto-update client** command. Run **debug** commands from a terminal session.

```
Auto-update client: Sent DeviceDetails to /cgi-bin/dda.pl of server 192.168.0.21
Auto-update client: Processing UpdateInfo from server 192.168.0.21
   Component: asdm, URL: http://192.168.0.21/asdm.bint, checksum:
0x94bced0261cc992ae710faf8d244cf32
   Component: config, URL: http://192.168.0.21/config-rms.xml, checksum:

```

The following syslog message is generated if the Auto Update process fails:

```
%ASA4-612002: Auto Update failed: file version: version reason: reason
```

The *file* is “image”, “asdm”, or “configuration”, depending on which update failed. The *version* is the version number of the update. And the *reason* is the reason that the update failed.

Failover Health Monitoring

The ASA monitors each unit for overall health and for interface health. See the following sections for more information about how the ASA performs tests to determine the state of each unit:

- Unit Health Monitoring, page 11-19
- Interface Monitoring, page 11-19

Unit Health Monitoring

The ASA determines the health of the other unit by monitoring the failover link. When a unit does not receive three consecutive hello messages on the failover link, the unit sends interface hello messages on each interface, including the failover interface, to validate whether or not the peer interface is responsive. The action that the ASA takes depends upon the response from the other unit. See the following possible actions:

- If the ASA receives a response on the failover interface, then it does not fail over.
- If the ASA does not receive a response on the failover link, but it does receive a response on another interface, then the unit does not failover. The failover link is marked as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.
- If the ASA does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

You can configure the frequency of the hello messages and the hold time before failover occurs. A faster poll time and shorter hold time speed the detection of unit failures and make failover occur more quickly, but it can also cause "false" failures due to network congestion delaying the keepalive packets.

Interface Monitoring

You can monitor up to 250 interfaces divided between all contexts. You should monitor important interfaces. For example, you might configure one context to monitor a shared interface. (Because the interface is shared, all contexts benefit from the monitoring.)

When a unit does not receive hello messages on a monitored interface for half of the configured hold time, it runs the following tests:

1. Link Up/Down test—A test of the interface status. If the Link Up/Down test indicates that the interface is operational, then the ASA performs network tests. The purpose of these tests is to generate network traffic to determine which (if either) unit has failed. At the start of each test, each unit clears its received packet count for its interfaces. At the conclusion of each test, each unit looks to see if it has received any traffic. If it has, the interface is considered operational. If one unit receives traffic for a test and the other unit does not, the unit that received no traffic is considered failed. If neither unit has received traffic, then the next test is used.
2. Network Activity test—A received network activity test. The unit counts all received packets for up to 5 seconds. If any packets are received at any time during this interval, the interface is considered operational and testing stops. If no traffic is received, the ARP test begins.
3. ARP test—A reading of the unit ARP cache for the 2 most recently acquired entries. One at a time, the unit sends ARP requests to these machines, attempting to stimulate network traffic. After each request, the unit counts all received traffic for up to 5 seconds. If traffic is received, the interface is considered operational. If no traffic is received, an ARP request is sent to the next machine. If at the end of the list no traffic has been received, the ping test begins.
4. Broadcast Ping test—A ping test that consists of sending out a broadcast ping request. The unit then counts all received packets for up to 5 seconds. If any packets are received at any time during this interval, the interface is considered operational and testing stops.

If an interface has IPv4 and IPv6 addresses configured on it, the ASA uses the IPv4 addresses to perform the health monitoring.

If an interface has only IPv6 addresses configured on it, then the ASA uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the ASA uses the IPv6 all nodes address (FE02::1).

If all network tests fail for an interface, but this interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed. If the threshold for failed interfaces is met, then a failover occurs. If the other unit interface also fails all the network tests, then both interfaces go into the "Unknown" state and do not count towards the failover limit.

An interface becomes operational again if it receives any traffic. A failed ASA returns to standby mode if the interface failure threshold is no longer met.

Note If a failed unit does not recover and you believe it should not be failed, you can reset the state by entering the **failover reset** command. If the failover condition persists, however, the unit will fail again.

Failover Times

Table 11-2 shows the minimum, default, and maximum failover times.

Table 11-2 Cisco ASA 5500 Series ASA Failover Times

Failover Condition	Minimum	Default	Maximum
Active unit loses power or stops normal operation.	800 milliseconds	15 seconds	45 seconds
Active unit main board interface link down.	500 milliseconds	5 seconds	15 seconds
Active unit 4GE module interface link down.	2 seconds	5 seconds	15 seconds
Active unit IPS or CSC module fails.	2 seconds	2 seconds	2 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

Failover Messages

When a failover occurs, both ASAs send out system messages. This section includes the following topics:

- Failover System Messages, page 11-20
- Debug Messages, page 11-21
- SNMP, page 11-21

Failover System Messages

The ASA issues a number of system messages related to failover at priority level 2, which indicates a critical condition. To view these messages, see the *syslog messages guide* guide. To enable logging, see Chapter 96, "Configuring Logging."

Note During switchover, failover logically shuts down and then bring up interfaces, generating syslog messages 411001 and 411002. This is normal activity.

Debug Messages

To see debug messages, enter the **debug fover** command. See the command reference for more information.

Note Because debugging output is assigned high priority in the CPU process, it can drastically affect system performance. For this reason, use the **debug fover** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco TAC.

SNMP

To receive SNMP syslog traps for failover, configure the SNMP agent to send SNMP traps to SNMP management stations, define a syslog host, and compile the Cisco syslog MIB into your SNMP management station. See Chapter 98, “Configuring SNMP” for more information.

Configuring Active/Standby Failover

This chapter describes how to configure Active/Standby failover and includes the following sections:

- Information About Active/Standby Failover, page 12-1
- Licensing Requirements for Active/Standby Failover, page 12-5
- Prerequisites for Active/Standby Failover, page 12-6
- Guidelines and Limitations, page 12-6
- Configuring Active/Standby Failover, page 12-7
- Controlling Failover, page 12-16
- Monitoring Active/Standby Failover, page 12-17
- Feature History for Active/Standby Failover, page 12-17

Information About Active/Standby Failover

This section describes Active/Standby failover and includes the following topics:

- Active/Standby Failover Overview, page 12-1
- Primary/Secondary Status and Active/Standby Status, page 12-2
- Device Initialization and Configuration Synchronization, page 12-2
- Command Replication, page 12-3
- Failover Triggers, page 12-4
- Failover Actions, page 12-4

Active/Standby Failover Overview

Active/Standby failover enables you to use a standby ASA to take over the functionality of a failed unit. When the active unit fails, it changes to the standby state while the standby unit changes to the active state. The unit that becomes active assumes the IP addresses (or, for transparent firewall, the management IP address) and MAC addresses of the failed unit and begins passing traffic. The unit that is now in standby state takes over the standby IP addresses and MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note For multiple context mode, the ASA can fail over the entire unit (including all contexts) but cannot fail over individual contexts separately.

Primary/Secondary Status and Active/Standby Status

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units based on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit is active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Device Initialization and Configuration Synchronization

Configuration synchronization occurs when one or both devices in the failover pair boot. Configurations are always synchronized from the active unit to the standby unit. When the standby unit completes its initial startup, it clears its running configuration (except for the failover commands needed to communicate with the active unit), and the active unit sends its entire configuration to the standby unit.

The active unit is determined by the following:

- If a unit boots and detects a peer already running as active, it becomes the standby unit.
- If a unit boots and does not detect a peer, it becomes the active unit.
- If both units boot simultaneously, then the primary unit becomes the active unit, and the secondary unit becomes the standby unit.

Note If the secondary unit boots without detecting the primary unit, it becomes the active unit. It uses its own MAC addresses for the active IP addresses. However, when the primary unit becomes available, the secondary unit changes the MAC addresses to those of the primary unit, which can cause an interruption in your network traffic. To avoid this, configure the failover pair with virtual MAC addresses. See the "Configuring Virtual MAC Addresses" section on page 12-15 for more information.

When the replication starts, the ASA console on the active unit displays the message "Beginning configuration replication: Sending to mate," and when it is complete, the ASA displays the message "End Configuration Replication to mate." During replication, commands entered on the active unit may not replicate properly to the standby unit, and commands entered on the standby unit may be overwritten by the configuration being replicated from the active unit. Avoid entering commands on either unit in the failover pair during the configuration replication process. Depending upon the size of the configuration, replication can take from a few seconds to several minutes.

Note The **crypto ca server** command and related sub commands are not synchronized to the failover peer.

Note On the standby unit, the configuration exists only in running memory. To save the configuration to the flash memory on the standby unit, choose **File > Save Running Configuration to Flash**. Startup configurations saved on external servers are accessible from either unit over the network and do not need to be saved separately for each unit. Alternatively, you can copy the contexts on disk from the active unit to an external server, and then copy them to disk on the standby unit, where they become available when the unit reloads.

Command Replication

Command replication always flows from the active unit to the standby unit. As you apply your changes to the active unit in ASDM, the associated commands are sent across the failover link to the standby unit. You do not have to save the active configuration to flash memory to replicate the commands.

The following commands that are replicated to the standby ASA:

- All configuration commands except for **mode**, **firewall**, and **failover lan unit**
- **copy running-config startup-config**
- **delete**
- **mkdir**
- **rename**
- **rmdir**
- **write memory**

The following commands that are *not* replicated to the standby ASA:

- All forms of the **copy** command except for **copy running-config startup-config**
- All forms of the **write** command except for **write memory**
- **debug**
- **failover lan unit**
- **firewall**
- **show**
- **terminal pager** and **pager**

Note Changes made on the standby unit are not replicated to the active unit. If you enter a command on the standby unit, the ASA displays the message `**** WARNING **** Configuration Replication is NOT performed from Standby unit to Active unit. Configurations are no longer synchronized.` This message appears even when you enter many commands that do not affect the configuration.

Replicated commands are stored in the running configuration. To save replicated commands to the flash memory on the standby unit, choose **File > Save Running Configuration to Flash**.

Note Standby Failover does not replicate the following files and configuration components:

- AnyConnect images
- CSD images

- ASA images
- AnyConnect profiles
- Local Certificate Authorities (CAs)
- ASDM images

Failover Triggers

The unit can fail if one of the following events occurs:

- The unit has a hardware failure or a power failure.
- The unit has a software failure.
- Too many monitored interfaces fail.
- You force a failover. (See the "Forcing Failover" section on page 12-16.)

Failover Actions

In Active/Standby failover, failover occurs on a unit basis. Even on systems running in multiple context mode, you cannot fail over individual or groups of contexts.

Table 12-1 shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 12-1 Failover Behavior

Failure Event	Policy	Active Action	Standby Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.
Failover link failed during operation	No failover	Mark failover interface as failed	Mark failover interface as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Mark failover interface as failed	Become active	If the failover link is down at startup, both units become active.
Stateful Failover link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.

Table 12-1 Failover Behavior (continued)

Failure Event	Policy	Active Action	Standby Action	Notes
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Optional Active/Standby Failover Settings

You can configure the following Active/Standby failover options when you initially configuring failover or after failover has been configured:

- HTTP replication with Stateful Failover—Allows connections to be included in the state information replication.
- Interface monitoring—Allows you to monitor up to 250 interfaces on a unit and control which interfaces affect your failover.
- Interface health monitoring—Enables the ASA to detect and respond to interface failures more quickly.
- Failover criteria setup—Allows you to specify a specific number of interfaces or a percentage of monitored interfaces that must fail before failover occurs.
- Virtual MAC address configuration—Ensures that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit.

Licensing Requirements for Active/Standby Failover

The following table shows the licensing requirements for this feature:

Model	License Requirement
ASA 5505	Security Plus License. (Stateful failover is not supported).
ASA 5510, ASA 5512-X	Security Plus License.
All other models	Base License.

Failover units do not require the same license on each unit. If you have licenses on both units, they combine into a single running failover cluster license. The exceptions to this rule include:

- Security Plus license for the ASA 5505, 5510, and 5512-X—The Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.
- IPS module license for the ASA 5500-X—You must purchase an IPS module license for each unit, just as you would need to purchase a hardware module for each unit for other models.
- Encryption license—Both units must have the same encryption license.

Prerequisites for Active/Standby Failover

Active/Standby failover has the following prerequisites:

- Both units must be identical ASAs that are connected to each other through a dedicated failover link and, optionally, a Stateful Failover link.
- Both units must have the same software configuration and the proper license.
- Both units must be in the same mode (single or multiple, transparent or routed).

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

- Supported in single and multiple context mode.
- For multiple context mode, perform all steps in the system execution space unless otherwise noted.

Firewall Mode Guidelines

- Supported in transparent and routed firewall mode.

IPv6 Guidelines

- IPv6 failover is supported.

Model Guidelines

- Stateful failover is not supported on the ASA 5505.

Additional Guidelines and Limitations

Configuring port security on the switch(es) connected to an ASA failover pair can cause communication problems when a failover event occurs. This is because if a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.

ASA failover replication fails if you try to make a configuration change in two or more contexts at the same time. The workaround is to make configuration changes on each unit sequentially.

The following guidelines and limitations apply for Active/Standby failover:

- To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces.
- The standby IP addresses are used on the ASA that is currently the standby unit, and they must be in the same subnet as the active IP address on the corresponding interface on the active unit.
- If you change the console terminal pager settings on the active unit in a failover pair, the active console terminal pager settings change, but the standby unit settings do not. A default configuration issued on the active unit does affect behavior on the standby unit.
- When you enable interface monitoring, you can monitor up to 250 interfaces on a unit.
- By default, the ASA does not replicate HTTP session information when Stateful Failover is enabled. Because HTTP sessions are typically short-lived, and because HTTP clients typically retry failed connection attempts, not replicating HTTP sessions increases system performance without causing

serious data or connection loss. The **failover replication http** command enables the stateful replication of HTTP sessions in a Stateful Failover environment, but it could have a negative impact upon system performance.

- AnyConnect images must be the same on both ASAs in a failover pair. If the failover pair has mismatched images when a hitless upgrade is performed, then the WebVPN connection terminates in the final reboot step of the upgrade process, the database shows an orphaned session, and the IP pool shows that the IP address assigned to the client is “in use.”

Configuring Active/Standby Failover

This section describes how to configure Active/Standby failover. This section includes the following topics:

- Using the High Availability and Scalability Wizard, page 12-7
- Configuring Failover (Without the Wizard), page 12-10
- Configuring Optional Active/Standby Failover Settings, page 12-13

Using the High Availability and Scalability Wizard

The High Availability and Scalability Wizard guides you through a step-by-step process of creating either an Active/Active failover configuration, an Active/Standby failover configuration, or a VPN Cluster Load Balancing configuration.

As you go through the wizard, screens appear according to the type of failover that you are configuring and the hardware platform that you are using.

This section includes the following topics:

- Task Flow for Using the High Availability and Scalability Wizard, page 12-7
- Start the Wizard, page 12-8
- Failover Peer Connectivity and Compatibility Check, page 12-8
- Failover Link Configuration, page 12-8
- State Link Configuration, page 12-9
- Standby Address Configuration, page 12-10
- Summary, page 12-10

Task Flow for Using the High Availability and Scalability Wizard

The following procedure provides a high-level overview for configuring Active/Standby failover using the High Availability and Scalability Wizard. Each step in the procedure corresponds to a wizard screen. Click **Next** after completing each step, except for the last one, before proceeding to the next step. Each step also includes a reference to additional information that you may need to complete the step.

Step 1 Start the wizard. See the “Start the Wizard” section on page 12-8.

Step 2 Enter the IP address of the failover peer on the Failover Peer Connectivity and Compatibility Check screen. Click **Test Compatibility**. You cannot move to the next screen until all compatibility tests have been passed. See the “Failover Peer Connectivity and Compatibility Check” section on page 12-8.

Step 3 Define the Failover Link in the Failover Link Configuration screen. See the "Failover Link Configuration" section on page 12-8.

Step 4 (Not available on the ASA 5505 ASA) Define the Stateful Failover link in the State Link Configuration screen. See the "State Link Configuration" section on page 12-9.

Step 5 Add standby addresses to the ASA interfaces in the Standby Address Configuration screen. See the "Standby Address Configuration" section on page 12-10.

Step 6 Review your configuration in the Summary screen. If necessary, click **Back** to go to a previous screen and make changes. See the "Summary" section on page 12-10.

Step 7 Click **Finish**. The failover configuration is sent to the ASA and to the failover peer.

Start the Wizard

Step 1 Choose **Wizards > High Availability and Scalability**.

Step 2 In the Configuration Type screen, click **Configure Active/Standby failover**.

Failover Peer Connectivity and Compatibility Check

The Failover Peer Connectivity and Compatibility Check screen lets you verify that the selected failover peer is reachable and compatible with the current unit. If any of the connectivity and compatibility tests fail, you must correct the problem before you can proceed with the wizard.

To check failover peer connectivity and compatibility, perform the following steps:

Step 1 Enter the IP address of the peer unit. This address does not have to be the failover link address, but it must be an interface that has ASDM access enabled on it. The field accepts both IPv4 and IPv6 addresses.

Step 2 Click **Next** to perform the following connectivity and compatibility tests:

- Connectivity test from this ASDM to the peer unit
- Connectivity test from this firewall device to the peer firewall device
- Hardware compatibility test for the platform
- Software version compatibility
- Failover license compatibility
- Firewall mode compatibility (routed or transparent)
- Context mode compatibility (single or multiple)

Failover Link Configuration

The Failover Link Configuration screen appears *only* if you are configuring LAN-based failover.

To configure LAN-based failover, perform the following steps:

Step 1 Choose the LAN interface to use for failover communication from the drop-down list.

Step 2 Enter a name for the interface.

Step 3 Enter the IP address used for the failover link on the unit that has failover group 1 in the active state. This field accepts an IPv4 or IPv6 address.

Step 4 Enter the IP address used for the failover link on the unit that has failover group 1 in the standby state. This field accepts an IPv4 or IPv6 address.

Step 5 Enter or choose a subnet mask (IPv4 addresses or a prefix (IPv6 Addresses) for the Active IP and Standby IP addresses.

Step 6 (For ASA 5505 only) Choose the switch port from the drop-down list, which includes the current VLAN assigned to each switch port and any name associated with the VLAN. Because a default VLAN exists for every switch port, do not choose VLAN 1 for the inside port, because one less inside port will be available for another use.

Note To provide sufficient bandwidth for failover, do not use trunks or PoE for failover.

Step 7 (Optional) Enter the secret key used to encrypt failover communication. If you leave this field blank, failover communication, including any passwords or keys in the configuration that are sent during command replication, will be in clear text.

State Link Configuration

Note The State Link Configuration screen does not appear on the ASA 5505.

The State Link Configuration screen lets you enable and disable Stateful Failover, and configure Stateful Failover link properties.

To enable Stateful Failover, perform the following steps:

Step 1 To pass state information across the LAN-based failover link, click **Use the LAN link as the State Link**.

Step 2 To disable Stateful Failover, click **Disable Stateful Failover**.

Step 3 To configure an unused interface as the Stateful Failover interface, click **Configure another interface for Stateful failover**.

Step 4 Choose the interface to use for Stateful Failover communication from the drop-down list.

Step 5 Enter the name for the Stateful Failover interface.

Step 6 Enter the IP address for the Stateful Failover link on the unit that has failover group 1 in the active state. This field accepts an IPv4 or IPv6 address.

Step 7 Enter the IP address for the Stateful Failover link on the unit that has failover group 1 in the standby state. This field accepts an IPv4 or IPv6 address.

Step 8 Enter or choose a subnet mask (IPv4 addresses or a prefix (IPv6 Addresses) for the Active IP and Standby IP addresses.

Standby Address Configuration

Use the Standby Address Configuration screen to assign standby IP addresses to the interface on the ASA. The interfaces currently configured on the failover devices appear. The interfaces are grouped by context, and the contexts are grouped by failover group.

To assign standby IP addresses to the interface on the ASA, perform the following steps:

Step 1 Click the plus sign (+) by a device name to display the interfaces on that device. Click the minus sign (-) by a device name to hide the interfaces on that device.

Step 2 Double-click the **Active IP** field to edit or add an active IP address. Changes to this field also appear in the Standby IP field for the corresponding interface on the failover peer unit. This field accepts IPv4 or IPv6 addresses.

Step 3 Double-click the **Standby IP** field to edit or add a standby IP address. Changes to this field also appear in the Active IP field for the corresponding interface on the failover peer unit. This field accepts IPv4 or IPv6 addresses.

Step 4 Check the **Is Monitored** check box to enable health monitoring for that interface. Uncheck the check box to disable health monitoring. By default, health monitoring of physical interfaces is enabled, and health monitoring of virtual interfaces is disabled.

Step 5 Choose the asynchronous group ID from the drop-down list. This setting is only available for physical interface. For virtual interfaces, this field displays “None.”

Summary

The Summary screen displays the results of the configuration steps that you performed in the previous wizard screens.

Verify your settings and click **Finish** to send your configuration to the device. If you are configuring failover, the configuration is also sent to the failover peer. If you need to change a setting, click **Back** to return to the screen that you want to change. Make the change, and click **Next** until you return to the Summary screen.

Configuring Failover (Without the Wizard)

Follow these steps to configure Active/Standby failover on both units.

The speed and duplex settings for the failover interface cannot be changed when Failover is enabled. To change these settings for the failover interface, you must configure them in the Configuration > Interfaces pane before enabling failover.

Step 1 Choose the **Configuration > Device Management > Failover > Setup** tab.

Step 2 Check the **Enable Failover** check box.

Note Failover is not actually enabled until you apply your changes to the device.

Step 3 To encrypt the failover link, do the following:

a. (Optional) Check the **Use 32 hexadecimal character key** check box to enter a hexadecimal value for the encryption key in the Shared Key field.

b. Enter the encryption key in the Shared Key field.

If you checked the Use 32 hexadecimal character key check box, then enter a hexadecimal encryption key. The key must be 32 hexadecimal characters (0-9, a-f).

If the Use 32 hexadecimal character key check box is unchecked, then enter an alphanumeric shared secret. The shared secret can be from 1 to 63 characters. Valid character are any combination of numbers, letters, or punctuation. The shared secret is used to generate the encryption key.

Step 4 Select the interface to use for the failover link from the Interface list. Failover requires a dedicated interface, however you can share the interface with Stateful Failover.

Only unconfigured interfaces or subinterfaces are displayed in this list and can be selected as the LAN Failover interface. Once you specify an interface as the LAN Failover interface, you cannot edit that interface in the Configuration > Interfaces pane.

Step 5 Specify the logical name of the interface used for failover communication in the Logical Name field.

Step 6 Specify the active IP address for the interface in the Active IP field. The IP address can be either an IPv4 or an IPv6 address. You cannot configure both types of addresses on the failover link interface.

Step 7 Depending upon the type of address specified for the Active IP, enter a subnet mask (IPv4 addresses) or a prefix length (IPv6 address) for the failover interface in the Subnet Mask/Prefix Length field. The name of the field changes depending upon the type of address specified in the Active IP field.

Step 8 Specify the IP address used by the secondary unit to communicate with the primary unit in the Standby IP field. The IP address can be an IPv4 or an IPv6 address.

Step 9 Select **Primary** or **Secondary** in the Preferred Role field to specify whether the preferred role for this ASA is as the primary or secondary unit.

Step 10 (Optional) Configure the Stateful Failover link by doing the following:

Note Stateful Failover is not available on the ASA 5505 platform. This area does not appear on ASDM running on an ASA 5505 ASA.

a. Specifies the interface used for state communication. You can choose an unconfigured interface or subinterface, the LAN Failover interface, or the Use Named option.

Note We recommend that you use two separate, dedicated interfaces for the LAN Failover interface and the Stateful Failover interface.

If you choose an unconfigured interface or subinterface, you must supply the Active IP, Subnet Mask, Standby IP, and Logical Name for the interface.

If you choose the LAN Failover interface, you do not need to specify the Active IP, Subnet Mask, Logical Name, and Standby IP values; the values specified for the LAN Failover interface are used.

If you choose the Use Named option, the Logical Name field becomes a drop-down list of named interfaces. Choose the interface from this list. The Active IP, Subnet Mask/Prefix Length, and Standby IP values do not need to be specified. The values specified for the interface are used. Be sure to specify a standby IP address for the selected interface on the Interfaces tab.

Note Because Stateful Failover can generate a large amount of traffic, performance for both Stateful Failover and regular traffic can suffer when you use a named interface.

b. Specify the IP address for the Stateful Failover interface in the Active IP field. The IP address can be either an IPv4 or an IPv6 address. You cannot configure both types of addresses on the failover link interface. This field is dimmed if the LAN Failover interface or Use Named option is chosen from the Interface drop-down list.

c. Specify the mask (IPv4 address) or prefix (IPv6 address) for the Stateful Failover interface in the Subnet Mask/Prefix Length. This field is dimmed if the LAN Failover interface or Use Named option is selected in the Interface drop-down list.

d. Specify the interface name used for failover communication in the Logical Name field. If you chose the Use Named option in the Interface drop-down list, this field displays a list of named interfaces. This field is dimmed if the LAN Failover interface is chosen from the Interface drop-down list.

e. Specify the IP address used by the secondary unit to communicate with the primary unit in the Standby IP field. The IP address can be an IPv4 or an IPv6 address. This field is dimmed if the LAN Failover interface or Use Named option is chosen from the Interface drop-down list.

f. (Optional) Enable HTTP replication by checking the **Enable HTTP Replication** check box. This enables Stateful Failover to copy active HTTP sessions to the standby firewall. If you do not allow HTTP replication, then HTTP connections are disconnected in the event of a failover.

Step 11 Click **Apply**.

The configuration is saved to the devices in the failover pair.

Configuring Interface Standby Addresses

Configuring standby IP address in ASDM changes depending upon the mode in which the unit is operating. This section includes the following topics:

- Configuring Interface Standby Addresses in Routed Firewall Mode, page 12-12
- Configuring the Management Interface Standby Address in Transparent Firewall Mode, page 12-13

Configuring Interface Standby Addresses in Routed Firewall Mode

To configure a standby address for each interface on the ASA, perform the following steps:

Step 1 Choose the **Configuration > Device Management > High Availability > Failover > Interfaces** tab.

A list of configured interfaces appears. The IP address for each interface appears in the Active IP Address column. If configured, the standby IP address for the interface appears in the Standby IP address column. The failover interface and Stateful failover interface do not display IP address; you cannot change those address from this tab.

Step 2 For each interface that does not have a standby IP address, double-click the Standby IP Address field and do one of the following:

- Click the **...** button and select an IP address from the list.

- Type an IP address into the field. The address can be an IPv4 or an IPv6 address.

You can also specify whether or not the interface is monitored from this tab. For more information about configuring interface monitoring, see the "Disabling and Enabling Interface Monitoring" section on page 12-13.

Configuring the Management Interface Standby Address in Transparent Firewall Mode

If you are in multiple context mode, you must perform this procedure in each context.

To configure the management interface standby address on the ASA, perform the following steps:

Step 1 Choose the **Configuration > Device Management > High Availability > Failover > Interfaces** tab.

A list of configured interfaces appears. Only the Management interface shows an IP address.

Step 2 For the Management interface that does not have a standby IP address, double-click the Standby IP Address field and do one of the following:

- Click the **...** button and select an IP address from the list.
- Type an IP address into the field. The address can be an IPv4 or an IPv6 address.

You can also specify whether or not the interface is monitored from this tab. For more information about configuring interface monitoring, see "Disabling and Enabling Interface Monitoring" section on page 12-13.

Configuring Optional Active/Standby Failover Settings

This section includes the following topics:

- Disabling and Enabling Interface Monitoring, page 12-13
- Configuring Failover Criteria, page 12-14
- Configuring the Unit and Interface Health Poll Times, page 12-15
- Configuring Virtual MAC Addresses, page 12-15

You can configure the optional Active/Standby failover settings when initially configuring the primary unit in a failover pair or on the active unit in the failover pair after the initial configuration.

Disabling and Enabling Interface Monitoring

You can control which interfaces affect your failover policy by disabling the monitoring of specific interfaces and enabling the monitoring of others. This feature enables you to exclude interfaces attached to less critical networks from affecting your failover policy.

You can monitor up to 250 interfaces on a unit. By default, monitoring physical interfaces is enabled and monitoring subinterfaces is disabled.

Hello messages are exchanged during every interface poll frequency time period between the ASA failover pair. The failover interface poll time is 3 to 15 seconds. For example, if the poll time is set to 5 seconds, testing begins on an interface if 5 consecutive hellos are not heard on that interface (25 seconds).

Monitored failover interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface or VLAN is administratively down.
- No Link—The physical link for the interface is down.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

To enable or disable health monitoring for specific interfaces on units in single configuration mode, enter one of the following commands. Alternately, for units in multiple configuration mode, you must enter the commands within each security context.

To disable or enable monitoring of an interface, perform the following steps:

Step 1 Choose the **Configuration > Device Management > High Availability > Failover > Interfaces** tab.

A list of configured interfaces appears. The Monitored column displays whether or not an interface is monitored as part of your failover criteria. If it is monitored, a check appears in the Monitored check box.

Step 2 To disable monitoring of a listed interface, uncheck the **Monitored** check box for the interface.

Step 3 To enable monitoring of a listed interface, check the **Monitored** check box for the interface.

Configuring Failover Criteria

You can specify a specific number of interface or a percentage of monitored interfaces that must fail before failover occurs. By default, a single interface failure causes failover.

Use the Configuration > Device Management > High Availability > Criteria tab to define criteria for failover, such as how many interfaces must fail and how long to wait between polls. The hold time specifies the interval to wait without receiving a response to a poll before unit failover.

For information about configuring the hold and poll times, see Configuring the Unit and Interface Health Poll Times, page 12-15.

To configure the interface policy, perform the following steps:

Step 1 Choose the **Configuration > Device Management > High Availability > Failover > Criteria** tab.

Step 2 In the Interface Policy area, do one of the following:

- To define a specific number of interfaces that must fail to trigger failover, enter a number from 1 to 250 in the Number of failed interfaces field. When the number of failed monitored interfaces exceeds the value you specify, the ASA fails over.
- To define a percentage of configured interfaces that must fail to trigger failover, enter a percentage in the Percentage of failed interfaces field. When the number of failed monitored interfaces exceeds the percentage you set, the ASA fails over.

Step 3 Click **Apply**.

Configuring the Unit and Interface Health Poll Times

The ASA sends hello packets out of each data interface to monitor interface health. The appliance sends hello messages across the failover link to monitor unit health. If the ASA does not receive a hello packet from the corresponding interface on the peer unit for over half of the hold time, then the additional interface testing begins. If a hello packet or a successful test result is not received within the specified hold time, the interface is marked as failed. Failover occurs if the number of failed interfaces meets the failover criteria.

Decreasing the poll and hold times enables the ASA to detect and respond to interface failures more quickly but may consume more system resources. Increasing the poll and hold times prevents the ASA from failing over on networks with higher latency.

Step 1 Choose the **Configuration > Device Management > High Availability > Failover > Criteria** tab.

Step 2 To configure the interface poll and hold times, change the following values in the Failover Poll Times area:

- Monitored Interfaces—The amount of time between polls among interfaces. The range is between 1and 15 seconds or 500 to 999 milliseconds.
- Interface Hold Time—Sets the time during which a data interface must receive a hello message on the data interface, after which the peer is declared failed. Valid values are from 5 to 75 seconds.

Step 3 To configure the unit poll and hold times, change the following values in the Failover Poll Times area:

- Unit Failover—The amount of time between hello messages among units. The range is between 1 and 15 seconds or between 200 and 999 milliseconds.
- Unit Hold Time—Sets the time during which a unit must receive a hello message on the failover link, or else the unit begins the testing process for peer failure. The range is between 1and 45 seconds or between 800 and 999 milliseconds. You cannot enter a value that is less than 3 times the polltime.

Step 4 Click **Apply**.

Configuring Virtual MAC Addresses

The Configuration > Device Management > High Availability > MAC Addresses tab displays the virtual MAC addresses for the interfaces in an Active/Standby failover pair.

Note This tab is not available on the ASA 5505 platform.

In Active/Standby failover, the MAC addresses for the primary unit are always associated with the active IP addresses. If the secondary unit boots first and becomes active, it uses the burned-in MAC address for its interfaces. When the primary unit comes online, the secondary unit obtains the MAC addresses from the primary unit. The change can disrupt network traffic.

You can configure virtual MAC addresses for each interface to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not specify virtual MAC addresses the failover pair uses the burned-in NIC addresses as the MAC addresses.

Note You cannot configure a virtual MAC address for the failover or Stateful Failover links. The MAC and IP addresses for those links do not change during failover.

To configure the virtual MAC address for an interface, perform the following steps:

Step 1 Open the **Configuration > Device Management > High Availability > Failover > MAC Addresses** tab.

Step 2 To edit an existing virtual MAC address entry, double-click the row for the interface whose MAC addresses you want to change. To add a new virtual MAC address entry, click **Add**.

The Add/Edit Interface MAC Address dialog box appears.

Step 3 Type the new MAC address for the active interface in the Active MAC Address field.

Step 4 Type the new MAC address for the standby interface in the Standby MAC Address field.

Step 5 Click **OK**.

Step 6 To delete a virtual MAC address entry, perform the following steps:

a. Click the interface to select the table row.

b. Click **Delete**.

c. Click **OK**.

Controlling Failover

This sections describes how to control and monitor failover. This section includes the following topics:

- Forcing Failover, page 12-16
- Disabling Failover, page 12-17
- Restoring a Failed Unit, page 12-17

Forcing Failover

To force the standby unit to become active, perform the following steps:

Step 1 Choose **Monitoring > Properties > Failover > Status**.

Step 2 Click one of the following buttons:

- Click **Make Active** to make the unit the active unit.
- Click **Make Standby** to make the other unit in the pair the active unit.

Disabling Failover

To disable failover, perform the following steps:

Step 1 Choose **Configuration > Device Management > High Availability > Failover**.

Step 2 Uncheck the **Enable Failover** check box.

Restoring a Failed Unit

To restore a failed unit to an unfailed state, perform the following steps:

Step 1 Choose **Monitoring > Properties > Failover > Status**.

Step 2 Click **Reset Failover**.

Note

Monitoring Active/Standby Failover

Note After a failover event you should either re-launch ASDM or switch to another device in the Devices pane and then come back to the original ASA to continue monitoring the device. This action is necessary because the monitoring connection does not become re-established when ASDM is disconnected from and then reconnected to the device.

Choose **Monitoring > Properties > Failover** to monitor Active/Standby failover.

Feature History for Active/Standby Failover

Table 12-2 lists the release history for this feature.

Table 12-2 Feature History for Optional Active/Standby Failover Settings

Feature Name	Releases	Feature Information
This feature was introduced.	7.0	This feature was introduced.
IPv6 support for failover added.	8.2(2)	We modified the following screens: Configuration > Device Management > High Availability > Failover > Setup Configuration > Device Management > High Availability > Failover > Interfaces

Configuring Active/Active Failover

This chapter describes how to configure Active/Active failover and includes the following sections:

- Information About Active/Active Failover, page 13-1
- Licensing Requirements for Active/Active Failover, page 13-6
- Prerequisites for Active/Active Failover, page 13-6
- Guidelines and Limitations, page 13-7
- Configuring Active/Active Failover, page 13-8
- Monitoring Active/Active Failover, page 13-22
- Feature History for Active/Active Failover, page 13-23

Information About Active/Active Failover

This section describes Active/Active failover. This section includes the following topics:

- Active/Active Failover Overview, page 13-1
- Primary/Secondary Status and Active/Standby Status, page 13-2
- Device Initialization and Configuration Synchronization, page 13-3
- Command Replication, page 13-3
- Failover Triggers, page 13-4
- Failover Actions, page 13-4

Active/Active Failover Overview

Active/Active failover is only available to ASAs in multiple context mode. In an Active/Active failover configuration, both ASAs can pass network traffic.

In Active/Active failover, you divide the security contexts on the ASA into *failover groups*. A failover group is simply a logical group of one or more security contexts. You can create a maximum of two failover groups. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default.

The failover group forms the base unit for failover in Active/Active failover. Interface failure monitoring, failover, and active/standby status are all attributes of a failover group rather than the unit. When an active failover group fails, it changes to the standby state while the standby failover group becomes

active. The interfaces in the failover group that becomes active assume the MAC and IP addresses of the interfaces in the failover group that failed. The interfaces in the failover group that is now in the standby state take over the standby MAC and IP addresses.

Note A failover group failing on a unit does not mean that the unit has failed. The unit may still have another failover group passing traffic on it.

When creating the failover groups, you should create them on the unit that will have failover group 1 in the active state.

Note Active/Active failover generates virtual MAC addresses for the interfaces in each failover group. If you have more than one Active/Active failover pair on the same network, it is possible to have the same default virtual MAC addresses assigned to the interfaces on one pair as are assigned to the interfaces of the other pairs because of the way the default virtual MAC addresses are determined. To avoid having duplicate MAC addresses on your network, make sure you assign each physical interface a virtual active and standby MAC address.

Primary/Secondary Status and Active/Standby Status

As in Active/Standby failover, one unit in an Active/Active failover pair is designated the primary unit, and the other unit the secondary unit. Unlike Active/Standby failover, this designation does not indicate which unit becomes active when both units start simultaneously. Instead, the primary/secondary designation does two things:

- Determines which unit provides the running configuration to the pair when they boot simultaneously.
- Determines on which unit each failover group appears in the active state when the units boot simultaneously. Each failover group in the configuration is configured with a primary or secondary unit preference. You can configure both failover groups be in the active state on a single unit in the pair, with the other unit containing the failover groups in the standby state. However, a more typical configuration is to assign each failover group a different role preference to make each one active on a different unit, distributing the traffic across the devices.

  Note The ASA also provides load balancing, which is different from failover. Both failover and load balancing can exist on the same configuration. For information about load balancing, see the "Configuring Load Balancing" section on page 86-20.

Which unit each failover group becomes active on is determined as follows:

- When a unit boots while the peer unit is not available, both failover groups become active on the unit.
- When a unit boots while the peer unit is active (with both failover groups in the active state), the failover groups remain in the active state on the active unit regardless of the primary or secondary preference of the failover group until one of the following occurs:
  - A failover occurs.
  - You manually force a failover.

  - You configured preemption for the failover group, which causes the failover group to automatically become active on the preferred unit when the unit becomes available.
- When both units boot at the same time, each failover group becomes active on its preferred unit after the configurations have been synchronized.

Device Initialization and Configuration Synchronization

Configuration synchronization occurs when one or both units in a failover pair boot. The configurations are synchronized as follows:

- When a unit boots while the peer unit is active (with both failover groups active on it), the booting unit contacts the active unit to obtain the running configuration regardless of the primary or secondary designation of the booting unit.
- When both units boot simultaneously, the secondary unit obtains the running configuration from the primary unit.

When the replication starts, the ASA console on the unit sending the configuration displays the message "Beginning configuration replication: Sending to mate," and when it is complete, the ASA displays the message "End Configuration Replication to mate." During replication, commands entered on the unit sending the configuration may not replicate properly to the peer unit, and commands entered on the unit receiving the configuration may be overwritten by the configuration being received. Avoid entering commands on either unit in the failover pair during the configuration replication process. Depending upon the size of the configuration, replication can take from a few seconds to several minutes.

Note On the unit receiving the configuration, the configuration exists only in running memory. To save the configuration to the flash memory on both units, select **File > Save Running Configuration to flash** from the menu bar in the system execution space on the unit that has failover group 1 in the active state. Startup configurations saved on external servers are accessible from either unit over the network and do not need to be saved separately for each unit. Alternatively, you can copy the contexts configuration files from the disk on the primary unit to an external server, and then copy them to disk on the secondary unit, where they become available when the unit reloads.

Command Replication

After both units are running, commands are replicated from one unit to the other as follows:

- Changes entered within a security context are replicated from the unit on which the security context appears in the active state to the peer unit.

Note A context is considered in the active state on a unit if the failover group to which it belongs is in the active state on that unit.

- Changes entered in the system execution space are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.
- Changes entered in the admin context are replicated from the unit on which failover group 1 is in the active state to the unit on which failover group 1 is in the standby state.

Failure to enter the changes on the appropriate unit for command replication to occur causes the configurations to be out of synchronization. Those changes may be lost the next time the initial configuration synchronization occurs.

Table 13-1 lists the commands that are and are not replicated to the standby unit.

Table 13-1 Command Replication

Commands Replicated to the Standby Unit	Commands Not Replicated to the Standby Unit
All configuration commands except for **mode**, **firewall**, and **failover lan unit**	All forms of the **copy** command except for **copy running-config startup-config**
copy running-config startup-config	All forms of the **write** command except for **write memory**
delete	**debug**
mkdir	**failover lan unit**
rename	**firewall**
rmdir	**mode**
write memory	**show**

Failover Triggers

In Active/Active failover, failover can be triggered at the unit level if one of the following events occurs:

- The unit has a hardware failure.
- The unit has a power failure.
- The unit has a software failure.
- You force a failover. (See Forcing Failover, page 13-21.)

Failover is triggered at the failover group level when one of the following events occurs:

- Too many monitored interfaces in the group fail.
- You force a failover. (See Forcing Failover, page 13-21.)

You configure the failover threshold for each failover group by specifying the number or percentage of interfaces within the failover group that must fail before the group fails. Because a failover group can contain multiple contexts, and each context can contain multiple interfaces, it is possible for all interfaces in a single context to fail without causing the associated failover group to fail.

See the "Failover Health Monitoring" section on page 11-18 for more information about interface and unit monitoring.

Failover Actions

In an Active/Active failover configuration, failover occurs on a failover group basis, not a system basis. For example, if you designate both failover groups as active on the primary unit, and failover group 1 fails, then failover group 2 remains active on the primary unit while failover group 1 becomes active on the secondary unit.

Note When configuring Active/Active failover, make sure that the combined traffic for both units is within the capacity of each unit.

Table 13-2 shows the failover action for each failure event. For each failure event, the policy (whether or not failover occurs), actions for the active failover group, and actions for the standby failover group are given.

Table 13-2 Failover Behavior for Active/Active Failover

Failure Event	Policy	Active Group Action	Standby Group Action	Notes
A unit experiences a power or software failure	Failover	Become standby Mark as failed	Become active Mark active as failed	When a unit in a failover pair fails, any active failover groups on that unit are marked as failed and become active on the peer unit.
Interface failure on active failover group above threshold	Failover	Mark active group as failed	Become active	None.
Interface failure on standby failover group above threshold	No failover	No action	Mark standby group as failed	When the standby failover group is marked as failed, the active failover group does not attempt to fail over, even if the interface failure threshold is surpassed.
Formerly active failover group recovers	No failover	No action	No action	Unless failover group preemption is configured, the failover groups remain active on their current unit.
Failover link failed at startup	No failover	Become active	Become active	If the failover link is down at startup, both failover groups on both units become active.
Stateful Failover link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Failover link failed during operation	No failover	n/a	n/a	Each unit marks the failover interface as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.

Optional Active/Active Failover Settings

You can configure the following Active/Standby failover options when you initially configuring failover or after failover has been configured:

- Failover Group Preemption—Assigns a primary or secondary priority to a failover group to specify on which unit in the failover group becomes active when both units boot simultaneously.
- HTTP replication with Stateful Failover—Allows connections to be included in the state information replication.
- Interface monitoring—Allows you to monitor up to 250 interfaces on a unit and control which interfaces affect your failover.
- Interface health monitoring—Enables the security appliance to detect and respond to interface failures more quickly.
- Failover criteria setup—Allows you to specify a specific number of interfaces or a percentage of monitored interfaces that must fail before failover occurs.
- Virtual MAC address configuration—Ensures that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit.

Licensing Requirements for Active/Active Failover

The following table shows the licensing requirements for this feature:

Model	License Requirement
ASA 5505	No support.
ASA 5510, ASA 5512-X	Security Plus License.
All other models	Base License.

Failover units do not require the same license on each unit. If you have licenses on both units, they combine into a single running failover cluster license. The exceptions to this rule include:

- Security Plus license for the ASA 5510 and 5512-X—The Base license does not support failover, so you cannot enable failover on a standby unit that only has the Base license.
- IPS module license for the ASA 5500-X—You must purchase an IPS module license for each unit, just as you would need to purchase a hardware module for each unit for other models.
- Encryption license—Both units must have the same encryption license.

Prerequisites for Active/Active Failover

In Active/Active failover, both units must have the following:

- The same hardware model.
- The same number of interfaces.
- The same types of interfaces.

- The same software version, with the same major (first number) and minor (second number) version numbers. However you can use different versions of the software during an upgrade process; for example you can upgrade one unit from Version 7.0(1) to Version 7.9(2) and have failover remain active. We recommend upgrading both units to the same version to ensure long-term compatibility.
- The same software configuration.
- The same mode (multiple context mode).
- The proper license.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in multiple context mode only.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

IPv6 failover is supported.

Model Guidelines

Active/Active failover is not available on the Cisco ASA 5505.

Additional Guidelines and Limitations

No two interfaces in the same context should be configured in the same ASR group.

Configuring port security on the switch(es) connected to an ASA failover pair can cause communication problems when a failover event occurs. This is because if a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.

ASA failover replication fails if you try to make a configuration change in two or more contexts at the same time. The workaround is to make configuration changes on each unit sequentially.

The following features are not supported for Active/Active failover:

- To receive packets from both units in a failover pair, standby IP addresses need to be configured on all interfaces.
- The standby IP address is used on the security appliance that is currently the standby unit, and it must be in the same subnet as the active IP address.
- You can define a maximum number of two failover groups.
- Failover groups can only be added to the system context of devices that are configured for multiple context mode.
- You can create and remove failover groups only when failover is disabled.
- Entering the **failover group** command puts you in the failover group command mode. The **primary**, **secondary**, **preempt**, **replication http**, **interface-policy**, **mac address**, and **polltime interface** commands are available in the failover group configuration mode. Use the **exit** command to return to global configuration mode.

- The **failover polltime interface**, **failover interface-policy**, **failover replication http**, and **failover mac address** commands have no affect on Active/Active failover configurations. They are overridden by the following failover group configuration mode commands: **polltime interface**, **interface-policy**, **replication http**, and **mac address**.
- When removing failover groups, you must remove failover group 1 last. Failover group1 always contains the admin context. Any context not assigned to a failover group defaults to failover group 1. You cannot remove a failover group that has contexts explicitly assigned to it.
- VPN failover is unavailable. (It is available in Active/Standby failover configurations only.)

Configuring Active/Active Failover

This section describes how to configure Active/Active failover using an Ethernet failover link. When configuring LAN-based failover, you must bootstrap the secondary device to recognize the failover link before the secondary device can obtain the running configuration from the primary device.

This section includes the following topics:

- Task Flow for Using the High Availability and Scalability Wizard, page 13-8
- Configuring Failover (Without the Wizard), page 13-12
- Configuring Asymmetric Routing Groups in Multiple Context Mode, page 13-20

Task Flow for Using the High Availability and Scalability Wizard

The following procedure provides a high-level overview for configuring Active/Active failover using the High Availability and Scalability Wizard. Each step in the procedure corresponds to a wizard screen. Click **Next** after completing each step, except for the last one, before proceeding to the next step. Each step also includes a reference to additional information that you may need to complete the step.

Step 1 Start the wizard. See the "Start the Wizard" section on page 13-9.

Step 2 Enter the IP address of the failover peer in the Failover Peer Connectivity and Compatibility Check screen. Click **Test Compatibility**. You cannot move to the next screen until all compatibility tests have been passed. See the "Failover Peer Connectivity and Compatibility Check" section on page 13-9.

Step 3 If the ASA or the failover peer are in single context mode, change them to multiple context mode in the Change Device to Multiple Mode screen. When you change the ASA to multiple context mode, it reboots. ASDM automatically reestablishes communication with the ASA when it has finished rebooting. See the "Change a Device to Multiple Mode" section on page 13-9.

Step 4 Assign security contexts to failover groups in the Context Configuration screen. You can add and delete contexts in this screen. See the "Security Context Configuration" section on page 13-10.

Step 5 Define the Failover Link in the Failover Link Configuration screen. See the "Failover Link Configuration" section on page 13-10.

Step 6 Define the Stateful Failover link in the State Link Configuration screen. See the "State Link Configuration" section on page 13-10.

Step 7 Add standby addresses to the ASA interfaces in the Standby Address Configuration screen. See the "Standby Address Configuration" section on page 13-11.

Step 8 Review your configuration in the Summary screen. See "Summary" section on page 13-11.

Step 9 Click **Finish**. The failover configuration is sent to the ASA and to the failover peer.

Start the Wizard

Step 1 Choose **Wizards > High Availability and Scalability**.

Step 2 In the Configuration Type screen, click **Configure Active/Active failover**.

Failover Peer Connectivity and Compatibility Check

The Failover Peer Connectivity and Compatibility Check screen lets you verify that the selected failover peer is reachable and compatible with the current unit. If any of the connectivity and compatibility tests fail, you must correct the problem before you can proceed with the wizard.

To check failover peer connectivity and compatibility, perform the following steps:

Step 1 Enter the IP address of the peer unit. This address does not have to be the failover link address, but it must be an interface that has ASDM access enabled on it. The field accepts both IPv4 and IPv6 addresses.

Step 2 Click **Next** to perform the following connectivity and compatibility tests:

- Connectivity test from this ASDM to the peer unit
- Connectivity test from this firewall device to the peer firewall device
- Hardware compatibility test for the platform
- Software version compatibility
- Failover license compatibility
- Firewall mode compatibility (routed or transparent)
- Context mode compatibility (single or multiple)

Change a Device to Multiple Mode

The Change Device to Multiple Mode dialog box requires that the ASA be in multiple context mode. This dialog box lets you convert a ASA in single context mode to multiple context mode.

When you convert from single context mode to multiple context mode, the ASA creates the system configuration and the admin context from the current running configuration. The admin context configuration is stored in the admin.cfg file. The conversion process does not save the previous startup configuration, so if the startup configuration differed from the running configuration, those differences are lost.

Converting the ASA from single context mode to multiple context mode causes the ASA and its peer to reboot. However, the High Availability and Scalability Wizard restores connectivity with the newly created admin context and reports the status in the Devices Status field in this dialog box.

Note You must convert both the current ASA and its peer to multiple context mode before you can proceed.

To change the current ASA to multiple context mode, perform the following steps:

Step 1 Click **Change *device* To Multiple Context**, where *device* is the hostname of the ASA.

Step 2 Repeat this step for the peer ASA.

The status of the ASA appears during conversion to multiple context mode.

Security Context Configuration

The Security Context Configuration screen lets you assign security contexts to failover groups. It displays the name of currently configured security contexts, lets you add new ones, and change or remove existing ones as needed. In addition, it displays the failover group number to which the context is assigned and lets you change the failover group as needed. Although you can create security contexts in this screen, you cannot assign interfaces to those contexts or configure other properties for them. To configure context properties and assign interfaces to a context, choose **System > Security Contexts**.

Failover Link Configuration

The Failover Link Configuration screen appears *only* if you are configuring LAN-based failover.

To configure LAN-based failover, perform the following steps:

Step 1 Choose the LAN interface to use for failover communication from the drop-down list.

Step 2 Enter a name for the interface.

Step 3 Enter the IP address used for the failover link on the unit that has failover group 1 in the active state. This field accepts an IPv4 or IPv6 address.

Step 4 Enter the IP address used for the failover link on the unit that has failover group 1 in the standby state. This field accepts an IPv4 or IPv6 address.

Step 5 Enter or choose a subnet mask (IPv4 addresses or a prefix (IPv6 Addresses) for the Active IP and Standby IP addresses.

Step 6 (Optional) Enter the secret key used to encrypt failover communication. If you leave this field blank, failover communication, including any passwords or keys in the configuration that are sent during command replication, will be in clear text.

State Link Configuration

The State Link Configuration screen lets you enable and disable Stateful Failover, and configure Stateful Failover link properties.

To enable Stateful Failover, perform the following steps:

Step 1 To pass state information across the LAN-based failover link, click **Use the LAN link as the State Link**.

Step 2 To disable Stateful Failover, click **Disable Stateful Failover**.

Step 3 To configure an unused interface as the Stateful Failover interface, click **Configure another interface for Stateful failover**.

Step 4 Choose the interface to use for Stateful Failover communication from the drop-down list.

Step 5 Enter the name for the Stateful Failover interface.

Step 6 Enter the IP address for the Stateful Failover link on the unit that has failover group 1 in the active state. This field accepts an IPv4 or IPv6 address.

Step 7 Enter the IP address for the Stateful Failover link on the unit that has failover group 1 in the standby state. This field accepts an IPv4 or IPv6 address.

Step 8 Enter or choose a subnet mask (IPv4 addresses or a prefix (IPv6 Addresses) for the Active IP and Standby IP addresses.

Standby Address Configuration

Use the Standby Address Configuration screen to assign standby IP addresses to the interface on the ASA. The interfaces currently configured on the failover devices appear. The interfaces are grouped by context, and the contexts are grouped by failover group.

To assign standby IP addresses to the interface on the ASA, perform the following steps:

Step 1 Click the plus sign (+) by a device, failover group, or context name to expand the list. Click the minus sign (-) by a device, failover group, or context name to collapse the list.

Step 2 Double-click the **Active IP** field to edit or add an active IP address. Changes to this field also appear in the Standby IP field for the corresponding interface on the failover peer unit. This field accepts IPv4 or IPv6 addresses.

Step 3 Double-click the **Standby IP** field to edit or add a standby IP address. Changes to this field also appear in the Active IP field for the corresponding interface on the failover peer unit. This field accepts IPv4 or IPv6 addresses.

Step 4 Check the **Is Monitored** check box to enable health monitoring for that interface. Uncheck the check box to disable health monitoring. By default, health monitoring of physical interfaces is enabled, and health monitoring of virtual interfaces is disabled.

Step 5 Choose the asynchronous group ID from the drop-down list. This setting is only available for physical interface. For virtual interfaces, this field displays “None.”

Summary

The Summary screen displays the results of the configuration steps that you performed in the previous wizard screens.

Verify your settings and click **Finish** to send your configuration to the device. If you are configuring failover, the configuration is also sent to the failover peer. If you need to change a setting, click **Back** to return to the screen that you want to change. Make the change, and click **Next** until you return to the Summary screen.

Configuring Failover (Without the Wizard)

- Failover-Multiple Mode, Security Context, page 13-12
- Failover - Routed, page 13-12
- Failover - Transparent, page 13-13
- Failover-Multiple Mode, System, page 13-14
- Failover > Setup Tab, page 13-14
- Failover > Criteria Tab, page 13-16
- Failover > Active/Active Tab, page 13-16
- Failover > MAC Addresses Tab, page 13-19

Failover-Multiple Mode, Security Context

The fields displayed on the Failover pane in multiple context mode change depending upon whether the context is in transparent or routed firewall mode.

This section includes the following topics:

- Failover - Routed
- Failover - Transparent

Failover - Routed

Use this pane to define the standby IP address for each interface in the security context and to specify whether the status of the interface should be monitored.

Fields

- Interface table—Lists the interfaces on the ASA and identifies their active IP address, standby IP address, and monitoring status.
  - Interface Name column—Identifies the interface name.
  - Active IP column—Identifies the active IP address for this interface.
  - Standby IP column—Identifies the IP address of the corresponding interface on the standby failover unit.
  - Is Monitored column—Specifies whether this interface is monitored for failure.
- Edit—Displays the Edit Failover Interface Configuration dialog box for the selected interface.

Edit Failover Interface Configuration

Use the Edit Failover Interface Configuration dialog box to define the standby IP address for an interface and to specify whether the status of the interface should be monitored.

Fields

- Interface Name—Identifies the interface name.
- Active IP Address—Identifies the IP address for this interface. This field does not appear if an IP address has not been assigned to the interface.

- Subnet Mask/Prefix Length—Identifies the mask (for IPv4 addresses) or prefix (for IPv6 addresses) for this interface. This field does not appear if an IP address has not been assigned to the interface.
- Standby IP Address—Specifies the IP address of the corresponding interface on the standby failover unit. This field does not appear if an IP address has not been assigned to the interface.
- Monitor interface for failure—Specifies whether this interface is monitored for failure. The number of interfaces that can be monitored for the security appliance is 250. Hello messages are exchanged between the security appliance failover pair during every interface poll time period. Monitored failover interfaces can have the following status:
  - Unknown—Initial status. This status can also mean the status cannot be determined.
  - Normal—The interface is receiving traffic.
  - Testing—Hello messages are not heard on the interface for five poll times.
  - Link Down—The interface is administratively down.
  - No Link—The physical link for the interface is down.
  - Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover - Transparent

Use this pane to define the standby IP address for the management interface for the security context and to specify whether the status of the interfaces on the security context should be monitored.

Fields

- Interface—Lists the interfaces for the security context and identifies their monitoring status.
  - Interface Name—Identifies the interface name.
  - Is Monitored—Specifies whether this interface is monitored for failure.
- Edit—Displays the Edit Failover Interface Configuration dialog box for the selected interface.
- Management IP Address—Identifies the active and standby management IP addresses for the security context.
  - Active—Identifies the management IP address for the active failover unit.
  - Standby—Specifies the management IP address for the standby failover unit.
- Management Netmask—Identifies the mask associated with the management address.

Edit Failover Interface Configuration

Use the Edit Failover Interface Configuration dialog box to specify whether the status of the interface should be monitored.

Fields

- Interface Name—Identifies the interface name.
- Monitor interface for failure—Specifies whether this interface is monitored for failure. The number of interfaces that can be monitored for the security appliance is 250. Hello messages are exchanged between the security appliance failover pair during every interface poll time period. Monitored failover interfaces can have the following status:
  - Unknown—Initial status. This status can also mean the status cannot be determined.
  - Normal—The interface is receiving traffic.

- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface is administratively down.
- No Link—The physical link for the interface is down.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover-Multiple Mode, System

This pane includes tabs for configuring the system-level failover settings in the system context of an ASA in multiple context mode. In multiple mode, you can configure Active/Standby or Active/Active failover. Active/Active failover is automatically enabled when you create failover groups in the device manager. For both types of failover, you need to provide system-level failover settings in the system context, and context-level failover settings in the individual security contexts. For more information about configuring failover in general, see Chapter 11, "Information About Failover.".

Seethe following topics for more information:

- Failover > Setup Tab
- Failover > Criteria Tab
- Failover > Active/Active Tab
- Failover > MAC Addresses Tab

Failover > Setup Tab

Use this tab to enable failover on a ASA in multiple context mode. You also designate the failover link and the state link, if using Stateful Failover, on this tab.

Note During a successful failover event on the ASA, the interfaces are brought down, roles are switched (IP addresses and MAC addresses are swapped), and the interfaces are brought up again. However, the process is transparent to users. The ASA does not send link-down messages or system log messages to notify users that interfaces were taken down during failover (or link-up messages for interfaces brought up by the failover process).

Fields

- Enable Failover—Checking this check box enables failover and lets you configure a standby ASA.

Note The speed and duplex settings for an interface cannot be changed when Failover is enabled. To change these settings for the failover interface, you must configure them in the Configuration > Interfaces pane before enabling failover.

- Use 32 hexadecimal character key—Check this check box to enter a hexadecimal value for the encryption key in the Shared Key field. Uncheck this check box to enter an alphanumeric shared secret in the Shared Key field.
- Shared Key—Specifies the failover shared secret or key for encrypted and authenticated communications between failover pairs.

  If you checked the Use 32 hexadecimal character key check box, then enter a hexadecimal encryption key. The key must be 32 hexadecimal characters (0-9, a-f).

If you cleared the Use 32 hexadecimal character key check box, then enter an alphanumeric shared secret. The shared secret can be from 1 to 63 characters. Valid character are any combination of numbers, letters, or punctuation. The shared secret is used to generate the encryption key.

- LAN Failover—Contains the fields for configuring LAN Failover.
  - Interface—Specifies the interface used for failover communication. Failover requires a dedicated interface, however, you can use the same interface for Stateful Failover.

    Only unconfigured interfaces or subinterfaces that have not been assigned to a context are displayed in this list and can be selected as the LAN Failover interface. Once you specify an interface as the LAN Failover interface, you cannot edit that interface in the Configuration > Interfaces pane or assign that interface to a context.
  - Active IP—Specifies the IP address for the failover interface on the active unit. The IP address can be an IPv4 or an IPv6 address.
  - Subnet Mask/Prefix Length—Depending upon the type of address specified for the Active IP, enter a subnet mask (IPv4 addresses) or a prefix length (IPv6 address) for the failover interface on the primary and secondary unit.
  - Logical Name—Specifies the logical name of the interface used for failover communication.
  - Standby IP—Specifies the IP address used by the secondary unit to communicate with the primary unit. The IP address can be an IPv4 or an IPv6 address.
  - Preferred Role—Specifies whether the preferred role for this ASA is as the primary or secondary unit in a LAN failover.
- State Failover—Contains the fields for configuring Stateful Failover.
  - Interface—Specifies the interface used for failover communication. You can choose an unconfigured interface or subinterfaces or the LAN Failover interface.

    If you choose the LAN Failover interface, the interface needs enough capacity to handle both the LAN Failover and Stateful Failover traffic. Also, you do not need to specify the Active IP, Subnet Mask, Logical Name, and Standby IP values; the values specified for the LAN Failover interface are used.

    Note We recommend that you use two separate, dedicated interfaces for the LAN Failover interface and the Stateful Failover interface.

  - Active IP—Specifies the IP address for the Stateful Failover interface on the primary unit. This field is dimmed if the LAN Failover interface or Use Named option is chosen from the Interface drop-down list.
  - Subnet Mask/Prefix Length—Specifies the mask (IPv4 address) or prefix (IPv6 address) for the Stateful Failover interfaces on the primary and secondary units. This field is dimmed if the LAN Failover interface or Use Named option is selected in the Interface drop-down list.
  - Logical Name—Specifies the logical interface used for failover communication. If you chose the Use Named option in the Interface drop-down list, this field displays a list of named interfaces. This field is dimmed if the LAN Failover interface is chosen from the Interface drop-down list.
  - Standby IP—Specifies the IP address used by the secondary unit to communicate with the primary unit. This field is dimmed if the LAN Failover interface or Use Named option is chosen from the Interface drop-down list.

- Enable HTTP replication—Checking this check box enables Stateful Failover to copy active HTTP sessions to the standby firewall. If you do not allow HTTP replication, then HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link.

Failover > Criteria Tab

Use this tab to define criteria for failover, such as how many interfaces must fail and how long to wait between polls. The hold time specifies the interval to wait without receiving a response to a poll before unit failover.

Note If you are configuring Active/Active failover, you do not use this tab to define the interface policy; instead, you define the interface policy for each failover group using the Failover > Active/Active Tab. With Active/Active failover, the interface policy settings defined for each failover group override the settings on this tab. If you disable Active/Active failover, then the settings on this tab are used.

Fields

- Interface Policy—Contains the fields for defining the policy for failover when monitoring detects an interface failure.
  - Number of failed interfaces that triggers failover—When the number of failed monitored interfaces exceeds the value you set with this command, then the ASA fails over. The range is between 1 and 250 failures.
  - Percentage of failed interfaces that triggers failover—When the number of failed monitored interfaces exceeds the percentage you set with this command, then the ASA fails over.
- Failover Poll Times—Contains the fields for defining how often hello messages are sent on the failover link, and, optionally, how long to wait before testing the peer for failure if no hello messages are received.
  - Unit Failover—The amount of time between hello messages among units. The range is between 1 and 15 seconds or between 200 and 999 milliseconds.
  - Unit Hold Time—Sets the time during which a unit must receive a hello message on the failover link, or else the unit begins the testing process for peer failure. The range is between 1and 45 seconds or between 800 and 999 milliseconds. You cannot enter a value that is less than 3 times the polltime.
  - Monitored Interfaces—The amount of time between polls among interfaces. The range is between 1and 15 seconds or 500 to 999 milliseconds.
  - Interface Hold Time—Sets the time during which a data interface must receive a hello message on the data interface, after which the peer is declared failed. Valid values are from 5 to 75 seconds.

Failover > Active/Active Tab

Use this tab to enable Active/Active failover on the ASA by defining failover groups. In an Active/Active failover configuration, both ASAs pass network traffic. Active/Active failover is only available to ASAs in multiple mode.

A failover group is simply a logical group of security contexts. You can create two failover groups on the ASA. You must create the failover groups on the active unit in the failover pair. The admin context is always a member of failover group 1. Any unassigned security contexts are also members of failover group 1 by default.

Note During a successful failover event on the ASA, the interfaces are brought down, roles are switched (IP addresses and MAC addresses are swapped), and the interfaces are brought up again. However, the process is transparent to users. The ASA does not send link-down messages or system log messages to notify users that interfaces were taken down during failover (or link-up messages for interfaces brought up by the failover process).

Note When configuring Active/Active failover, make sure that the combined traffic for both units is within the capacity of each unit.

Fields

- Failover Groups—Lists the failover groups currently defined on the ASA.
  - Group Number—Specifies the failover group number. This number is used when assigning contexts to failover groups.
  - Preferred Role—Specifies the unit in the failover pair, primary or secondary, on which the failover group appears in the active state when both units start up simultaneously or when the preempt option is specified. You can have both failover groups be in the active state on a single unit in the pair, with the other unit containing the failover groups in the standby state. However, a more typical configuration is to assign each failover group a different role preference to make each one active on a different unit, balancing the traffic across the devices.
  - Preempt Enabled—Specifies whether the unit that is the preferred failover device for this failover group should become the active unit after rebooting.
  - Preempt Delay—Specifies the number of seconds that the preferred failover device should wait after rebooting before taking over as the active unit for this failover group. The range is between 0 and 1200 seconds.
  - Interface Policy—Specifies either the number of monitored interface failures or the percentage of failures that are allowed before the group fails over. The range is between 1 and 250 failures or 1 and 100 percent.
  - Interface Poll Time—Specifies the amount of time between polls among interfaces. The range is between 1 and 15 seconds.
  - Replicate HTTP—Identifies whether Stateful Failover should copy active HTTP sessions to the standby firewall for this failover group. If you do not allow HTTP replication, then HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link. This setting overrides the HTTP replication setting on the Setup tab.
- Add—Displays the Add Failover Group dialog box. This button is only enabled if less than 2 failover groups exist. See Add/Edit Failover Group for more information.
- Edit—Displays the Edit Failover Group dialog box for the selected failover group. See Add/Edit Failover Group for more information.
- Delete—Removes the currently selected failover group from the failover groups table. This button is only enabled if the last failover group in the list is selected.

Add/Edit Failover Group

Use the Add/Edit Failover Group dialog box to define failover groups for an Active/Active failover configuration.

Fields

- Preferred Role—Specifies the unit in the failover pair, primary or secondary, on which the failover group appears in the active state. You can have both failover groups be in the active state on a single unit in the pair, with the other unit containing the failover groups in the standby state. However, a more typical configuration is to assign each failover group a different role preference to make each one active on a different unit, balancing the traffic across the devices.
- Preempt after booting with optional delay of—Checking this check box causes the unit that is the preferred failover device for a failover group to become the active unit after rebooting. Checking this check box also enables the Preempt after booting with optional delay of field in which you can specify a period of time that the device should wait before becoming the active unit.
- Preempt after booting with optional delay of—Specifies the number of seconds that a unit should wait after rebooting before taking over as the active unit for any failover groups for which it is the preferred failover device. The range is between 0 and 1200 seconds.
- Interface Policy—Contains the fields for defining the policy for failover when monitoring detects an interface failure. These settings override any interface policy settings on the Criteria tab.
  - Number of failed interfaces that triggers failover—When the number of failed monitored interfaces exceeds the value you set with this command, then the ASA fails over. The range is between 1 and 250 failures.
  - Percentage of failed interfaces that triggers failover—When the number of failed monitored interfaces exceeds the percentage you set with this command, then the ASA fails over.
- Poll time interval for monitored interfaces—The amount of time between polls among interfaces. The range is between 1 and 15 seconds.
- Enable HTTP replication—Checking this check box enables Stateful Failover to copy active HTTP sessions to the standby firewall. If you do not allow HTTP replication, then HTTP connections are disconnected at failover. Disabling HTTP replication reduces the amount of traffic on the state link. This setting overrides the HTTP replication setting on the Setup tab.
- MAC Addresses—Lists physical interfaces on the ASA for which an active and standby virtual MAC address has been configured.
  - Physical Interface—Displays the physical interface for which failover virtual MAC addresses are configured.
  - Active MAC Address—Displays the MAC address for the interface and failover group on the unit where the failover group is active.
  - Standby MAC Address—Displays the MAC address for the interface and failover group on the unit where the failover group is in the standby state.
- Add—Displays the Add Interface MAC Address dialog box. You cannot assign virtual MAC addresses to the LAN failover and Stateful Failover interfaces. See Add/Edit Interface MAC Address for more information.
- Edit—Displays the Edit Interface MAC Address dialog box for the selected interface. See Add/Edit Interface MAC Address for more information.
- Delete—Removes the currently selected interface from the MAC addresses table. There is no confirmation or undo.

Add/Edit Interface MAC Address

Use the Add/Edit Interface MAC Address dialog box to define the active and standby virtual MAC addresses for the interfaces in a failover group. If you do not specify a virtual MAC address for an interface, the interface is given a default virtual MAC address as follows:

- Active unit default MAC address: 00a0.c9*physical_port_number.failover_group_id*01.
- Standby unit default MAC address: 00a0.c9:*physical_port_number.failover_group_id*02.

Note If you have more than one Active/Active failover pair on the same network, it is possible to have the same default virtual MAC addresses assigned to the interfaces on one pair as are assigned to the interfaces of the other pairs because of the way the default virtual MAC addresses are determined. To avoid having duplicate MAC addresses on your network, make sure you assign each physical interface a virtual active and standby MAC address.

These MAC addresses override the physical MAC addresses for the interface.

Fields

- Physical Interface—Specifies the physical interface for which you are defining failover virtual MAC addresses. Because the MAC addresses do not change for the LAN failover and Stateful Failover interfaces during failover, you cannot choose these interfaces.
- MAC Addresses—Contains the fields for specifying the active and standby virtual MAC addresses for the interface.
  - Active Interface—Specifies the MAC address for the interface and failover group on the unit where the failover group is active. Each interface may have up to two MAC addresses, one for each failover group, which override the physical MAC address. Enter the MAC address in hexadecimal format (for example, 0123.4567.89AB).
  - Standby Interface—Specifies the MAC address for the interface and failover group on the unit where the failover group is in the standby state. Each interface may have up to two MAC addresses, one for each failover group, which override the physical MAC address. Enter the MAC address in hexadecimal format (for example, 0123.4567.89AB).

Failover > MAC Addresses Tab

The MAC Addresses tab lets you configure the virtual MAC addresses for the interfaces in an Active/Standby failover pair.

In Active/Standby failover, the MAC addresses for the primary unit are always associated with the active IP addresses. If the secondary unit boots first and becomes active, it uses the burned-in MAC address for its interfaces. When the primary unit comes online, the secondary unit obtains the MAC addresses from the primary unit. The change can disrupt network traffic.

You can configure virtual MAC addresses for each interface to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not specify virtual MAC addresses, then the failover pair uses the burned-in NIC address as the MAC address.

Note You cannot configure a virtual MAC address for the failover or state links. The MAC and IP addresses for those links do not change during failover.

In Active/Active failover, the MAC addresses configured on this tab are not in effect. Instead, the MAC addresses defined in the failover groups are used.

Fields

- MAC Addresses—Lists physical interfaces on the ASA for which an active and standby virtual MAC address has been configured.
  - Physical Interface—Identifies the physical interface for which failover virtual MAC addresses are configured.
  - Active MAC Address—Identifies the MAC address on the active ASA (usually primary).
  - Standby MAC Address—Identifies the MAC address on the standby ASA (usually secondary).
- Add—Displays the Add/Edit Interface MAC Address dialog box.
- Edit—Displays the Add/Edit Interface MAC Address dialog box for the selected interface.
- Delete—Removes the currently selected interface from the MAC addresses table. There is no confirmation or undo.

Add/Edit Interface MAC Address

Use the Add/Edit Interface MAC Address dialog box to define the active and standby virtual MAC addresses for an interface.

Fields

- Physical Interface—Specifies the physical interface for which you are defining failover virtual MAC addresses. Because the MAC addresses do not change for the LAN failover and Stateful Failover interfaces during failover, you cannot choose these interfaces.
- MAC Addresses—Contains the fields for specifying the active and standby virtual MAC addresses for the interface.
  - Active Interface—Specifies the MAC address of the interface on the active ASA (usually primary). Enter the MAC address in hexadecimal format (for example, 0123.4567.89AB).
  - Standby Interface—Specifies the MAC address of the interface on the standby ASA (usually secondary). Enter the MAC address in hexadecimal format (for example, 0123.4567.89AB).

Configuring Asymmetric Routing Groups in Multiple Context Mode

Note To configure asymmetric routing (ASR) groups, you must be in the admin context and it must be active.

To configure ASR groups, perform the following steps:

Step 1 Choose **Configuration > Device Management > Routing > ASR Groups**.

Step 2 Specify the ASR group IDs of the configured interfaces from the ASR Group ID drop-down list. The maximum number of groups that you can assign to one interface is eight. If other contexts have assigned interfaces, to a group, you may assign fewer groups to this context,

Step 3 Click **Apply** to save your changes to the running configuration.

Controlling Failover

This sections describes how to control and monitor failover. This section includes the following topics:

- Forcing Failover, page 13-21
- Disabling Failover, page 13-21
- Restoring a Failed Unit or Failover Group, page 13-22

Forcing Failover

To force failover at the unit level, follow these steps:

Step 1 Open **System > Monitoring > Failover > System**.

Step 2 Click one of the following buttons:

- Click **Make Active** to make the unit the active unit.
- Click **Make Standby** to make the other unit the active unit.

To force failover at the failover group level, follow these steps:

Step 1 Open **System > Monitoring > Failover > Failover Group #**, where # is the number of the failover group you want to control.

Step 2 Cick one of the following buttons:

- Click **Make Active** to make the the failover group active on the security appliance.
- Click **Make Standby** to make the failover group active on the other security appliance.

Disabling Failover

Disabling failover on an Active/Active failover pair causes the failover groups to remain in the active state on whichever unit they are active, no matter which unit they are configured to prefer. Enter the **no failover** command in the system execution space.

To disable failover, perform the following steps:

Step 1 Open the **System > Configuration> Device Setup > High Availability > Failover > Setup** tab.

Step 2 Clear the **Enable Failover** checkbox.

Restoring a Failed Unit or Failover Group

Restoring a failed unit or failover group moves the unit or failover group from the failed state to the standby state; it does not automatically make the failover group or unit active. Restored units or groups remain in the standby state until made active by failover (forced or natural). An exception is a failover group configured with failover preemption. If previously active, a failover group becomes active if it is configured with preemption and if the unit on which it failed is the preferred unit.

To restore a failed unit to an unfailed state, follow these steps:

Step 1 Open **System > Monitoring > Failover > System**.

Step 2 Click **Reset Failover**. Clicking this button on the active unit resets the standby unit.

To restore a failed failover group to an unfailed state, follow these steps:

Step 1 Open Open **System > Monitoring > Failover > Failover Group #**, where # is the number of the failover group you want to restore.

Step 2 Click **Reset Failover**.

Monitoring Active/Active Failover

Use the following screens in the Monitoring > Properties > Failover area to monitor Active/Active failover:

- System, page 13-22
- Failover Group 1 and Failover Group 2, page 13-23

System

The System pane displays the failover state of the system. You can also control the failover state of the system by:

- Toggling the active/standby state of the device.
- Resetting a failed device.
- Reloading the standby unit.

Fields

Failover state of the system—*Display only.* Displays the failover state of the ASA. The information shown is the same output you would receive from the **show failover** command. Refer to *Cisco ASA 5500 Series Command Reference* for more information about the displayed output.

The following actions are available on the System pane:

- Make Active—Click this button to make the ASA the active unit in an active/standby configuration. In an active/active configuration, clicking this button causes both failover groups to become active on the ASA.

- Make Standby—Click this button to make the ASA the standby unit in an active/standby pair. In an active/active configuration, clicking this button causes both failover groups to go to the standby state on the ASA.
- Reset Failover—Click this button to reset a system from the failed state to the standby state. You cannot reset a system to the active state. Clicking this button on the active unit resets the standby unit.
- Reload Standby—Click this button to force the standby unit to reload.
- Refresh—Click this button to refresh the status information in the Failover state of the system field.

Failover Group 1 and Failover Group 2

The Failover Group 1 and Failover Group 2 panes display the failover state of the selected group.You can also control the failover state of the group by toggling the active/standby state of the group or by resetting a failed group.

Fields

Failover state of Group[*x*]—*Display only*. Displays the failover state of the selected failover group. The information shown is the same as the output you would receive from the **show failover group** command.

You can perform the following actions from this pane:

- Make Active—Click this button to make the failover group active unit on the ASA.
- Make Standby—Click this button to force the failover group into the standby state on the ASA.
- Reset Failover—Click this button to reset a system from the failed state to the standby state. You cannot reset a system to the active state. Clicking this button on the active unit resets the standby unit.
- Refresh—Click this button to refresh the status information in the Failover state of the system field.

Feature History for Active/Active Failover

Table 13-3 lists the release history for this feature.

Table 13-3 Feature History for Active/Active Failover

Feature Name	Releases	Feature Information
Active/Active failover	7.0	In an Active/Active failover configuration, both ASAs can pass network traffic. We introduced this feature and the relevant commands.
IPv6 Support in failover	8.2(2)	We modified the following screens: Configuration > Device Managment > High Availability > Failover > Setup Configuration > Device Managment > High Availability > Failover > Interfaces

PART 2

Configuring Interfaces

Starting Interface Configuration (ASA 5510 and Higher)

This chapter includes tasks for starting your interface configuration for the ASA 5510 and higher, including configuring Ethernet settings, redundant interfaces, and EtherChannels.

Note This chapter only applies to the ASA 5500 series appliances; for the ASASM, starting interface configuration consists of configuring switch ports and VLANs on the switch, and then assigning VLANs to the ASASM according to Chapter 2, "Configuring the Switch for Use with the ASA Services Module." To complete your interface configuration, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

For ASA 5505 configuration, see Chapter 16, "Starting Interface Configuration (ASA 5505)."

For multiple context mode, complete all tasks in this section in the system execution space. If you are not already in the system execution space, in the Configuration > Device List pane, double-click **System** under the active device IP address.

For ASA cluster interfaces, which have special requirements, see Chapter 10, "Configuring a Cluster of ASAs."

This chapter includes the following sections:

- Information About Starting ASA 5510 and Higher Interface Configuration, page 15-2
- Licensing Requirements for ASA 5510 and Higher Interfaces, page 15-8
- Guidelines and Limitations, page 15-10
- Default Settings, page 15-12
- Starting Interface Configuration (ASA 5510 and Higher), page 15-12
- Monitoring Interfaces, page 15-37
- Where to Go Next, page 15-41
- Feature History for ASA 5510 and Higher Interfaces, page 15-41

Information About Starting ASA 5510 and Higher Interface Configuration

This section includes the following topics:

- Auto-MDI/MDIX Feature, page 15-2
- Interfaces in Transparent Mode, page 15-2
- Management Interface, page 15-2
- Redundant Interfaces, page 15-5
- EtherChannels, page 15-5

Auto-MDI/MDIX Feature

For RJ-45 interfaces on the ASA 5500 series, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Interfaces in Transparent Mode

Interfaces in transparent mode belong to a "bridge group," one bridge group for each network. You can have up to eight bridge groups of four interfaces each per context or in single mode. For more information about bridge groups, see the "Bridge Groups in Transparent Mode" section on page 18-2.

Management Interface

- Management Interface Overview, page 15-2
- Management Slot/Port Interface, page 15-3
- Using Any Interface for Management-Only Traffic, page 15-3
- Management Interface for Transparent Mode, page 15-4
- No Support for Redundant Management Interfaces, page 15-4
- Management 0/0 Interface on the ASA 5512-X through ASA 5555-X, page 15-4

Management Interface Overview

You can manage the ASA by connecting to:

- Any through-traffic interface
- A dedicated Management *Slot*/*Port* interface (if available for your model)

You may need to configure management access to the interface according to Chapter 52, "Configuring Management Access."

Management *Slot/Port* Interface

Table 15-1 shows the Management interfaces per model.-

Table 15-1 Management Interfaces Per Model

Model	Configurable for Through Traffic[1]	Management 0/0[2]	Management 0/1	Management 1/0	Management 1/1
ASA 5505	N/A	No	No	No	No
ASA 5510	**Yes**	**Yes**	No	No	No
ASA 5520	**Yes**	**Yes**	No	No	No
ASA 5540	**Yes**	**Yes**	No	No	No
ASA 5550	**Yes**	**Yes**	No	No	No
ASA 5580	**Yes**	**Yes**	**Yes**	No	No
ASA 5512-X	No	**Yes**	No	No	No
ASA 5515-X	No	**Yes**	No	No	No
ASA 5525-X	No	**Yes**	No	No	No
ASA 5545-X	No	**Yes**	No	No	No
ASA 5555-X	No	**Yes**	No	No	No
ASA 5585-X	**Yes**	**Yes**	**Yes**	**Yes**[3]	**Yes**[3]
ASASM	N/A	No	No	No	No

1. By default, the Management 0/0 interface is configured for management-only traffic. For supported models in routed mode, you can remove the limitation and pass through traffic. If your model includes additional Management interfaces, you can use them for through traffic as well. The Management interfaces might not be optimized for through-traffic, however.
2. The Management 0/0 interface is configured for ASDM access as part of the default factory configuration. See the "Factory Default Configurations" section on page 3-17 for more information.
3. If you installed an SSP in slot 1, then Management 1/0 and 1/1 provide management access to the SSP in slot 1 only.

Note If you installed an IPS module, then the IPS module management interface(s) provides management access for the IPS module only. For the ASA 5512-X through ASA 5555-X, the IPS SSP software module uses the same physical Management 0/0 interface as the ASA.

Using Any Interface for Management-Only Traffic

You can use any interface as a dedicated management-only interface by configuring it for management traffic, including an EtherChannel interface.

Management Interface for Transparent Mode

In transparent firewall mode, in addition to the maximum allowed through-traffic interfaces, you can also use the Management interface (either the physical interface, a subinterface (if supported for your model), or an EtherChannel interface comprised of Management interfaces (if you have multiple Management interfaces)) as a separate management interface. You cannot use any other interface types as management interfaces.

If your model does not include a Management interface, you must manage the transparent firewall from a data interface.

In multiple context mode, you cannot share any interfaces, including the Management interface, across contexts. To provide management per context, you can create subinterfaces of the Management interface and allocate a Management subinterface to each context. Note that the ASA 5512-X through ASA 5555-X do not allow subinterfaces on the Management interface, so for per-context management, you must connect to a data interface.

For 8.4(1) and later, the management interface is not part of a normal bridge group. Note that for operational purposes, it is part of a non-configurable bridge group.

Note In transparent firewall mode, the management interface updates the MAC address table in the same manner as a data interface; therefore you should not connect both a management and a data interface to the same switch unless you configure one of the switch ports as a routed port (by default Cisco Catalyst switches share a MAC address for all VLAN switch ports). Otherwise, if traffic arrives on the management interface from the physically-connected switch, then the ASA updates the MAC address table to use the *management* interface to access the switch, instead of the data interface. This action causes a temporary traffic interruption; the ASA will not re-update the MAC address table for packets from the switch to the data interface for at least 30 seconds for security reasons.

No Support for Redundant Management Interfaces

Redundant interfaces do not support Management *slot*/*port* interfaces as members. You also cannot set a redundant interface comprised of non-Management interfaces as management-only.

Management 0/0 Interface on the ASA 5512-X through ASA 5555-X

The Management 0/0 interface on the ASA 5512-X through ASA 5555-X has the following characteristics:

- No through traffic support
- No subinterface support
- No priority queue support
- No multicast MAC support
- The IPS SSP software module shares the Management 0/0 interface. Separate MAC addresses and IP addresses are supported for the ASA and IPS module. You must perform configuration of the IPS IP address within the IPS operating system. However, physical characteristics (such as enabling the interface) are configured on the ASA.

Redundant Interfaces

A logical redundant interface consists of a pair of physical interfaces: an active and a standby interface. When the active interface fails, the standby interface becomes active and starts passing traffic. You can configure a redundant interface to increase the ASA reliability. This feature is separate from device-level failover, but you can configure redundant interfaces as well as device-level failover if desired.

Redundant Interface MAC Address

The redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. Alternatively, you can assign a MAC address to the redundant interface, which is used regardless of the member interface MAC addresses (see the "Configuring the MAC Address and MTU" section on page 17-13 or the "Configuring Multiple Contexts" section on page 9-15). When the active interface fails over to the standby, the same MAC address is maintained so that traffic is not disrupted.

EtherChannels

An 802.3ad EtherChannel is a logical interface (called a port-channel interface) consisting of a bundle of individual Ethernet links (a channel group) so that you increase the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels.

This section includes the following topics:

- Channel Group Interfaces, page 15-5
- Connecting to an EtherChannel on Another Device, page 15-5
- Link Aggregation Control Protocol, page 15-6
- Load Balancing, page 15-7
- EtherChannel MAC Address, page 15-8

Channel Group Interfaces

Each channel group can have eight active interfaces. Note that you can assign up to 16 interfaces to a channel group. While only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

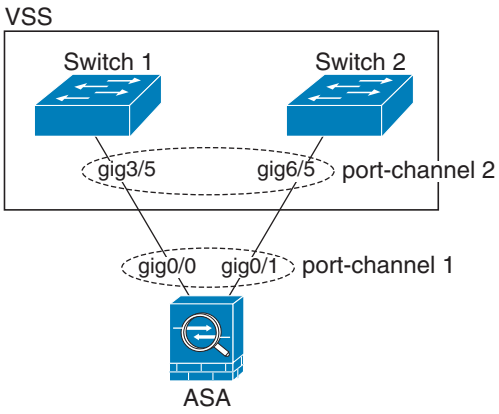
The EtherChannel aggregates the traffic across all the available active interfaces in the channel. The port is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and vlan numbers.

Connecting to an EtherChannel on Another Device

The device to which you connect the ASA EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch.

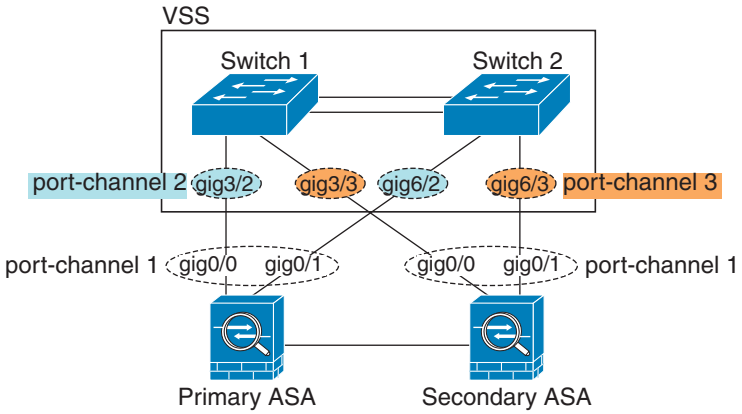
When the switch is part of a Virtual Switching System (VSS), then you can connect ASA interfaces within the same EtherChannel to separate switches in the VSS. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch (see Figure 15-1).

Figure 15-1 Connecting to a VSS



If you use the ASA in an Active/Standby failover deployment, then you need to create separate EtherChannels on the switches in the VSS, one for each ASA (see Figure 15-1). On each ASA, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both ASAs (in this case, the EtherChannel will not be established because of the separate ASA system IDs), a single EtherChannel would not be desirable because you do not want traffic sent to the standby ASA.

Figure 15-2 Active/Standby Failover and VSS



Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

Load Balancing

The ASA distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable; see the "Customizing the EtherChannel" section on page 15-31). The hash result is a 3-bit value (0 to 7).

The eight hash result values are distributed in a round robin fashion between the channel group interfaces, starting with the interface with the lowest ID (slot/port). For example, all packets with a hash result of 0 go to GigabitEthernet 0/0, packets with a hash result of 1 go to GigabitEthernet 0/1, packets with a hash result of 2 go to GigabitEthernet 0/2, and so on.

Because there are eight hash result values regardless of how many active interfaces are in the EtherChannel, packets might not be distributed evenly depending on the number of active interfaces.

Table 15-2 shows the load balancing amounts per interface for each number of active interfaces. The active interfaces in **bold** have even distribution.

Table 15-2 Load Distribution per Interface

# of Active Interfaces	% Distribution Per Interface							
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**
1	**100%**	—	—	—	—	—	—	—
2	**50%**	**50%**	—	—	—	—	—	—
3	37.5%	37.5%	25%	—	—	—	—	—
4	**25%**	**25%**	**25%**	**25%**	—	—	—	—
5	25%	25%	25%	12.5%	12.5%	—	—	—
6	25%	25%	12.5%	12.5%	12.5%	12.5%	—	—
7	25%	12.5%	12.5%	12.5%	12.5%	12.5%	12.5%	—
8	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

EtherChannel MAC Address

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

The port-channel interface uses the lowest numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can manually configure a MAC address for the port-channel interface. In multiple context mode, you can automatically assign unique MAC addresses to interfaces, including an EtherChannel port interface. We recommend manually, or in multiple context mode, automatically configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.

Licensing Requirements for ASA 5510 and Higher Interfaces

Model	License Requirement
ASA 5510	VLANs: Base License: 50 Security Plus License: 100 Interface Speed: Base License—All interfaces Fast Ethernet. Security Plus License—Ethernet 0/0 and 0/1: Gigabit Ethernet; all others Fast Ethernet. Interfaces of all types[1]: Base License: 52 Security Plus License: 120
ASA 5520	VLANs: Base License: 150. Interfaces of all types[1]: Base License: 640
ASA 5540	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 840
ASA 5550	VLANs: Base License: 400 Interfaces of all types[1]: Base License: 1640

Model	License Requirement
ASA 5580	VLANs: Base License: 1024 Interfaces of all types[1]: Base License: 4176
ASA 5512-X	VLANs: Base License: 50 Interfaces of all types[1]: Base License: 328
ASA 5515-X	VLANs: Base License: 100 Interfaces of all types[1]: Base License: 528
ASA 5525-X	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 928
ASA 5545-X	VLANs: Base License: 300 Interfaces of all types[1]: Base License: 1328

Interfaces of all types[1]: Base License: 4176

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, bridge group, and EtherChannel interfaces.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

In multiple context mode, configure the physical interfaces in the system execution space according to the "Starting Interface Configuration (ASA 5510 and Higher)" section on page 15-12. Then, configure the logical interface parameters in the context execution space according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Firewall Mode Guidelines

- For transparent mode, you can configure up to eight bridge groups per context or for a single mode device.
- Each bridge group can include up to four interfaces.
- For multiple context, transparent mode, each context must use different interfaces; you cannot share an interface across contexts.

Failover Guidelines

- When you use a redundant or EtherChannel interface as a failover link, it must be pre-configured on both units in the failover pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because *the failover link itself is required for replication*.
- If you use a redundant or EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal.
- You can monitor redundant or EtherChannel interfaces for failover. When an active member interface fails over to a standby interface, this activity does not cause the redundant or EtherChannel interface to appear to be failed when being monitored for device-level failover. Only when all physical interfaces fail does the redundant or EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable).
- If you use an EtherChannel interface for a failover or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link. To alter the configuration, you need to either shut down the EtherChannel while you make changes, or temporarily disable failover; either action prevents failover from occurring for the duration.
- Although you can configure the failover and failover state links on a port channel link, this port channel cannot be shared with other firewall traffic.

Clustering Guidelines

- When you use a redundant or EtherChannel interface as the cluster control link, it must be pre-configured on all units in the cluster; you cannot configure it on the primary unit and expect it to replicate to member units because *the cluster control link itself is required for replication*.
- To configure a spanned EtherChannel, see the "Configuring Spanned EtherChannels" section on page 10-37.
- To configure an individual cluster interface, see the "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32.

Redundant Interface Guidelines

- You can configure up to 8 redundant interface pairs.
- All ASA configuration refers to the logical redundant interface instead of the member physical interfaces.
- You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the ASA if they do not use the same physical interfaces.
- If you shut down the active interface, then the standby interface becomes active.
- Redundant interfaces do not support Management *slot*/*port* interfaces as members. You also cannot set a redundant interface comprised of non-Management interfaces as management-only.
- For failover guidelines, see the "Failover Guidelines" section on page 15-10.
- For clustering guidelines, see the "Clustering Guidelines" section on page 15-10.

EtherChannel Guidelines

- You can configure up to 48 EtherChannels.
- Each channel group can have eight active interfaces. Note that you can assign up to 16 interfaces to a channel group. While only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.
- The device to which you connect the ASA EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch.
- The ASA does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the ASA will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch. In multiple context mode, these messages are not included in a packet capture, so you cannot diagnose the issue effectively.
- The ASA does not support connecting an EtherChannel to a switch stack. If the ASA EtherChannel is connected cross stack, and if the Master switch is powered down, then the EtherChannel connected to the remaining switch will not come up.
- All ASA configuration refers to the logical EtherChannel interface instead of the member physical interfaces.
- You cannot use a redundant interface as part of an EtherChannel, nor can you use an EtherChannel as part of a redundant interface. You cannot use the same physical interfaces in a redundant interface and an EtherChannel interface. You can, however, configure both types on the ASA if they do not use the same physical interfaces.
- You cannot use interfaces on the 4GE SSM, including the integrated 4GE SSM in slot 1 on the ASA 5550, as part of an EtherChannel.
- For failover guidelines, see the "Failover Guidelines" section on page 15-10.
- For clustering guidelines, see the "Clustering Guidelines" section on page 15-10.

Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the "Factory Default Configurations" section on page 3-17.

Default State of Interfaces

The default state of an interface depends on the type and the context mode.

In multiple context mode, all allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.

In single mode or in the system execution space, interfaces have the following default states:

- Physical interfaces—Disabled.
- Redundant Interfaces—Enabled. However, for traffic to pass through the redundant interface, the member physical interfaces must also be enabled.
- Subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.

Default Speed and Duplex

- By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.
- The fiber interface for the ASA 5550 (slot 1) and the 4GE SSM has a fixed speed and does not support duplex, but you can set the interface to negotiate link parameters (the default) or not to negotiate.
- For fiber interfaces for the ASA 5580 and 5585-X, the speed is set for automatic link negotiation.

Default Connector Type

The ASA 5550 (slot 1) and the 4GE SSM for the ASA 5510 and higher ASA include two connector types: copper RJ-45 and fiber SFP. RJ-45 is the default. You can configure the ASA to use the fiber SFP connectors.

Default MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

Starting Interface Configuration (ASA 5510 and Higher)

This section includes the following topics:

- Task Flow for Starting Interface Configuration, page 15-13
- Converting In-Use Interfaces to a Redundant or EtherChannel Interface, page 15-14
- Enabling the Physical Interface and Configuring Ethernet Parameters, page 15-23
- Configuring a Redundant Interface, page 15-25

- Configuring an EtherChannel, page 15-28
- Configuring VLAN Subinterfaces and 802.1Q Trunking, page 15-34
- Enabling Jumbo Frame Support (Supported Models), page 15-37

Task Flow for Starting Interface Configuration

Note If you have an existing configuration, and want to convert interfaces that are in use to a redundant or EtherChannel interface, perform your configuration offline using the CLI to minimize disruption. See the "Converting In-Use Interfaces to a Redundant or EtherChannel Interface" section on page 15-14.

To start configuring interfaces, perform the following steps:

Step 1 (Multiple context mode) Complete all tasks in this section in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

Step 2 Enable the physical interface, and optionally change Ethernet parameters. See the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Physical interfaces are disabled by default.

Step 3 (Optional) Configure redundant interface pairs. See the "Configuring a Redundant Interface" section on page 15-25.

A logical redundant interface pairs an active and a standby physical interface. When the active interface fails, the standby interface becomes active and starts passing traffic.

Step 4 (Optional) Configure an EtherChannel. See the "Configuring an EtherChannel" section on page 15-28.

An EtherChannel groups multiple Ethernet interfaces into a single logical interface.

Note You cannot use interfaces on the 4GE SSM, including the integrated 4GE SSM in slot 1 on the ASA 5550, as part of an EtherChannel.

Step 5 (Optional) Configure VLAN subinterfaces. See the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.

Step 6 (Optional) Enable jumbo frame support on the ASA 5580 and 5585-X according to the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

Step 7 (Multiple context mode only) To complete the configuration of interfaces in the system execution space, perform the following tasks that are documented in Chapter 9, "Configuring Multiple Context Mode":

- To assign interfaces to contexts, see the "Configuring a Security Context" section on page 9-20.
- (Optional) To automatically assign unique MAC addresses to context interfaces, see the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24.

The MAC address is used to classify packets within a context. If you share an interface, but do not have unique MAC addresses for the interface in each context, then the destination IP address is used to classify packets. Alternatively, you can manually assign MAC addresses within the context according to the "Configuring the MAC Address and MTU" section on page 17-13.

Step 8 Complete the interface configuration according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Converting In-Use Interfaces to a Redundant or EtherChannel Interface

If you have an existing configuration and want to take advantage of the redundant or EtherChannel interface feature for interfaces that are currently in use, you will have some amount of downtime when you convert to the logical interfaces.

This section provides an overview of how to convert your existing interfaces to a redundant or EtherChannel interface with minimal downtime. See the "Configuring a Redundant Interface" section on page 15-25 and the "Configuring an EtherChannel" section on page 15-28 fore more information.

- Detailed Steps (Single Mode), page 15-14
- Detailed Steps (Multiple Mode), page 15-19

Detailed Steps (Single Mode)

We recommend that you update your configuration offline as a text file, and reimport the whole configuration for the following reasons:

- Because you cannot add a named interface as a member of a redundant or EtherChannel interface, you must remove the name from the interface. When you remove the name from the interface, any command that referred to that name is deleted. Because commands that refer to interface names are widespread throughout the configuration and affect multiple features, removing a name from an in-use interface at the CLI or in ASDM would cause significant damage to your configuration, not to mention significant downtime while you reconfigure all your features around a new interface name.
- Changing your configuration offline lets you use the same interface names for your new logical interfaces, so you do not need to touch the feature configurations that refer to interface names. You only need to change the interface configuration.
- Clearing the running configuration and immediately applying a new configuration will minimize the downtime of your interfaces. You will not be waiting to configure the interfaces in real time.

Step 1 Connect to the ASA; if you are using failover, connect to the active ASA.

Step 2 If you are using failover, disable failover by choosing **Configuration > Device Management > High Availability > Failover** and unchecking the **Enable failover** check box. Click **Apply**, and continue at the warning.

Step 3 Copy the running configuration by choosing **Tools > Backup Configurations** and backing up the running configuration to your local computer. You can then expand the zip file and edit the running-config.cfg file with a text editor.

Be sure to save an extra copy of the old configuration in case you make an error when you edit it.

Step 4 For each in-use interface that you want to add to a redundant or EtherChannel interface, cut and paste all commands under the **interface** command to the end of the interface configuration section for use in creating your new logical interfaces. The only exceptions are the following commands, which should stay with the physical interface configuration:

- **media-type**

- **speed**
- **duplex**
- flowcontrol

Note You can only add *physical* interfaces to an EtherChannel or redundant interface; you cannot have VLANs configured for the physical interfaces.

Be sure to match the above values for all interfaces in a given EtherChannel or redundant interface. Note that the duplex setting for an EtherChannel interface must be Full or Auto.

For example, you have the following interface configuration. The bolded commands are the ones we want to use with three new EtherChannel interfaces, and that you should cut and paste to the end of the interface section.

```
interface GigabitEthernet0/0
 nameif outside
 security-level 0
 ip address 10.86.194.225 255.255.255.0
 no shutdown
!
interface GigabitEthernet0/1
 nameif inside
 security-level 100
 ip address 192.168.1.3 255.255.255.0
 no shutdown
!
interface GigabitEthernet0/2
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/3
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/4
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/5
 shutdown
 no nameif
 no security-level
 no ip address
!
interface Management0/0
 nameif mgmt
 security-level 100
 ip address 10.1.1.5 255.255.255.0
 no shutdown
!
interface Management0/1
 shutdown
 no nameif
```

```
 no security-level
 no ip address
```

Step 5 Above each pasted command section, create your new logical interfaces by entering one of the following commands:

- **interface redundant** *number* [1-8]
- **interface port-channel** *channel_id* [1-48]

For example:

```
...

interface port-channel 1
 nameif outside
 security-level 0
 ip address 10.86.194.225 255.255.255.0
 no shutdown
!
interface port-channel 2
 nameif inside
 security-level 100
 ip address 192.168.1.3 255.255.255.0
 no shutdown
!
interface port-channel 3
 nameif mgmt
 security-level 100
 ip address 10.1.1.5 255.255.255.0
 no shutdown
```

Step 6 Assign the physical interfaces to the new logical interfaces:

- Redundant interface—Enter the following commands under the new **interface redundant** command:

  member-interface *physical_interface1*
  member-interface *physical_interface2*

  Where the physical interfaces are any two interfaces of the same type (either formerly in use or unused). You cannot assign a Management interface to a redundant interface.

  For example, to take advantage of existing cabling, you would continue to use the formerly in-use interfaces in their old roles as part of the inside and outside redundant interfaces:

  ```
  interface redundant 1
   nameif outside
   security-level 0
   ip address 10.86.194.225 255.255.255.0
   member-interface GigabitEthernet0/0
   member-interface GigabitEthernet0/2

  interface redundant 2
   nameif inside
   security-level 100
   ip address 192.168.1.3 255.255.255.0
   member-interface GigabitEthernet0/1
   member-interface GigabitEthernet0/3
  ```

- EtherChannel interface—Enter the following command under each interface you want to add to the EtherChannel (either formerly in use or unused). You can assign up to 16 interfaces per EtherChannel, although only eight can be active; the others are in a standby state in case of failure.

  channel-group *channel_id* **mode active**

For example, to take advantage of existing cabling, you would continue to use the formerly in-use interfaces in their old roles as part of the inside and outside EtherChannel interfaces:

```
interface GigabitEthernet0/0
 channel-group 1 mode active
 no shutdown
!
interface GigabitEthernet0/1
 channel-group 2 mode active
 no shutdown
!
interface GigabitEthernet0/2
 channel-group 1 mode active
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/3
 channel-group 1 mode active
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/4
 channel-group 2 mode active
 shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/5
 channel-group 2 mode active
 shutdown
 no nameif
 no security-level
 no ip address
!
interface Management0/0
 channel-group 3 mode active
 no shutdown
!
interface Management0/1
 channel-group 3 mode active
 shutdown
 no nameif
 no security-level
 no ip address

...
```

Step 7 Enable each formerly unused interface that is now part of a logical interface by adding **no** in front of the **shutdown** command.

For example, your final EtherChannel configuration is:

```
interface GigabitEthernet0/0
 channel-group 1 mode active
 no shutdown
!
interface GigabitEthernet0/1
 channel-group 2 mode active
```

```
 no shutdown
!
interface GigabitEthernet0/2
 channel-group 1 mode active
 no shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/3
 channel-group 1 mode active
 no shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/4
 channel-group 2 mode active
 no shutdown
 no nameif
 no security-level
 no ip address
!
interface GigabitEthernet0/5
 channel-group 2 mode active
 no shutdown
 no nameif
 no security-level
 no ip address
!
interface Management0/0
 channel-group 3 mode active
 no shutdown
!
interface Management0/1
 channel-group 3 mode active
 no shutdown
 no nameif
 no security-level
 no ip address
!
interface port-channel 1
 nameif outside
 security-level 0
 ip address 10.86.194.225 255.255.255.0
!
interface port-channel 2
 nameif inside
 security-level 100
 ip address 192.168.1.3 255.255.255.0
!
interface port-channel 3
 nameif mgmt
 security-level 100
 ip address 10.1.1.5 255.255.255.0
```

Note Other optional EtherChannel parameters can be configured after you import the new configuration. See the "Configuring an EtherChannel" section on page 15-28.

Step 8 Save the entire new configuration, including the altered interface section.

Step 9 Re-zip the backup folder with the altered configuration.

Step 10 Choose **Tools > Restore Configurations**, and choose the altered configuration zip file. Be sure to replace the existing running configuration; do not merge them. See the "Restoring Configurations" section on page 101-25 for more information.

Step 11 Reenable failover by choosing **Configuration > Device Management > High Availability > Failover**, and checking the **Enable failover** check box. Click **Apply**, and click **No** when prompted if you want to configure basic failover settings.

Detailed Steps (Multiple Mode)

We recommend that you update your system and context configurations offline as text files, and reimport them for the following reasons:

- Because you cannot add an allocated interface as a member of a redundant or EtherChannel interface, you must deallocate the interface from any contexts. When you deallocate the interface, any context command that referred to that interface is deleted. Because commands that refer to interfaces are widespread throughout the configuration and affect multiple features, removing an allocation from an in-use interface at the CLI or in ASDM would cause significant damage to your configuration, not to mention significant downtime while you reconfigure all your features around a new interface.
- Changing your configuration offline lets you use the same interface names for your new logical interfaces, so you do not need to touch the feature configurations that refer to interface names. You only need to change the interface configuration.
- Clearing the running system configuration and immediately applying a new configuration will minimize the downtime of your interfaces. You will not be waiting to configure the interfaces in real time.

Step 1 Connect to the ASA, and change to the system; if you are using failover, connect to the active ASA.

Step 2 If you are using failover, disable failover by choosing **Configuration > Device Management > High Availability > Failover** and unchecking the **Enable failover** check box. Click **Apply**, and continue at the warning.

Step 3 In the system, copy the running configuration by choosing **File > Show Running Configuration in New Window** and copying the display output to a text editor.

Be sure to save an extra copy of the old configuration in case you make an error when you edit it.

For example, you have the following interface configuration and allocation in the system configuration, with shared interfaces between two contexts.

System

```
interface GigabitEthernet0/0
    no shutdown
interface GigabitEthernet0/1
    no shutdown
interface GigabitEthernet0/2
    shutdown
interface GigabitEthernet0/3
    shutdown
interface GigabitEthernet0/4
    shutdown
interface GigabitEthernet0/5
    shutdown
```

```
interface Management0/0
    no shutdown
interface Management1/0
    shutdown
!
context customerA
    allocate-interface gigabitethernet0/0 int1
    allocate-interface gigabitethernet0/1 int2
    allocate-interface management0/0 mgmt
context customerB
    allocate-interface gigabitethernet0/0
    allocate-interface gigabitethernet0/1
    allocate-interface management0/0
```

Step 4 Get copies of *all* context configurations that will use the new EtherChannel or redundant interface.See the "Backing Up and Restoring Configurations or Other Files" section on page 101-20.

For example, you download the following context configurations (interface configuration shown):

CustomerA Context

```
interface int1
 nameif outside
 security-level 0
 ip address 10.86.194.225 255.255.255.0
!
interface int2
 nameif inside
 security-level 100
 ip address 192.168.1.3 255.255.255.0
 no shutdown
!
interface mgmt
 nameif mgmt
 security-level 100
 ip address 10.1.1.5 255.255.255.0
 management-only
```

CustomerB Context

```
interface GigabitEthernet0/0
 nameif outside
 security-level 0
 ip address 10.20.15.5 255.255.255.0
!
interface GigabitEthernet0/1
 nameif inside
 security-level 100
 ip address 192.168.6.78 255.255.255.0
!
interface Management0/0
 nameif mgmt
 security-level 100
 ip address 10.8.1.8 255.255.255.0
 management-only
```

Step 5 In the system configuration, create the new logical interfaces according to the "Configuring a Redundant Interface" section on page 15-25 or the "Configuring an EtherChannel" section on page 15-28. Be sure to enter the **no shutdown** command on any additional physical interfaces you want to use as part of the logical interface.

Note You can only add *physical* interfaces to an EtherChannel or redundant interface; you cannot have VLANs configured for the physical interfaces.

Be sure to match physical interface parameters such as speed and duplex for all interfaces in a given EtherChannel or redundant interface. Note that the duplex setting for an EtherChannel interface must be Full or Auto.

For example, the new configuration is:

System

```
interface GigabitEthernet0/0
 channel-group 1 mode active
 no shutdown
!
interface GigabitEthernet0/1
 channel-group 2 mode active
 no shutdown
!
interface GigabitEthernet0/2
 channel-group 1 mode active
 no shutdown
!
interface GigabitEthernet0/3
 channel-group 1 mode active
 no shutdown
!
interface GigabitEthernet0/4
 channel-group 2 mode active
 no shutdown
!
interface GigabitEthernet0/5
 channel-group 2 mode active
 no shutdown
!
interface Management0/0
 channel-group 3 mode active
 no shutdown
!
interface Management0/1
 channel-group 3 mode active
 no shutdown
!
interface port-channel 1
interface port-channel 2
interface port-channel 3
```

Step 6 Change the interface allocation per context to use the new EtherChannel or redundant interfaces. See the "Configuring a Security Context" section on page 9-20.

For example, to take advantage of existing cabling, you would continue to use the formerly in-use interfaces in their old roles as part of the inside and outside redundant interfaces:

```
context customerA
    allocate-interface port-channel1 int1
    allocate-interface port-channel2 int2
    allocate-interface port-channel3 mgmt
context customerB
    allocate-interface port-channel1
    allocate-interface port-channel2
```

```
allocate-interface port-channel3
```

Note You might want to take this opportunity to assign mapped names to interfaces if you have not done so already. For example, the configuration for customerA does not need to be altered at all; it just needs to be reapplied on the ASA. The customerB configuration, however, needs to have all of the interface IDs changed; if you assign mapped names for customerB, you still have to change the interface IDs in the context configuration, but mapped names might help future interface changes.

Step 7 For contexts that do not use mapped names, change the context configuration to use the new EtherChannel or redundant interface ID. (Contexts that use mapped interface names do not require any alteration.)

For example:

CustomerB Context

```
interface port-channel1
 nameif outside
 security-level 0
 ip address 10.20.15.5 255.255.255.0
!
interface port-channel2
 nameif inside
 security-level 100
 ip address 192.168.6.78 255.255.255.0
!
interface port-channel3
 nameif mgmt
 security-level 100
 ip address 10.8.1.8 255.255.255.0
 management-only
```

Step 8 Copy the new context configuration files over the old ones. For example, for contexts in flash memory, in the system choose **Tools > File Management**, then choose **File Transfer > Between Local PC and Flash**. This tool lets you choose each configuration file and copy it to your local computer. This change only affects the startup configuration; the running configuration is still using the old context configuration.

Step 9 Copy the entire new system configuration to the clipboard, including the altered interface section.

Step 10 In ASDM, choose **Tools > Command Line Interface**, and click the **Multiple Line** radio button.

Step 11 Enter **clear configure all** as the first line, paste the new configuration after it, and click **Send**. The **clear** command clears the running configuration (both system and contexts), before applying the new configuration.

Traffic through the ASA stops at this point. All of the new context configurations now reload. When they are finished reloading, traffic through the ASA resumes.

Step 12 Close the Command Line Interface dialog box, and choose **File > Refresh ASDM with the Running Configuration**.

Step 13 Reenable failover by choosing **Configuration > Device Management > High Availability > Failover**, and checking the **Enable failover** check box. Click **Apply**, and click **No** when prompted if you want to configure basic failover settings.

Enabling the Physical Interface and Configuring Ethernet Parameters

This section describes how to:

- Enable the physical interface
- Set a specific speed and duplex (if available)
- Enable pause frames for flow control

Prerequisites

For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

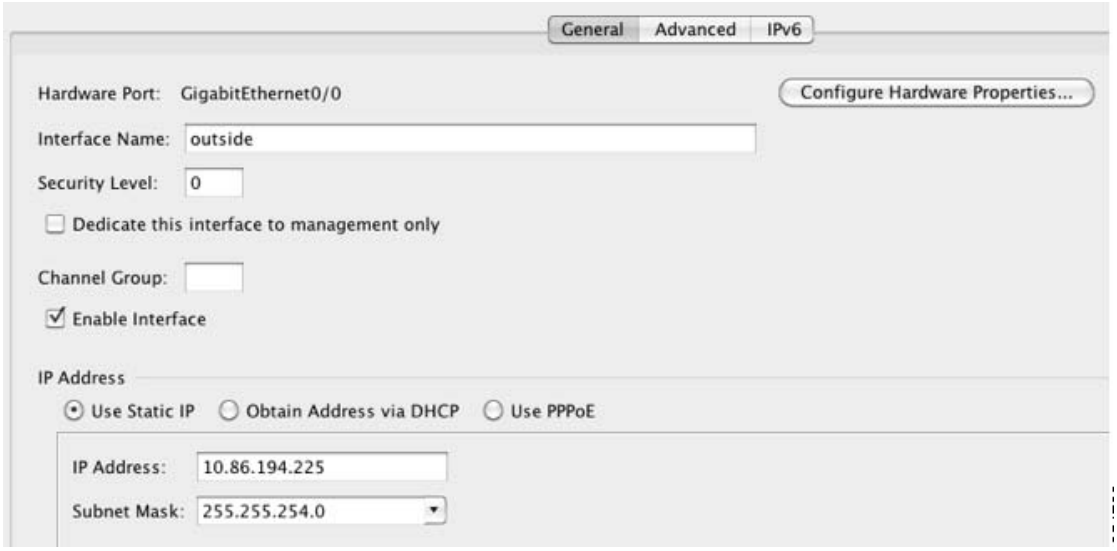
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

By default, all physical interfaces are listed.

Step 2 Click a physical interface that you want to configure, and click **Edit**.

The Edit Interface dialog box appears.



Note In single mode, this procedure only covers a subset of the parameters on the Edit Interface dialog box; to configure other parameters, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)." Note that in multiple context mode, before you complete your interface configuration, you need to allocate interfaces to contexts. See the "Configuring Multiple Contexts" section on page 9-15.

Step 3 To enable the interface, check the **Enable Interface** check box.

Step 4 To add a description, enter text in the Description field.

The description can be up to 240 characters on a single line, without carriage returns. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Step 5 (Optional) To set the media type, duplex, speed, and enable pause frames for flow control, click **Configure Hardware Properties**.

a. For slot 1 on the ASA 5550 ASA or the 4GE SSM, you can choose either **RJ-45** or **SFP** from the Media Type drop-down list.

RJ-45 is the default.

b. To set the duplex for RJ-45 interfaces, choose **Full**, **Half**, or **Auto**, depending on the interface type, from the Duplex drop-down list.

Note The duplex setting for an EtherChannel interface must be Full or Auto.

c. To set the speed, choose a value from the Speed drop-down list.

The speeds available depend on the interface type. For SFP interfaces, you can set the speed to Negotiate or Nonegotiate. Negotiate (the default) enables link negotiation, which exchanges flow-control parameters and remote fault information. Nonegotiate does not negotiate link parameters. For RJ-45 interfaces on the ASA 5500 series ASA, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. See the "Auto-MDI/MDIX Feature" section on page 15-2.

d. To enable pause (XOFF) frames for flow control on 1-Gigabit and 10-Gigabit Ethernet interfaces, check the **Enable Pause Frame** check box.

If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. Pause (XOFF) and XON frames are generated automatically by the NIC hardware based on the FIFO buffer usage. A pause frame is sent when the buffer usage exceeds the high-water mark. The default *high_water* value is 128 KB (10 GigabitEthernet) and 24 KB (1 GigabitEthernet); you can set it between 0 and 511 (10 GigabitEthernet) or 0 and 47 KB (1 GigabitEthernet). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark. By default, the *low_water* value is 64 KB (10 GigabitEthernet) and 16 KB (1 GigabitEthernet); you can set it between 0 and 511 (10 GigabitEthernet) or 0 and

47 KB (1 GigabitEthernet). The link partner can resume traffic after receiving an XON, or after the XOFF expires, as controlled by the timer value in the pause frame. The default *pause_time* value is 26624; you can set it between 0 and 65535. If the buffer usage is consistently above the high-water mark, pause frames are sent repeatedly, controlled by the pause refresh threshold value.

To change the default values for the Low Watermark, High Watermark, and Pause Time, uncheck the **Use Default Values** check box.

Note Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

e. Click **OK** to accept the Hardware Properties changes.

Step 6 Click **OK** to accept the Interface changes.

What to Do Next

Optional Tasks:

- Configure redundant interface pairs. See the "Configuring a Redundant Interface" section on page 15-25.
- Configure an EtherChannel. See the "Configuring an EtherChannel" section on page 15-28.
- Configure VLAN subinterfaces. See the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the "Configuring Multiple Contexts" section on page 9-15.
- For single context mode, complete the interface configuration. See Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Configuring a Redundant Interface

A logical redundant interface consists of a pair of physical interfaces: an active and a standby interface. When the active interface fails, the standby interface becomes active and starts passing traffic. You can configure a redundant interface to increase the ASA reliability. This feature is separate from device-level failover, but you can configure redundant interfaces as well as failover if desired.

This section describes how to configure redundant interfaces and includes the following topics:

- Configuring a Redundant Interface, page 15-25
- Changing the Active Interface, page 15-28

Configuring a Redundant Interface

This section describes how to create a redundant interface. By default, redundant interfaces are enabled.

Guidelines and Limitations

- You can configure up to 8 redundant interface pairs.
- Redundant interface delay values are configurable, but by default the ASA inherits the default delay values based on the physical type of its member interfaces.
- See also the "Redundant Interface Guidelines" section on page 15-11.

Prerequisites

- Both member interfaces must be of the same physical type. For example, both must be Ethernet.
- You cannot add a physical interface to the redundant interface if you configured a name for it. You must first remove the name in the Configuration > Device Setup > Interfaces pane.
- For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

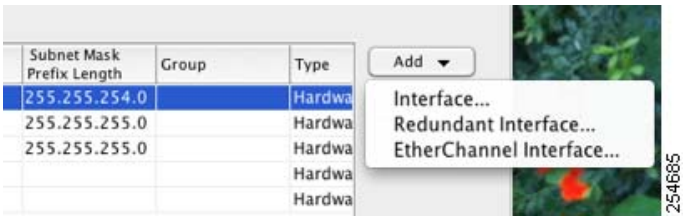
Caution If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Detailed Steps

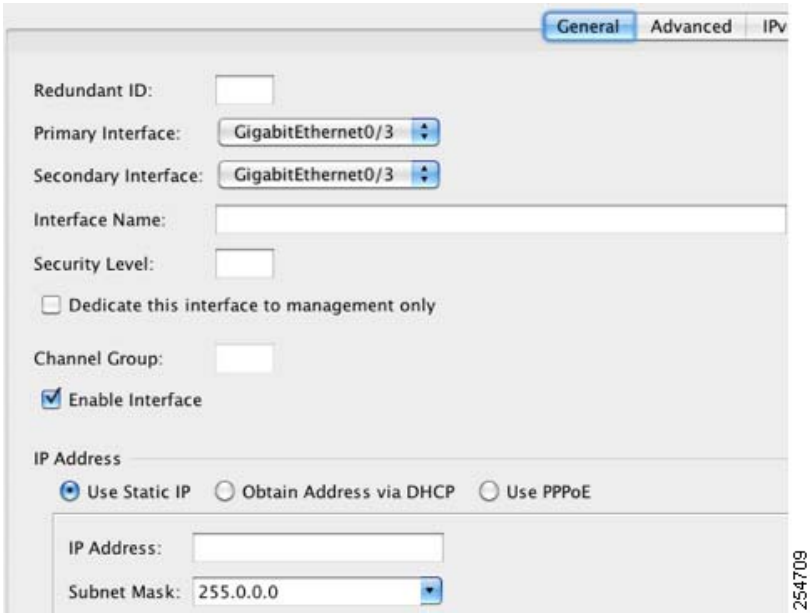
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Choose **Add > Redundant Interface**.



The Add Redundant Interface dialog box appears.



Note In single mode, this procedure only covers a subset of the parameters on the Edit Redundant Interface dialog box; to configure other parameters, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)." Note that in multiple context mode, before you complete your interface configuration, you need to allocate interfaces to contexts. See the "Configuring Multiple Contexts" section on page 9-15.

Step 3 In the Redundant ID field, enter an integer between 1 and 8.

Step 4 From the Primary Interface drop-down list, choose the physical interface you want to be primary.

Be sure to pick an interface that does not have a subinterface and that has not already been allocated to a context. Redundant interfaces do not support Management *slot*/*port* interfaces as members.

Step 5 From the Secondary Interface drop-down list, choose the physical interface you want to be secondary.

Step 6 If the interface is not already enabled, check the **Enable Interface** check box.

The interface is enabled by default. To disable it, uncheck the check box.

Step 7 To add a description, enter text in the Description field.

The description can be up to 240 characters on a single line, without carriage returns. For multiple context mode, the system description is independent of the context description. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Step 8 Click **OK**.

You return to the Interfaces pane. The member interfaces now show a lock to the left of the interface ID showing that only basic parameters can be configured for it. The redundant interface is added to the table.

GigabitEthernet0/2	Enabled	No	Redundant8	Hardware	native
GigabitEthernet0/3	Enabled	No		Hardware	native
GigabitEthernet0/3.10	Enabled	No		Logical	vlan100
GigabitEthernet0/3.11	Enabled	No		Logical	vlan11
Management0/0	Enabled	No		Hardware	native
Redundant8	Enabled	Yes		Logical	native

What to Do Next

Optional Task:

- Configure VLAN subinterfaces. See the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the "Configuring Multiple Contexts" section on page 9-15.
- For single context mode, complete the interface configuration. See the Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Changing the Active Interface

By default, the active interface is the first interface listed in the configuration, if it is available. To view which interface is active, enter the following command in the Tools > Command Line Interface tool:

```
show interface redundantnumber detail | grep Member
```

For example:

```
show interface redundant1 detail | grep Member
      Members GigabitEthernet0/3(Active), GigabitEthernet0/2
```

To change the active interface, enter the following command:

```
redundant-interface redundantnumber active-member physical_interface
```

where the **redundant***number* argument is the redundant interface ID, such as **redundant1**.

The *physical_interface* is the member interface ID that you want to be active.

Configuring an EtherChannel

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

This section includes the following topics:

- Adding Interfaces to the EtherChannel, page 15-29
- Customizing the EtherChannel, page 15-31

Adding Interfaces to the EtherChannel

This section describes how to create an EtherChannel port-channel interface and assign interfaces to the EtherChannel. By default, port-channel interfaces are enabled.

Guidelines and Limitations

- You can configure up to 48 EtherChannels.
- Each channel group can have eight active interfaces. Note that you can assign up to 16 interfaces to a channel group. While only eight interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- You cannot use interfaces on the 4GE SSM, including the integrated 4GE SSM in slot 1 on the ASA 5550, as part of an EtherChannel.
- To configure a spanned EtherChannel for clustering, see the "Configuring Spanned EtherChannels" section on page 10-37 instead of this procedure.
- See also the "EtherChannel Guidelines" section on page 15-11.

Prerequisites

- All interfaces in the channel group must be the same type, speed, and duplex. Half duplex is not supported.
- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name in the Configuration > Device Setup > Interfaces pane.
- For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

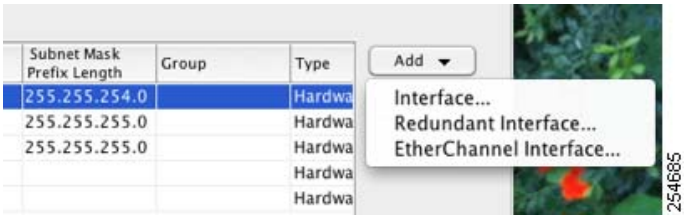
Caution If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Detailed Steps

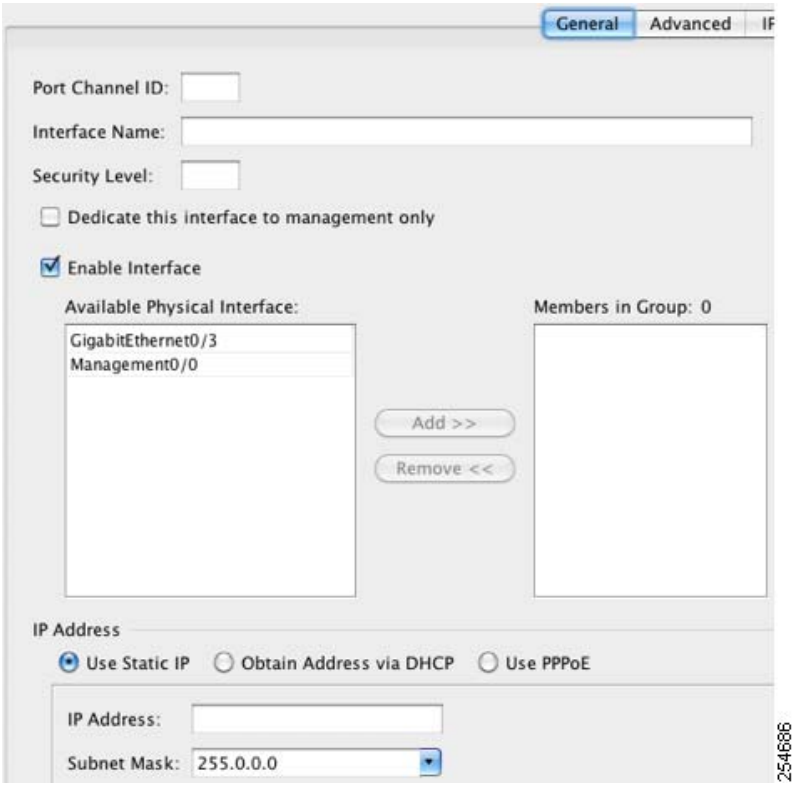
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Choose **Add > EtherChannel Interface**.



The Add EtherChannel Interface dialog box appears.



Note In single mode, this procedure only covers a subset of the parameters on the Edit EtherChannel Interface dialog box; to configure other parameters, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)." Note that in multiple context mode, before you complete your interface configuration, you need to allocate interfaces to contexts. See the "Configuring Multiple Contexts" section on page 9-15.

Step 3 In the Port Channel ID field, enter a number between 1 and 48.

Step 4 In the Available Physical Interface area, click an interface and then click **Add >>** to move it to the Members in Group area.

In transparent mode, if you create a channel group with multiple Management interfaces, then you can use this EtherChannel as the management-only interface.

Step 5 Repeat for each interface you want to add to the channel group.

Make sure all interfaces are the same type and speed. The first interface you add determines the type and speed of the EtherChannel. Any non-matching interfaces you add will be put into a suspended state. ASDM does not prevent you from adding non-matching interfaces.

Step 6 Click **OK**.

You return to the Interfaces pane. The member interfaces now show a lock to the left of the interface ID showing that only basic parameters can be configured for it. The EtherChannel interface is added to the table.

What to Do Next

Optional Tasks:

- Customize the EtherChannel interface. See the "Customizing the EtherChannel" section on page 15-31.
- Configure VLAN subinterfaces. See the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the "Configuring Multiple Contexts" section on page 9-15.
- For single context mode, complete the interface configuration. See the Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Customizing the EtherChannel

This section describes how to set the maximum number of interfaces in the EtherChannel, the minimum number of operating interfaces for the EtherChannel to be active, the load balancing algorithm, and other optional parameters.

Detailed Steps

Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Click the port-channel interface you want to customize, and click **Edit**.

The Edit Interface dialog box appears.

Step 3 To override the media type, duplex, speed, and pause frames for flow control for all member interfaces, click **Configure Hardware Properties**. This method provides a shortcut to set these parameters because these parameters must match for all interfaces in the channel group.

a. For slot 1 on the ASA 5550 ASA or the 4GE SSM, you can choose either **RJ-45** or **SFP** from the Media Type drop-down list.

   RJ-45 is the default.

b. To set the duplex for RJ-45 interfaces, choose **Full** or **Auto**, depending on the interface type, from the Duplex drop-down list. Half is not supported for the EtherChannel.

c. To set the speed, choose a value from the Speed drop-down list.

   The speeds available depend on the interface type. For SFP interfaces, you can set the speed to Negotiate or Nonegotiate. Negotiate (the default) enables link negotiation, which exchanges flow-control parameters and remote fault information. Nonegotiate does not negotiate link parameters. For RJ-45 interfaces on the ASA 5500 series ASA, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. See the "Auto-MDI/MDIX Feature" section on page 15-2.

d. To enable pause (XOFF) frames for flow control on 1-Gigabit and 10-Gigabit Ethernet interfaces, check the **Enable Pause Frame** check box.

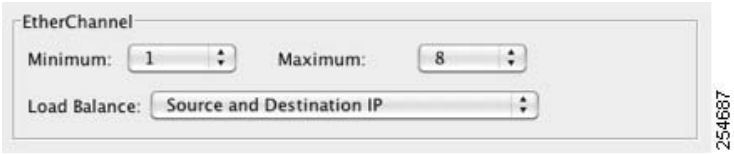
   If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. Pause (XOFF) and XON frames are generated automatically by the NIC hardware based on the FIFO buffer usage. A pause frame is sent when the buffer usage exceeds the High Watermark. The default value is 128 KB; you can set it between 0 and 511. After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the Low Watermark. By default, the value is 64 KB; you can set it between 0 and 511. The link partner can resume traffic after receiving an XON, or after the XOFF expires, as controlled by the Pause Time value in the pause frame. The default value is 26624; you can set it between 0 and 65535. If the buffer usage is consistently above the High Watermark, pause frames are sent repeatedly, controlled by the pause refresh threshold value.

   To change the default values for the Low Watermark, High Watermark, and Pause Time, uncheck the **Use Default Values** check box.

   Note Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

e. Click **OK** to accept the Hardware Properties changes.

Step 4 To customize the EtherChannel, click the **Advanced** tab.



a. In the EtherChannel area, from the Minimum drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 8. The default is 1.

b. From the Maximum drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 8. The default is 8.

c. From the Load Balance drop-down list, select the criteria used to load balance the packets across the group channel interfaces. By default, the ASA balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see the "Load Balancing" section on page 15-7.

Step 5 Click **OK**.

You return to the Interfaces pane.

Step 6 To set the mode and priority for a physical interface in the channel group:

a. Click the physical interface in the Interfaces table, and click **Edit**.

The Edit Interface dialog box appears.

b. Click the **Advanced** tab.

c. In the EtherChannel area, from the Mode drop down list, choose **Active**, **Passive**, or **On**. We recommend using Active mode (the default). For information about active, passive, and on modes, see the "Link Aggregation Control Protocol" section on page 15-6.

d. In the LACP Port Priority field, set the port priority between 1 and 65535. The default is 32768. The higher the number, the lower the priority. The ASA uses this setting to decide which interfaces are active and which are standby if you assign more interfaces than can be used. If the port priority setting is the same for all interfaces, then the priority is determined by the interface ID (slot/port). The lowest interface ID is the highest priority. For example, GigabitEthernet 0/0 is a higher priority than GigabitEthernet 0/1.

If you want to prioritize an interface to be active even though it has a higher interface ID, then set this command to have a lower value. For example, to make GigabitEthernet 1/3 active before GigabitEthernet 0/7, then make the priority value be 12345 on the 1/3 interface vs. the default 32768 on the 0/7 interface.

If the device at the other end of the EtherChannel has conflicting port priorities, the system priority is used to determine which port priorities to use. See Step 9 to set the system priority.

Step 7 Click **OK**.

You return to the Interfaces pane.

Step 8 Click **Apply**.

Step 9 To set the LACP system priority, perform the following steps. If the device at the other end of the EtherChannel has conflicting port priorities, the system priority is used to determine which port priorities to use. See Step 6d for more information.

a. Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > EtherChannel** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > EtherChannel** pane.

b. In the LACP System Priority field, enter a priority between 1 and 65535.

The default is 32768.

What to Do Next

Optional Task:

- Configure VLAN subinterfaces. See the "Configuring VLAN Subinterfaces and 802.1Q Trunking" section on page 15-34.

Required Tasks:

- For multiple context mode, assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See the "Configuring Multiple Contexts" section on page 9-15.
- For single context mode, complete the interface configuration. See the Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Configuring VLAN Subinterfaces and 802.1Q Trunking

Subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs allow you to keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or ASAs. This feature is particularly useful in multiple context mode so that you can assign unique interfaces to each context.

Guidelines and Limitations

- Maximum subinterfaces—To determine how many VLAN subinterfaces are allowed for your platform, see the "Licensing Requirements for ASA 5510 and Higher Interfaces" section on page 15-8.
- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair.

Because the physical or redundant interface must be enabled for the subinterface to pass traffic, ensure that the physical or redundant interface does not pass traffic by not configuring a name for the interface. If you want to let the physical or redundant interface pass untagged packets, you can configure the name as usual. See Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)," for more information about completing the interface configuration.

- (ASA 5512-X through ASA 5555-X) You cannot configure subinterfaces on the Management 0/0 interface.

Prerequisites

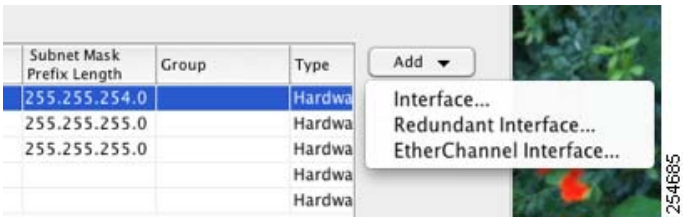
For multiple context mode, complete this procedure in the system execution space. If you are not already in the System configuration mode, in the Configuration > Device List pane, double-click **System** under the active device IP address.

Detailed Steps

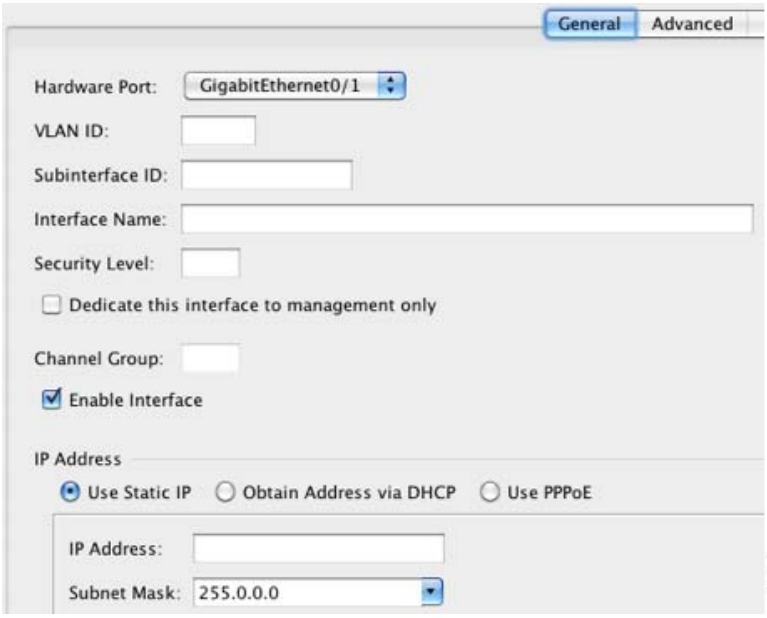
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

Step 2 Choose **Add > Interface**.



The Add Interface dialog box appears.



Note In single mode, this procedure only covers a subset of the parameters on the Edit Interface dialog box; to configure other parameters, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)." Note that in multiple context mode, before you complete your interface configuration, you need to allocate interfaces to contexts. See the "Configuring Multiple Contexts" section on page 9-15.

Step 3 From the Hardware Port drop-down list, choose the physical, redundant, or port-channel interface to which you want to add the subinterface.

Step 4 If the interface is not already enabled, check the **Enable Interface** check box.

The interface is enabled by default. To disable it, uncheck the check box.

Step 5 In the VLAN ID field, enter the VLAN ID between 1 and 4095.

Some VLAN IDs might be reserved on connected switches, so check the switch documentation for more information. For multiple context mode, you can only set the VLAN in the system configuration.

Step 6 In the Subinterface ID field, enter the subinterface ID as an integer between 1 and 4294967293.

The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.

Step 7 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns. For multiple context mode, the system description is independent of the context description. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Step 8 Click **OK**.

You return to the Interfaces pane.

What to Do Next

(Optional) Enable jumbo frame support according to the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

Enabling Jumbo Frame Support (Supported Models)

A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists.

Supported models include:

- ASA 5512-X
- ASA 5515-X
- ASA 5525-X
- ASA 5545-X
- ASA 5555-X
- ASA 5580
- ASA 5585-X

Prerequisites

- In multiple context mode, set this option in the system execution space.
- Changes in this setting require you to reload the ASA.
- Be sure to set the MTU for each interface that needs to transmit jumbo frames to a higher value than the default 1500; for example, set the value to 9000. See the "Configuring the MAC Address and MTU" section on page 17-13. In multiple context mode, set the MTU within each context.

Detailed Steps

- Multiple mode—To enable jumbo frame support, choose **Configuration > Context Management > Interfaces**, and click the **Enable jumbo frame support** check box.
- Single mode—Setting the MTU larger than 1500 bytes automatically enables jumbo frames. To manually enable or disable this setting, choose **Configuration > Device Setup > Interfaces**, and click the **Enable jumbo frame support** check box.

Monitoring Interfaces

This section includes the following topics:

- ARP Table, page 15-38
- MAC Address Table, page 15-38

- Interface Graphs, page 15-38

ARP Table

The Monitoring > Interfaces > ARP Table pane displays the ARP table, including static and dynamic entries. The ARP table includes entries that map a MAC address to an IP address for a given interface.

Fields

- Interface—Lists the interface name associated with the mapping.
- IP Address—Shows the IP address.
- MAC Address—Shows the MAC address.
- Proxy ARP—Displays Yes if proxy ARP is enabled on the interface. Displays No if proxy ARP is not enabled on the interface.
- Clear—Clears the dynamic ARP table entries. Static entries are not cleared.
- Refresh—Refreshes the table with current information from the ASA and updates Last Updated date and time.
- Last Updated—*Display only.* Shows the date and time the display was updated.

MAC Address Table

The Monitoring > Interfaces > MAC Address Table pane shows the static and dynamic MAC address entries. See the "MAC Address Table" section on page 15-38 for more information about the MAC address table and adding static entries.

Fields

- Interface—Shows the interface name associated with the entry.
- MAC Address—Shows the MAC address.
- Type—Shows if the entry is static or dynamic.
- Age—Shows the age of the entry, in minutes. To set the timeout, see the "MAC Address Table" section on page 15-38.
- Refresh—Refreshes the table with current information from the ASA.

Interface Graphs

The Monitoring > Interfaces > Interface Graphs pane lets you view interface statistics in graph or table form. If an interface is shared among contexts, the ASA shows only statistics for the current context. The number of statistics shown for a subinterface is a subset of the number of statistics shown for a physical interface.

Fields

- Available Graphs for—Lists the types of statistics available for monitoring. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.
  - Byte Counts—Shows the number of bytes input and output on the interface.

- Packet Counts—Shows the number of packets input and output on the interface.
- Packet Rates—Shows the rate of packets input and output on the interface.
- Bit Rates—Shows the bit rate for the input and output of the interface.
- Drop Packet Count—Shows the number of packets dropped on the interface.

These additional statistics display for physical interfaces:

- Buffer Resources—Shows the following statistics:

  Overruns—The number of times that the ASA was incapable of handing received data to a hardware buffer because the input rate exceeded the ASA capability to handle the data.

  Underruns—The number of times that the transmitter ran faster than the ASA could handle.

  No Buffer—The number of received packets discarded because there was no buffer space in the main system. Compare this with the ignored count. Broadcast storms on Ethernet networks are often responsible for no input buffer events.

- Packet Errors—Shows the following statistics:

  CRC—The number of Cyclical Redundancy Check errors. When a station sends a frame, it appends a CRC to the end of the frame. This CRC is generated from an algorithm based on the data in the frame. If the frame is altered between the source and destination, the ASA notes that the CRC does not match. A high number of CRCs is usually the result of collisions or a station transmitting bad data.

  Frame—The number of frame errors. Bad frames include packets with an incorrect length or bad frame checksums. This error is usually the result of collisions or a malfunctioning Ethernet device.

  Input Errors—The number of total input errors, including the other types listed here. Other input-related errors can also cause the input error count to increase, and some datagrams might have more than one error; therefore, this sum might exceed the number of errors listed for the other types.

  Runts—The number of packets that are discarded because they are smaller than the minimum packet size, which is 64 bytes. Runts are usually caused by collisions. They might also be caused by poor wiring and electrical interference.

  Giants—The number of packets that are discarded because they exceed the maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.

  Deferred—For FastEthernet interfaces only. The number of frames that were deferred before transmission due to activity on the link.

- Miscellaneous—Shows statistics for received broadcasts.

- Collision Counts—For FastEthernet interfaces only. Shows the following statistics:

  Output Errors—The number of frames not transmitted because the configured maximum number of collisions was exceeded. This counter should only increment during heavy network traffic.

  Collisions—The number of messages retransmitted due to an Ethernet collision (single and multiple collisions). This usually occurs on an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once by the output packets.

  Late Collisions—The number of frames that were not transmitted because a collision occurred outside the normal collision window. A late collision is a collision that is detected late in the transmission of the packet. Normally, these should never happen. When two Ethernet hosts try to talk at once, they should collide early in the packet and both back off, or the second host

should see that the first one is talking and wait. If you get a late collision, a device is jumping in and trying to send the packet on the Ethernet while the ASA is partly finished sending the packet. The ASA does not resend the packet, because it may have freed the buffers that held the first part of the packet. This is not a real problem because networking protocols are designed to cope with collisions by resending packets. However, late collisions indicate a problem exists in your network. Common problems are large repeated networks and Ethernet networks running beyond the specification.

  - Input Queue—Shows the number of packets in the input queue, the current and the maximum, including the following statistics:

    Hardware Input Queue—The number of packets in the hardware queue.

    Software Input Queue—The number of packets in the software queue.

  - Output Queue—Shows the number of packets in the output queue, the current and the maximum, including the following statistics:

    Hardware Output Queue—The number of packets in the hardware queue.

    Software Output Queue—The number of packets in the software queue.

- Add—Adds the selected statistic type to the selected graph window.
- Remove—Removes the selected statistic type from the selected graph window. This button name changes to Delete if the item you are removing was added from another panel, and is not being returned to the Available Graphs pane.
- Show Graphs—Shows the graph window name to which you want to add a statistic type. If you have a graph window already open, a new graph window is listed by default. If you want to add a statistic type to an already open graph, choose the open graph window name. The statistics already included on the graph are shown in the Selected Graphs pane, to which you can add additional types. Graph windows are named for ASDM followed by the interface IP address and the name “Graph”. Subsequent graphs are named “Graph (2)” and so on.
- Selected Graphs—Shows the statistic types you want to show in the selected graph window. You an include up to four types.
  - Show Graphs—Shows the graph window or updates the graph with additional statistic types if added.

Graph/Table

The Monitoring > Interfaces > Interface Graphs > Graph/Table window shows a graph for the selected statistics. The Graph window can show up to four graphs and tables at a time. By default, the graph or table displays the real-time statistics. If you enable History Metrics (see the “Enabling History Metrics” section on page 4-34), you can view statistics for past time periods.

Fields

- View—Sets the time period for the graph or table. To view any time period other than real-time, enable History Metrics (see the “Enabling History Metrics” section on page 4-34). The data is updated according to the specification of the following options:
  - Real-time, data every 10 sec
  - Last 10 minutes, data every 10 sec
  - Last 60 minutes, data every 1 min
  - Last 12 hours, data every 12 min

  - Last 5 days, data every 2 hours

- Export—Exports the graph in comma-separated value format. If there is more than one graph or table on the Graph window, the Export Graph Data dialog box appears. Choose one or more of the graphs and tables listed by checking the check box next to the name.
- Print—Prints the graph or table. If there is more than one graph or table on the Graph window, the Print Graph dialog box appears. Choose the graph or table you want to print from the Graph/Table Name list.
- Bookmark—Opens a browser window with a single link for all graphs and tables on the Graphs window, as well as individual links for each graph or table. You can then copy these URLs as bookmarks in your browser. ASDM does not have to be running when you open the URL for a graph; the browser launches ASDM and then displays the graph.

Where to Go Next

- For multiple context mode:
  a. Assign interfaces to contexts and automatically assign unique MAC addresses to context interfaces. See Chapter 9, "Configuring Multiple Context Mode."
  b. Complete the interface configuration according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."
- For single context mode, complete the interface configuration according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Feature History for ASA 5510 and Higher Interfaces

Table 15-3 lists the release history for this feature.

Table 15-3 Feature History for Interfaces

Feature Name	Releases	Feature Information
Increased VLANs	7.0(5)	Increased the following limits: • ASA5510 Base license VLANs from 0 to 10. • ASA5510 Security Plus license VLANs from 10 to 25. • ASA5520 VLANs from 25 to 100. • ASA5540 VLANs from 100 to 200.
Increased interfaces for the Base license on the ASA 5510	7.2(2)	For the Base license on the ASA 5510, the maximum number of interfaces was increased from 3 plus a management interface to unlimited interfaces.
Increased VLANs	7.2(2)	VLAN limits were increased for the ASA 5510 (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 (from 100 to 150), the ASA 5550 (from 200 to 250).

Table 15-3 Feature History for Interfaces (continued)

Feature Name	Releases	Feature Information
Gigabit Ethernet Support for the ASA 5510 Security Plus License	7.2(3)	The ASA 5510 ASA now supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1.
Jumbo packet support for the ASA 5580	8.1(1)	The Cisco ASA 5580 supports jumbo frames. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. This feature is also supported on the ASA 5585-X. We modified the following screen: Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced.
Increased VLANs for the ASA 5580	8.1(2)	The number of VLANs supported on the ASA 5580 are increased from 100 to 250.
Support for Pause Frames for Flow Control on the ASA 5580 10-Gigabit Ethernet Interfaces	8.2(2)	You can now enable pause (XOFF) frames for flow control. This feature is also supported on the ASA 5585-X. We modified the following screens: (Single Mode) Configuration > Device Setup > Interfaces > Add/Edit Interface > General (Multiple Mode, System) Configuration > Interfaces > Add/Edit Interface.
Support for Pause Frames for Flow Control on 1-Gigabit Ethernet Interfaces	8.2(5)/8.4(2)	You can now enable pause (XOFF) frames for flow control for 1-Gigabit interfaces on all models. We modified the following screens: (Single Mode) Configuration > Device Setup > Interfaces > Add/Edit Interface > General (Multiple Mode, System) Configuration > Interfaces > Add/Edit Interface.
EtherChannel support	8.4(1)	You can configure up to 48 802.3ad EtherChannels of eight active interfaces each. We modified or introduced the following screens: Configuration > Device Setup > Interfaces Configuration > Device Setup > Interfaces > Add/Edit EtherChannel Interface Configuration > Device Setup > Interfaces > Add/Edit Interface Configuration > Device Setup > EtherChannel **Note** EtherChannel is not supported on the ASA 5505.

Starting Interface Configuration (ASA 5505)

This chapter includes tasks for starting your interface configuration for the ASA 5505, including creating VLAN interfaces and assigning them to switch ports.

For ASA 5510 and higher configuration, see the "Feature History for ASA 5505 Interfaces" section on page 16-16.

This chapter includes the following sections:

- Information About ASA 5505 Interfaces, page 16-1
- Licensing Requirements for ASA 5505 Interfaces, page 16-4
- Guidelines and Limitations, page 16-5
- Default Settings, page 16-5
- Starting ASA 5505 Interface Configuration, page 16-6
- Monitoring Interfaces, page 16-12
- Where to Go Next, page 16-15
- Feature History for ASA 5505 Interfaces, page 16-16

Information About ASA 5505 Interfaces

This section describes the ports and interfaces of the ASA 5505 and includes the following topics:

- Understanding ASA 5505 Ports and Interfaces, page 16-2
- Maximum Active VLAN Interfaces for Your License, page 16-2
- VLAN MAC Addresses, page 16-4
- Power over Ethernet, page 16-4
- Monitoring Traffic Using SPAN, page 16-4
- Auto-MDI/MDIX Feature, page 16-4

Understanding ASA 5505 Ports and Interfaces

The ASA 5505 supports a built-in switch. There are two kinds of ports and interfaces that you need to configure:

- Physical switch ports—The ASA has 8 Fast Ethernet switch ports that forward traffic at Layer 2, using the switching function in hardware. Two of these ports are PoE ports. See the "Power over Ethernet" section on page 16-4 for more information. You can connect these interfaces directly to user equipment such as PCs, IP phones, or a DSL modem. Or you can connect to another switch.
- Logical VLAN interfaces—In routed mode, these interfaces forward traffic between VLAN networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces forward traffic between the VLANs on the same network at Layer 2, using the configured security policy to apply firewall services. See the "Maximum Active VLAN Interfaces for Your License" section for more information about the maximum VLAN interfaces. VLAN interfaces let you divide your equipment into separate VLANs, for example, home, business, and Internet VLANs.

To segregate the switch ports into separate VLANs, you assign each switch port to a VLAN interface. Switch ports on the same VLAN can communicate with each other using hardware switching. But when a switch port on VLAN 1 wants to communicate with a switch port on VLAN 2, then the ASA applies the security policy to the traffic and routes or bridges between the two VLANs.

Maximum Active VLAN Interfaces for Your License

In routed mode, you can configure the following VLANs depending on your license:

- Base license—3 active VLANs. The third VLAN can only be configured to initiate traffic to one other VLAN. See Figure 16-1 for more information.
- Security Plus license—20 active VLANs.

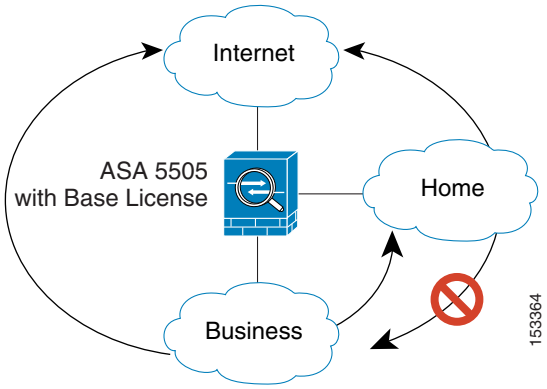
In transparent firewall mode, you can configure the following VLANs depending on your license:

- Base license—2 active VLANs in 1 bridge group.
- Security Plus license—3 active VLANs: 2 active VLANs in 1 bridge group, and 1 active VLAN for the failover link.

Note An *active VLAN* is a VLAN with a **nameif** command configured.

With the Base license in routed mode, the third VLAN can only be configured to initiate traffic to one other VLAN. See Figure 16-1 for an example network where the Home VLAN can communicate with the Internet, but cannot initiate contact with Business.

Figure 16-1 ASA 5505 with Base License

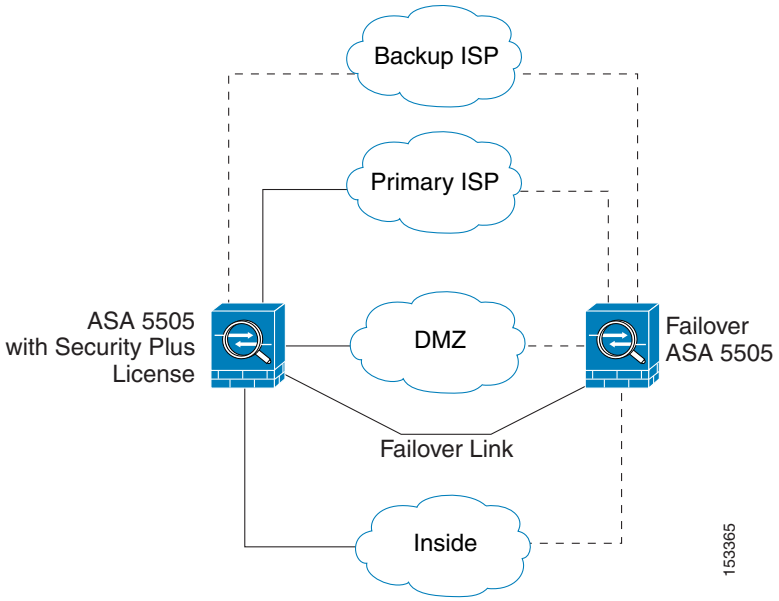


With the Security Plus license, you can configure 20 VLAN interfaces in routed mode, including a VLAN interface for failover and a VLAN interface as a backup link to your ISP. You can configure the backup interface to not pass through traffic unless the route through the primary interface fails. You can configure trunk ports to accommodate multiple VLANs per port.

Note The ASA 5505 supports Active/Standby failover, but not Stateful Failover.

See Figure 16-2 for an example network.

Figure 16-2 ASA 5505 with Security Plus License



VLAN MAC Addresses

- Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See the "Configuring the MAC Address and MTU" section on page 17-13.
- Transparent firewall mode—Each VLAN has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See the "Configuring the MAC Address and MTU" section on page 18-14.

Power over Ethernet

Ethernet 0/6 and Ethernet 0/7 support PoE for devices such as IP phones or wireless access points. If you install a non-PoE device or do not connect to these switch ports, the ASA does not supply power to the switch ports.

If you shut down the switch port, you disable power to the device. Power is restored when you enable the portd. See the "Configuring and Enabling Switch Ports as Access Ports" section on page 16-8 for more information about shutting down a switch port.

Monitoring Traffic Using SPAN

If you want to monitor traffic that enters or exits one or more switch ports, you can enable SPAN, also known as switch port monitoring. The port for which you enable SPAN (called the destination port) receives a copy of every packet transmitted or received on a specified source port. The SPAN feature lets you attach a sniffer to the destination port so you can monitor all traffic; without SPAN, you would have to attach a sniffer to every port you want to monitor. You can only enable SPAN for one destination port.

You can only enable SPAN monitoring using the Command Line Interface tool by entering the **switchport monitor** command. See the **switchport monitor** command in the command reference for more information.

Auto-MDI/MDIX Feature

All ASA 5505 interfaces include the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. You cannot disable Auto-MDI/MDIX.

Licensing Requirements for ASA 5505 Interfaces

Model	License Requirement
ASA 5505	VLANs: Base License: 3 (2 regular zones and 1 restricted zone that can only communicate with 1 other zone) Security Plus License: 20 VLAN Trunks: Base License: None. Security Plus License: 8. Interfaces of all types[1]: Base License: 52. Security Plus License: 120.

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, and bridge group interfaces.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

The ASA 5505 does not support multiple context mode.

Firewall Mode Guidelines

- In transparent mode, you can configure up to eight bridge groups. Note that you must use at least one bridge group; data interfaces must belong to a bridge group.
- Each bridge group can include up to four VLAN interfaces, up to the license limit.

Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the "Factory Default Configurations" section on page 3-17.

Default State of Interfaces

Interfaces have the following default states:

- Switch ports—Disabled.
- VLANs—Enabled. However, for traffic to pass through the VLAN, the switch port must also be enabled.

Default Speed and Duplex

By default, the speed and duplex are set to auto-negotiate.

Starting ASA 5505 Interface Configuration

This section includes the following topics:

- Task Flow for Starting Interface Configuration, page 16-6
- Configuring VLAN Interfaces, page 16-6
- Configuring and Enabling Switch Ports as Access Ports, page 16-8
- Configuring and Enabling Switch Ports as Trunk Ports, page 16-10

Task Flow for Starting Interface Configuration

To configure interfaces in single mode, perform the following steps:

Step 1 Configure VLAN interfaces. See the "Configuring VLAN Interfaces" section on page 16-6.

Step 2 Configure and enable switch ports as access ports. See the "Configuring and Enabling Switch Ports as Access Ports" section on page 16-8.

Step 3 (Optional for Security Plus licenses) Configure and enable switch ports as trunk ports. See the "Configuring and Enabling Switch Ports as Trunk Ports" section on page 16-10.

Step 4 Complete the interface configuration according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Configuring VLAN Interfaces

This section describes how to configure VLAN interfaces. For more information about ASA 5505 interfaces, see the "Information About ASA 5505 Interfaces" section on page 16-1.

Guidelines

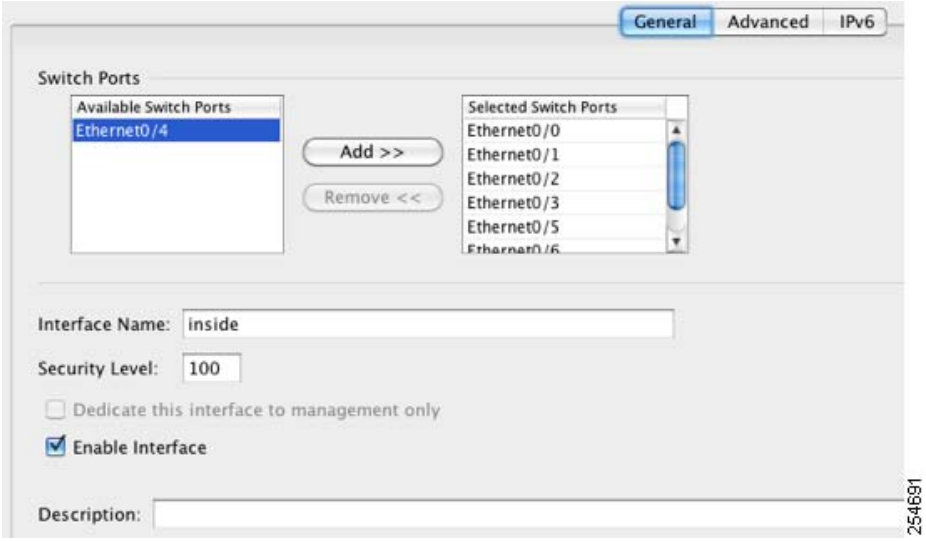
We suggest that you finalize your interface configuration before you enable Easy VPN. If you enabled Easy VPN, you cannot add or delete VLAN interfaces, nor can you edit the security level or interface name.

Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 On the Interfaces tab, click **Add**.

The Add Interface dialog box appears with the General tab selected.



Step 3 In the Available Switch Ports pane, choose a switch port, and click **Add**.

You see the following message:

"*switchport* is associated with *name* interface. Adding it to this interface, will remove it from *name* interface. Do you want to continue?"

Click **OK** to add the switch port.

You will always see this message when adding a switch port to an interface; switch ports are assigned to the VLAN 1 interface by default even when you do not have any configuration.

Repeat for any other switch ports that you want to carry this VLAN.

Note Removing a switch port from an interface essentially just reassigns that switch port to VLAN 1, because the default VLAN interface for switch ports is VLAN 1.

Step 4 Click the **Advanced** tab.

Note You receive an error message about setting the IP address. You can either set the IP address and other parameters now, or you can finish configuring the VLAN and switch ports by clicking **Yes**, and later set the IP address and other parameters according to Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Step 5 In the VLAN ID field, enter the VLAN ID for this interface, between 1 and 4090.

If you do not want to assign the VLAN ID, ASDM assigns one for you randomly.

Step 6 (Optional for the Base license) To allow this interface to be the third VLAN by limiting it from initiating contact to one other VLAN, in the Block Traffic From this Interface to drop-down list, choose the VLAN to which this VLAN interface cannot initiate traffic.

With the Base license, you can only configure a third VLAN if you use this command to limit it.

For example, you have one VLAN assigned to the outside for Internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can use this option on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

If you already have two VLAN interfaces configured with a name, be sure to configure this setting before setting the name on the third interface; the ASA does not allow three fully functioning VLAN interfaces with the Base license on the ASA 5505.

Note If you upgrade to the Security Plus license, you can remove this option and achieve full functionality for this interface. If you leave this option enabled, this interface continues to be limited even after upgrading.

To configure the MAC address and MTU, see the "Configuring the MAC Address and MTU" section on page 17-13.

Step 7 Click **OK**.

What to Do Next

Configure the switch ports. See the "Configuring and Enabling Switch Ports as Access Ports" section on page 16-8 and the "Configuring and Enabling Switch Ports as Trunk Ports" section on page 16-10.

Configuring and Enabling Switch Ports as Access Ports

By default (with no configuration), all switch ports are shut down, and assigned to VLAN 1. To assign a switch port to a single VLAN, configure it as an access port. To create a trunk port to carry multiple VLANs, see the "Configuring and Enabling Switch Ports as Trunk Ports" section on page 16-10. If you have a factory default configuration, see the "ASA 5505 Default Configuration" section on page 3-20 to check if you want to change the default interface settings according to this procedure.

For more information about ASA 5505 interfaces, see the "Information About ASA 5505 Interfaces" section on page 16-1.

Caution The ASA 5505 does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the ASA does not end up in a network loop.

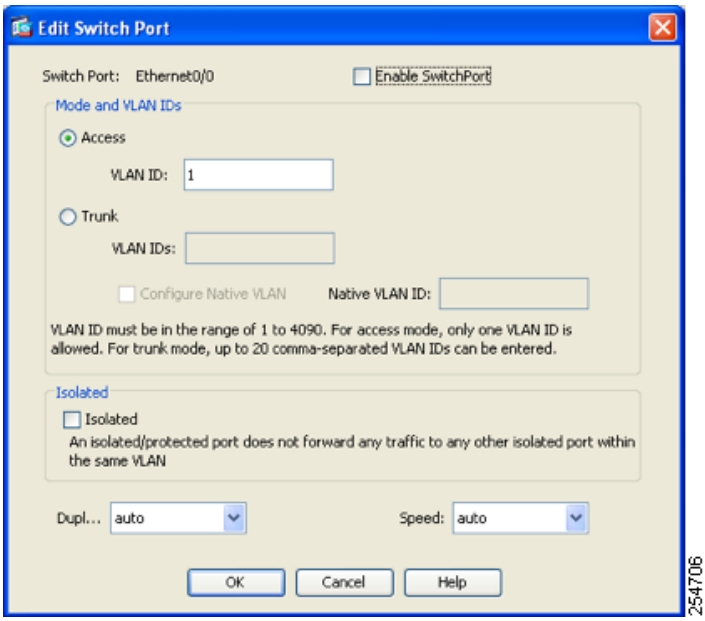
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Click the **Switch Ports** tab.

Step 3 Click the switch port you want to edit.

The Edit Switch Port dialog box appears.



Step 4 To enable the switch port, check the **Enable SwitchPort** check box.

Step 5 In the Mode and VLAN IDs area, click the **Access** radio button.

Step 6 In the VLAN ID field, enter the VLAN ID associated with this switch port. The VLAN ID can be between 1 and 4090.

By default, the VLAN ID is derived from the VLAN interface configuration you completed in "Configuring VLAN Interfaces" section on page 16-6 (on the Configuration > Device Setup > Interfaces > Interfaces > Add/Edit Interface dialog box). You can change the VLAN assignment in this dialog box. Be sure to apply the change to update the VLAN configuration with the new information. If you want to specify a VLAN that has not yet been added, we suggest you add the VLAN according to the "Configuring VLAN Interfaces" section on page 16-6 rather than specifying it in this dialog box; in either case, you need to add the VLAN according to the "Configuring VLAN Interfaces" section on page 16-6 and assign the switch port to it.

Step 7 (Optional) To prevent the switch port from communicating with other protected switch ports on the same VLAN, check the **Isolated** check box.

This option prevents the switch port from communicating with other protected switch ports on the same VLAN. You might want to prevent switch ports from communicating with each other if the devices on those switch ports are primarily accessed from other VLANs, you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you apply the Protected option to each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) From the Duplex drop-down list, choose **Full**, **Half**, or **Auto**.

The Auto setting is the default. If you set the duplex to anything other than Auto on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Step 9 (Optional) From the Speed drop-down list, choose **10**, **100**, or **Auto**.

The Auto setting is the default. If you set the speed to anything other than Auto on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Step 10 Click **OK**.

What to Do Next

- If you want to configure a switch port as a trunk port, see the "Configuring and Enabling Switch Ports as Trunk Ports" section on page 16-10.
- To complete the interface configuration, see Chapter 17, "Completing Interface Configuration (Routed Mode)," or Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Configuring and Enabling Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk mode is available only with the Security Plus license.

To create an access port, where an interface is assigned to only one VLAN, see the "Configuring and Enabling Switch Ports as Access Ports" section on page 16-8.

Guidelines

This switch port cannot pass traffic until you assign at least one VLAN to it, native or non-native.

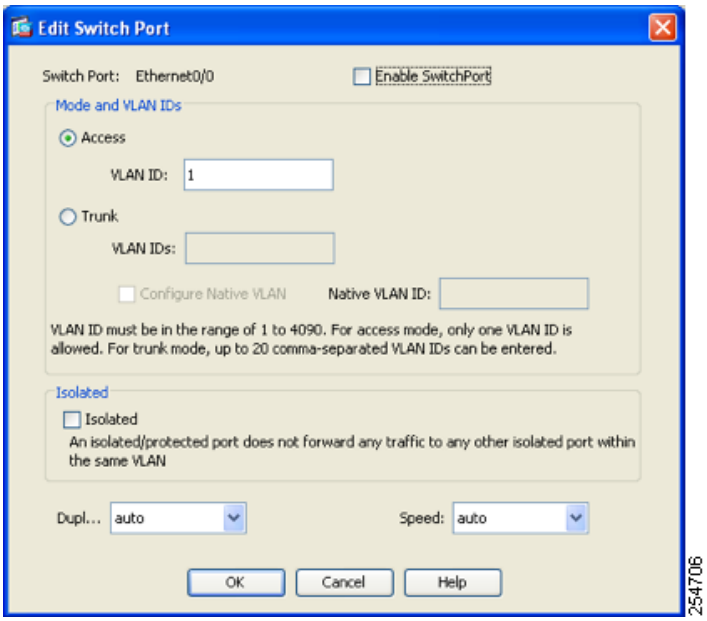
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Click the **Switch Ports** tab.

Step 3 Click the switch port you want to edit.

The Edit Switch Port dialog box appears.



Step 4 To enable the switch port, check the **Enable SwitchPort** check box.

Step 5 In the Mode and VLAN IDs area, click the **Trunk** radio button.

Step 6 In the VLAN IDs field, enter the VLAN IDs associated with this switch port, separated by commas. The VLAN ID can be between 1 and 4090.

You can include the native VLAN in this field, but it is not required; the native VLAN is passed whether it is included in this field or not.

This switch port cannot pass traffic until you assign at least one VLAN to it, native or non-native.

If the VLANs are already in your configuration, after you apply the change, the Configuration > Device Setup > Interfaces > Interfaces tab shows this switch port added to each VLAN. If you want to specify a VLAN that has not yet been added, we suggest you add the VLAN according to the "Configuring VLAN Interfaces" section on page 16-6 rather than specifying it in this dialog box; in either case, you need to add the VLAN according to the "Configuring VLAN Interfaces" section on page 16-6 and assign the switch port to it.

Step 7 To configure the native VLAN, check the **Configure Native VLAN** check box, and enter the VLAN ID in the Native VLAN ID field. The VLAN ID can be between 1 and 4090.

Packets on the native VLAN are not modified when sent over the trunk. For example, if a port has VLANs 2, 3 and 4 assigned to it, and VLAN 2 is the native VLAN, then packets on VLAN 2 that egress the port are not modified with an 802.1Q header. Frames which ingress (enter) this port and have no 802.1Q header are put into VLAN 2.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

Step 8 (Optional) To prevent the switch port from communicating with other protected switch ports on the same VLAN, check the **Isolated** check box.

This option prevents the switch port from communicating with other protected switch ports on the same VLAN. You might want to prevent switch ports from communicating with each other if the devices on those switch ports are primarily accessed from other VLANs, you do not need to allow intra-VLAN access, and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each

other if you apply the Protected option to each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 9 (Optional) From the Duplex drop-down list, choose **Full**, **Half**, or **Auto**.

The Auto setting is the default. If you set the duplex to anything other than Auto on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Step 10 (Optional) From the Speed drop-down list, choose **10**, **100**, or **Auto**.

The Auto setting is the default. If you set the speed to anything other than Auto on PoE ports Ethernet 0/6 or 0/7, then Cisco IP phones and Cisco wireless access points that do not support IEEE 802.3af will not be detected and supplied with power.

Step 11 Click **OK**.

Monitoring Interfaces

This section includes the following topics:

- ARP Table, page 16-12
- MAC Address Table, page 16-12
- Interface Graphs, page 16-13

ARP Table

The Monitoring > Interfaces > ARP Table pane displays the ARP table, including static and dynamic entries. The ARP table includes entries that map a MAC address to an IP address for a given interface.

Fields

- Interface—Lists the interface name associated with the mapping.
- IP Address—Shows the IP address.
- MAC Address—Shows the MAC address.
- Proxy ARP—Displays Yes if proxy ARP is enabled on the interface. Displays No if proxy ARP is not enabled on the interface.
- Clear—Clears the dynamic ARP table entries. Static entries are not cleared.
- Refresh—Refreshes the table with current information from the ASA and updates Last Updated date and time.
- Last Updated—*Display only.* Shows the date and time the display was updated.

MAC Address Table

The Monitoring > Interfaces > MAC Address Table pane shows the static and dynamic MAC address entries. See the "MAC Address Table" section on page 16-12 for more information about the MAC address table and adding static entries.

Fields

- Interface—Shows the interface name associated with the entry.
- MAC Address—Shows the MAC address.
- Type—Shows if the entry is static or dynamic.
- Age—Shows the age of the entry, in minutes. To set the timeout, see the "MAC Address Table" section on page 16-12.
- Refresh—Refreshes the table with current information from the ASA.

Interface Graphs

The Monitoring > Interfaces > Interface Graphs pane lets you view interface statistics in graph or table form. If an interface is shared among contexts, the ASA shows only statistics for the current context. The number of statistics shown for a subinterface is a subset of the number of statistics shown for a physical interface.

Fields

- Available Graphs for—Lists the types of statistics available for monitoring. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.
  - Byte Counts—Shows the number of bytes input and output on the interface.
  - Packet Counts—Shows the number of packets input and output on the interface.
  - Packet Rates—Shows the rate of packets input and output on the interface.
  - Bit Rates—Shows the bit rate for the input and output of the interface.
  - Drop Packet Count—Shows the number of packets dropped on the interface.

  These additional statistics display for physical interfaces:
  - Buffer Resources—Shows the following statistics:

    Overruns—The number of times that the ASA was incapable of handing received data to a hardware buffer because the input rate exceeded the ASA capability to handle the data.

    Underruns—The number of times that the transmitter ran faster than the ASA could handle.

    No Buffer—The number of received packets discarded because there was no buffer space in the main system. Compare this with the ignored count. Broadcast storms on Ethernet networks are often responsible for no input buffer events.
  - Packet Errors—Shows the following statistics:

    CRC—The number of Cyclical Redundancy Check errors. When a station sends a frame, it appends a CRC to the end of the frame. This CRC is generated from an algorithm based on the data in the frame. If the frame is altered between the source and destination, the ASA notes that the CRC does not match. A high number of CRCs is usually the result of collisions or a station transmitting bad data.

    Frame—The number of frame errors. Bad frames include packets with an incorrect length or bad frame checksums. This error is usually the result of collisions or a malfunctioning Ethernet device.

Input Errors—The number of total input errors, including the other types listed here. Other input-related errors can also cause the input error count to increase, and some datagrams might have more than one error; therefore, this sum might exceed the number of errors listed for the other types.

Runts—The number of packets that are discarded because they are smaller than the minimum packet size, which is 64 bytes. Runts are usually caused by collisions. They might also be caused by poor wiring and electrical interference.

Giants—The number of packets that are discarded because they exceed the maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.

Deferred—For FastEthernet interfaces only. The number of frames that were deferred before transmission due to activity on the link.

- Miscellaneous—Shows statistics for received broadcasts.
- Collision Counts—For FastEthernet interfaces only. Shows the following statistics:

  Output Errors—The number of frames not transmitted because the configured maximum number of collisions was exceeded. This counter should only increment during heavy network traffic.

  Collisions—The number of messages retransmitted due to an Ethernet collision (single and multiple collisions). This usually occurs on an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once by the output packets.

  Late Collisions—The number of frames that were not transmitted because a collision occurred outside the normal collision window. A late collision is a collision that is detected late in the transmission of the packet. Normally, these should never happen. When two Ethernet hosts try to talk at once, they should collide early in the packet and both back off, or the second host should see that the first one is talking and wait. If you get a late collision, a device is jumping in and trying to send the packet on the Ethernet while the ASA is partly finished sending the packet. The ASA does not resend the packet, because it may have freed the buffers that held the first part of the packet. This is not a real problem because networking protocols are designed to cope with collisions by resending packets. However, late collisions indicate a problem exists in your network. Common problems are large repeated networks and Ethernet networks running beyond the specification.

- Input Queue—Shows the number of packets in the input queue, the current and the maximum, including the following statistics:

  Hardware Input Queue—The number of packets in the hardware queue.

  Software Input Queue—The number of packets in the software queue.

- Output Queue—Shows the number of packets in the output queue, the current and the maximum, including the following statistics:

  Hardware Output Queue—The number of packets in the hardware queue.

  Software Output Queue—The number of packets in the software queue.

- Add—Adds the selected statistic type to the selected graph window.
- Remove—Removes the selected statistic type from the selected graph window. This button name changes to Delete if the item you are removing was added from another panel, and is not being returned to the Available Graphs pane.
- Show Graphs—Shows the graph window name to which you want to add a statistic type. If you have a graph window already open, a new graph window is listed by default. If you want to add a statistic type to an already open graph, choose the open graph window name. The statistics already included

on the graph are shown in the Selected Graphs pane, to which you can add additional types. Graph windows are named for ASDM followed by the interface IP address and the name “Graph”. Subsequent graphs are named “Graph (2)” and so on.

- Selected Graphs—Shows the statistic types you want to show in the selected graph window. You an include up to four types.
  - Show Graphs—Shows the graph window or updates the graph with additional statistic types if added.

Graph/Table

The Monitoring > Interfaces > Interface Graphs > Graph/Table window shows a graph for the selected statistics. The Graph window can show up to four graphs and tables at a time. By default, the graph or table displays the real-time statistics. If you enable History Metrics (see the “Enabling History Metrics” section on page 4-34), you can view statistics for past time periods.

Fields

- View—Sets the time period for the graph or table. To view any time period other than real-time, enable History Metrics (see the “Enabling History Metrics” section on page 4-34). The data is updated according to the specification of the following options:
  - Real-time, data every 10 sec
  - Last 10 minutes, data every 10 sec
  - Last 60 minutes, data every 1 min
  - Last 12 hours, data every 12 min
  - Last 5 days, data every 2 hours
- Export—Exports the graph in comma-separated value format. If there is more than one graph or table on the Graph window, the Export Graph Data dialog box appears. Choose one or more of the graphs and tables listed by checking the check box next to the name.
- Print—Prints the graph or table. If there is more than one graph or table on the Graph window, the Print Graph dialog box appears. Choose the graph or table you want to print from the Graph/Table Name list.
- Bookmark—Opens a browser window with a single link for all graphs and tables on the Graphs window, as well as individual links for each graph or table. You can then copy these URLs as bookmarks in your browser. ASDM does not have to be running when you open the URL for a graph; the browser launches ASDM and then displays the graph.

Where to Go Next

Complete the interface configuration according to Chapter 17, “Completing Interface Configuration (Routed Mode),” or Chapter 18, “Completing Interface Configuration (Transparent Mode, 8.4 and Later).”

Feature History for ASA 5505 Interfaces

Table 16-1 lists the release history for this feature.

Table 16-1 Feature History for Interfaces

Feature Name	Releases	Feature Information
Increased VLANs	7.2(2)	The maximum number of VLANs for the Security Plus license on the ASA 5505 was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration.
Native VLAN support for the ASA 5505	7.2(4)/8.0(4)	You can now include the native VLAN in an ASA 5505 trunk port. We modified the following screen: Configuration > Device Setup > Interfaces > Switch Ports > Edit Switch Port.

Completing Interface Configuration (Routed Mode)

This chapter includes tasks to complete the interface configuration for all models in routed firewall mode. This chapter includes the following sections:

- Information About Completing Interface Configuration in Routed Mode, page 17-1
- Licensing Requirements for Completing Interface Configuration in Routed Mode, page 17-2
- Guidelines and Limitations, page 17-5
- Default Settings, page 17-6
- Completing Interface Configuration in Routed Mode, page 17-6
- Turning Off and Turning On Interfaces, page 17-22
- Monitoring Interfaces, page 17-22
- Feature History for Interfaces in Routed Mode, page 17-30

Note For multiple context mode, complete the tasks in this section in the context execution space. In the Configuration > Device List pane, double-click the context name under the active device IP address.

Information About Completing Interface Configuration in Routed Mode

This section includes the following topics:

- Security Levels, page 17-1
- Dual IP Stack (IPv4 and IPv6), page 17-2

Security Levels

Each interface must have a security level from 0 (lowest) to 100 (highest). For example, you should assign your most secure network, such as the inside host network, to level 100. While the outside network connected to the Internet can be level 0. Other networks, such as DMZs can be in between. You can assign interfaces to the same security level. See the "Allowing Same Security Level Communication" section on page 17-20 for more information.

The level controls the following behavior:

- Network access—By default, there is an implicit permit from a higher security interface to a lower security interface (outbound). Hosts on the higher security interface can access any host on a lower security interface. You can limit access by applying an access list to the interface.

  If you enable communication for same security interfaces (see the "Allowing Same Security Level Communication" section on page 17-20), there is an implicit permit for interfaces to access other interfaces on the same security level or lower.

- Inspection engines—Some application inspection engines are dependent on the security level. For same security interfaces, inspection engines apply to traffic in either direction.
  - NetBIOS inspection engine—Applied only for outbound connections.
  - SQL*Net inspection engine—If a control connection for the SQL*Net (formerly OraServ) port exists between a pair of hosts, then only an inbound data connection is permitted through the ASA.

- Filtering—HTTP(S) and FTP filtering applies only for outbound connections (from a higher level to a lower level).

  If you enable communication for same security interfaces, you can filter traffic in either direction.

- **established** command—This command allows return connections from a lower security host to a higher security host if there is already an established connection from the higher level host to the lower level host.

  If you enable communication for same security interfaces, you can configure **established** commands for both directions.

Dual IP Stack (IPv4 and IPv6)

The ASA supports the configuration of both IPv6 and IPv4 on an interface. You do not need to enter any special commands to do so; simply enter the IPv4 configuration commands and IPv6 configuration commands as you normally would. Make sure you configure a default route for both IPv4 and IPv6.

Licensing Requirements for Completing Interface Configuration in Routed Mode

Model	License Requirement
ASA 5505	VLANs: Base License: 3 (2 regular zones and 1 restricted zone that can only communicate with 1 other zone) Security Plus License: 20 VLAN Trunks: Base License: None. Security Plus License: 8. Interfaces of all types[1]: Base License: 52. Security Plus License: 120.

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, and bridge group interfaces.

Model	License Requirement
ASA 5510	VLANs: Base License: 50 Security Plus License: 100 Interface Speed: Base License—All interfaces Fast Ethernet. Security Plus License—Ethernet 0/0 and 0/1: Gigabit Ethernet; all others Fast Ethernet. Interfaces of all types[1]: Base License: 52 Security Plus License: 120
ASA 5520	VLANs: Base License: 150. Interfaces of all types[1]: Base License: 640
ASA 5540	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 840
ASA 5550	VLANs: Base License: 400 Interfaces of all types[1]: Base License: 1640

Model	License Requirement
ASA 5580	VLANs: Base License: 1024 Interfaces of all types[1]: Base License: 4176
ASA 5512-X	VLANs: Base License: 50 Interfaces of all types[1]: Base License: 328
ASA 5515-X	VLANs: Base License: 100 Interfaces of all types[1]: Base License: 528
ASA 5525-X	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 928
ASA 5545-X	VLANs: Base License: 300 Interfaces of all types[1]: Base License: 1328
ASA 5555-X	VLANs: Base License: 500 Interfaces of all types[1]: Base License: 2128
ASA 5585-X	VLANs: Base License: 1024 Interface Speed for SSP-10 and SSP-20: Base License—1-Gigabit Ethernet for fiber interfaces 10 GE I/O License (Security Plus)—10-Gigabit Ethernet for fiber interfaces (SSP-40 and SSP-60 support 10-Gigabit Ethernet by default.) Interfaces of all types[1]: Base License: 4176

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, bridge group, and EtherChannel interfaces.

Model	License Requirement
ASASM	VLANs: Base License: 1000

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

- For the ASA 5510 and higher in multiple context mode, configure the physical interfaces in the system execution space according to Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)." Then, configure the logical interface parameters in the context execution space according to this chapter. For the ASASM in multiple context mode, configure switch ports and VLANs on the switch, and then assign VLANs to the ASASM according to Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

  The ASA 5505 does not support multiple context mode.
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- PPPoE is not supported in multiple context mode.

Firewall Mode Guidelines

Supported in routed firewall mode. For transparent mode, see Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later)."

Failover Guidelines

Do not finish configuring failover interfaces with the procedures in this chapter. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links. In multiple context mode, failover interfaces are configured in the system configuration.

IPv6 Guidelines

Supports IPv6.

VLAN ID Guidelines for the ASASM

You can add any VLAN ID to the configuration, but only VLANs that are assigned to the ASA by the switch can pass traffic. To view all VLANs assigned to the ASA, use the **show vlan** command.

If you add an interface for a VLAN that is not yet assigned to the ASA by the switch, the interface will be in the down state. When you assign the VLAN to the ASA, the interface changes to an up state. See the **show interface** command for more information about interface states.

Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the "Factory Default Configurations" section on page 3-17.

Default Security Level

The default security level is 0. If you name an interface "inside" and you do not set the security level explicitly, then the ASA sets the security level to 100.

Note If you change the security level of an interface, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Default State of Interfaces for the ASASM

- In single mode or in the system execution space, VLAN interfaces are enabled by default.
- In multiple context mode, all allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.

Jumbo Frame Support

By default, the ASASM supports jumbo frames. Just configure the MTU for the desired packet size according to the "Configuring the MAC Address and MTU" section on page 17-13.

Completing Interface Configuration in Routed Mode

This section includes the following topics:

- Task Flow for Completing Interface Configuration, page 17-7
- Configuring General Interface Parameters, page 17-7
- Configuring the MAC Address and MTU, page 17-13
- Configuring IPv6 Addressing, page 17-15
- Allowing Same Security Level Communication, page 17-20

Task Flow for Completing Interface Configuration

Step 1 Set up your interfaces depending on your model:

- ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
- ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
- ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

Step 2 (Multiple context mode) Allocate interfaces to the context according to the "Configuring Multiple Contexts" section on page 9-15.

Step 3 (Multiple context mode) In the Configuration > Device List pane, double-click the context name under the active device IP address.

Step 4 Configure general interface parameters, including the interface name, security level, and IPv4 address. See the "Configuring General Interface Parameters" section on page 17-7.

Step 5 (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 17-13.

Step 6 (Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 17-15.

Step 7 (Optional) Allow same security level communication, either by allowing communication between two interfaces or by allowing traffic to enter and exit the same interface. See the "Allowing Same Security Level Communication" section on page 17-20.

Configuring General Interface Parameters

This procedure describes how to set the name, security level, IPv4 address and other options.

For the ASA 5510 and higher, you must configure interface parameters for the following interface types:

- Physical interfaces
- VLAN subinterfaces
- Redundant interfaces
- EtherChannel interfaces

For the ASA 5505 and ASASM, you must configure interface parameters for the following interface types:

- VLAN interfaces

Guidelines and Limitations

- For the ASA 5550, for maximum throughput, be sure to balance your traffic over the two interface slots; for example, assign the inside interface to slot 1 and the outside interface to slot 0.
- If you are using failover, do not use this procedure to name interfaces that you are reserving for failover and Stateful Failover communications. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links.

Restrictions

- PPPoE is not supported in multiple context mode.
- PPPoE and DHCP are not supported on the ASASM.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

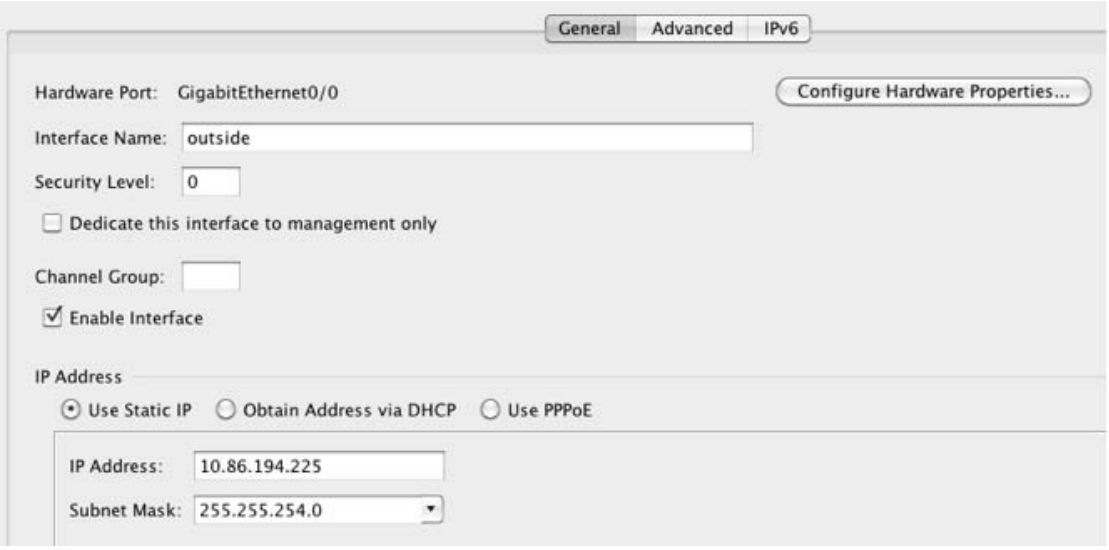
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

For the ASA 5505, the Interfaces tab shows by default.

Step 2 Choose the interface row, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.



Step 3 In the Interface Name field, enter a name up to 48 characters in length.

Step 4 In the Security level field, enter a level between 0 (lowest) and 100 (highest).

See the "Security Levels" section on page 17-1 for more information.

Step 5 (Optional; not supported for redundant interfaces) To set this interface as a management-only interface, check the **Dedicate this interface to management-only** check box.

Through traffic is not accepted on a management-only interface. For the ASA 5510 and higher, see the "Prerequisites" section on page 17-8 for more information.

(ASA 5512-X through ASA 5555-X) You cannot disable this option on the Management 0/0 interface.

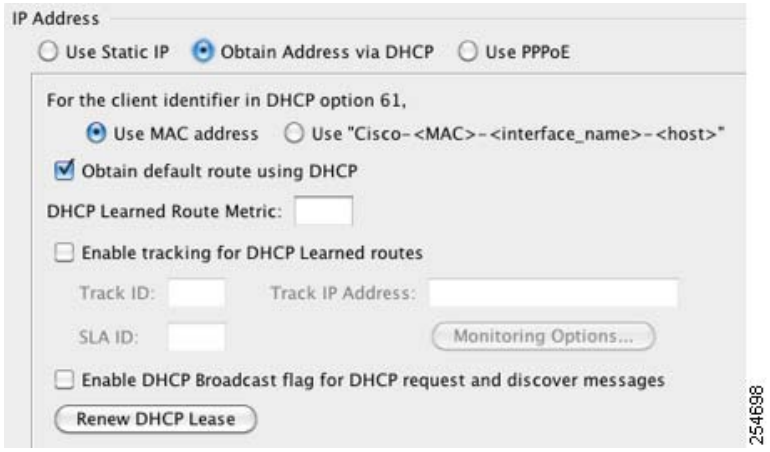
Note The Channel Group field is read-only and indicates if the interface is part of an EtherChannel.

Step 6 If the interface is not already enabled, check the **Enable Interface** check box.

Step 7 To set the IP address, one of the following options.

Note For use with failover, you must set the IP address and standby address manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the Configuration > Device Management > High Availability > Failover > Interfaces tab.

- To set the IP address manually, click the **Use Static IP** radio button and enter the IP address and mask.
- To obtain an IP address from a DHCP server, click the **Obtain Address via DHCP** radio button.



a. To force a MAC address to be stored inside a DHCP request packet for option 61, click the **Use MAC Address** radio button.

   Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned.

b. To use a generated string for option 61, click **Use "Cisco-<MAC>-<interface_name>-<host>"**.

c. (Optional) To obtain the default route from the DHCP server, check **Obtain Default Route Using DHCP**.

d. (Optional) To assign an administrative distance to the learned route, enter a value between 1 and 255 in the DHCP Learned Route Metric field. If this field is left blank, the administrative distance for the learned routes is 1.

e. (Optional) To enable tracking for DHCP-learned routes, check **Enable Tracking for DHCP Learned Routes**. Set the following values:

Track ID—A unique identifier for the route tracking process. Valid values are from 1 to 500.

Track IP Address—Enter the IP address of the target being tracked. Typically, this would be the IP address of the next hop gateway for the route, but it could be any network object available off of that interface.

Note Route tracking is only available in single, routed mode.

SLA ID—A unique identifier for the SLA monitoring process. Valid values are from 1 to 2147483647.

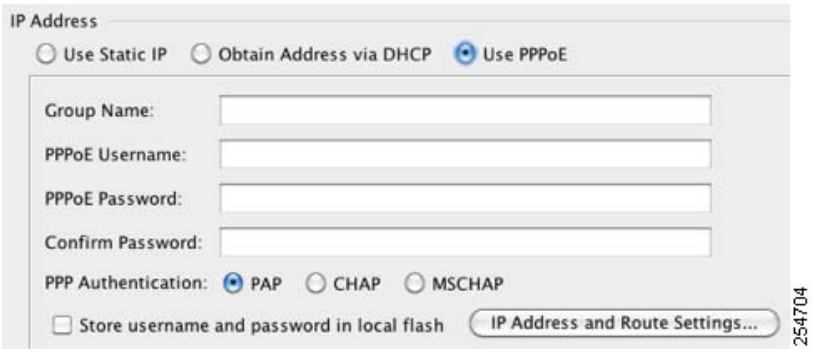
Monitor Options—Click this button to open the Route Monitoring Options dialog box. In the Route Monitoring Options dialog box you can configure the parameters of the tracked object monitoring process.

f. (Optional) To set the broadcast flag to 1 in the DHCP packet header when the DHCP client sends a discover requesting an IP address, check **Enable DHCP Broadcast flag for DHCP request and discover messages**.

The DHCP server listens to this broadcast flag and broadcasts the reply packet if the flag is set to 1.

g. (Optional) To renew the lease, click **Renew DHCP Lease**.

- (Single mode only) To obtain an IP address using PPPoE, check **Use PPPoE**.



a. In the Group Name field, specify a group name.

b. In the PPPoE Username field, specify the username provided by your ISP.

c. In the PPPoE Password field, specify the password provided by your ISP.

d. In the Confirm Password field, retype the password.

e. For PPP authentication, click either the **PAP**, **CHAP**, or **MSCHAP** radio button.

PAP passes cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.

f. (Optional) To store the username and password in Flash memory, check the **Store Username and Password in Local Flash** check box.

The ASA stores the username and password in a special location of NVRAM. If an Auto Update Server sends a **clear configure** command to the ASA, and the connection is then interrupted, the ASA can read the username and password from NVRAM and re-authenticate to the Access Concentrator.

g. (Optional) To display the PPPoE IP Address and Route Settings dialog box where you can choose addressing and tracking options, click **IP Address and Route Settings**. See the "PPPoE IP Address and Route Settings" section on page 17-11 for more information.

Step 8 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Note (ASA 5510 and higher) For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

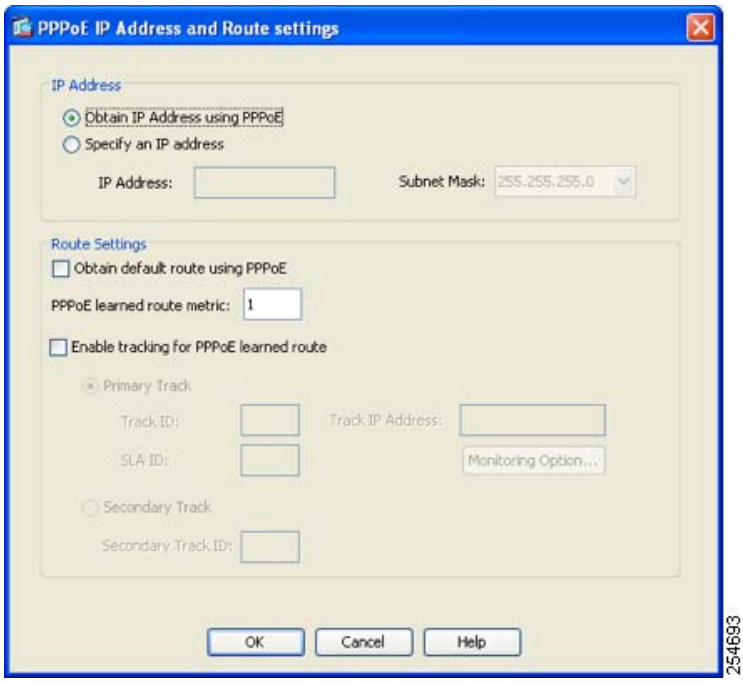
Step 9 Click **OK**.

What to Do Next

- (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 17-13.
- (Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 17-15.

PPPoE IP Address and Route Settings

The Configuration > Interfaces > Add/Edit Interface > General > PPPoE IP Address and Route Settings > PPPoE IP Address and Route Settings dialog box lets you choose addressing and tracking options for PPPoE connections.



Fields

- IP Address area—Lets you choose between Obtaining an IP address using PPP or specifying an IP address, and contains the following fields:
  - Obtain IP Address using PPP—Select to enable the ASA to use PPP to get an IP address.
  - Specify an IP Address—Specify an IP address and mask for the ASA to use instead of negotiating with the PPPoE server to assign an address dynamically.
- Route Settings Area—Lets you configure route and tracking settings and contains the following fields:
  - Obtain default route using PPPoE—Sets the default routes when the PPPoE client has not yet established a connection. When using this option, you cannot have a statically defined route in the configuration.

    PPPoE learned route metric—Assigns an administrative distance to the learned route. Valid values are from 1 to 255. If this field is left blank, the administrative distance for the learned routes is 1.
  - Enable tracking—Check this check box to enable route tracking for PPPoE-learned routes.

    Note Route tracking is only available in single, routed mode.
  - Primary Track—Select this option to configure the primary PPPoE route tracking.
  - Track ID—A unique identifier for the route tracking process. Valid values are from 1 to 500.
  - Track IP Address—Enter the IP address of the target being tracked. Typically, this would be the IP address of the next hop gateway for the route, but it could be any network object available off of that interface.

- SLA ID—A unique identifier for the SLA monitoring process. Valid values are from 1 to 2147483647.
- Monitor Options—Click this button to open the Route Monitoring Options dialog box. In the Route Monitoring Options dialog box you can configure the parameters of the tracked object monitoring process.
- Secondary Track—Select this option to configure the secondary PPPoE route tracking.
- Secondary Track ID—A unique identifier for the route tracking process. Valid values are from 1 to 500.

Configuring the MAC Address and MTU

This section describes how to configure MAC addresses for interfaces and how to set the MTU.

Information About MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

For the ASASM, all VLANs use the same MAC address provided by the backplane.

A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. If you assign a MAC address to the redundant interface using this command, then it is used regardless of the member interface MAC addresses.

For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses the lowest numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can manually configure a MAC address for the port-channel interface. In multiple context mode, you can automatically assign unique MAC addresses to interfaces, including an EtherChannel port interface. We recommend manually, or in multiple context mode, automatically configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.

In multiple context mode, if you share an interface between contexts, you can assign a unique MAC address to the interface in each context. This feature lets the ASA easily classify packets into the appropriate context. Using a shared interface without unique MAC addresses is possible, but has some limitations. See the "How the ASA Classifies Packets" section on page 9-3 for more information. You can assign each MAC address manually, or you can automatically generate MAC addresses for shared interfaces in contexts. See the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24 to automatically generate MAC addresses. If you automatically generate MAC addresses, you can use this procedure to override the generated address.

For single context mode, or for interfaces that are not shared in multiple context mode, you might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address.

Information About the MTU

The MTU is the maximum datagram size that is sent on a connection. Data that is larger than the MTU value is fragmented before being sent.

The ASA supports IP path MTU discovery (as defined in RFC 1191), which allows a host to dynamically discover and cope with the differences in the maximum allowable MTU size of the various links along the path. Sometimes, the ASA cannot forward a datagram because the packet is larger than the MTU that you set for the interface, but the "don't fragment" (DF) bit is set. The network software sends a message to the sending host, alerting it to the problem. The host has to fragment packets for the destination so that they fit the smallest packet size of all the links along the path.

The default MTU is 1500 bytes in a block for Ethernet interfaces. This value is sufficient for most applications, but you can pick a lower number if network conditions require it.

Jumbo frames are supported by default on the ASASM. To enable jumbo frames, see the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. Jumbo frames require extra memory to process, and assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. To use jumbo frames, set the value higher, for example, to 9000 bytes.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

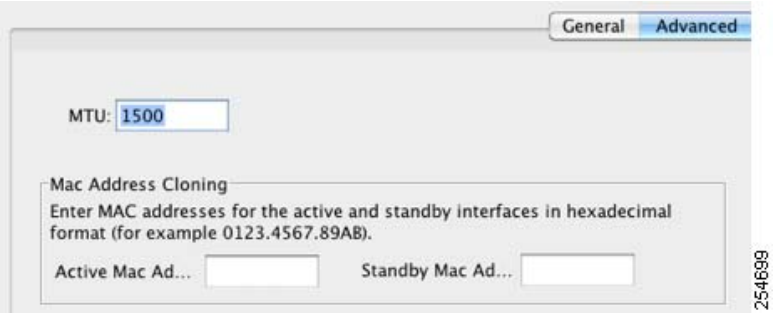
Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

For the ASA 5505, the Interfaces tab shows by default.

Step 2 Choose the interface row, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **Advanced** tab.



Step 4 To set the MTU or to enable jumbo frame support (supported models only), enter the value in the MTU field, between 300 and 65,535 bytes.

The default is 1500 bytes.

Note When you set the MTU for a redundant or port-channel interface, the ASA applies the setting to all member interfaces.

- For models that support jumbo frames in single mode—If you enter a value for any interface that is greater than 1500, then you enable jumbo frame support automatically for all interfaces. If you set the MTU for all interfaces back to a value under 1500, then jumbo frame support is disabled.
- For models that support jumbo frames in multiple mode—If you enter a value for any interface that is greater than 1500, then be sure to enable jumbo frame support in the system configuration. See the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

Note Enabling or disabling jumbo frame support requires you to reload the ASA.

Step 5 To manually assign a MAC address to this interface, enter a MAC address in the Active Mac Address field in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The first two bytes of a manual MAC address cannot be A2 if you also want to use auto-generated MAC addresses.

Step 6 If you use failover, enter the standby MAC address in the Standby Mac Address field. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

What to Do Next

(Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 17-15.

Configuring IPv6 Addressing

This section describes how to configure IPv6 addressing. For more information about IPv6, see the "IPv6 Addresses" section on page A-5.

This section includes the following topics:

- Information About IPv6, page 17-16

- Configuring a Global IPv6 Address, page 17-16
- Configuring IPv6 Neighbor Discovery, page 17-18
- (Optional) Configuring the Link-Local Addresses Automatically, page 17-19
- (Optional) Configuring the Link-Local Addresses Manually, page 17-19

Information About IPv6

This section includes information about how to configure IPv6, and includes the following topics:

- IPv6 Addressing, page 17-16
- Modified EUI-64 Interface IDs, page 17-16

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the ND functions such as address resolution and neighbor discovery.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The ASA can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
%ASA-3-325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

Configuring a Global IPv6 Address

To configure a global IPv6 address, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately.

Restrictions

The ASA does not support IPv6 anycast addresses.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

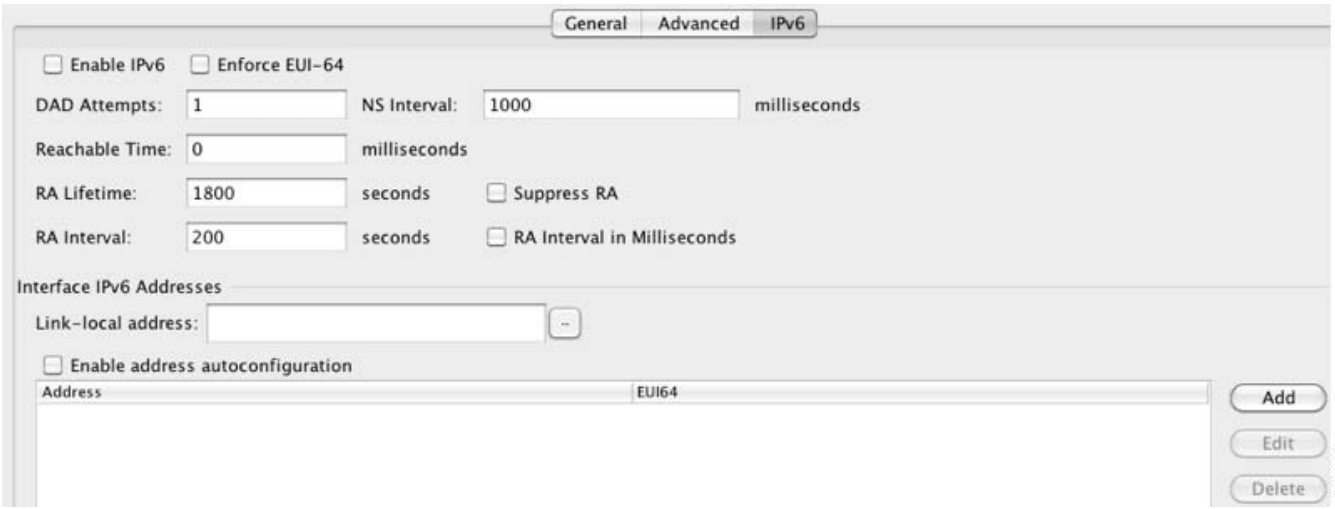
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Choose an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.



Step 4 Check the **Enable IPv6** check box.

Step 5 (Optional) To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.

See the "Modified EUI-64 Interface IDs" section on page 17-16 for more information.

Step 6 (Optional) In the top area, customize the IPv6 configuration by referring to Chapter 37, "Configuring IPv6 Neighbor Discovery."

Step 7 Configure the global IPv6 address using one of the following methods.

- Stateless autoconfiguration—In the Interface IPv6 Addresses area, check the **Enable address autoconfiguration** check box.

  Enabling stateless autconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

  Note Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the ASA does send Router Advertisement messages in this case. See the **Suppress RA chck box** to suppress messages.

- Manual configuration—To manually configure a global IPv6 address:

  a. In the Interface IPv6 Addresses area, click **Add**.

  The Add IPv6 Address for Interface dialog box appears.

  b. In the Address/Prefix Length field, enter either full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. If you only enter the prefix, then be sure to check the **EUI 64** checkbox to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked). See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

  Note For information about the ASA Cluster IP Pool, see the "Configuring Individual Interfaces (Recommended for the Management Interface)" section on page 10-32.

  c. Click **OK**.

Step 8 (Optional) To configure which IPv6 prefixes are included in IPv6 router advertisements, refer to the "Configuring the IPv6 Prefix in Router Advertisements" section on page 37-11.

Step 9 Click **OK**.

You return to the Configuration > Device Setup > Interfaces pane.

Configuring IPv6 Neighbor Discovery

See Chapter 37, "Configuring IPv6 Neighbor Discovery," to configure IPv6 neighbor discovery.

(Optional) Configuring the Link-Local Addresses Automatically

If you do not want to configure a global address, and only need to configure a link-local address, you have the option of generating the link-local addresses based on the interface MAC addresses (Modified EUI-64 format. Because MAC addresses use 48 bits, additional bits must be inserted to fill the 64 bits required for the interface ID.)

To manually assign the link-local address (not recommended), see the "(Optional) Configuring the Link-Local Addresses Manually" section on page 17-19.

For other IPv6 options, including enforcing the Modified EUI-64 format, and DAD settings, see the "Configuring a Global IPv6 Address" section on page 17-16.

To automatically configure the link-local addresses for an interface, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Select an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.

Step 4 In the IPv6 configuration area, check the **Enable IPv6** check box.

This option enables IPv6 and automatically generates the link-local address using the Modified EUI-64 interface ID based on the interface MAC address.

Step 5 Click **OK**.

(Optional) Configuring the Link-Local Addresses Manually

If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

To automatically assign the link-local address (recommended), see the "(Optional) Configuring the Link-Local Addresses Automatically" section on page 17-19.

For other IPv6 options, including enforcing the Modified EUI-64 format, and DAD settings, see the "Configuring a Global IPv6 Address" section on page 17-16.

To assign a link-local address to an interface, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Select an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.

Step 4 To set the link-local address, enter an address in the Link-local address field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

Step 5 Click **OK**.

Allowing Same Security Level Communication

By default, interfaces on the same security level cannot communicate with each other, and packets cannot enter and exit the same interface. This section describes how to enable inter-interface communication when interfaces are on the same security level, and how to enable intra-interface communication.

Information About Inter-Interface Communication

Allowing interfaces on the same security level to communicate with each other provides the following benefits:

- You can configure more than 101 communicating interfaces.

  If you use different levels for each interface and do not assign any interfaces to the same security level, you can configure only one interface per level (0 to 100).
- You want traffic to flow freely between all same security interfaces without access lists.

If you enable same security interface communication, you can still configure interfaces at different security levels as usual.

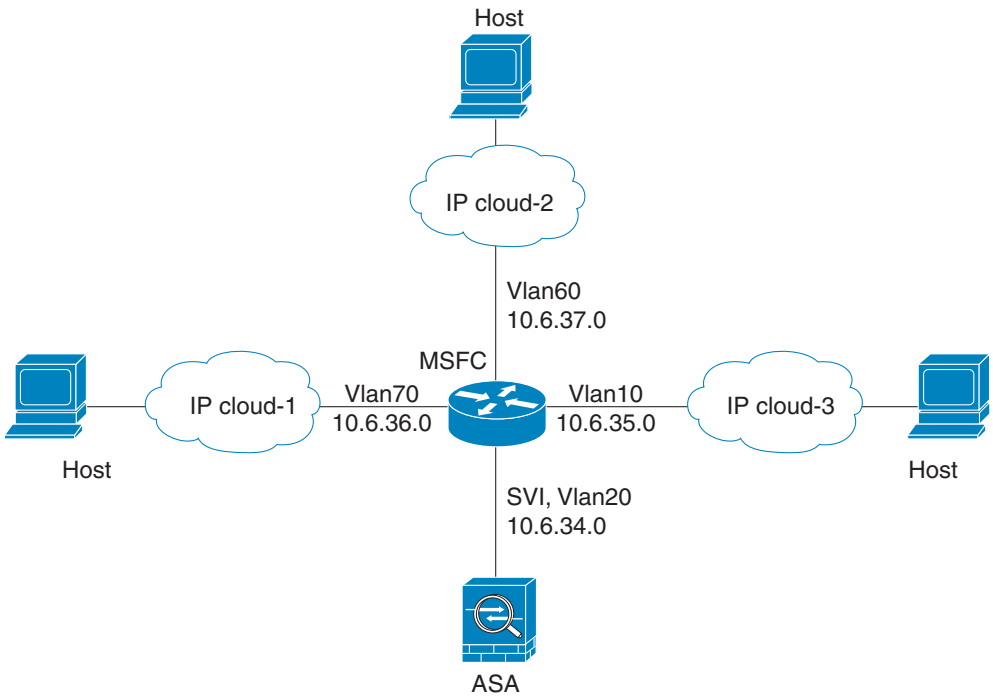
Information About Intra-Interface Communication

Intra-interface communication might be useful for VPN traffic that enters an interface, but is then routed out the same interface. The VPN traffic might be unencrypted in this case, or it might be reencrypted for another VPN connection. For example, if you have a hub and spoke VPN network, where the ASA is the hub, and remote VPN networks are spokes, for one spoke to communicate with another spoke, traffic must go into the ASA and then out again to the other spoke.

Note All traffic allowed by this feature is still subject to firewall rules. Be careful not to create an asymmetric routing situation that can cause return traffic not to traverse the ASA.

For the ASASM, before you can enable this feature, you must first correctly configure the MSFC so that packets are sent to the ASA MAC address instead of being sent directly through the switch to the destination host. Figure 17-1 shows a network where hosts on the same interface need to communicate.

Figure 17-1 Communication Between Hosts on the Same Interface



The following sample configuration shows the Cisco IOS **route-map** commands used to enable policy routing in the network shown in Figure 17-1:

```
route-map intra-inter3 permit 0
    match ip address 103
    set interface Vlan20
    set ip next-hop 10.6.34.7
!
route-map intra-inter2 permit 20
    match ip address 102
    set interface Vlan20
    set ip next-hop 10.6.34.7
!
route-map intra-inter1 permit 10
    match ip address 101
    set interface Vlan20
    set ip next-hop 10.6.34.7
```

Detailed Steps

- To enable interfaces on the same security level to communicate with each other, from the Configuration > Interfaces pane, check **Enable traffic between two or more interfaces which are configured with same security level**.
- To enable communication between hosts connected to the same interface, check **Enable traffic between two or more hosts connected to the same interface**.

Turning Off and Turning On Interfaces

This section describes how to turn off and on an interface.

All interfaces are enabled by default. In multiple context mode, if you disable or reenable the interface within a context, only that context interface is affected. But if you disable or reenable the interface in the system execution space, then you affect that interface for all contexts.

Detailed Steps

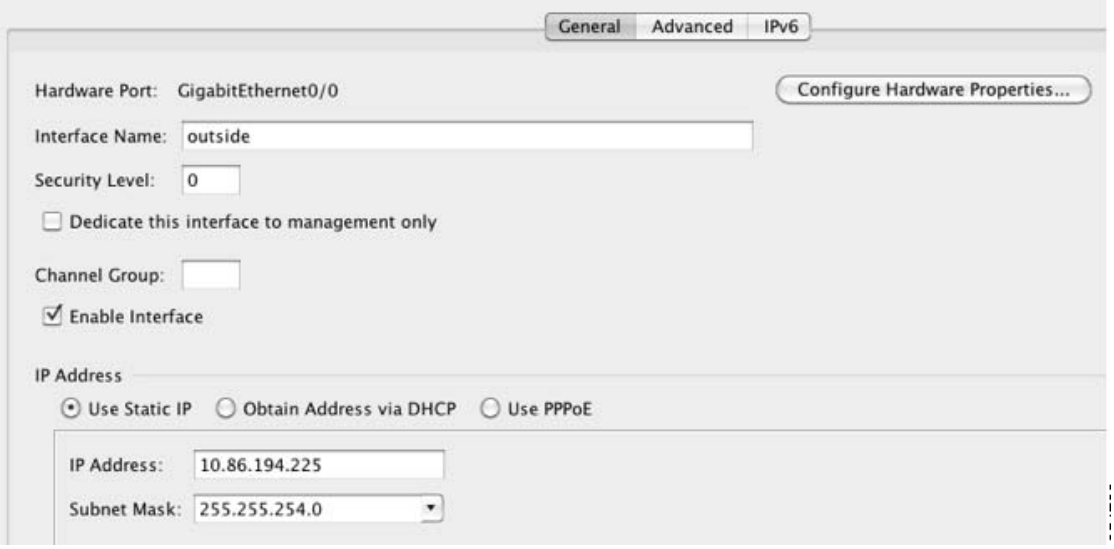
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

By default, all physical interfaces are listed.

Step 2 Click a VLAN interface that you want to configure, and click **Edit**.

The Edit Interface dialog box appears.



Step 3 To enable or disable the interface, check or uncheck the **Enable Interface** check box.

Monitoring Interfaces

This section includes the following topics:

- ARP Table, page 17-23
- DHCP, page 17-23
- MAC Address Table, page 17-26
- Dynamic ACLs, page 17-26

- Interface Graphs, page 17-26
- PPPoE Client, page 17-29
- Interface Connection, page 17-29

ARP Table

The Monitoring > Interfaces > ARP Table pane displays the ARP table, including static and dynamic entries. The ARP table includes entries that map a MAC address to an IP address for a given interface.

Fields

- Interface—Lists the interface name associated with the mapping.
- IP Address—Shows the IP address.
- MAC Address—Shows the MAC address.
- Proxy ARP—Displays Yes if proxy ARP is enabled on the interface. Displays No if proxy ARP is not enabled on the interface.
- Clear—Clears the dynamic ARP table entries. Static entries are not cleared.
- Refresh—Refreshes the table with current information from the ASA and updates Last Updated date and time.
- Last Updated—*Display only.* Shows the date and time the display was updated.

DHCP

The ASA lets you monitor DHCP status, including the addresses assigned to clients, the lease information for the ASA interface, and DHCP statistics.

DHCP Server Table

The Monitoring > Interfaces > DHCP > DHCP Server Table lists the IP addresses assigned to DHCP clients.

Fields

- IP Address—Shows the IP address assigned to the client.
- Client-ID—Shows the client MAC address or ID.
- Lease Expiration—Shows the date that the DHCP lease expires. The lease indicates how long the client can use the assigned IP address. Remaining time is also specified in the number of seconds and is based on the timestamp in the Last Updated display-only field.
- Number of Active Leases—Shows the total number of DHCP leases.
- Refresh—Refreshes the information from the ASA.
- Last Updated—Shows when the data in the table was last updated.

DHCP Client Lease Information

If you obtain the ASA interface IP address from a DHCP server, the Monitoring > Interfaces > DHCP > DHCP Server Table > DHCP Client Lease Information pane shows information about the DHCP lease.

Fields

- Select an interface—Lists the ASA interfaces. Choose the interface for which you want to view the DHCP lease. If an interface has multiple DHCP leases, then choose the interface and IP address pair you want to view.
- Attribute and Value—Lists the attributes and values of the interface DHCP lease.
  - Temp IP addr—*Display only.* The IP address assigned to the interface.
  - Temp sub net mask—*Display only.* The subnet mask assigned to the interface.
  - DHCP lease server—*Display only.* The DHCP server address.
  - state—*Display only.* The state of the DHCP lease, as follows:

    Initial—The initialization state, where the ASA begins the process of acquiring a lease. This state is also shown when a lease ends or when a lease negotiation fails.

    Selecting—The ASA is waiting to receive DHCPOFFER messages from one or more DHCP servers, so it can choose one.

    Requesting—The ASA is waiting to hear back from the server to which it sent its request.

    Purging—The ASA is removing the lease because of an error.

    Bound—The ASA has a valid lease and is operating normally.

    Renewing—The ASA is trying to renew the lease. It regularly sends DHCPREQUEST messages to the current DHCP server, and waits for a reply.

    Rebinding—The ASA failed to renew the lease with the original server, and now sends DHCPREQUEST messages until it gets a reply from any server or the lease ends.

    Holddown—The ASA started the process to remove the lease.

    Releasing—The ASA sends release messages to the server indicating that the IP address is no longer needed.
  - Lease—*Display only.* The length of time, specified by the DHCP server, that the interface can use this IP address.
  - Renewal—*Display only.* The length of time until the interface automatically attempts to renew this lease.
  - Rebind—*Display only.* The length of time until the ASA attempts to rebind to a DHCP server. Rebinding occurs if the ASA cannot communicate with the original DHCP server, and 87.5 percent of the lease time has expired. The ASA then attempts to contact any available DHCP server by broadcasting DHCP requests.
  - Next timer fires after—*Display only.* The number of seconds until the internal timer triggers.
  - Retry count—*Display only.* If the ASA is attempting to establish a lease, this field shows the number of times the ASA tried sending a DHCP message. For example, if the ASA is in the Selecting state, this value shows the number of times the ASA sent discover messages. If the ASA is in the Requesting state, this value shows the number of times the ASA sent request messages.
  - Client-ID—*Display only.* The client ID used in all communication with the server.

  - Proxy—*Display only.* Specifies if this interface is a proxy DHCP client for VPN clients, True or False.
  - Hostname—*Display only.* The client hostname.

DHCP Statistics

The Monitoring > Interfaces > DHCP > DHCP Statistics pane shows statistics for the DHCP server feature.

Fields

- Message Type—Lists the DHCP message types sent or received:
  - BOOTREQUEST
  - DHCPDISCOVER
  - DHCPREQUEST
  - DHCPDECLINE
  - DHCPRELEASE
  - DHCPINFORM
  - BOOTREPLY
  - DHCPOFFER
  - DHCPACK
  - DHCPNAK
- Count—Shows the number of times a specific message was processed.
- Direction—Shows if the message type is Sent or Received.
- Total Messages Received—Shows the total number of messages received by the ASA.
- Total Messages Sent—Shows the total number of messages sent by the ASA.
- Counter—Shows general statistical DHCP data, including the following:
  - DHCP UDP Unreachable Errors
  - DHCP Other UDP Errors
  - Address Pools
  - Automatic Bindings
  - Expired Bindings
  - Malformed Messages
- Value—Shows the number of each counter item.
- Refresh—Updates the DHCP table listings.
- Last Updated—Shows when the data in the tables was last updated.

MAC Address Table

The Monitoring > Interfaces > MAC Address Table pane shows the static and dynamic MAC address entries. See the "MAC Address Table" section on page 17-26 for more information about the MAC address table and adding static entries.

Fields

- Interface—Shows the interface name associated with the entry.
- MAC Address—Shows the MAC address.
- Type—Shows if the entry is static or dynamic.
- Age—Shows the age of the entry, in minutes. To set the timeout, see the "MAC Address Table" section on page 17-26.
- Refresh—Refreshes the table with current information from the ASA.

Dynamic ACLs

The Monitoring > Interfaces > Dynamic ACLs pane shows a table of the Dynamic ACLs, which are functionally identical to the user-configured ACLs except that they are created, activated and deleted automatically by the ASA. These ACLs do not show up in the configuration and are only visible in this table. They are identified by the "(dynamic)" keyword in the ACL header.

When you choose an ACL in this table, the contents of the ACL are shown in the bottom text field.

Fields

- ACL—Shows the name of the dynamic ACL.
- Element Count—Shows the number of elements in the ACL
- Hit Count—Shows the total hit count for all of the elements in the ACL.

Interface Graphs

The Monitoring > Interfaces > Interface Graphs pane lets you view interface statistics in graph or table form. If an interface is shared among contexts, the ASA shows only statistics for the current context. The number of statistics shown for a subinterface is a subset of the number of statistics shown for a physical interface.

Fields

- Available Graphs for—Lists the types of statistics available for monitoring. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.
  - Byte Counts—Shows the number of bytes input and output on the interface.
  - Packet Counts—Shows the number of packets input and output on the interface.
  - Packet Rates—Shows the rate of packets input and output on the interface.
  - Bit Rates—Shows the bit rate for the input and output of the interface.
  - Drop Packet Count—Shows the number of packets dropped on the interface.

  These additional statistics display for physical interfaces:

- Buffer Resources—Shows the following statistics:

  Overruns—The number of times that the ASA was incapable of handing received data to a hardware buffer because the input rate exceeded the ASA capability to handle the data.

  Underruns—The number of times that the transmitter ran faster than the ASA could handle.

  No Buffer—The number of received packets discarded because there was no buffer space in the main system. Compare this with the ignored count. Broadcast storms on Ethernet networks are often responsible for no input buffer events.

- Packet Errors—Shows the following statistics:

  CRC—The number of Cyclical Redundancy Check errors. When a station sends a frame, it appends a CRC to the end of the frame. This CRC is generated from an algorithm based on the data in the frame. If the frame is altered between the source and destination, the ASA notes that the CRC does not match. A high number of CRCs is usually the result of collisions or a station transmitting bad data.

  Frame—The number of frame errors. Bad frames include packets with an incorrect length or bad frame checksums. This error is usually the result of collisions or a malfunctioning Ethernet device.

  Input Errors—The number of total input errors, including the other types listed here. Other input-related errors can also cause the input error count to increase, and some datagrams might have more than one error; therefore, this sum might exceed the number of errors listed for the other types.

  Runts—The number of packets that are discarded because they are smaller than the minimum packet size, which is 64 bytes. Runts are usually caused by collisions. They might also be caused by poor wiring and electrical interference.

  Giants—The number of packets that are discarded because they exceed the maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.

  Deferred—For FastEthernet interfaces only. The number of frames that were deferred before transmission due to activity on the link.

- Miscellaneous—Shows statistics for received broadcasts.

- Collision Counts—For FastEthernet interfaces only. Shows the following statistics:

  Output Errors—The number of frames not transmitted because the configured maximum number of collisions was exceeded. This counter should only increment during heavy network traffic.

  Collisions—The number of messages retransmitted due to an Ethernet collision (single and multiple collisions). This usually occurs on an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once by the output packets.

  Late Collisions—The number of frames that were not transmitted because a collision occurred outside the normal collision window. A late collision is a collision that is detected late in the transmission of the packet. Normally, these should never happen. When two Ethernet hosts try to talk at once, they should collide early in the packet and both back off, or the second host should see that the first one is talking and wait. If you get a late collision, a device is jumping in and trying to send the packet on the Ethernet while the ASA is partly finished sending the packet. The ASA does not resend the packet, because it may have freed the buffers that held the first part of the packet. This is not a real problem because networking protocols are designed to cope with collisions by resending packets. However, late collisions indicate a problem exists in your network. Common problems are large repeated networks and Ethernet networks running beyond the specification.

  - Input Queue—Shows the number of packets in the input queue, the current and the maximum, including the following statistics:

    Hardware Input Queue—The number of packets in the hardware queue.

    Software Input Queue—The number of packets in the software queue.

  - Output Queue—Shows the number of packets in the output queue, the current and the maximum, including the following statistics:

    Hardware Output Queue—The number of packets in the hardware queue.

    Software Output Queue—The number of packets in the software queue.

- Add—Adds the selected statistic type to the selected graph window.
- Remove—Removes the selected statistic type from the selected graph window. This button name changes to Delete if the item you are removing was added from another panel, and is not being returned to the Available Graphs pane.
- Show Graphs—Shows the graph window name to which you want to add a statistic type. If you have a graph window already open, a new graph window is listed by default. If you want to add a statistic type to an already open graph, choose the open graph window name. The statistics already included on the graph are shown in the Selected Graphs pane, to which you can add additional types. Graph windows are named for ASDM followed by the interface IP address and the name "Graph". Subsequent graphs are named "Graph (2)" and so on.
- Selected Graphs—Shows the statistic types you want to show in the selected graph window. You an include up to four types.
  - Show Graphs—Shows the graph window or updates the graph with additional statistic types if added.

Graph/Table

The Monitoring > Interfaces > Interface Graphs > Graph/Table window shows a graph for the selected statistics. The Graph window can show up to four graphs and tables at a time. By default, the graph or table displays the real-time statistics. If you enable History Metrics (see the "Enabling History Metrics" section on page 4-34), you can view statistics for past time periods.

Fields

- View—Sets the time period for the graph or table. To view any time period other than real-time, enable History Metrics (see the "Enabling History Metrics" section on page 4-34). The data is updated according to the specification of the following options:
  - Real-time, data every 10 sec
  - Last 10 minutes, data every 10 sec
  - Last 60 minutes, data every 1 min
  - Last 12 hours, data every 12 min
  - Last 5 days, data every 2 hours
- Export—Exports the graph in comma-separated value format. If there is more than one graph or table on the Graph window, the Export Graph Data dialog box appears. Choose one or more of the graphs and tables listed by checking the check box next to the name.
- Print—Prints the graph or table. If there is more than one graph or table on the Graph window, the Print Graph dialog box appears. Choose the graph or table you want to print from the Graph/Table Name list.

- Bookmark—Opens a browser window with a single link for all graphs and tables on the Graphs window, as well as individual links for each graph or table. You can then copy these URLs as bookmarks in your browser. ASDM does not have to be running when you open the URL for a graph; the browser launches ASDM and then displays the graph.

PPPoE Client

The Monitoring > Interfaces > PPPoE Client > PPPoE Client Lease Information pane displays information about current PPPoE connections.

Fields

Select a PPPoE interface—Select an interface that you want to view PPPoE client lease information.

Refresh—loads the latest PPPoE connection information from the ASA for display.

Interface Connection

The Monitoring > Interfaces > *interface* connection node in the Monitoring > Interfaces tree only appears if static route tracking is configured. If you have several routes tracked, there will be a node for each interface that contains a tracked route.

See the following for more information about the route tracking information available:

- Track Status for, page 17-29
- Monitoring Statistics for, page 17-29

Track Status for

The Monitoring > Interfaces > interface connection > Track Status for pane displays information about the tracked object.

Fields

- Tracked Route—*Display only.* Displays the route associated with the tracking process.
- Route Statistics—*Display only.* Displays the reachability of the object, when the last change in reachability occurred, the operation return code, and the process that is performing the tracking.

Monitoring Statistics for

The Monitoring > Interfaces > interface connection > Monitoring Statistics for pane displays statistics for the SLA monitoring process.

Fields

- SLA Monitor ID—*Display only.* Displays the ID of the SLA monitoring process.
- SLA statistics—*Display only.* Displays SLA monitoring statistics, such as the last time the process was modified, the number of operations attempted, the number of operations skipped, and so on.

Feature History for Interfaces in Routed Mode

Table 17-1 lists the release history for this feature.

Table 17-1 Feature History for Interfaces

Feature Name	Releases	Feature Information
Increased VLANs	7.0(5)	Increased the following limits: • ASA5510 Base license VLANs from 0 to 10. • ASA5510 Security Plus license VLANs from 10 to 25. • ASA5520 VLANs from 25 to 100. • ASA5540 VLANs from 100 to 200.
Increased VLANs	7.2(2)	The maximum number of VLANs for the Security Plus license on the ASA 5505 was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration. VLAN limits were also increased for the ASA 5510 (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 (from 100 to 150), the ASA 5550 (from 200 to 250).
Gigabit Ethernet Support for the ASA 5510 Security Plus License	7.2(3)	The ASA 5510 now supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1.
Native VLAN support for the ASA 5505	7.2(4)/8.0(4)	You can now include the native VLAN in an ASA 5505 trunk port. We modified the following screen: Configuration > Device Setup > Interfaces > Switch Ports > Edit Switch Port.
Jumbo packet support for the ASA 5580	8.1(1)	The Cisco ASA 5580 supports jumbo frames. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. We modified the following screen: Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced.

Table 17-1 Feature History for Interfaces (continued)

Feature Name	Releases	Feature Information
Increased VLANs for the ASA 5580	8.1(2)	The number of VLANs supported on the ASA 5580 are increased from 100 to 250.
IPv6 support for transparent mode	8.2(1)	IPv6 support was introduced for transparent firewall mode.
Support for Pause Frames for Flow Control on the ASA 5580 10 Gigabit Ethernet Interfaces	8.2(2)	You can now enable pause (XOFF) frames for flow control. We modified the following screens: (Single Mode) Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced (Multiple Mode, System) Configuration > Interfaces > Add/Edit Interface

Completing Interface Configuration (Transparent Mode, 8.4 and Later)

This chapter includes tasks to complete the interface configuration for all models in transparent firewall mode.

For Version 8.3 and earlier, see Chapter 19, "Completing Interface Configuration (Transparent Mode, 8.3 and Earlier)."

This chapter includes the following sections:

- Information About Completing Interface Configuration in Transparent Mode (8.4 and Later), page 18-1
- Licensing Requirements for Completing Interface Configuration in Transparent Mode, page 18-3
- Guidelines and Limitations, page 18-5
- Default Settings, page 18-6
- Completing Interface Configuration in Transparent Mode (8.4 and Later), page 18-7
- Turning Off and Turning On Interfaces, page 18-21
- Monitoring Interfaces, page 18-22
- Feature History for Interfaces in Transparent Mode, page 18-30

Note For multiple context mode, complete the tasks in this section in the context execution space. In the Configuration > Device List pane, double-click the context name under the active device IP address.

Information About Completing Interface Configuration in Transparent Mode (8.4 and Later)

This section includes the following topics:

- Bridge Groups in Transparent Mode, page 18-2
- Security Levels, page 18-2

Bridge Groups in Transparent Mode

If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the ASA, and traffic must exit the ASA before it is routed by an external router back to another bridge group in the ASA. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context. At least one bridge group is required per context or in single mode.

Each bridge group requires a management IP address. For another method of management, see the "Management Interface" section.

Note The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported.

Security Levels

Each interface must have a security level from 0 (lowest) to 100 (highest). For example, you should assign your most secure network, such as the inside host network, to level 100. While the outside network connected to the Internet can be level 0. Other networks, such as DMZs can be in between. You can assign interfaces to the same security level. See the "Allowing Same Security Level Communication" section on page 18-21 for more information.

The level controls the following behavior:

- Network access—By default, there is an implicit permit from a higher security interface to a lower security interface (outbound). Hosts on the higher security interface can access any host on a lower security interface. You can limit access by applying an access list to the interface.

  If you enable communication for same security interfaces (see the "Allowing Same Security Level Communication" section on page 18-21), there is an implicit permit for interfaces to access other interfaces on the same security level or lower.

- Inspection engines—Some application inspection engines are dependent on the security level. For same security interfaces, inspection engines apply to traffic in either direction.
  - NetBIOS inspection engine—Applied only for outbound connections.
  - SQL*Net inspection engine—If a control connection for the SQL*Net (formerly OraServ) port exists between a pair of hosts, then only an inbound data connection is permitted through the ASA.

- Filtering—HTTP(S) and FTP filtering applies only for outbound connections (from a higher level to a lower level).

  If you enable communication for same security interfaces, you can filter traffic in either direction.

- **established** command—This command allows return connections from a lower security host to a higher security host if there is already an established connection from the higher level host to the lower level host.

  If you enable communication for same security interfaces, you can configure **established** commands for both directions.

Licensing Requirements for Completing Interface Configuration in Transparent Mode

Model	License Requirement
ASA 5505	VLANs: Base License: 3 (2 regular zones and 1 restricted zone that can only communicate with 1 other zone) Security Plus License: 20 VLAN Trunks: Base License: None. Security Plus License: 8. Interfaces of all types[1]: Base License: 52. Security Plus License: 120.

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, and bridge group interfaces.

Model	License Requirement
ASA 5510	VLANs: Base License: 50 Security Plus License: 100 Interface Speed: Base License—All interfaces Fast Ethernet. Security Plus License—Ethernet 0/0 and 0/1: Gigabit Ethernet; all others Fast Ethernet. Interfaces of all types[1]: Base License: 52 Security Plus License: 120
ASA 5520	VLANs: Base License: 150. Interfaces of all types[1]: Base License: 640
ASA 5540	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 840

Model	License Requirement
ASA 5550	VLANs: Base License: 400 Interfaces of all types[1]: Base License: 1640
ASA 5580	VLANs: Base License: 1024 Interfaces of all types[1]: Base License: 4176
ASA 5512-X	VLANs: Base License: 50 Interfaces of all types[1]: Base License: 328
ASA 5515-X	VLANs: Base License: 100 Interfaces of all types[1]: Base License: 528
ASA 5525-X	VLANs: Base License: 200 Interfaces of all types[1]: Base License: 928
ASA 5545-X	VLANs: Base License: 300 Interfaces of all types[1]: Base License: 1328
ASA 5555-X	VLANs: Base License: 500 Interfaces of all types[1]: Base License: 2128
ASA 5585-X	VLANs: Base License: 1024 Interface Speed for SSP-10 and SSP-20: Base License—1-Gigabit Ethernet for fiber interfaces 10 GE I/O License (Security Plus)—10-Gigabit Ethernet for fiber interfaces (SSP-40 and SSP-60 support 10-Gigabit Ethernet by default.) Interfaces of all types[1]: Base License: 4176

1. The maximum number of combined interfaces; for example, VLANs, physical, redundant, bridge group, and EtherChannel interfaces.

Model	License Requirement
ASASM	VLANs: Base License: 1000

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

- For the ASA 5510 and higher in multiple context mode, configure the physical interfaces in the system execution space according to Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)." Then, configure the logical interface parameters in the context execution space according to this chapter. For the ASASM in multiple context mode, configure switch ports and VLANs on the switch, and then assign VLANs to the ASASM according to Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

  The ASA 5505 does not support multiple context mode.

- You can only configure context interfaces that you already assigned to the context in the system configuration.

Firewall Mode Guidelines

- You can configure up to 8 bridge groups in single mode or per context in multiple mode. Note that you must use at least 1 bridge group; data interfaces must belong to a bridge group.

  Note Although you can configure multiple bridge groups on the ASA 5505, the restriction of 2 data interfaces in transparent mode on the ASA 5505 means you can only effectively use 1 bridge group.

- Each bridge group can include up to 4 interfaces.
- For IPv4, a management IP address is required for each bridge group for both management traffic and for traffic to pass through the ASA.

  Unlike routed mode, which requires an IP address for each interface, a transparent firewall has an IP address assigned to the entire bridge group. The ASA uses this IP address as the source address for packets originating on the ASA, such as system messages or AAA communications. In addition to the bridge group management address, you can optionally configure a management interface for some models; see the "Management Interface" section on page 15-2 for more information.

  The management IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255). The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported. See the "Configuring Bridge Groups" section on page 18-8 for more information about management IP subnets.

- For IPv6, at a minimum you need to configure link-local addresses for each interface for through traffic. For full functionality, including the ability to manage the ASA, you need to configure a global IPv6 address for each bridge group.
- For multiple context mode, each context must use different interfaces; you cannot share an interface across contexts.
- For multiple context mode, each context typically uses a different subnet. You can use overlapping subnets, but your network topology requires router and NAT configuration to make it possible from a routing standpoint.

Failover Guidelines

Do not finish configuring failover interfaces with the procedures in this chapter. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links. In multiple context mode, failover interfaces are configured in the system configuration.

IPv6 Guidelines

- Supports IPv6.
- No support for IPv6 anycast addresses in transparent mode.

VLAN ID Guidelines for the ASASM

You can add any VLAN ID to the configuration, but only VLANs that are assigned to the ASA by the switch can pass traffic. To view all VLANs assigned to the ASA, use the **show vlan** command.

If you add an interface for a VLAN that is not yet assigned to the ASA by the switch, the interface will be in the down state. When you assign the VLAN to the ASA, the interface changes to an up state. See the **show interface** command for more information about interface states.

Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the "Factory Default Configurations" section on page 3-17.

Default Security Level

The default security level is 0. If you name an interface "inside" and you do not set the security level explicitly, then the ASA sets the security level to 100.

Note If you change the security level of an interface, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Default State of Interfaces for the ASASM

- In single mode or in the system execution space, VLAN interfaces are enabled by default.
- In multiple context mode, all allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.

Jumbo Frame Support

By default, the ASASM supports jumbo frames. Just configure the MTU for the desired packet size according to the "Configuring the MAC Address and MTU" section on page 18-14.

Completing Interface Configuration in Transparent Mode (8.4 and Later)

This section includes the following topics:

- Task Flow for Completing Interface Configuration, page 18-7
- Configuring Bridge Groups, page 18-8
- Configuring General Interface Parameters, page 18-9
- Configuring a Management Interface (ASA 5510 and Higher), page 18-11
- Configuring the MAC Address and MTU, page 18-14
- Configuring IPv6 Addressing, page 18-16
- Allowing Same Security Level Communication, page 18-21

Task Flow for Completing Interface Configuration

Step 1 Set up your interfaces depending on your model:

- ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
- ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
- ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

Step 2 (Multiple context mode) Allocate interfaces to the context according to the "Configuring Multiple Contexts" section on page 9-15.

Step 3 (Multiple context mode) In the Configuration > Device List pane, double-click the context name under the active device IP address.

Step 4 Configure one or more bridge groups, including the IPv4 address. See the "Configuring Bridge Groups" section on page 18-8.

Step 5 Configure general interface parameters, including the interface name and security level. See the "Configuring General Interface Parameters" section on page 18-9.

Step 6 (Optional; not supported for the ASA 5505) Configure a management interface. See the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 18-11.

Step 7 (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 18-14.

Step 8 (Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 18-16.

Step 9 (Optional) Allow same security level communication, either by allowing communication between two interfaces or by allowing traffic to enter and exit the same interface. See the "Allowing Same Security Level Communication" section on page 18-21.

Configuring Bridge Groups

Each bridge group requires a management IP address. The ASA uses this IP address as the source address for packets originating from the bridge group. The management IP address must be on the same subnet as the connected network. For IPv4 traffic, the management IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

Guidelines and Limitations

You can configure up to 8 bridge groups in single mode or per context in multiple mode. Note that you must use at least one bridge group; data interfaces must belong to a bridge group.

Note For a separate management interface (for supported models), a non-configurable bridge group (ID 101) is automatically added to your configuration. This bridge group is not included in the bridge group limit.

Detailed Steps

Step 1 Choose the **Configuration > Interfaces** pane, and choose **Add > Bridge Group Interface**.

The Add Bridge Group dialog box appears.

Step 2 In the Bridge Group ID field, enter the bridge group ID between 1 and 100.

Step 3 In the IP Address field, enter the management IPv4 address.

The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported.

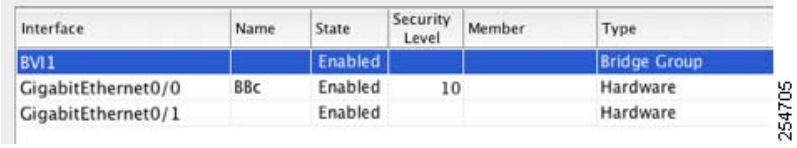
Step 4 In the Subnet Mask field, enter the subnet mask or choose one from the menu.

Do not assign a host address (/32 or 255.255.255.255) to the transparent firewall. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The ASA drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the ASA drops the ARP request from the downstream router to the upstream router.

Step 5 (Optional) In the Description field, enter a description for this bridge group.

Step 6 Click **OK**.

Step 7 A Bridge Group Virtual Interface (BVI) is added to the interface table, along with the physical and subinterfaces.



What to Do Next

Configure general interface parameters. See the "Configuring General Interface Parameters" section on page 18-9.

Configuring General Interface Parameters

This procedure describes how to set the name, security level, and bridge group for each transparent interface.

To configure a separate management interface, see the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 18-11.

For the ASA 5510 and higher, you must configure interface parameters for the following interface types:

- Physical interfaces
- VLAN subinterfaces
- Redundant interfaces
- EtherChannel interfaces

For the ASA 5505 and the ASASM, you must configure interface parameters for the following interface types:

- VLAN interfaces

Guidelines and Limitations

- You can configure up to four interfaces per bridge group.
- For the ASA 5550, for maximum throughput, be sure to balance your traffic over the two interface slots; for example, assign the inside interface to slot 1 and the outside interface to slot 0.
- For information about security levels, see the "Security Levels" section on page 18-2.
- If you are using failover, do not use this procedure to name interfaces that you are reserving for failover and Stateful Failover communications. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."

- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

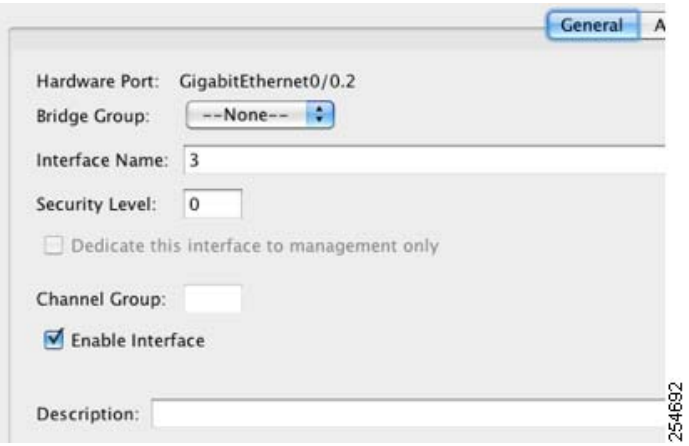
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

BVIs appear in the table alongside physical interfaces, subinterfaces, redundant interfaces, and EtherChannel port-channel interfaces. In multiple context mode, only interfaces that were assigned to the context in the System execution space appear in the table.

Step 2 Choose the row for a non-BVI interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.



Do not use this procedure for Management interfaces; see the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 18-11 to configure the Management interface.

Step 3 In the Bridge Group drop-down menu, choose the bridge group to which you want to assign this interface.

Step 4 In the Interface Name field, enter a name up to 48 characters in length.

Step 5 In the Security level field, enter a level between 0 (lowest) and 100 (highest).

See the "Security Levels" section on page 18-2 for more information.

Note Do not click the **Dedicate this interface to management only** check box; see the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 18-11 for this option.

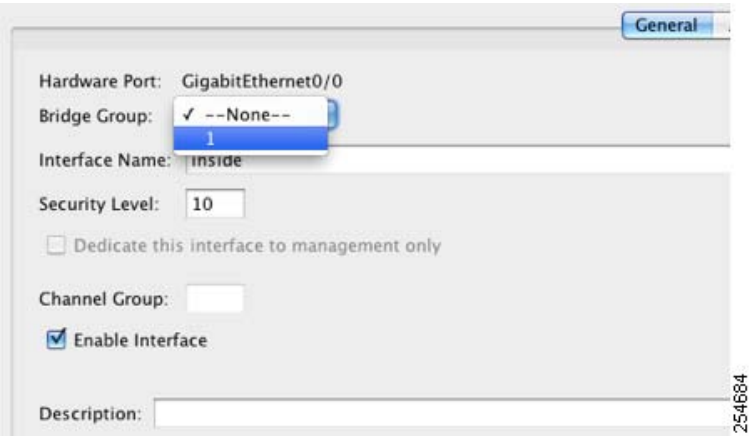
Step 6 If the interface is not already enabled, check the **Enable Interface** check box.

Note The Channel Group field is read-only and indicates if the interface is part of an EtherChannel.

Step 7 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Note (ASA 5510 and higher, single mode) For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.



Step 8 Click **OK**.

What to Do Next

- (Optional) Configure a management interface. See the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 18-11.
- (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 18-14.
- (Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 18-16.

Configuring a Management Interface (ASA 5510 and Higher)

You can configure one management interface separate from the bridge group interfaces in single mode or per context. For more information, see the "Management Interface" section on page 15-2.

Restrictions

- See the "Management Interface" section on page 15-2.
- Do not assign this interface to a bridge group; a non-configurable bridge group (ID 101) is automatically added to your configuration. This bridge group is not included in the bridge group limit.

- If your model does not include a Management interface, you must manage the transparent firewall from a data interface; skip this procedure. (For example, on the ASA 5505.)
- In multiple context mode, you cannot share any interfaces, including the Management interface, across contexts. To provide management per context, you can create subinterfaces of the Management interface and allocate a Management subinterface to each context. Note that the ASA 5512-X through ASA 5555-X do not allow subinterfaces on the Management interface, so for per-context management, you must connect to a data interface.

Prerequisites

- Complete the procedures in Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

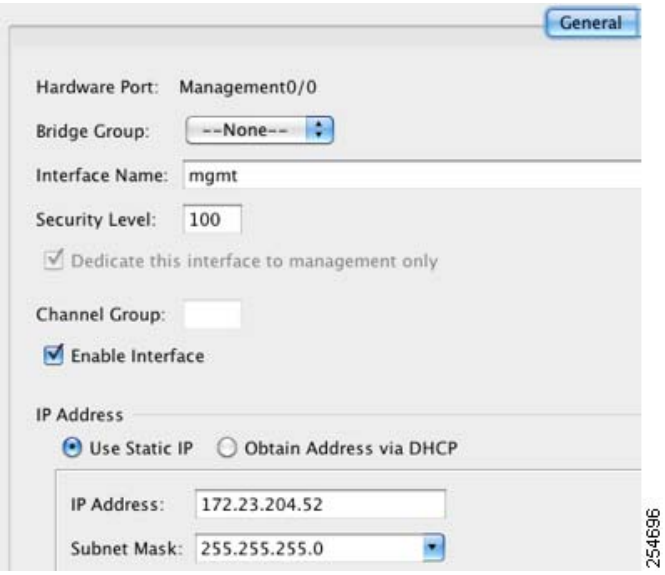
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

BVIs appear in the table alongside physical interfaces, subinterfaces, redundant interfaces, and EtherChannel port-channel interfaces. In multiple context mode, only interfaces that were assigned to the context in the System execution space appear in the table.

Step 2 Choose the row for a Management interface, subinterface, or EtherChannel port-channel interface comprised of Management interfaces, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.



Step 3 In the Bridge Group drop-down menu, leave the default **--None--**. You cannot assign a management interface to a bridge group.

Step 4 In the Interface Name field, enter a name up to 48 characters in length.

Step 5 In the Security level field, enter a level between 0 (lowest) and 100 (highest).

See the "Security Levels" section on page 18-2 for more information.

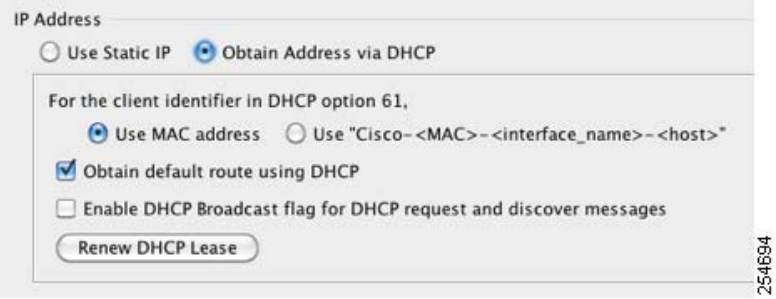
Note The **Dedicate this interface to management only** check box is enabled by default and is non-configurable.

Step 6 If the interface is not already enabled, check the **Enable Interface** check box.

Step 7 To set the IP address, use one of the following options.

Note For use with failover, you must set the IP address and standby address manually; DHCP is not supported. Set the standby IP addresses on the Configuration > Device Management > High Availability > Failover > Interfaces tab.

- To set the IP address manually, click the **Use Static IP** radio button and enter the IP address and mask.
- To obtain an IP address from a DHCP server, click the **Obtain Address via DHCP** radio button.



a. To force a MAC address to be stored inside a DHCP request packet for option 61, click the **Use MAC Address** radio button.

   Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned.

b. To use a generated string for option 61, click **Use "Cisco-<MAC>-<interface_name>-<host>"**.

c. (Optional) To obtain the default route from the DHCP server, check **Obtain Default Route Using DHCP**.

d. (Optional) To set the broadcast flag to 1 in the DHCP packet header when the DHCP client sends a discover requesting an IP address, check **Enable DHCP Broadcast flag for DHCP request and discover messages**.

   The DHCP server listens to this broadcast flag and broadcasts the reply packet if the flag is set to 1.

e. (Optional) To renew the lease, click **Renew DHCP Lease**.

Step 8 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns.

Note (ASA 5510 and higher, single mode) For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Step 9 Click **OK**.

What to Do Next

- (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 18-14.
- (Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 18-16.

Configuring the MAC Address and MTU

This section describes how to configure MAC addresses for interfaces and how to set the MTU.

Information About MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

For the ASASM, all VLANs use the same MAC address provided by the backplane.

A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. If you assign a MAC address to the redundant interface using this command, then it is used regardless of the member interface MAC addresses.

For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses the lowest numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can manually configure a MAC address for the port-channel interface. In multiple context mode, you can automatically assign unique MAC addresses to interfaces, including an EtherChannel port interface. We recommend manually, or in multiple context mode, automatically configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.

In multiple context mode, if you share an interface between contexts, you can assign a unique MAC address to the interface in each context. This feature lets the ASA easily classify packets into the appropriate context. Using a shared interface without unique MAC addresses is possible, but has some limitations. See the "How the ASA Classifies Packets" section on page 9-3 for more information. You can assign each MAC address manually, or you can automatically generate MAC addresses for shared interfaces in contexts. See the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24 to automatically generate MAC addresses. If you automatically generate MAC addresses, you can use this procedure to override the generated address.

For single context mode, or for interfaces that are not shared in multiple context mode, you might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address.

Information About the MTU

The MTU is the maximum datagram size that is sent on a connection. Data that is larger than the MTU value is fragmented before being sent.

The ASA supports IP path MTU discovery (as defined in RFC 1191), which allows a host to dynamically discover and cope with the differences in the maximum allowable MTU size of the various links along the path. Sometimes, the ASA cannot forward a datagram because the packet is larger than the MTU that you set for the interface, but the "don't fragment" (DF) bit is set. The network software sends a message to the sending host, alerting it to the problem. The host has to fragment packets for the destination so that they fit the smallest packet size of all the links along the path.

The default MTU is 1500 bytes in a block for Ethernet interfaces. This value is sufficient for most applications, but you can pick a lower number if network conditions require it.

Jumbo frames are supported by default on the ASASM. To enable jumbo frames, see the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. Jumbo frames require extra memory to process, and assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. To use jumbo frames, set the value higher, for example, to 9000 bytes.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

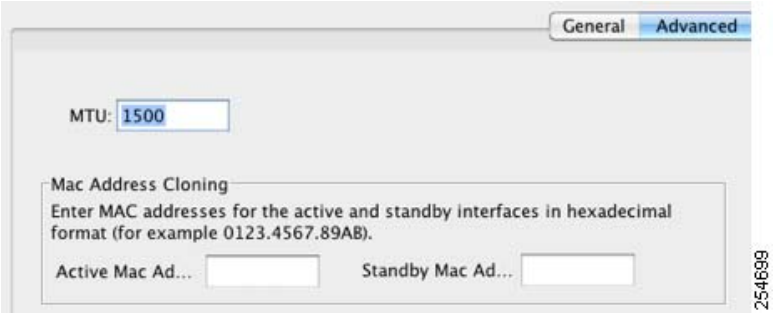
Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

For the ASA 5505, the Interfaces tab shows by default.

Step 2 Choose the interface row, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **Advanced** tab.



Step 4 To set the MTU or to enable jumbo frame support (supported models only), enter the value in the MTU field, between 300 and 65,535 bytes.

The default is 1500 bytes.

Note When you set the MTU for a redundant or port-channel interface, the ASA applies the setting to all member interfaces.

- For models that support jumbo frames in single mode—If you enter a value for any interface that is greater than 1500, then you enable jumbo frame support automatically for all interfaces. If you set the MTU for all interfaces back to a value under 1500, then jumbo frame support is disabled.
- For models that support jumbo frames in multiple mode—If you enter a value for any interface that is greater than 1500, then be sure to enable jumbo frame support in the system configuration. See the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

Note Enabling or disabling jumbo frame support requires you to reload the ASA.

Step 5 To manually assign a MAC address to this interface, enter a MAC address in the Active Mac Address field in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The first two bytes of a manual MAC address cannot be A2 if you also want to use auto-generated MAC addresses.

Step 6 If you use failover, enter the standby MAC address in the Standby Mac Address field. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

What to Do Next

(Optional) Configure IPv6 addressing. See the "Configuring IPv6 Addressing" section on page 18-16.

Configuring IPv6 Addressing

This section describes how to configure IPv6 addressing. For more information about IPv6, see the "IPv6 Addresses" section on page A-5.

This section includes the following topics:

- Information About IPv6, page 18-17

- Configuring a Global IPv6 Address, page 18-18
- Configuring IPv6 Neighbor Discovery, page 18-19
- (Optional) Configuring the Link-Local Addresses Automatically, page 18-19
- (Optional) Configuring the Link-Local Addresses Manually, page 18-20

Information About IPv6

This section includes information about how to configure IPv6, and includes the following topics:

- IPv6 Addressing, page 18-17
- Modified EUI-64 Interface IDs, page 18-17
- Unsupported Commands, page 18-18

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. This address needs to be configured for each bridge group, and not per-interface. You can also configure a global IPv6 address for the management interface.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the ND functions such as address resolution and neighbor discovery. Because the link-local address is only available on a segment, and is tied to the interface MAC address, you need to configure the link-local address per interface.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local addresses is automatically configured on each interface, so you do not also need to specifically configure a link-local address. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The ASA can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
%ASA-3-325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

Unsupported Commands

The following IPv6 commands are not supported in transparent firewall mode, because they require router capabilities:

- **ipv6 address autoconfig**
- **ipv6 nd prefix**
- **ipv6 nd ra-interval**
- **ipv6 nd ra-lifetime**
- **ipv6 nd suppress-ra**

Configuring a Global IPv6 Address

To configure a global IPv6 address for a bridge group or management interface, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately.

Restrictions

The ASA does not support IPv6 anycast addresses.

Prerequisites

- Set up your interfaces depending on your model:
  - ASA 5510 and higher—Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)."
  - ASA 5505—Chapter 16, "Starting Interface Configuration (ASA 5505)."
  - ASASM—Chapter 2, "Configuring the Switch for Use with the ASA Services Module."
- In multiple context mode, you can only configure context interfaces that you already assigned to the context in the system configuration according to the "Configuring Multiple Contexts" section on page 9-15.
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

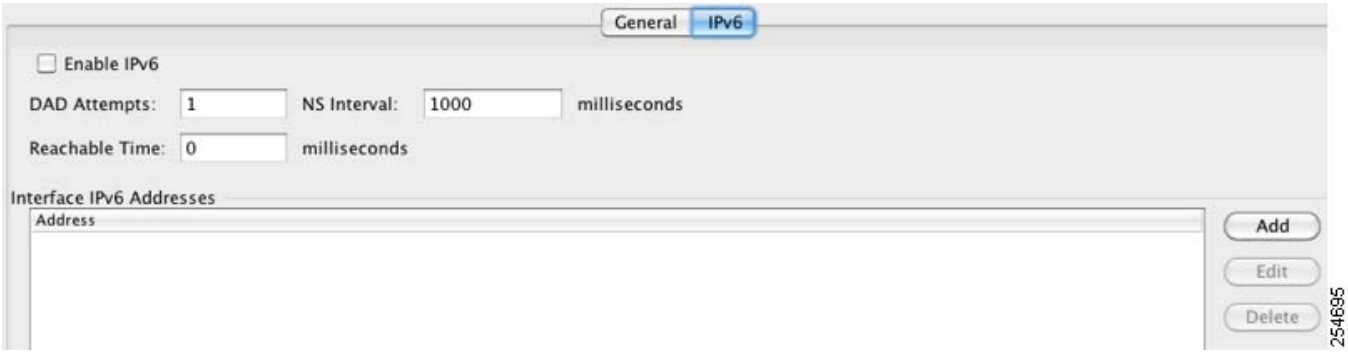
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Choose a BVI or management interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.



Step 4 Check the **Enable IPv6** check box.

Step 5 (Optional) To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.

See the "Modified EUI-64 Interface IDs" section on page 18-17 for more information.

Step 6 (Optional) In the top area, customize the IPv6 configuration by referring to Chapter 37, "Configuring IPv6 Neighbor Discovery."

Step 7 To configure the global IPv6 address:

a. In the Interface IPv6 Addresses area, click **Add**.

The Add IPv6 Address for Interface dialog box appears.

b. In the Address/Prefix Length field, enter the global IPv6 address and the IPv6 prefix length. For example, 2001:0DB8::BA98:0:3210/48. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

c. Click **OK**.

Step 8 Click **OK**.

You return to the Configuration > Device Setup > Interfaces pane.

Configuring IPv6 Neighbor Discovery

See Chapter 37, "Configuring IPv6 Neighbor Discovery," to configure IPv6 neighbor discovery.

(Optional) Configuring the Link-Local Addresses Automatically

If you do not want to configure a global address, and only need to configure a link-local address, you have the option of generating the link-local addresses based on the interface MAC addresses (Modified EUI-64 format. Because MAC addresses use 48 bits, additional bits must be inserted to fill the 64 bits required for the interface ID.)

To manually assign the link-local address (not recommended), see the "(Optional) Configuring the Link-Local Addresses Manually" section on page 18-20.

For other IPv6 options, including enforcing the Modified EUI-64 format, and DAD settings, see the "Configuring a Global IPv6 Address" section on page 18-18.

To automatically configure the link-local addresses for a management interface or bridge group member interfaces, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Select a BVI or management interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.

Step 4 In the IPv6 configuration area, check **Enable IPv6**.

This option enables IPv6 and automatically generates the link-local addresses for member interfaces using the Modified EUI-64 interface ID based on the interface MAC address.

Step 5 Click **OK**.

(Optional) Configuring the Link-Local Addresses Manually

If you do not want to configure a global address, and only need to configure a link-local address on the physical interfaces or subinterfaces, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

To automatically assign the link-local address (recommended), see the "(Optional) Configuring the Link-Local Addresses Automatically" section on page 18-19.

For other IPv6 options, including enforcing the Modified EUI-64 format, and DAD settings, see the "Configuring a Global IPv6 Address" section on page 18-18.

To assign a link-local address to a physical interface or subinterface, including the management interface, perform the following steps:

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Select an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.

Step 4 To set the link-local address, enter an address in the Link-local address field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

Step 5 Click **OK**.

Allowing Same Security Level Communication

By default, interfaces on the same security level cannot communicate with each other, and packets cannot enter and exit the same interface. This section describes how to enable inter-interface communication when interfaces are on the same security level.

Information About Inter-Interface Communication

Allowing interfaces on the same security level to communicate with each other is useful if you want traffic to flow freely between all same security interfaces without access lists.

If you enable same security interface communication, you can still configure interfaces at different security levels as usual.

Detailed Steps

To enable interfaces on the same security level to communicate with each other, from the Configuration > Interfaces pane, check **Enable traffic between two or more interfaces which are configured with same security level**.

Turning Off and Turning On Interfaces

This section describes how to turn off and on an interface.

All interfaces are enabled by default. In multiple context mode, if you disable or reenable the interface within a context, only that context interface is affected. But if you disable or reenable the interface in the system execution space, then you affect that interface for all contexts.

Detailed Steps

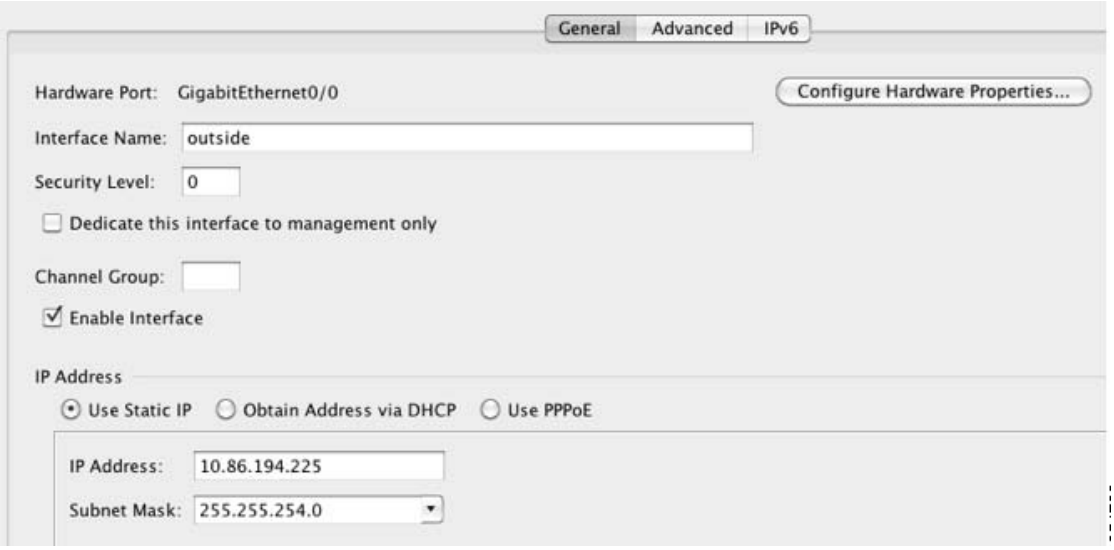
Step 1 Depending on your context mode:

- For single mode, choose the **Configuration > Device Setup > Interfaces** pane.
- For multiple mode in the System execution space, choose the **Configuration > Context Management > Interfaces** pane.

By default, all physical interfaces are listed.

Step 2 Click a VLAN interface that you want to configure, and click **Edit**.

The Edit Interface dialog box appears.



Step 3 To enable or disable the interface, check or uncheck the **Enable Interface** check box.

Monitoring Interfaces

This section includes the following topics:

- ARP Table, page 18-22
- DHCP, page 18-23
- MAC Address Table, page 18-25
- Dynamic ACLs, page 18-25
- Interface Graphs, page 18-26
- PPPoE Client, page 18-28
- Interface Connection, page 18-28

ARP Table

The Monitoring > Interfaces > ARP Table pane displays the ARP table, including static and dynamic entries. The ARP table includes entries that map a MAC address to an IP address for a given interface.

Fields

- Interface—Lists the interface name associated with the mapping.
- IP Address—Shows the IP address.
- MAC Address—Shows the MAC address.
- Proxy ARP—Displays Yes if proxy ARP is enabled on the interface. Displays No if proxy ARP is not enabled on the interface.
- Clear—Clears the dynamic ARP table entries. Static entries are not cleared.

- Refresh—Refreshes the table with current information from the ASA and updates Last Updated date and time.
- Last Updated—*Display only.* Shows the date and time the display was updated.

DHCP

The ASA lets you monitor DHCP status, including the addresses assigned to clients, the lease information for a ASA interface, and DHCP statistics.

DHCP Server Table

The Monitoring > Interfaces > DHCP > DHCP Server Table lists the IP addresses assigned to DHCP clients.

Fields

- IP Address—Shows the IP address assigned to the client.
- Client-ID—Shows the client MAC address or ID.
- Lease Expiration—Shows the date that the DHCP lease expires. The lease indicates how long the client can use the assigned IP address. Remaining time is also specified in the number of seconds and is based on the timestamp in the Last Updated display-only field.
- Number of Active Leases—Shows the total number of DHCP leases.
- Refresh—Refreshes the information from the ASA.
- Last Updated—Shows when the data in the table was last updated.

DHCP Client Lease Information

If you obtain the ASA interface IP address from a DHCP server, the Monitoring > Interfaces > DHCP > DHCP Server Table > DHCP Client Lease Information pane shows information about the DHCP lease.

Fields

- Select an interface—Lists the ASA interfaces. Choose the interface for which you want to view the DHCP lease. If an interface has multiple DHCP leases, then choose the interface and IP address pair you want to view.
- Attribute and Value—Lists the attributes and values of the interface DHCP lease.
  - Temp IP addr—*Display only.* The IP address assigned to the interface.
  - Temp sub net mask—*Display only.* The subnet mask assigned to the interface.
  - DHCP lease server—*Display only.* The DHCP server address.
  - state—*Display only.* The state of the DHCP lease, as follows:

    Initial—The initialization state, where the ASA begins the process of acquiring a lease. This state is also shown when a lease ends or when a lease negotiation fails.

    Selecting—The ASA is waiting to receive DHCPOFFER messages from one or more DHCP servers, so it can choose one.

    Requesting—The ASA is waiting to hear back from the server to which it sent its request.

    Purging—The ASA is removing the lease because of an error.

Bound—The ASA has a valid lease and is operating normally.

Renewing—The ASA is trying to renew the lease. It regularly sends DHCPREQUEST messages to the current DHCP server, and waits for a reply.

Rebinding—The ASA failed to renew the lease with the original server, and now sends DHCPREQUEST messages until it gets a reply from any server or the lease ends.

Holddown—The ASA started the process to remove the lease.

Releasing—The ASA sends release messages to the server indicating that the IP address is no longer needed.

- Lease—*Display only.* The length of time, specified by the DHCP server, that the interface can use this IP address.
- Renewal—*Display only.* The length of time until the interface automatically attempts to renew this lease.
- Rebind—*Display only.* The length of time until the ASA attempts to rebind to a DHCP server. Rebinding occurs if the ASA cannot communicate with the original DHCP server, and 87.5 percent of the lease time has expired. The ASA then attempts to contact any available DHCP server by broadcasting DHCP requests.
- Next timer fires after—*Display only.* The number of seconds until the internal timer triggers.
- Retry count—*Display only.* If the ASA is attempting to establish a lease, this field shows the number of times the ASA tried sending a DHCP message. For example, if the ASA is in the Selecting state, this value shows the number of times the ASA sent discover messages. If the ASA is in the Requesting state, this value shows the number of times the ASA sent request messages.
- Client-ID—*Display only.* The client ID used in all communication with the server.
- Proxy—*Display only.* Specifies if this interface is a proxy DHCP client for VPN clients, True or False.
- Hostname—*Display only.* The client hostname.

DHCP Statistics

The Monitoring > Interfaces > DHCP > DHCP Statistics pane shows statistics for the DHCP server feature.

Fields

- Message Type—Lists the DHCP message types sent or received:
  - BOOTREQUEST
  - DHCPDISCOVER
  - DHCPREQUEST
  - DHCPDECLINE
  - DHCPRELEASE
  - DHCPINFORM
  - BOOTREPLY
  - DHCPOFFER
  - DHCPACK

  - DHCPNAK
- Count—Shows the number of times a specific message was processed.
- Direction—Shows if the message type is Sent or Received.
- Total Messages Received—Shows the total number of messages received by the ASA.
- Total Messages Sent—Shows the total number of messages sent by the ASA.
- Counter—Shows general statistical DHCP data, including the following:
  - DHCP UDP Unreachable Errors
  - DHCP Other UDP Errors
  - Address Pools
  - Automatic Bindings
  - Expired Bindings
  - Malformed Messages
- Value—Shows the number of each counter item.
- Refresh—Updates the DHCP table listings.
- Last Updated—Shows when the data in the tables was last updated.

MAC Address Table

The Monitoring > Interfaces > MAC Address Table pane shows the static and dynamic MAC address entries. See the "MAC Address Table" section on page 18-25 for more information about the MAC address table and adding static entries.

Fields

- Interface—Shows the interface name associated with the entry.
- MAC Address—Shows the MAC address.
- Type—Shows if the entry is static or dynamic.
- Age—Shows the age of the entry, in minutes. To set the timeout, see the "MAC Address Table" section on page 18-25.
- Refresh—Refreshes the table with current information from the ASA.

Dynamic ACLs

The Monitoring > Interfaces > Dynamic ACLs pane shows a table of the Dynamic ACLs, which are functionally identical to the user-configured ACLs except that they are created, activated and deleted automatically by the ASA. These ACLs do not show up in the configuration and are only visible in this table. They are identified by the "(dynamic)" keyword in the ACL header.

When you choose an ACL in this table, the contents of the ACL are shown in the bottom text field.

Fields

- ACL—Shows the name of the dynamic ACL.
- Element Count—Shows the number of elements in the ACL

- Hit Count—Shows the total hit count for all of the elements in the ACL.

Interface Graphs

The Monitoring > Interfaces > Interface Graphs pane lets you view interface statistics in graph or table form. If an interface is shared among contexts, the ASA shows only statistics for the current context. The number of statistics shown for a subinterface is a subset of the number of statistics shown for a physical interface.

Fields

- Available Graphs for—Lists the types of statistics available for monitoring. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.
  - Byte Counts—Shows the number of bytes input and output on the interface.
  - Packet Counts—Shows the number of packets input and output on the interface.
  - Packet Rates—Shows the rate of packets input and output on the interface.
  - Bit Rates—Shows the bit rate for the input and output of the interface.
  - Drop Packet Count—Shows the number of packets dropped on the interface.

  These additional statistics display for physical interfaces:
  - Buffer Resources—Shows the following statistics:

    Overruns—The number of times that the ASA was incapable of handing received data to a hardware buffer because the input rate exceeded the ASA capability to handle the data.

    Underruns—The number of times that the transmitter ran faster than the ASA could handle.

    No Buffer—The number of received packets discarded because there was no buffer space in the main system. Compare this with the ignored count. Broadcast storms on Ethernet networks are often responsible for no input buffer events.
  - Packet Errors—Shows the following statistics:

    CRC—The number of Cyclical Redundancy Check errors. When a station sends a frame, it appends a CRC to the end of the frame. This CRC is generated from an algorithm based on the data in the frame. If the frame is altered between the source and destination, the ASA notes that the CRC does not match. A high number of CRCs is usually the result of collisions or a station transmitting bad data.

    Frame—The number of frame errors. Bad frames include packets with an incorrect length or bad frame checksums. This error is usually the result of collisions or a malfunctioning Ethernet device.

    Input Errors—The number of total input errors, including the other types listed here. Other input-related errors can also cause the input error count to increase, and some datagrams might have more than one error; therefore, this sum might exceed the number of errors listed for the other types.

    Runts—The number of packets that are discarded because they are smaller than the minimum packet size, which is 64 bytes. Runts are usually caused by collisions. They might also be caused by poor wiring and electrical interference.

    Giants—The number of packets that are discarded because they exceed the maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.

Deferred—For FastEthernet interfaces only. The number of frames that were deferred before transmission due to activity on the link.

- Miscellaneous—Shows statistics for received broadcasts.
- Collision Counts—For FastEthernet interfaces only. Shows the following statistics:

  Output Errors—The number of frames not transmitted because the configured maximum number of collisions was exceeded. This counter should only increment during heavy network traffic.

  Collisions—The number of messages retransmitted due to an Ethernet collision (single and multiple collisions). This usually occurs on an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once by the output packets.

  Late Collisions—The number of frames that were not transmitted because a collision occurred outside the normal collision window. A late collision is a collision that is detected late in the transmission of the packet. Normally, these should never happen. When two Ethernet hosts try to talk at once, they should collide early in the packet and both back off, or the second host should see that the first one is talking and wait. If you get a late collision, a device is jumping in and trying to send the packet on the Ethernet while the ASA is partly finished sending the packet. The ASA does not resend the packet, because it may have freed the buffers that held the first part of the packet. This is not a real problem because networking protocols are designed to cope with collisions by resending packets. However, late collisions indicate a problem exists in your network. Common problems are large repeated networks and Ethernet networks running beyond the specification.

- Input Queue—Shows the number of packets in the input queue, the current and the maximum, including the following statistics:

  Hardware Input Queue—The number of packets in the hardware queue.

  Software Input Queue—The number of packets in the software queue.

- Output Queue—Shows the number of packets in the output queue, the current and the maximum, including the following statistics:

  Hardware Output Queue—The number of packets in the hardware queue.

  Software Output Queue—The number of packets in the software queue.

- Add—Adds the selected statistic type to the selected graph window.
- Remove—Removes the selected statistic type from the selected graph window. This button name changes to Delete if the item you are removing was added from another panel, and is not being returned to the Available Graphs pane.
- Show Graphs—Shows the graph window name to which you want to add a statistic type. If you have a graph window already open, a new graph window is listed by default. If you want to add a statistic type to an already open graph, choose the open graph window name. The statistics already included on the graph are shown in the Selected Graphs pane, to which you can add additional types. Graph windows are named for ASDM followed by the interface IP address and the name “Graph”. Subsequent graphs are named “Graph (2)” and so on.
- Selected Graphs—Shows the statistic types you want to show in the selected graph window. You an include up to four types.
  - Show Graphs—Shows the graph window or updates the graph with additional statistic types if added.

Graph/Table

The Monitoring > Interfaces > Interface Graphs > Graph/Table window shows a graph for the selected statistics. The Graph window can show up to four graphs and tables at a time. By default, the graph or table displays the real-time statistics. If you enable History Metrics (see the "Enabling History Metrics" section on page 4-34), you can view statistics for past time periods.

Fields

- View—Sets the time period for the graph or table. To view any time period other than real-time, enable History Metrics (see the "Enabling History Metrics" section on page 4-34). The data is updated according to the specification of the following options:
  - Real-time, data every 10 sec
  - Last 10 minutes, data every 10 sec
  - Last 60 minutes, data every 1 min
  - Last 12 hours, data every 12 min
  - Last 5 days, data every 2 hours
- Export—Exports the graph in comma-separated value format. If there is more than one graph or table on the Graph window, the Export Graph Data dialog box appears. Choose one or more of the graphs and tables listed by checking the box next to the name.
- Print—Prints the graph or table. If there is more than one graph or table on the Graph window, the Print Graph dialog box appears. Choose the graph or table you want to print from the Graph/Table Name list.
- Bookmark—Opens a browser window with a single link for all graphs and tables on the Graphs window, as well as individual links for each graph or table. You can then copy these URLs as bookmarks in your browser. ASDM does not have to be running when you open the URL for a graph; the browser launches ASDM and then displays the graph.

PPPoE Client

The Monitoring > Interfaces > PPPoE Client > PPPoE Client Lease Information pane displays information about current PPPoE connections.

Fields

Select a PPPoE interface—Select an interface that you want to view PPPoE client lease information.

Refresh—loads the latest PPPoE connection information from the ASA for display.

Interface Connection

The Monitoring > Interfaces > *interface* connection node in the Monitoring > Interfaces tree only appears if static route tracking is configured. If you have several routes tracked, there will be a node for each interface that contains a tracked route.

See the following for more information about the route tracking information available:

- Track Status for, page 18-29
- Monitoring Statistics for, page 18-29

Track Status for

The Monitoring > Interfaces > interface connection > Track Status for pane displays information about the tracked object.

Fields

- Tracked Route—*Display only.* Displays the route associated with the tracking process.
- Route Statistics—*Display only.* Displays the reachability of the object, when the last change in reachability occurred, the operation return code, and the process that is performing the tracking.

Monitoring Statistics for

The Monitoring > Interfaces > interface connection > Monitoring Statistics for pane displays statistics for the SLA monitoring process.

Fields

- SLA Monitor ID—*Display only.* Displays the ID of the SLA monitoring process.
- SLA statistics—*Display only.* Displays SLA monitoring statistics, such as the last time the process was modified, the number of operations attempted, the number of operations skipped, and so on.

Feature History for Interfaces in Transparent Mode

Table 18-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 18-1 Feature History for Interfaces in Transparent Mode

Feature Name	Platform Releases	Feature Information
Increased VLANs	7.0(5)	Increased the following limits: • ASA5510 Base license VLANs from 0 to 10. • ASA5510 Security Plus license VLANs from 10 to 25. • ASA5520 VLANs from 25 to 100. • ASA5540 VLANs from 100 to 200.
Increased VLANs	7.2(2)	The maximum number of VLANs for the Security Plus license on the ASA 5505 was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration. VLAN limits were also increased for the ASA 5510 (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 (from 100 to 150), the ASA 5550 (from 200 to 250).
Gigabit Ethernet Support for the ASA 5510 Security Plus License	7.2(3)	The ASA 5510 now supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1.
Native VLAN support for the ASA 5505	7.2(4)/8.0(4)	You can now include the native VLAN in an ASA 5505 trunk port. We modified the following screen: Configuration > Device Setup > Interfaces > Switch Ports > Edit Switch Port.

Table 18-1 Feature History for Interfaces in Transparent Mode (continued)

Feature Name	Platform Releases	Feature Information
Jumbo packet support for the ASA 5580	8.1(1)	The Cisco ASA 5580 supports jumbo frames. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. We modified the following screen: Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced.
Increased VLANs for the ASA 5580	8.1(2)	The number of VLANs supported on the ASA 5580 are increased from 100 to 250.
IPv6 support for transparent mode	8.2(1)	IPv6 support was introduced for transparent firewall mode.
Support for Pause Frames for Flow Control on the ASA 5580 10-Gigabit Ethernet Interfaces	8.2(2)	You can now enable pause (XOFF) frames for flow control. We modified the following screens: (Single Mode) Configuration > Device Setup > Interfaces > Add/Edit Interface > General (Multiple Mode, System) Configuration > Interfaces > Add/Edit Interface.
Bridge groups for transparent mode	8.4(1)	If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups. You can configure up to eight bridge groups of four interfaces each in single mode or per context. We modified or introduced the following screens: Configuration > Device Setup > Interfaces Configuration > Device Setup > Interfaces > Add/Edit Bridge Group Interface Configuration > Device Setup > Interfaces > Add/Edit Interface

Completing Interface Configuration (Transparent Mode, 8.3 and Earlier)

This chapter includes tasks to complete the interface configuration for all models in transparent firewall mode.

For Version 8.4 and later, see Chapter 19, "Completing Interface Configuration (Transparent Mode, 8.3 and Earlier)."

This chapter includes the following sections:

- Information About Completing Interface Configuration in Transparent Mode (8.3 and Earlier), page 19-1
- Licensing Requirements for Completing Interface Configuration in Transparent Mode, page 19-3
- Guidelines and Limitations, page 19-3
- Default Settings, page 19-4
- Setting the Management IP Address for a Transparent Firewall (8.3 and Earlier), page 19-4
- Completing Interface Configuration in Transparent Mode (8.3 and Earlier), page 19-9
- Monitoring Interfaces, page 19-17
- Feature History for Interfaces in Transparent Mode, page 19-18

Note For multiple context mode, complete the tasks in this section in the context execution space. In the Configuration > Device List pane, double-click the context name under the active device IP address.

Information About Completing Interface Configuration in Transparent Mode (8.3 and Earlier)

This section includes the following topics:

- Information About the Global Management IP Address, page 19-2
- Security Levels, page 19-2

Information About the Global Management IP Address

A transparent firewall does not participate in IP routing. The only IP configuration required for the ASA is to set the management IP address. This address is required because the ASA uses this address as the source address for traffic originating on the ASA, such as system messages or communications with AAA servers. You can also use this address for remote management access.

For IPv4 traffic, the management IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

Note In addition to the management IP address for the device, you can configure an IP address for the Management interface. This IP address can be on a separate subnet from the main management IP address.

Although you do not configure IPv4 or global IPv6 addresses for other interfaces, you still need to configure the security level and interface name according to the "Configuring General Interface Parameters" section on page 19-10.

Security Levels

Each interface must have a security level from 0 (lowest) to 100 (highest). For example, you should assign your most secure network, such as the inside host network, to level 100. While the outside network connected to the Internet can be level 0. Other networks, such as DMZs can be in between. You can assign interfaces to the same security level. See the "Allowing Same Security Level Communication" section on page 19-17 for more information.

The level controls the following behavior:

- Network access—By default, there is an implicit permit from a higher security interface to a lower security interface (outbound). Hosts on the higher security interface can access any host on a lower security interface. You can limit access by applying an access list to the interface.

  If you enable communication for same security interfaces (see the "Allowing Same Security Level Communication" section on page 19-17), there is an implicit permit for interfaces to access other interfaces on the same security level or lower.

- Inspection engines—Some application inspection engines are dependent on the security level. For same security interfaces, inspection engines apply to traffic in either direction.
  - NetBIOS inspection engine—Applied only for outbound connections.
  - SQL*Net inspection engine—If a control connection for the SQL*Net (formerly OraServ) port exists between a pair of hosts, then only an inbound data connection is permitted through the ASA.

- Filtering—HTTP(S) and FTP filtering applies only for outbound connections (from a higher level to a lower level).

  If you enable communication for same security interfaces, you can filter traffic in either direction.

- **established** command—This command allows return connections from a lower security host to a higher security host if there is already an established connection from the higher level host to the lower level host.

If you enable communication for same security interfaces, you can configure **established** commands for both directions.

Licensing Requirements for Completing Interface Configuration in Transparent Mode

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

- In multiple context mode, configure the physical interfaces in the system execution space according to Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)." Then, configure the logical interface parameters in the context execution space according to this chapter.
- You can only configure context interfaces that you already assigned to the context in the system configuration.

Firewall Mode Guidelines

- For IPv4, a management IP address is required for both management traffic and for traffic to pass through the ASA.

  Unlike routed mode, which requires an IP address for each interface, a transparent firewall has an IP address assigned to the entire device. The ASA uses this IP address as the source address for packets originating on the ASA, such as system messages or AAA communications. In addition to the global management address, you can optionally configure a management interface; see the "Management Interface" section on page 15-2 for more information.

  The management IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255). The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported. See the "Setting the Management IP Address for a Transparent Firewall (8.3 and Earlier)" section on page 19-4 for more information about management IP subnets.
- For IPv6, at a minimum you need to configure link-local addresses for each interface for through traffic. For full functionality, including the ability to manage the ASA, you need to configure a global IPv6 address.
- For multiple context mode, each context must use different interfaces; you cannot share an interface across contexts.
- For multiple context mode, each context typically uses a different subnet. You can use overlapping subnets, but your network topology requires router and NAT configuration to make it possible from a routing standpoint.

Failover Guidelines

Do not finish configuring failover interfaces with the procedures in this chapter. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links. In multiple context mode, failover interfaces are configured in the system configuration.

IPv6 Guidelines

- Supports IPv6.
- No support for IPv6 anycast addresses in transparent mode.

Default Settings

This section lists default settings for interfaces if you do not have a factory default configuration. For information about the factory default configurations, see the "Factory Default Configurations" section on page 3-17.

Default Security Level

The default security level is 0. If you name an interface "inside" and you do not set the security level explicitly, then the ASA sets the security level to 100.

Note If you change the security level of an interface, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Setting the Management IP Address for a Transparent Firewall (8.3 and Earlier)

This section describes how to configure the management IP address for transparent firewall mode, and includes the following topics:

- Configuring the IPv4 Address, page 19-4
- Configuring the IPv6 Address, page 19-5

Configuring the IPv4 Address

This section tells how to configure the IPv4 address.

Detailed Steps

Step 1 Go to Configuration > Device Management > Management Access > Management IP Address.

Step 2 In the IPv4 Address area, enter the IP address in the Management IP Address field.

This address must be on the same subnet as the upstream and downstream routers. You cannot set the subnet to a host subnet (255.255.255.255). The **standby** keyword and address is used for failover.

Step 3 From the Subnet Mask drop-down list, choose a subnet mask, or enter a subnet mask directly in the field.

Step 4 Click **Apply**.

Configuring the IPv6 Address

This section describes how to configure the global address or the link-local address, and includes the following topics:

- Information About IPv6, page 19-5
- Configuring the Global Address, page 19-7
- Configuring the Link-Local Addresses Automatically, page 19-7
- Configuring the Link-Local Address on an Interface Manually, page 19-8
- Configuring DAD Settings, page 19-8

Information About IPv6

This section includes information about how to configure IPv6, and includes the following topics:

- IPv6 Addressing, page 19-5
- Duplicate Address Detection, page 19-6
- Modified EUI-64 Interface IDs, page 19-6
- Unsupported Commands, page 19-6

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. This address needs to be configured per device or context, and not per-interface. You can also configure a global IPv6 address for the management interface.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the ND functions such as address resolution and neighbor discovery. Because the link-local address is only available on a segment, and is tied to the interface MAC address, you need to configure the link-local address per interface.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local addresses is automatically configured on each interface, so you do not also need to specifically configure a link-local address. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Duplicate Address Detection

During the stateless autoconfiguration process, duplicate address detection (DAD) verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection is performed first on the new link-local address. When the link local address is verified as unique, then duplicate address detection is performed all the other IPv6 unicast addresses on the interface.

Duplicate address detection is suspended on interfaces that are administratively down. While an interface is administratively down, the unicast IPv6 addresses assigned to the interface are set to a pending state. An interface returning to an administratively up state restarts duplicate address detection for all of the unicast IPv6 addresses on the interface.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
%ASA-4-325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used. However, all configuration commands associated with the duplicate address remain as configured while the state of the address is set to DUPLICATE.

If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address and all of the other IPv6 address associated with the interface are regenerated (duplicate address detection is performed only on the new link-local address).

The ASA uses neighbor solicitation messages to perform duplicate address detection. By default, the number of times an interface performs duplicate address detection is 1.

Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The ASA can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
%ASA-3-325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

Unsupported Commands

The following IPv6 commands are not supported in transparent firewall mode, because they require router capabilities:

- **ipv6 address autoconfig**
- **ipv6 nd prefix**
- **ipv6 nd ra-interval**

- **ipv6 nd ra-lifetime**
- **ipv6 nd suppress-ra**

The **ipv6 local pool** VPN command is not supported, because transparent mode does not support VPN.

Configuring the Global Address

To set the management IPv6 address, perform the following steps.

Detailed Steps

Step 1 Go to Configuration > Device Management > Management Access > Management IP Address.

Step 2 In the IPv6 Addresses area, click **Add**.

The Add IPv6 Management Address dialog box appears.

Step 3 In the IP Address field, enter an IPv6 address.

For example, 2001:0DB8::BA98:0:3210. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

Step 4 In the Prefix Length field, enter the prefix length.

For example, 48. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

Step 5 Click **OK**.

Step 6 To configure additional addresses, repeat Step 2 through Step 5.

Step 7 Click **Apply**.

Configuring the Link-Local Addresses Automatically

If you only need to configure a link-local address and are not going to assign any other IPv6 addresses, you have the option of generating the link-local addresses based on the interface MAC addresses (Modified EUI-64 format).

Detailed Steps

Step 1 Go to Configuration > Device Management > Management Access > Management IP Address.

Step 2 In the IPv6 configuration area, check **Enable IPv6**.

This option enables IPv6 on all interfaces and automatically generates the link-local addresses using the Modified EUI-64 interface ID based on the interface MAC address.

Note You do not need to check this option if you configure any IPv6 addresses (either global or link-local); IPv6 support is automatically enabled as soon as you assign an IPv6 address. Similarly, unchecking this option does not disable IPv6 if you configured IPv6 addresses.

To configure IPv6 DAD parameters, shown in this area, see the "Configuring DAD Settings" section on page 19-8.

Step 3 Click **Apply**.

Configuring the Link-Local Address on an Interface Manually

If you only need to configure a link-local address and are not going to assign any other IPv6 addresses, you have the option of manually defining the link-local address.

Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Select an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.

Step 4 (Optional) To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.

If the interface identifiers do not conform to the modified EUI-64 format, an error message appears. See the "Modified EUI-64 Interface IDs" section on page 19-6 for more information.

Step 5 To set the link-local address, enter an address in the Link-local address field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

Step 6 Click **OK**.

Configuring DAD Settings

DAD verifies the uniqueness of new unicast IPv6 addresses before they are assigned and ensures that duplicate IPv6 addresses are detected in the network on a link basis.

For information about the Enable IPv6 parameter, see the "Configuring the Link-Local Addresses Automatically" section on page 19-7.

Detailed Steps

Step 1 Go to Configuration > Device Management > Management Access > Management IP Address.

Step 2 In the IPv6 configuration area, in the DAD attempts field, enter the number of allowed DAD attempts.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. Valid values are from 0 to 600. A zero value disables DAD processing on the specified interface. The default is one message.

Step 3 In the NS Interval field, enter the neighbor solicitation message interval.

The neighbor solicitation message requests the link-layer address of a target node. Valid values are from 1000 to 3600000 milliseconds. The default is 1000 milliseconds.

Step 4 In the Reachable Time field, enter the amount of time in seconds that a remote IPv6 node is considered reachable after a leachability confirmation event has occurred.

Valid values are from 1000 to 3600000 milliseconds. The default is zero. A configured time enables the detection of unavailable neighbors. Shorter times enable detection more quickly; however, very short configured times are not recommended in normal IPv6 operation.

Step 5 Click **Apply**.

Completing Interface Configuration in Transparent Mode (8.3 and Earlier)

This section includes tasks to complete the interface configuration for all models in transparent mode.

Note For multiple context mode, complete the tasks in this section in the context execution space. In the Configuration > Device List pane, double-click the context name under the active device IP address.

This section includes the following topics:

- Task Flow for Completing Interface Configuration, page 19-9
- Configuring General Interface Parameters, page 19-10
- Configuring a Management Interface (ASA 5510 and Higher), page 19-11
- Configuring the MAC Address and MTU, page 19-15
- Allowing Same Security Level Communication, page 19-17

Task Flow for Completing Interface Configuration

Step 1 Complete the procedures in the "Starting Interface Configuration (ASA 5510 and Higher)" section on page 15-12 or the "Starting ASA 5505 Interface Configuration" section on page 16-6.

Step 2 (Multiple context mode) In the Configuration > Device List pane, double-click the context name under the active device IP address.

Step 3 Configure general interface parameters, including the interface name and security level. See the "Configuring General Interface Parameters" section on page 19-10.

Step 4 (Optional) Configure a management interface. See the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 19-11.

Step 5 (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 19-15.

Step 6 (Optional) Allow same security level communication, either by allowing communication between two interfaces or by allowing traffic to enter and exit the same interface. See the "Allowing Same Security Level Communication" section on page 19-17.

Configuring General Interface Parameters

This procedure describes how to set the name, security level, and bridge group for each transparent interface.

To configure a separate management interface, see the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 19-11.

For the ASA 5510 and higher, you must configure interface parameters for the following interface types:

- Physical interfaces
- VLAN subinterfaces
- Redundant interfaces

For the ASA 5505, you must configure interface parameters for the following interface types:

- VLAN interfaces

Guidelines and Limitations

- You can configure up to two interfaces per context.
- For the ASA 5550 ASA, for maximum throughput, be sure to balance your traffic over the two interface slots; for example, assign the inside interface to slot 1 and the outside interface to slot 0.
- For information about security levels, see the "Security Levels" section on page 19-2.
- If you are using failover, do not use this procedure to name interfaces that you are reserving for failover and Stateful Failover communications. See the "Configuring Active/Standby Failover" section on page 12-7 or the "Configuring Active/Active Failover" section on page 13-8 to configure the failover and state links.

Prerequisites

- Complete the procedures in Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)," or Chapter 16, "Starting Interface Configuration (ASA 5505)."
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

In multiple context mode, only interfaces that were assigned to the context in the System execution space appear in the table.

Step 2 Choose the row for an interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 In the Interface Name field, enter a name up to 48 characters in length.

Step 4 In the Security level field, enter a level between 0 (lowest) and 100 (highest).

See the "Security Levels" section on page 19-2 for more information.

Step 5 If the interface is not already enabled, check the **Enable Interface** check box.

Step 6 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns. In the case of a failover or state link, the description is fixed as "LAN Failover Interface," "STATE Failover Interface," or "LAN/STATE Failover Interface," for example. You cannot edit this description. The fixed description overwrites any description you enter here if you make this interface a failover or state link.

Note (ASA 5510 and higher, single mode) For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Step 7 Click **OK**.

What to Do Next

- (Optional) Configure a management interface. See the "Configuring a Management Interface (ASA 5510 and Higher)" section on page 19-11.
- (Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 19-15.

Configuring a Management Interface (ASA 5510 and Higher)

You can configure one management interface separate from the network interfaces in single mode or per context. You can use the Management *slot*/*port* interface (either the physical interface or a subinterface) as a separate management interface. You cannot use any other interface type as a management interface. For more information, see the "Management Interface" section on page 15-2.

This section includes the following topics:

- Configuring General Parameters and the IPv4 Address, page 19-11
- Configuring a Global IPv6 Address and Other Options, page 19-13

Configuring General Parameters and the IPv4 Address

This section describes how to configure the name, security level, and IPv4 address for a management interface.

Prerequisites

- Complete the procedures in Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)," or Chapter 16, "Starting Interface Configuration (ASA 5505)."
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

In multiple context mode, only interfaces that were assigned to the context in the System execution space appear in the table.

Step 2 Choose the row for a Management interface or subinterface and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 In the Interface Name field, enter a name up to 48 characters in length.

Step 4 In the Security level field, enter a level between 0 (lowest) and 100 (highest).

See the "Security Levels" section on page 19-2 for more information.

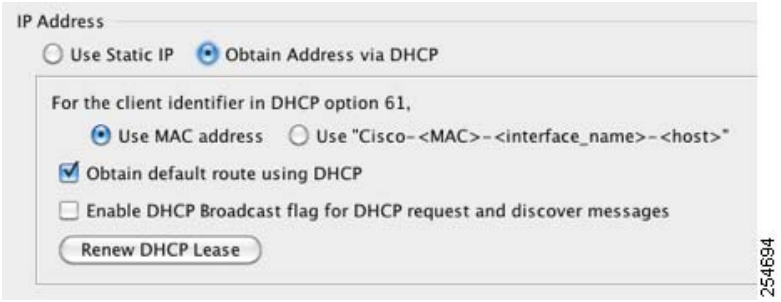
Note The **Dedicate this interface to management only** check box is enabled by default and is non-configurable.

Step 5 If the interface is not already enabled, check the **Enable Interface** check box.

Step 6 To set the IP address, use one of the following options.

Note For use with failover, you must set the IP address and standby address manually; DHCP is not supported. Set the standby IP addresses on the Configuration > Device Management > High Availability > Failover > Interfaces tab.

- To set the IP address manually, click the **Use Static IP** radio button and enter the IP address and mask.
- To obtain an IP address from a DHCP server, click the **Obtain Address via DHCP** radio button.



a. To force a MAC address to be stored inside a DHCP request packet for option 61, click the **Use MAC Address** radio button.

   Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned.

b. To use a generated string for option 61, click **Use "Cisco-<MAC>-<interface_name>-<host>"**.

c. (Optional) To obtain the default route from the DHCP server, check **Obtain Default Route Using DHCP**.

d. (Optional) To set the broadcast flag to 1 in the DHCP packet header when the DHCP client sends a discover requesting an IP address, check **Enable DHCP Broadcast flag for DHCP request and discover messages**.

   The DHCP server listens to this broadcast flag and broadcasts the reply packet if the flag is set to 1.

e. (Optional) To renew the lease, click **Renew DHCP Lease**.

Step 7 (Optional) In the Description field, enter a description for this interface.

The description can be up to 240 characters on a single line, without carriage returns.

Note (ASA 5510 and higher, single mode) For information about the Configure Hardware Properties button, see the "Enabling the Physical Interface and Configuring Ethernet Parameters" section on page 15-23.

Step 8 Click **OK**.

Configuring a Global IPv6 Address and Other Options

To configure a global IPv6 address and other options for the management interface, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately.

Restrictions

The ASA does not support IPv6 anycast addresses.

Prerequisites

- Complete the procedures in Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)," or Chapter 16, "Starting Interface Configuration (ASA 5505)."
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

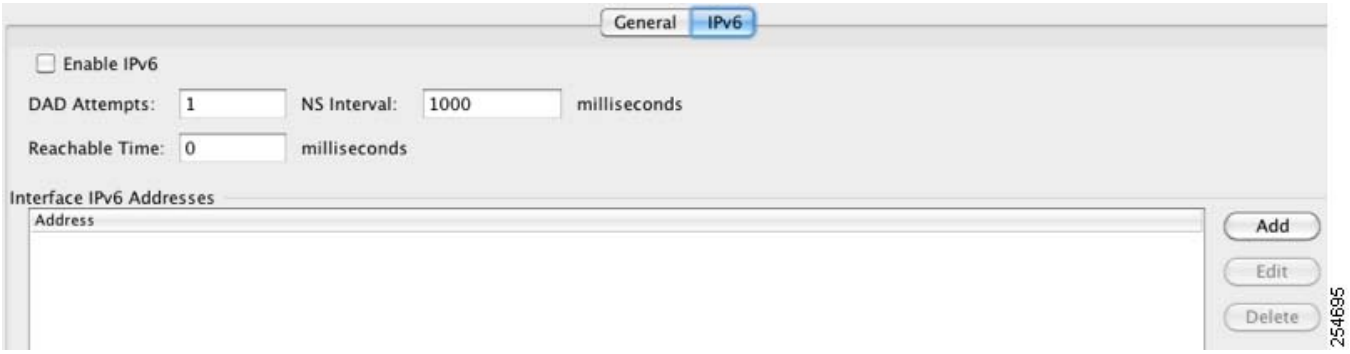
Detailed Steps

Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

Step 2 Choose a management interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **IPv6** tab.



Step 4 (Optional) To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.

See the "Modified EUI-64 Interface IDs" section on page 19-6 for more information.

Step 5 To configure the global IPv6 address:

a. In the Interface IPv6 Addresses area, click **Add**.

The Add IPv6 Address for Interface dialog box appears.

b. In the Address/Prefix Length field, enter the global IPv6 address and the IPv6 prefix length. For example, 2001:0DB8::BA98:0:3210/48. See the "IPv6 Addresses" section on page A-5 for more information about IPv6 addressing.

c. Click **OK**.

Step 6 (Optional) In the top area, customize the IPv6 configuration by configuring the following options:

- DAD Attempts—This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. Valid values are from 0 to 600. A zero value disables DAD processing on the specified interface. The default is one message.
- NS Interval—Enter the neighbor solicitation message interval. The neighbor solicitation message requests the link-layer address of a target node. Valid values are from 1000 to 3600000 milliseconds. The default is 1000 milliseconds.
- Reachable Time—Enter the amount of time in seconds that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred. Valid values are from 0 to 3600000 milliseconds. The default is zero. A configured time enables the detection of unavailable neighbors. Shorter times enable detection more quickly; however, very short configured times are not recommended in normal IPv6 operation.

Step 7 Click **OK**.

You return to the Configuration > Device Setup > Interfaces pane.

What to Do Next

(Optional) Configure the MAC address and the MTU. See the "Configuring the MAC Address and MTU" section on page 19-15.

Configuring the MAC Address and MTU

This section describes how to configure MAC addresses for interfaces and how to set the MTU.

Information About MAC Addresses

By default, the physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.

A redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. If you assign a MAC address to the redundant interface using this command, then it is used regardless of the member interface MAC addresses.

For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses the lowest numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can manually configure a MAC address for the port-channel interface. In multiple context mode, you can automatically assign unique MAC addresses to interfaces, including an EtherChannel port interface. We recommend manually, or in multiple context mode, automatically configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.

In multiple context mode, if you share an interface between contexts, you can assign a unique MAC address to the interface in each context. This feature lets the ASA easily classify packets into the appropriate context. Using a shared interface without unique MAC addresses is possible, but has some limitations. See the "How the ASA Classifies Packets" section on page 9-3 for more information. You can assign each MAC address manually, or you can automatically generate MAC addresses for shared interfaces in contexts. See the "Automatically Assigning MAC Addresses to Context Interfaces" section on page 9-24 to automatically generate MAC addresses. If you automatically generate MAC addresses, you can use this procedure to override the generated address.

For single context mode, or for interfaces that are not shared in multiple context mode, you might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address.

Prerequisites

- Complete the procedures in Chapter 15, "Starting Interface Configuration (ASA 5510 and Higher)," or Chapter 16, "Starting Interface Configuration (ASA 5505)."
- In multiple context mode, complete this procedure in the context execution space. To change from the system to a context configuration, in the Configuration > Device List pane, double-click the context name under the active device IP address.

Detailed Steps

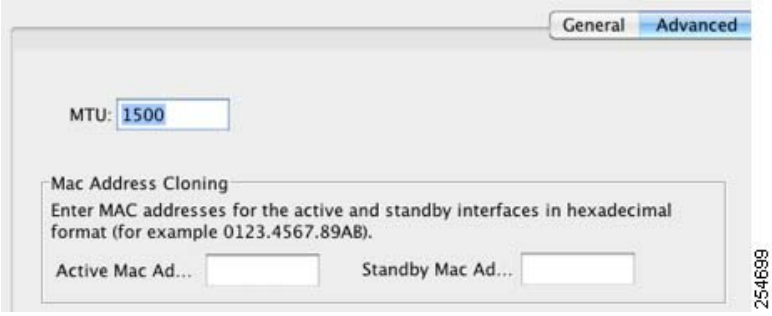
Step 1 Choose the **Configuration > Device Setup > Interfaces** pane.

BVIs appear in the table alongside physical interfaces, subinterfaces, redundant interfaces, and EtherChannel port-channel interfaces. In multiple context mode, only interfaces that were assigned to the context in the System execution space appear in the table.

Step 2 Choose the row for a physical interface, subinterface, redundant interface, or EtherChannel port-interface, and click **Edit**.

The Edit Interface dialog box appears with the General tab selected.

Step 3 Click the **Advanced** tab.



Step 4 To set the MTU or to enable jumbo frame support (ASA 5580 only), enter the value in the MTU field, between 300 and 65,535 bytes.

The default is 1500 bytes.

Note When you set the MTU for a redundant or port-channel interface, the ASA applies the setting to all member interfaces.

- For the ASA 5580 in single mode—If you enter a value for any interface that is greater than 1500, then you enable jumbo frame support automatically for all interfaces. If you set the MTU for all interfaces back to a value under 1500, then jumbo frame support is disabled.
- For the ASA 5580 in multiple mode—If you enter a value for any interface that is greater than 1500, then be sure to enable jumbo frame support in the system configuration. See the "Enabling Jumbo Frame Support (Supported Models)" section on page 15-37.

Note Enabling or disabling jumbo frame support requires you to reboot the ASA.

A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. Jumbo frames require extra memory to process, and assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists.

Step 5 To manually assign a MAC address to this interface, enter a MAC address in the Active Mac Address field in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The first two bytes of a manual MAC address cannot be A2 if you also want to use auto-generated MAC addresses.

Step 6 If you use failover, enter the standby MAC address in the Standby Mac Address field. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Allowing Same Security Level Communication

By default, interfaces on the same security level cannot communicate with each other, and packets cannot enter and exit the same interface. This section describes how to enable inter-interface communication when interfaces are on the same security level.

Information About Inter-Interface Communication

Allowing interfaces on the same security level to communicate with each other is useful if you want traffic to flow freely between all same security interfaces without access lists.

If you enable same security interface communication, you can still configure interfaces at different security levels as usual.

Detailed Steps

To enable interfaces on the same security level to communicate with each other, from the Configuration > Interfaces pane, check **Enable traffic between two or more interfaces which are configured with same security level**.

Monitoring Interfaces

For information about monitoring screens, see the "Monitoring Interfaces" section on page 18-22.

Feature History for Interfaces in Transparent Mode

Table 19-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 19-1 Feature History for Interfaces in Transparent Mode

Feature Name	Platform Releases	Feature Information
Increased VLANs	7.0(5)	Increased the following limits: • ASA5510 Base license VLANs from 0 to 10. • ASA5510 Security Plus license VLANs from 10 to 25. • ASA5520 VLANs from 25 to 100. • ASA5540 VLANs from 100 to 200.
Increased VLANs	7.2(2)	The maximum number of VLANs for the Security Plus license on the ASA 5505 ASA was increased from 5 (3 fully functional; 1 failover; one restricted to a backup interface) to 20 fully functional interfaces. In addition, the number of trunk ports was increased from 1 to 8. Now there are 20 fully functional interfaces, you do not need to use the backup interface command to cripple a backup ISP interface; you can use a fully-functional interface for it. The backup interface command is still useful for an Easy VPN configuration. VLAN limits were also increased for the ASA 5510 ASA (from 10 to 50 for the Base license, and from 25 to 100 for the Security Plus license), the ASA 5520 ASA (from 100 to 150), the ASA 5550 ASA (from 200 to 250).
Gigabit Ethernet Support for the ASA 5510 Security Plus License	7.2(3)	The ASA 5510 ASA now supports GE (Gigabit Ethernet) for port 0 and 1 with the Security Plus license. If you upgrade the license from Base to Security Plus, the capacity of the external Ethernet0/0 and Ethernet0/1 ports increases from the original FE (Fast Ethernet) (100 Mbps) to GE (1000 Mbps). The interface names will remain Ethernet 0/0 and Ethernet 0/1.
Native VLAN support for the ASA 5505	7.2(4)/8.0(4)	You can now include the native VLAN in an ASA 5505 trunk port. We modified the following screen: Configuration > Device Setup > Interfaces > Switch Ports > Edit Switch Port.

Table 19-1 Feature History for Interfaces in Transparent Mode (continued)

Feature Name	Platform Releases	Feature Information
Jumbo packet support for the ASA 5580	8.1(1)	The Cisco ASA 5580 supports jumbo frames. A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. You can enable support for jumbo frames for all interfaces by increasing the amount of memory to process Ethernet frames. Assigning more memory for jumbo frames might limit the maximum use of other features, such as access lists. We modified the following screen: Configuration > Device Setup > Interfaces > Add/Edit Interface > Advanced.
Increased VLANs for the ASA 5580	8.1(2)	The number of VLANs supported on the ASA 5580 are increased from 100 to 250.
IPv6 support for transparent mode	8.2(1)	IPv6 support was introduced for transparent firewall mode.
Support for Pause Frames for Flow Control on the ASA 5580 10-Gigabit Ethernet Interfaces	8.2(2)	You can now enable pause (XOFF) frames for flow control. We modified the following screens: (Single Mode) Configuration > Device Setup > Interfaces > Add/Edit Interface > General (Multiple Mode, System) Configuration > Interfaces > Add/Edit Interface.
Bridge groups for transparent mode (see Chapter 18, "Completing Interface Configuration (Transparent Mode, 8.4 and Later).")	8.4(1)	If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups. You can configure up to eight bridge groups of four interfaces each in single mode or per context. We modified or introduced the following screens: Configuration > Device Setup > Interfaces Configuration > Device Setup > Interfaces > Add/Edit Bridge Group Interface Configuration > Device Setup > Interfaces > Add/Edit Interface

PART 3

Configuring Basic Settings

Configuring Basic Settings

This chapter describes how to configure basic settings on the ASA that are typically required for a functioning configuration and includes the following sections:

- Configuring the Hostname, Domain Name, and Passwords, page 21-1
- Setting the Date and Time, page 21-2
- Configuring the Master Passphrase, page 21-4
- Configuring the DNS Server, page 21-8
- Changing the Heap Memory Size, page 21-9
- Monitoring DNS Cache, page 21-9

Configuring the Hostname, Domain Name, and Passwords

This section includes the following topic:

- Setting the Hostname, Domain Name, and the enable and Telnet Passwords, page 21-1

Setting the Hostname, Domain Name, and the enable and Telnet Passwords

To set the hostname, domain name, and the enable and Telnet passwords, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Device Name/Password**.

Step 2 Enter the hostname. The default hostname depends on your platform.

The hostname appears in the command line prompt, and if you establish sessions to multiple devices, the hostname helps you keep track of where you enter commands. The hostname is also used in syslog messages.

For multiple context mode, the hostname that you set in the system execution space appears in the command line prompt for all contexts. The hostname that you optionally set within a context does not appear in the command line; it can be used for a banner.

Step 3 Enter the domain name. The default domain name is default.domain.invalid.

The ASA appends the domain name as a suffix to unqualified names. For example, if you set the domain name to “example.com” and specify a syslog server by the unqualified name of “jupiter,” then the ASA qualifies the name to “jupiter.example.com.”

Note In multiple context mode, the Enable Password area only appears in contexts; it does not appear in the system execution space.

Step 4 Change the privileged mode (enable) password.

The enable password lets you access privileged EXEC mode after you log in. Also, this password is used to access ASDM as the default user, which is blank. The default user shows as "enable_15" in the User Accounts pane. (If you configure user authentication for enable access, then each user has a separate password, and this enable password is not used. In addition, you can configure authentication for HTTP/ASDM access.)

Step 5 Enter the old password.

Step 6 Enter the new password.

Step 7 Confirm the new password.

Note In multiple context mode, the Telnet Password area only appears in contexts; it does not appear in the system execution space.

Step 8 Change the login password to access the platform console.

The Telnet password sets the login password. By default, it is "cisco." This password applies to both Telnet and SSH access. The login password lets you access EXEC mode if you connect to the ASA using a Telnet or SSH session. (If you configure user authentication for Telnet or SSH access, then each user has a separate password, and this login password is not used.)

Step 9 Enter the old password.

Step 10 Enter the new password.

Step 11 Confirm the new password.

Step 12 Click **Apply** to save your changes.

Setting the Date and Time

Note Do not set the date and time for the ASASM; it receives these settings from the host switch.

This section includes the following topics:

- Setting the Date and Time Using an NTP Server, page 21-3
- Setting the Date and Time Manually, page 21-4

Setting the Date and Time Using an NTP Server

To obtain the date and time from an NTP server, choose Configuration > Device Setup > System Time > NTP:

Detailed Steps

Use the NTP pane to define NTP servers for setting the time dynamically on the ASA. The time appears in the status bar at the bottom of the main ASDM window. Time derived from an NTP server overrides any time set manually in the Clock pane.

NTP is used to implement a hierarchical system of servers that provide a precisely synchronized time among network systems. This kind of accuracy is required for time-sensitive operations, such as validating CRLs, which include a precise time stamp. You can configure multiple NTP servers. The ASA chooses the server with the lowest stratum—a measure of how reliable the data is.

Adding or Editing the NTP Server Configuration

To add or edit an NTP server, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > System Time > NTP**.

Step 2 Click **Add** to display the Add NTP Server Configuration dialog box.

Step 3 Enter the NTP server IP address.

Step 4 Check the **Preferred** check box to set this server as a preferred server. NTP uses an algorithm to determine which server is the most accurate and synchronizes to it. If servers are of similar accuracy, then the preferred server is used. However, if a server is significantly more accurate than the preferred one, the ASA uses the more accurate one.

Step 5 Choose the interface from the drop-down list. This setting specifies the outgoing interface for NTP packets. If the interface is blank, then the ASA uses the default admin context interface according to the routing table. To change the admin context (and the available interfaces), choose None (the default interface) for stability.

Step 6 Choose the key number from the drop-down list. This setting specifies the key ID for this authentication key, which enables you to use MD5 authentication to communicate with the NTP server. The NTP server packets must also use this key ID. If you have previously configured a key ID for another server, you can select it from the list; otherwise, enter a number between 1 and 4294967295.

Step 7 Check the **Trusted** check box to set this authentication key as a trusted key, which is required for authentication to succeed.

Step 8 Enter the key value to set the authentication key, which is a string that can be up to 32 characters long.

Step 9 Reenter the key value to make sure that you enter it correctly twice.

Step 10 Click **OK**.

Step 11 Check the **Enable NTP authentication** check box to turn on NTP authentication.

Step 12 Click **Apply** to save your changes.

Setting the Date and Time Manually

The time is based on a 24-hour clock and displays in the status bar at the bottom of the main ASDM pane.

In multiple context mode, you can set the time in the system configuration only.

To dynamically set the time using an NTP server, choose **Configuration > Device Setup > System Time > NTP**; time derived from an NTP server overrides any time set manually in the Clock pane.

To manually set the date and time for the ASA, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > System Time > Clock**.

Step 2 Choose the time zone from the drop-down list. This setting specifies the time zone as GMT plus or minus the appropriate number of hours. If you select the Eastern Time, Central Time, Mountain Time, or Pacific Time zone, then the time adjusts automatically for daylight savings time, from 2:00 a.m. on the second Sunday in March to 2:00 a.m. on the first Sunday in November.

Note Changing the time zone on the ASA may drop the connection to intelligent SSMs.

Step 3 Click the Date drop-down list to display a calendar. Then find the correct date using the following methods:

- Click the name of the month to display a list of months, then click the desired month. The calendar updates to that month.
- Click the year to change the year. Use the up and down arrows to scroll through the years, or enter a year in the entry field.
- Click the arrows to the right and left of the month and year to scroll the calendar forward and backward one month at a time.
- Click a day on the calendar to set the date.

Step 4 Enter the time manually in hours, minutes, and seconds.

Step 5 Click **Update Display Time** to update the time shown in the bottom right corner of the ASDM pane. The current time updates automatically every ten seconds.

Configuring the Master Passphrase

This section includes the following topics:

- Information About the Master Passphrase, page 21-5
- Licensing Requirements for the Master Passphrase, page 21-5
- Guidelines and Limitations, page 21-5
- Adding or Changing the Master Passphrase, page 21-5
- Disabling the Master Passphrase, page 21-6
- Recovering the Master Passphrase, page 21-7
- Feature History for the Master Passphrase, page 21-7

Information About the Master Passphrase

The master passphrase allows you to securely store plain text passwords in encrypted format and provides a key that is used to universally encrypt or mask all passwords, without changing any functionality. Features that use the master passphrase include the following:

- OSPF
- EIGRP
- VPN load balancing
- VPN (remote access and site-to-site)
- Failover
- AAA servers
- Logging
- Shared licenses

Licensing Requirements for the Master Passphrase

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Failover Guidelines

If failover is enabled but no failover shared key is set, an error message appears if you change the master passphrase, informing you that you must enter a failover shared key to protect the master passphrase changes from being sent as plain text.

Choose **Configuration > Device Management > High Availability > Failover**, enter any character in the Shared Key field or 32 hexadecimal numbers (0-9A-Fa-f) if a failover hexadecimal key is selected, except a backspace. Then click **Apply.**

Adding or Changing the Master Passphrase

To add or change the master passphrase, perform the following steps:

Step 1 In single context mode, choose **Configuration > Device Management > Advanced > Master Passphrase**.

In multiple context mode, choose **Configuration > Device Management > Device Administration > Master Passphrase.**

Step 2 Check the **Advanced Encryption Standard (AES) password encryption** check box.

If no master passphrase is in effect, a warning message appears when you click **Apply**. You can click **OK** or **Cancel** to continue.

If you later disable password encryption, all existing encrypted passwords are left unchanged, and as long as the master passphrase exists, the encrypted passwords will be decrypted as required by the application.

Step 3 Check the **Change the encryption master passphrase** check box to enable you to enter and confirm your new master passphrases. By default, they are disabled.

Your new master passphrase must be between 8 and 128 characters long.

If you are changing an existing passphrase, you must enter the old passphrase before you can enter a new one.

To delete the master passphrase, leave the New and Confirm master passphrase fields blank.

Step 4 Click **Apply**.

When you click **Apply**, warning messages appear under the following conditions:

- The Change the encryption master passphrase field is enabled, and the New master passphrase field is empty. The **no key configuration-key password-encrypt** command is then sent to the device.
- The old master passphrase does not match the hash value in the **show password encryption** command output.
- You use non-portable characters, particularly those with the high-order bit set in an 8-bit representation.
- A master passphrase and failover are in effect, then an error message appears if an attempt to remove the failover shared key occurs.
- Encryption is disabled, but a new or replacement master passphrase is supplied. Click **OK** or **Cancel** to continue.
- If the master passphrase is changed in multiple context mode.
- If Active/Active failover is configured and the master passphrase is changed.
- If any running configurations are configured so that their configurations cannot be saved to their server, such as with context configuration URLs that use HTTP or HTTPS, and the master passphrase is changed.

Disabling the Master Passphrase

Disabling the master passphrase reverts encrypted passwords into plain text passwords. Removing the passphrase might be useful if you downgrade to a previous software version that does not support encrypted passwords.

You must know the current master passphrase to disable it. If you do not know the passphrase, see the "Recovering the Master Passphrase" section on page 21-7.

To disable the master passphrase, perform the following steps:

Step 1 In single context mode, choose **Configuration > Device Management > Advanced > Master Passphrase**.

In multiple context mode, choose **Configuration > Device Management > Device Administration > Master Passphrase**.

Step 2 Check the **Advanced Encryption Standard (AES) password encryption** check box.

If no master passphrase is in effect, a warning statement appears when you click **Apply**. Click **OK** or **Cancel** to continue.

Step 3 Check the **Change the encryption master passphrase** check box.

Step 4 Enter the old master passphrase in the Old master passphrase field. You must provide the old master passphrase to disable it.

Step 5 Leave the New master passphrase and the Confirm master passphrase fields empty.

Step 6 Click **Apply**.

Recovering the Master Passphrase

You cannot recover the master passphrase. If the master passphrase is lost or unknown, you can remove it.

To remove the master passphrase, perform the following steps:

Feature History for the Master Passphrase

Table 21-1 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 21-1 Feature History for the Master Passphrase

Feature Name	Platform Releases	Feature Information
Master Passphrase	8.3(1)	We introduced this feature. We introduced the following screens: Configuration > Device Management > Advanced > Master Passphrase. Configuration > Device Management > Device Administration > Master Passphrase.

Configuring the DNS Server

Some ASA features require use of a DNS server to access external servers by domain name; for example, the Botnet Traffic Filter feature requires a DNS server to access the dynamic database server and to resolve entries in the static database. Other features, such as the **ping** or **traceroute** command, let you enter a name that you want to ping or traceroute, and the ASA can resolve the name by communicating with a DNS server. Many SSL VPN and certificate commands also support names.

Note The ASA has limited support for using the DNS server, depending on the feature. For these feature, to resolve the server name to an IP address, you must enter the IP address manually by adding the server name in the Configuration > Firewall > Objects > Network Object/Groups pane.

For information about dynamic DNS, see the "Configuring Dynamic DNS" section on page 22-2.

Prerequisites

Make sure that you configure the appropriate routing for any interface on which you enable DNS domain lookup so you can reach the DNS server. See the "Information About Routing" section on page 30-1 for more information about routing.

Step 1 In the ASDM main application window, choose **Configuration > Device Management > DNS > DNS Client**.

Step 2 In the DNS Setup area, choose one of the following options:

- Configure one DNS server group.
- Configure multiple DNS server groups.

Step 3 Click **Add** to display the Add DNS Server Group dialog box.

Step 4 Specify up to six addresses to which DNS requests can be forwarded. The ASA tries each DNS server in order until it receives a response.

Note You must first enable DNS on at least one interface before you can add a DNS server. The DNS Lookup area shows the DNS status of an interface. A False setting indicates that DNS is disabled. A True setting indicates that DNS is enabled.

Step 5 Enter the name of each configured DNS server group.

Step 6 Enter the IP addresses of the configured servers, and click **Add** to include them in the server group. To remove a configured server from the group, click **Delete**.

Step 7 To change the sequence of the configured servers, click **Move Up** or **Move Down**.

Step 8 In the Other Settings area, enter the number of seconds to wait before trying the next DNS server in the list, between 1 and 30 seconds. The default is 2 seconds. Each time the ASA retries the list of servers, the timeout time doubles.

Step 9 Enter the number of seconds to wait before trying the next DNS server in the group.

Step 10 Enter a valid DNS domain name for the group of configured servers.

Step 11 Click **OK** to close the Add DNS Server Group dialog box.

The new DNS server settings appear.

Step 12 To change these settings, click **Edit** to display the Edit DNS Server Group dialog box.

Step 13 Make your desired changes, then click **OK** to close the Edit DNS Server Group dialog box.

The revised DNS server settings appear.

Step 14 To enable a DNS server group to receive DNS requests, click **Set Active**.

Step 15 In the DNS Guard area, to enforce one DNS response per query, check the **Enable DNS Guard on all interfaces** check box. If DNS inspection is enabled, this setting is ignored on the selected interface.

Step 16 Click **Apply** to save your changes, or click **Reset** to discard those changes and enter new ones.

Changing the Heap Memory Size

Along with using troubleshooting information in this guide, see the *ASDM Troubleshooting* document at the following URL:

http://www.cisco.com/en/US/products/ps6121/products_tech_note09186a0080aaeff5.shtml

ASDM supports a maximum configuration size of 512 KB. If you exceed this amount you may experience performance issues. For example, when you load the configuration, the status dialog box shows the percentage of the configuration that is complete, yet with large configurations it stops incrementing and appears to suspend operation, even though ASDM might still be processing the configuration. If this situation occurs, we recommend that you consider increasing the ASDM system heap memory.

To increase the ASDM heap memory size, modify the launcher shortcut by performing the following procedure:

Step 1 Right-click the shortcut for the ASDM-IDM Launcher, and choose **Properties**.

Step 2 Click the **Shortcut** tab.

Step 3 In the Target field, change the argument prefixed with "-Xmx" to specify your desired heap size. For example, change it to -Xmx768m for 768 MB or -Xmx1g for 1 GB. For more information about this parameter, see the Oracle document in the following location:
http://docs.oracle.com/javase/1.5.0/docs/tooldocs/windows/java.html

Monitoring DNS Cache

The ASA provides a local cache of DNS information from external DNS queries that are sent for certain clientless SSL VPN and certificate commands. Each DNS translation request is first looked for in the local cache. If the local cache has the information, the resulting IP address is returned. If the local cache

can not resolve the request, a DNS query is sent to the various DNS servers that have been configured. If an external DNS server resolves the request, the resulting IP address is stored in the local cache with its corresponding hostname.

To monitor the DNS cache, see the following pane:

Path	Purpose
Tools > Command Line Interface Enter the **show** dns-hosts command, then press **Send.**	Show the DNS cache, which includes dynamically learned entries from a DNS server as well as manually entered name and IP addresses using the **name** command.

Configuring Dynamic DNS

This chapter describes how to configure DDNS update methods and includes the following topics:

- Information About DDNS, page 22-1
- Licensing Requirements for DDNS, page 22-2
- Guidelines and Limitations, page 22-2
- Configuring Dynamic DNS, page 22-2
- DDNS Monitoring, page 22-4
- Feature History for DDNS, page 22-4

Information About DDNS

DDNS update integrates DNS with DHCP. The two protocols are complementary: DHCP centralizes and automates IP address allocation; DDNS update automatically records the association between assigned addresses and hostnames at predefined intervals. DDNS allows frequently changing address-hostname associations to be updated frequently. Mobile hosts, for example, can then move freely on a network without user or administrator intervention. DDNS provides the necessary dynamic update and synchronization of the name-to-address mapping and address-to-name mapping on the DNS server. To configure the DNS server for other uses, see the "Configuring the DNS Server" section on page 21-8. To configure DHCP, see the "Configuring a DHCP Server" section on page 23-3.

EDNS allows DNS requesters to advertise the size of their UDP packets and facilitates the transfer of packets larger than 512 octets. When a DNS server receives a request over UDP, it identifies the size of the UDP packet from the OPT resource record (RR) and scales its response to contain as many resource records as are allowed in the maximum UDP packet size specified by the requester. The size of the DNS packets can be up to 4096 bytes for BIND or 1280 bytes for the Windows 2003 DNS Server. Several additional **message-length maximum** commands are available:

- The existing global limit: **message-length maximum 512**
- A client or server specific limit: **message-length maximum client 4096**
- The dynamic value specified in the OPT RR field: **message-length maximum client auto**

If the three commands are present at the same time, the ASA enforces the minimum of the three specified values.

Licensing Requirements for DDNS

The following table shows the licensing requirements for DDNS:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

Failover Guidelines

Supports Active/Active and Active/Standby failover.

Firewall Mode Guidelines

Supported in routed firewall mode.

Context Mode Guidelines

Supported in single and multiple context modes.

Supported in transparent mode for the DNS Client pane.

IPv6 Guidelines

Supports IPv6.

Configuring Dynamic DNS

Dynamic DNS provides address and domain name mapping so that hosts can find each other, even though their DHCP-assigned IP addresses change frequently. The DDNS name and address mapping are stored on the DHCP server in two resource records: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names. Of the two methods for performing DDNS updates—the IETF standard defined by RFC 2136 and a generic HTTP method—the ASA supports the IETF method in this release.

The Dynamic DNS pane shows the configured DDNS update methods and the interfaces that have been configured for DDNS. By automatically recording the association between assigned addresses and hostnames at pre-defined intervals, DDNS allows frequently changing address-hostname associations to be updated regularly. Mobile hosts, for example, can then move freely on a network without user or administrator intervention.

To configure dynamic DNS client settings for updating the DNS server, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Device Management > DNS > Dynamic DNS**.

Step 2 Click **Add** to display the Add Dynamic DNS Update Method dialog box.

Step 3 Enter the name for the DDNS update method.

Step 4 Specify the update interval between DNS update attempts configured for the update method in days, hours, minutes, and seconds.

- Choose the number of days between update attempts from 0 to 364.
- Choose the number of hours (in whole numbers) between update attempts from 0 to 23.
- Choose the number of minutes (in whole numbers) between update attempts from 0 to 59.
- Choose the number of seconds (in whole numbers) between update attempts from 0 to 59.

These units are additive. That is, if you enter 0 days, 0 hours, 5 minutes and 15 seconds, the update method tries an update every 5 minutes and 15 seconds for as long as the method is active.

Step 5 To store server resource record updates that the DNS client updates, choose one of the following options:

- Both the A resource record and the PTR resource record.
- The A resource records only.

Step 6 Click **OK** to close the Add Dynamic DNS Update Method dialog box.

The new dynamic DNS client settings appear.

Step 7 To change these settings, click **Edit** to display the Edit Dynamic DDNS Update Method dialog box. When you edit an existing method, the Name field is *display-only* and shows the name of the selected method for editing

Step 8 Make your desired changes, and then click OK to close the Edit Dynamic DDNS Update Method dialog box.

The revised dynamic DNS client settings appear.

Step 9 To remove configured settings, choose the settings from the list, and then click **Delete**.

Step 10 To add DDNS settings for each interface configured for DDNS, click **Add** to display the Add Dynamic DNS Interface Settings dialog box.

Step 11 Choose the interface from the drop-down list.

Step 12 Choose the update method assigned to the interface from the drop-down list.

Step 13 Enter the hostname of the DDNS client.

Step 14 To store resource record updates, choose one of the following options:

- Default (PTR Records) to specify that the client request PTR record updating by the server.
- Both (PTR Records and A Records) to specify that the client request both the A and PTR DNS resource records by the server.
- None to specify that the client request no updates by the server.

Note DHCP must be enabled on the selected interface for this action to take effect.

Step 15 Click **OK** to close the Add Dynamic DNS Interface Settings dialog box.

The new dynamic DNS interface settings appear.

Step 16 To change these settings, click **Edit** to display the Edit Dynamic DNS Interface Settings dialog box.

Step 17 Make your desired changes, and then click **OK** to close the Edit Dynamic DNS Interface Settings dialog box.

The revised dynamic DNS interface settings appear.

Step 18 To remove configured settings, choose the settings from the list, and then click **Delete**.

Step 19 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

DDNS Monitoring

To monitor DDNS, perform the following steps:

Path	Purpose
Tools > Command Line Interface Enter the **showrunning-config ddns** command, then click **Send**.	Shows the current DDNS configuration.
Tools > Command Line Interface Enter the **show running-config dns server-group** command, then click **Send**.	Shows the current DNS server group status.

Feature History for DDNS

Table 22-1 lists each feature change and the platform release in which it was implemented.

ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 22-1 Feature History for DDNS

Feature Name	Releases	Feature Information
DDNS	7.0(1)	We introduced this feature. We introduced the following screens: Configuration > Device Management> DNS > DNS Client. Configuration > Device Management > DNS > Dynamic DNS.

Configuring DHCP

This chapter describes how to configure the DHCP server and includes the following sections:

- Information About DHCP, page 23-1
- Licensing Requirements for DHCP, page 23-2
- Guidelines and Limitations, page 23-2
- Configuring the DHCP Relay Service, page 23-6
- Configuring a DHCP Server, page 23-3
- Additional References, page 23-8
- DHCP Monitoring, page 23-9
- Feature History for DHCP, page 23-10

Information About DHCP

The DHCP Relay Agent sends Dynamic Host Configuration Protocol (DHCP) messages between DHCP clients and servers on different IP networks. DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The ASA can provide a DHCP server or DHCP relay service to DHCP clients attached to ASA interfaces. The DHCP server provides network configuration parameters directly to DHCP clients. The DHCP relay service sends DHCP requests received on one interface to an external DHCP server located on a different interface.

A client locates a DHCP server to request the assignment of configuration information using a reserved, link-scoped multicast address, which indicates that the client and server should be attached to the same link. However, in some cases where ease of management, economy, or scalability is the concern, we recommend that you allow a DHCP client to send a message to a server that is not connected to the same link. The DHCP relay agent, which may reside on the client network, can relay messages between the client and server. The relay agent operation is transparent to the client.

DHCP for IPv6 (DHCPv6) specified in RFC 3315 enables IPv6 DHCP servers to send configuration parameters such as network addresses or prefixes and DNS server addresses to IPv6 nodes (that is, DHCP clients). DHCPv6 uses the following multicast addresses:

- All_DHCP_Relay_Agents_and_Servers (FF02::1:2) is a link-scoped multicast address used by a client to communicate with neighboring (that is, on-link) relay agents and servers. All DHCPv6 servers and relay agents are members of this multicast group.
- The DHCPv6 relay service and server listen for messages on UDP port 547. The ASA DHCPv6 relay agent listens on both UDP port 547 and the All_DHCP_Relay_Agents_and_Servers multicast address.

Licensing Requirements for DHCP

Table 23-1 shows the licensing requirements for DHCP.

Table 23-1 Licensing Requirements

Model	License Requirement
All models	Base License.

For the ASA 5505, the maximum number of DHCP client addresses varies depending on the license:

- If the limit is 10 hosts, the maximum available DHCP pool is 32 addresses.
- If the limit is 50 hosts, the maximum available DHCP pool is 128 addresses.
- If the number of hosts is unlimited, the maximum available DHCP pool is 256 addresses.

Note The ASA 5505 ships with a 10-user license.

Guidelines and Limitations

Use the following guidelines to configure the DHCP server:

- You can configure only one DHCP server on each interface of the ASA. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure a DHCP client or DHCP relay service on an interface on which the server is enabled. Additionally, DHCP clients must be directly connected to the interface on which the server is enabled.
- The ASA does not support QIP DHCP servers for use with the DHCP proxy service.
- The relay agent cannot be enabled if the DHCP server is also enabled.
- The ASA DHCP server does not support BOOTP requests. In multiple context mode, you cannot enable the DHCP server or DHCP relay service on an interface that is used by more than one context.
- When it receives a DHCP request, the ASA sends a discovery message to the DHCP server. This message includes the IP address (within a subnetwork) that was configured with the **dhcp-network-scope** command in the group policy. If the server has an address pool that falls within that subnetwork, the server sends the offer message with the pool information to the IP address—not to the source IP address of the discovery message.

  For example, if the server has a pool in the range of 209.165.200.225 to 209.165.200.254, mask 255.255.255.0, and the IP address specified by the **dhcp-network-scope** command is 209.165.200.1, the server sends that pool in the offer message to the ASA.

Use the following guidelines to configure the DHCP relay service:

- DHCP clients must be directly connected to the ASA and cannot send requests through another relay agent or a router.

- For multiple context mode, you cannot enable DHCP relay service on an interface that is used by more than one context.
- The DHCP relay service is not available in transparent firewall mode. An ASA in transparent firewall mode only allows ARP traffic through; all other traffic requires an access list. To allow DHCP requests and replies through the ASA in transparent firewall mode, you must configure two access lists: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.
- When the DHCP relay service is enabled and more than one DHCP relay server is defined, the ASA forwards client requests to each defined DHCP relay server. Replies from the servers are also forwarded to the client until the client DHCP relay binding is removed. The binding is removed when the ASA receives any of the following DHCP messages: ACK, NACK, or decline.
- You cannot enable DHCP relay service on an interface running as a DHCP proxy service. You must remove the VPN DHCP configuration first or an error message appears. This error occurs if both DHCP relay and DHCP proxy services are enabled. Make sure that either the DHCP relay or DHCP proxy service is enabled, but not both.

Firewall Mode Guidelines

Supported in routed firewall mode.

Not supported in transparent firewall mode.

Context Mode Guidelines

Supported in single and multiple context mode.

Failover Guidelines

Supports Active/Active and Active/Standby failover.

IPv6 Guidelines

Supports IPv6.

Configuring a DHCP Server

This section includes the following topics:

- Editing DHCP Server Settings, page 23-4
- Configuring Advanced DHCP Options, page 23-5

To configure an ASA interface as a DHCP server, perform the following steps:

Step 1 In the Global DHCP Options area, check the **Enable Auto-configuration from interface** check box to enable DHCP auto configuration and choose the interface from the drop-down list.

DHCP auto configuration enables the DHCP Server to provide DHCP clients with DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. If information obtained through auto configuration is also specified manually in the Global DHCP Options area, the manually specified information takes precedence over the discovered information.

Step 2 To override the interface DHCP or PPPoE client WINS parameter with the VPN client parameter, check the **Allow VPN override** check box.

Step 3 In the DNS Server 1 field, enter the IP address of the primary DNS server for a DHCP client.

Step 4 In the DNS Server 2 field, enter the IP address of the alternate DNS server for a DHCP client.

Step 5 In the Domain Name field, enter the DNS domain name for DHCP clients (for example, example.com).

Step 6 In the Lease Length field, enter the amount of time, in seconds, that the client can use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).

Step 7 In the Primary WINS Server field, enter the IP address of the primary WINS server for a DHCP client.

Step 8 In the Secondary WINS Server field, enter the IP address of the alternate WINS server for a DHCP client.

Step 9 To avoid address conflicts, the ASA sends two ICMP ping packets to an address before assigning that address to a DHCP client. In the Ping Timeout field, enter the amount of time, in milliseconds, that the ASA waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.

Step 10 To specify additional DHCP options and their parameters, click **Advanced** to display the Configuring Advanced DHCP Options dialog box. For more information, see the "Configuring Advanced DHCP Options" section on page 23-5.

Step 11 In the Dynamic DNS Settings for DHCP Server area, you configure the DDNS update settings for the DHCP server. Check the **Update DNS Clients** check box to specify that, in addition to the default action of updating the client PTR resource records, the selected DHCP server should also perform the following update actions:

- Check the **Update Both Records** check box to specify that the DHCP server should update both the A and PTR RRs.
- Check the **Override Client Settings** check box to specify that the DHCP server actions should override any update actions requested by the DHCP client.

Step 12 To modify DHCP server settings, click **Edit** to display the Edit DHCP Server dialog box. Alternatively, you may double-click the row for a particular interface to open the Edit DHCP Server dialog box for that interface. For more information, see the "Editing DHCP Server Settings" section on page 23-4.

Step 13 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Editing DHCP Server Settings

To enable DHCP, specify the DHCP address pool, and modify other DHCP server parameters for the selected interface, perform the following steps:

Step 1 The selected interface ID appears as *display-only*. To enable the DHCP server on the selected interface, check the **Enable DHCP Server** check box. To disable DHCP on the selected interface, uncheck this check box. Disabling the DHCP server on the selected interface does not clear the specified DHCP address pool.

Step 2 In the DHCP Address Pool field, enter the range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.

Step 3 Check the **Update DNS Clients** check box to specify that, in addition to the default action of updating the client PTR resource records, the selected DHCP server should also perform the following update actions:

- To specify that the DHCP server should update both the A and PTR RRs, check the **Update Both Records** check box.

- To specify that DHCP server actions should override any update actions requested by the DHCP client, check the **Override Client Settings** check box

Step 4 To enable DHCP on the interface, check the **Enable DHCP Server** check box. The DHCP Enabled column displays "Yes" if DHCP is enabled, or "No" if DHCP is disabled on the interface.

Step 5 In the DNS Address Pool field, enter the revised range of IP addresses that have been assigned to the DHCP address pool.

Step 6 In the Optional Parameters area, modify the following settings:

a. The DNS servers (1 and 2) configured for the interface.

b. The WINS servers (primary and secondary) configured for the interface.

c. The domain name of the interface.

d. The time in milliseconds that the ASA will wait for an ICMP ping response on the interface.

e. The duration of time that the DHPC server configured on the interface allows DHCP clients to use an assigned IP address.

f. The interface on a DHCP client that provides DNS, WINS, and domain name information for automatic configuration.

Step 7 To configure more DHCP options, click **Advanced** to display the Advanced DHCP Options dialog box. For more information, see the "Configuring Advanced DHCP Options" section on page 23-5.

Step 8 Click **OK** to close the Edit DHCP Server dialog box.

Step 9 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Configuring Advanced DHCP Options

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

For example, you can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

To configure advanced DHCP options, perform the following steps:

Step 1 In the Option to be Added area, define the following settings:

a. Choose the option code from the drop-down list. All DHCP options (options 1 through 255) are supported except 1, 12, 50–54, 58–59, 61, 67, and 82.

b. Choose the options that you want to configure. Some options are standard. For standard options, the option name is shown in parentheses after the option number and the option parameters are limited to those supported by the option. For all other options, only the option number is shown and you

must choose the appropriate parameters to supply with the option. For example, if you choose DHCP Option 2 (Time Offset), you can only enter a hexadecimal value for the option. For all other DHCP options, all of the option value types are available and you must choose the appropriate options value type.

c. In the Option Data area, specify the type of information that the option returns to the DHCP client. For standard DHCP options, only the supported option value type is available. For all other DHCP options, all of the option value types are available. Click **Add** to add the option to the DHCP option list. Click **Delete** to remove the option from the DHCP option list.

   – Click **IP Address** to indicate that an IP address is returned to the DHCP client. You can specify up to two IP addresses. IP Address 1 and IP Address 2 indicate an IP address in dotted-decimal notation.

Note The name of the associated IP address fields can change based on the DHCP option that you chose. For example, if you choose DHCP Option 3 (Router), the fields names change to Router 1 and Router 2.

   – Click **ASCII** to specify that an ASCII value is returned to the DHCP client. In the Data field, enter an ASCII character string. The string cannot include spaces.

Note The name of the associated Data field can change based on the DHCP option that you chose. For example, if you choose DHCP Option 14 (Merit Dump File), the associated Data field names change to File Name.

   – Click **Hex** to specify that a hexadecimal value is returned to the DHCP client. In the Data field, enter a hexadecimal string with an even number of digits and no spaces. You do not need to use a 0x prefix.

Note The name of the associated Data field can change based on the DHCP option you chose. For example, if you choose DHCP Option 2 (Time Offset), the associated Data field becomes the Offset field.

Step 2 Click **OK** to close the Advanced DHCP Options dialog box.

Step 3 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Configuring the DHCP Relay Service

The DHCP Relay pane lets you configure the DHCP relay service on the ASA through ASDM.

This section includes the following topics:

- Editing DHCP Relay Agent Settings, page 23-7
- Adding or Editing Global DHCP Relay Server Settings, page 23-8

To configure the DHCP relay service, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Device Management > DHCP > DHCP Relay**.

Step 2 To configure a new external server to which DHCP requests may be relayed, click **Add** to display the Add Global DHCP Relay Server dialog box. You can define up to ten global DHCP relay servers for IPv4 and ten global DHCP relay servers for IPv6 on the ASA. If you already have defined ten DHCP relay global servers for IPv4 and ten DHCP relay global servers for IPv6, the Add button is dimmed.

Step 3 Enter the IP address of the DHCP server, or click the ellipses to display the Browse DHCP Server dialog box.

Step 4 Double-click a DHCP server from the list to add it to the DHCP Server field, then click **OK** to close the Browse DHCP Server dialog box.

The newly selected DHCP server appears in the DHCP Server field.

Step 5 Choose the interface to which the specified DHCP server is attached from the drop-down list, then click **OK** to close the Add Global DHCP Relay Server dialog box.

The newly added global DHCP relay server appears in the Global DHCP Relay Servers list.

Step 6 To change a selected DHCP relay server settings, click **Edit** to display the Edit Global DHCP Relay Server dialog box.

Step 7 Make your desired changes, then click **OK** to close the Edit Global DHCP Relay Server dialog box. To remove a selected DHCP relay server from the list, click **Delete**.

Step 8 The DHCP Relay Agent area shows the following information:

- The configured interfaces.
- The IPv4 DHCP Relay Enabled column and IPv6 DHCP Relay Enabled column indicate whether or not the selected DHCP relay agent is enabled on the interface. The check box is checked if the DHCP relay agent is enabled, and is unchecked if the DHCP relay agent is not enabled on the interface.
- The Set Route column indicates whether or not the selected DHCP relay agent is configured to modify the default router address in the information returned from the DHCP server. The check box is checked if the DHCP relay agent is configured to change the default router address to the interface address, and is unchecked if the DHCP relay agent does not modify the default router address.

Step 9 Enter the amount of time, in seconds, allowed for DHCP address handling in the IPv4 timeout or IPv6 timeout field. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

Step 10 Click **Apply** to save your settings, or click **Reset** to discard them and enter new ones.

Step 11 To change DHCP relay agent settings, see the "Editing DHCP Relay Agent Settings" section on page 23-7.

Editing DHCP Relay Agent Settings

To modify DHCP relay agent settings, perform the following steps:

Step 1 To enable the DHCP relay agent on the selected interface, check the **Enable DHCP Relay Agent** check box.

Step 2 To specify whether the DHCP relay agent is configured to modify the default router address in the information returned from the DHCP server, check the **Set Route** check box. The DHCP relay agent then substitutes the address of the selected interface for the default router address in the information returned from the DHCP server.

Step 3 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Step 4 To add or edit global DHCP relay server settings, see the "Adding or Editing Global DHCP Relay Server Settings" section on page 23-8.

Adding or Editing Global DHCP Relay Server Settings

To add or edit a global DHCP relay server to which DHCP requests are relayed, perform the following steps:

Step 1 In the Global DHCP Relay Servers area, click **Add** to display the Add Global Relay Servers dialog box.

Step 2 In the DHCP Server field, enter either the IP4 address or hostname or the IPv6 address or hostname of the external DHCP server to which DHCP requests are forwarded. Alternatively, click the ellipses to display the Browse DHCP Server dialog box.

Step 3 Double-click a DHCP server from the list, then click **OK** to close the Browse DHCP Server dialog box.

The newly added external DHCP server appears in the list.

Step 4 Choose the interface through which DHCP requests are forwarded to the external DHCP server from the drop-down list.

Step 5 Click **OK** to close the Add Global Relay Servers dialog box.

The newly added global DHCP relay server appears in the list.

Step 6 To modify global DHCP relay server settings, click **Edit** to display the Edit DHCP Global Relay Servers dialog box.

Step 7 Make the desired changes, then click **OK** to close the Edit DHCP Global Relay Servers dialog box. The updated global DHCP relay server settings appear in the list.

Step 8 To change the timeout value, enter the number of seconds for IPv4 or IPv6.

Step 9 Click **Apply** to save your changes, or click **Reset** to discard them and enter new ones.

Additional References

For additional information related to implementing DHCPv6, see the following section:

- RFCs, page 23-9

RFCs

RFC	Title
2132	DHCP Options and BOOTP Vendor Extensions
2462	IPv6 Stateless Address Autoconfiguration
5510	DHCP for IPv6

DHCP Monitoring

To monitor DHCP, perform one or more of the following steps:

Path	Purpose
Tools > Command Line Interface Enter the **show running-config dhcpd** command, then click **Send**.	Shows the current DHCP configuration.
Tools > Command Line Interface Enter the **show running-config dhcprelay** command, then click **Send**.	Shows the current DHCP relay service status.
Tools > Command Line Interface Enter the **show ipv6 dhcprelay binding** command, then click **Send**.	Shows the relay binding entries that were created by the relay agent.
Tools > Command Line Interface Enter the **show ipv6 dhcprelay statistics** command, then click **Send**.	Shows DHCP relay agent statistics for IPv6.
Tools > Command Line Interface Enter the **clear config ipv6 dhcprelay** command, then click **Send**.	Clears the IPv6 DHCP relay configuration.
Monitoring > Interfaces > DHCP > DHCP Client Lease Information	Shows configured DHCP client IP addresses.
Monitoring > Interfaces > DHCP > DHCP Server Table	Shows configured dynamic DHCP client IP addreses.
Monitoring > Interfaces > DHCP > DHCP Statistics	Shows DHCP message types, counters, values, directions, messages received, and messages sent.

Feature History for DHCP

Table 23-2 each feature change and the platform release in which it was implemented.

ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 23-2 Feature History for DHCP

Feature Name	Releases	Description
DHCP	7.0(1)	The ASA can provide a DHCP server or DHCP relay services to DHCP clients attached to ASA interfaces. We introduced the following screens: Configuration > Device Management > DHCP > DHCP Relay. Configuration > Device Management > DHCP > DHCP Server.
DHCP for IPv6 (DHCPv6)	9.0(1)	Support for IPv6 was added. We modified the following screen: Configuration > Device Management > DHCP > DHCP Relay.

PART 4

Configuring Objects and ACLs

Configuring Objects

This chapter describes how to configure reusable named objects and groups for use in your configuration, and it includes the following sections:

- Information About Objects, page 25-1
- Licensing Requirements for Objects, page 25-1
- Configuring Objects, page 25-2
- Monitoring Objects, page 25-16
- Feature History for Objects, page 25-16

Information About Objects

Objects are reusable components for use in your configuration. They can be defined and used in ASA configurations in the place of inline IP addresses, services, names, and so on. Objects make it easy to maintain your configurations because you can modify an object in one place and have it be reflected in all other places that are referencing it. Without objects you would have to modify the parameters for every feature when required, instead of just once. For example, if a network object defines an IP address and subnet mask, and you want to change the address, you only need to change it in the object definition, not in every feature that refers to that IP address.

Licensing Requirements for Objects

Model	License Requirement
All models	Base License.

Guidelines and Limitations

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

- Supports IPv6.
- The ASA does not support IPv6 nested network object groups, so you cannot group an object with IPv6 entries under another IPv6 object group.
- You can mix IPv4 and IPv6 entries in a network object group; you cannot use a mixed object group for NAT.

Additional Guidelines and Limitations

- Object must have unique names. While you might want to create a network object group named "Engineering" and a service object group named "Engineering," you need to add an identifier (or "tag") to the end of at least one object group name to make it unique. For example, you can use the names "Engineering_admins" and "Engineering_hosts" to make the object group names unique and to aid in identification.
- Objects and object groups share the same name space.
- You cannot remove an object or make an object empty if it is used in a command.

Configuring Objects

- Configuring Network Objects and Groups, page 25-2
- Configuring Service Objects and Service Groups, page 25-4
- Configuring Local User Groups, page 25-7
- Configuring Security Group Object Groups, page 25-8
- Configuring Regular Expressions, page 25-10
- Configuring Time Ranges, page 25-15

Note For other objects not included in this chapter, see the following chapters:

- Local Users—See Chapter 46, "Configuring AAA Servers and the Local Database."
- Class Maps—See Chapter 57, "Getting Started with Application Layer Protocol Inspection."
- Inspect Maps—See Chapter 57, "Getting Started with Application Layer Protocol Inspection."
- TCP Maps—See the "Configuring Connection Settings" section on page 71-5.

Configuring Network Objects and Groups

This section describes how to configure network objects and groups, and it includes the following topics:

- Configuring a Network Object, page 25-3
- Configuring a Network Object Group, page 25-3

Configuring a Network Object

A network object can contain a host, a network IP address, or a range of IP addresses, a fully qualified domain name (FQDN). You can also enable NAT rules on the object (excepting FQDN objects). (See Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)," for more information.)

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Network Objects/Group**.

Step 2 Click **Add**, and choose **Network Object** to add a new object, or choose an existing object to edit, and click **Edit**.

You can also add or edit network objects from the Addresses side pane in a rules window or when you are adding a rule.

To find an object in the list, enter a name or IP address in the Filter field, and click **Filter**. The wildcard characters asterisk (*) and question mark (?) are allowed.

The Add/Edit Network Object dialog box appears.

Step 3 Fill in the following values:

- Name—The object name. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must contain 64 characters or fewer.
- Type—Either Network, Host, Range, or FQDN.
- IP Address—An IPv4 or an IPv6 address, either a host or network address. When you enter a colon (:) in this field for an IPv6 address, the Netmask field changes to Prefix Length. If you select Range as the object type, the IP Address field changes to allow you to enter a Start Address and an End address.
- Netmask or Prefix Length—If the IP address is an IPv4 address, enter the subnet mask. If the IP address is an IPv6 address, enter the prefix. (This field is not available if you enter the object type as Host.)
- Description—(Optional) The description of the network object (up to 200 characters in length).

Note To add NAT rules to the network object, see Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)," for more information.

Step 4 Click **OK**.

Step 5 Click **Apply** to save the configuration.

You can now use this network object when you create a rule. If you edit an object, the change is inherited automatically by any rules using the object.

Configuring a Network Object Group

Network object groups can contain multiple network objects as well as inline networks. Network object groups can support a mix of both IPv4 and IPv6 addresses.

Restrictions

You cannot use a mixed IPv4 and IPv6 object group for NAT, or object groups that include FQDN objects.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Network Objects/Groups**.

Step 2 Click click **Add > Network Object Group** to add either a new object or a new object group.

You can also add or edit network object groups from the Addresses side pane in a rules window, or when you add a rule.

To find an object in the list, enter a name or IP address in the Filter field, and click Filter. The wildcard characters asterisk (*) and question mark (?) are allowed.

The Add Network Object Group dialog box appears.

Step 3 In the Group Name field, enter a group name.

Use characters a to z, A to Z, 0 to 9, a period, a comma, a dash, or an underscore. The name must contain 64 characters or fewer.

Step 4 (Optional) In the Description field, enter a description, up to 200 characters in length.

Step 5 You can add existing objects or groups to the new group (nested groups are allowed), or you can create a new address to add to the group:

- To add an existing network object or group to the new group, double-click the object in the Existing Network Objects/Groups pane.

  You can also select the object, and then click **Add**. The object or group is added to the right-hand Members in Group pane.

- To add a new address, fill in the values under the Create New Network Object Member area, and click **Add**.

  The object or group is added to the right-hand Members in Group pane. This address is also added to the network object list.

To remove an object, double-click the object in the Members in Group pane, or select the object and click **Remove**.

Step 6 After you add all the member objects, click **OK**.

You can now use this network object group when you create a rule. For an edited object group, the change is inherited automatically by any rules using the group.

Configuring Service Objects and Service Groups

Service objects and groups identify protocols and ports. This section describes how to configure service objects, service groups, TCP and UDP port service groups, protocol groups, and ICMP groups, and it includes the following topics:

- Configuring a Service Object, page 25-5
- Configuring a Service Group, page 25-5
- Configuring a TCP or UDP Port Service Group, page 25-6

- Configuring an ICMP Group, page 25-6
- Configuring an ICMP Group, page 25-6

Configuring a Service Object

The service object can contain a protocol, ICMP, ICMPv6, TCP or UDP port or port ranges.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Service Object/Group**.

Step 2 Choose **Add > Service Object** from the drop-down list.

Step 3 In the name field, enter a name for the service object. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must be 64 characters or fewer.

Step 4 From the Service Type field, choose the desired type: tcp, udp, icmp, or icmp6 protocol.

Step 5 (Optional) If you chose tcp or udp as the Service Type, enter the following:

- Destination Port/Range
- Source Port/Range—Lists the protocol source ports/ranges.
- Description—Lists the service group description.

Step 6 (Optional) If you chose icmp or icmp6 as the Service Type, enter the following:

- ICMP Type—Lists the service group ICMP type.
- ICMP Code—(Optional) Valid values range from 1 to 255.
- Description—(Optional) Lists the service group description.

Step 7 If you chose protocol as the Service Type, enter the following:

- Protocol—Lists the service group protocol.
- Description—(Optional) Lists the service group description.

Step 8 Click **OK**, and then **Apply**.

Configuring a Service Group

A service object group includes a mix of protocols, if desired, including optional source and destination ports for TCP or UDP.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Service Object/Group**.

Step 2 Choose **Add > Service Group** from the drop-down list.

The Add Service Group dialog box appears.

Step 3 In the Name field, enter a name for the new service group. The name can be up to 64 characters in length and must be unique for all object groups. A service group name cannot share a name with other objects and groups.

Step 4 In the Description field, enter a description for this service group (up to 200 characters in length).

Step 5 To add an existing service object or group, or predefined protocol or port, click the **Existing Service/Service Group** radio button, select the entry from the Name field, and click **Add**.

Step 6 To create a new service, click the **Create new member** radio button and then choose the Service Type from the drop-down list:

- If you choose tcp, udp, or tcp/udp, enter a name, the destination port/range, the source port/range, and an optional description.
- If you choose icmp or icmp6, enter a name, the ICMP Type (from the Existing Service/Service Group list), an ICMP Code (a value from 0-255), and an optional description.
- If you choose protocol, enter a name, the protocol, and an optional description.

Click **Add** to add the new service.

Step 7 Click **OK**, and then **Apply**.

Configuring a TCP or UDP Port Service Group

A TCP or UDP service group includes a group of ports for a specific protocol (TCP, UDP, or TCP-UDP).

Step 1 Choose **Configuration > Firewall > Objects > Service Object/Group**.

Step 2 Choose **Add > TCP Service Group**, **UDP Service Group**, or **TCP-UDP Service Group** from the drop-down list.

The Add Service Group dialog box appears.

Step 3 In the Name field, enter a name for the new service group. The name can be up to 64 characters in length and must be unique for all object groups. A service group name cannot share a name with other objects and groups.

Step 4 In the Description field, enter a description for this service group (up to 200 characters in length).

Step 5 To add an existing service group, or predefined port, click the **Existing Service/Service Group** radio button, select the entry from the Name field, and click **Add**.

Step 6 To create a new port, click the **Create new member** radio button, enter the port name, number, or range and then click **Add** to add the new port.

Step 7 Click **OK**, and then **Apply**.

Configuring an ICMP Group

An ICMP group includes multiple ICMP types.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Service Object/Group**.

Step 2 Choose **Add > ICMP Group** from the drop-down list.

The Add ICMP Group dialog box appears.

Step 3 In the Name field, enter a name for the new ICMP group. The name can be up to 64 characters in length and must be unique for all object groups. An ICMP group name cannot share a name with other objects and groups..

Step 4 In the Description field, enter a description for this ICMP group (up to 200 characters in length).

Step 5 To add an existing ICMP group, or predefined type, click the **Existing Service/Service Group** radio button, select the entry from the Name field, and click **Add**.

Step 6 To create a new type, click the **Create new member** radio button, enter the type name or number, and then click **Add** to add the new type.

Step 7 Click **OK**, and then **Apply**.

Configuring a Protocol Group

A protocol group contains IP protocol types.

Detailed Steps

Step 1 Choose **Configuration > Firewall > Objects > Service Object/Group**.

Step 2 Choose **Add > Protocol Group** from the drop-down list.

The Add Protocol Group dialog box appears.

Step 3 In the Name field, enter a name for the new group. The name can be up to 64 characters in length and must be unique for all object groups. A group name cannot share a name with other objects and groups.

Step 4 In the Description field, enter a description for this group (up to 200 characters in length).

Step 5 To add an existing protocol group, or predefined protocol, click the **Existing Service/Service Group** radio button, select the entry from the Name field, and click **Add**.

Step 6 To create a new protocol, click the **Create new member** radio button, enter the protocol name or number, and then click **Add** to add the new protocol.

Step 7 Click **OK**, and then **Apply**.

Configuring Local User Groups

You can create local user groups for use in features that support the identity firewall (IDFW) by including the group in an extended ACL, which in turn can be used in an access rule, for example.

The ASA sends an LDAP query to the Active Directory server for user groups globally defined in the Active Directory domain controller. The ASA imports these groups for identity-based rules. However, the ASA might have localized network resources that are not defined globally that require local user groups with localized security policies. Local user groups can contain nested groups and user groups that are imported from Active Directory. The ASA consolidates local and Active Directory groups.

A user can belong to local user groups and user groups imported from Active Directory.

Prerequisites

See Chapter 47, “Configuring the Identity Firewall,” to enable IDFW.

Detailed Steps

Step 1 Open the **Configuration > Firewall > Objects > Local User Groups** pane.

A table of user groups and their members appears.

Step 2 To add a group, click **Add**. The Add User Object Group dialog appears.

Step 3 Enter a name and description for the group.

The group name can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If the group name contains a space, you must enclose the name in quotation marks.

Step 4 From the Domain list, select the default domain for users in this group or click **Manage** to add a new domain or edit and existing domain.

Step 5 To add existing groups to this group, enter a search string in the text box and click **Find**.

Step 6 To add users to the group, enter a search string in the text box and click **Find**.

Step 7 Select groups and click the **Add** button to add them to the group.

Step 8 Select users and click the **Add** button to add them to the group.

Step 9 Click **OK** to save your changes.

Configuring Security Group Object Groups

You can create security group object groups for use in features that support Cisco TrustSec by including the group in an extended ACL, which in turn can be used in an access rule, for example.

When integrated with Cisco TrustSec, the ASA downloads security group information from the ISE. The ISE acts as an identity repository, by providing Cisco TrustSec tag to user identity mapping and Cisco TrustSec tag to server resource mapping. You provision and manage security group access lists centrally on the ISE.

However, the ASA might have localized network resources that are not defined globally that require local security groups with localized security policies. Local security groups can contain nested security groups that are downloaded from the ISE. The ASA consolidates local and central security groups.

To create local security groups on the ASA, you create a local security object group. A local security object group can contain one or more nested security object groups or Security IDs or security group names. User can also create a new Security ID or security group name that does not exist on the ASA.

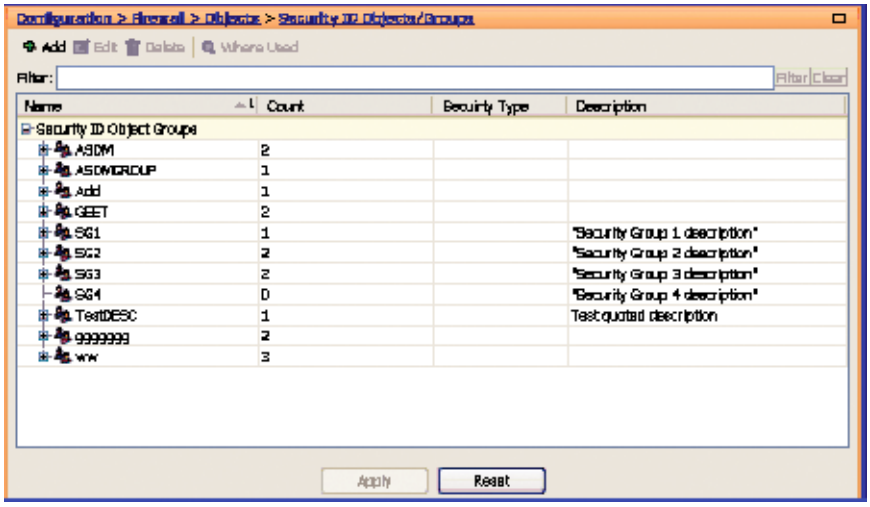
You can use the security object groups you create on the ASA to control access to network resources. You can use the security object group as part of an access group or service policy.

Prerequisites

See Chapter 48, “Configuring the ASA to Integrate with Cisco TrustSec,” to enable TrustSec.

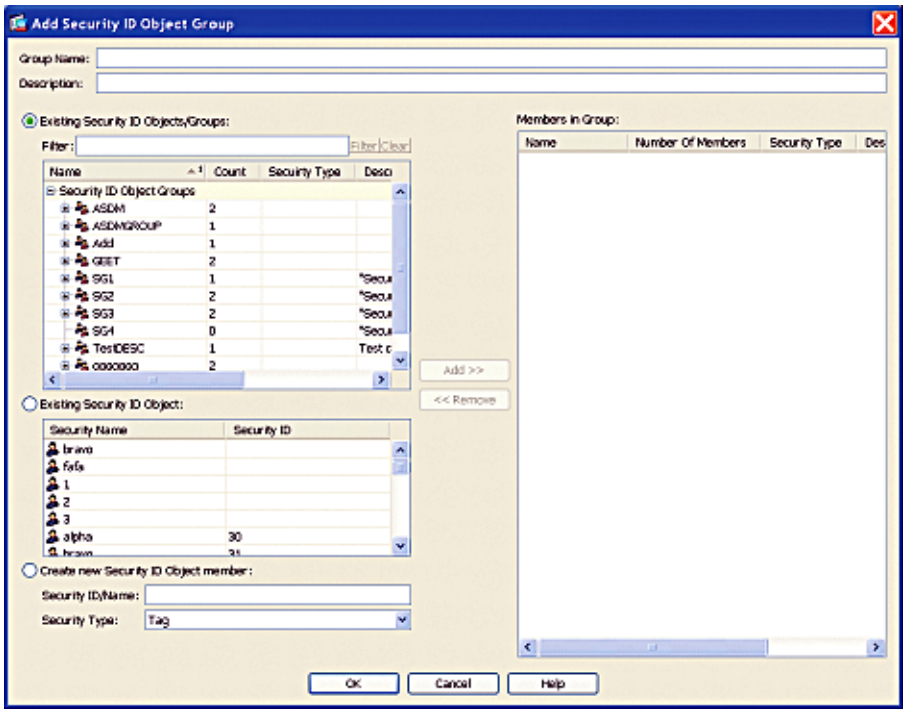
Detailed Steps

Step 1 In the main ASDM application window, choose **Configuration > Firewall > Objects > Security Group Object Groups**. The Security Group Object Groups pane appears:



The Security Group Object Groups pane lists the members of the security object group and shows the number of members in the Count column. Click **Where Used** to display where the selected security group object is used in an access list or nested in another security group object.

Step 2 Click **Add**. The Add Security ID Object Group dialog box appears.



Step 3 In the Group Name field, enter the name for the group as a 32-byte case sensitive string. The group name can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.].

Step 4 In the Description field, enter a description for the group.

Step 5 Add members to the security group object by performing the following task:

a. Select one of the following options:

- Existing Security ID Objects/Groups radio button
- Existing Security ID Object radio button

  In the Filter field, enter the security object ID number or the name of the security group and click **Filter**. Use wildcards to broaden the search for security groups.

b. Click **Add** to select it as Members in Group.

A security object group must contain at least one member.

c. Continue selecting members and clicking Add. You can create nested security object groups by selecting existing security ID object/groups and existing security ID objects.

Step 6 Create a locally defined object by performing the following tasks:

a. Click the **Create new Security ID Object member** radio button.

b. From the Security Type drop-down field, select Tag or Name.

An SGT is assigned to a device through IEEE 802.1X authentication, web authentication, or MAC authentication bypass (MAB) by the ISE. Security group names are created on the ISE and provide user-friendly names for security groups. The security group table maps SGTs to security group names.

c. In the Security ID/Name field, enter a number from 1 to 65533 for A Tag security type or a 32-byte case-sensitive string for a Name security type.

A security group has a single name assigned to it. The same name can only be associated with a single SGT.

Step 7 Click OK. The Security ID Objects/Groups pane reappears.

Step 8 Click **Apply** to save the changes to the running configuration.

Configuring Regular Expressions

- Creating a Regular Expression, page 25-10
- Creating a Regular Expression Class Map, page 25-14

Creating a Regular Expression

A regular expression matches text strings either literally as an exact string, or by using *metacharacters* so that you can match multiple variants of a text string. You can use a regular expression to match the content of certain application traffic; for example, you can match a URL string inside an HTTP packet.

Guidelines

Note As an optimization, the ASA searches on the deobfuscated URL. Deobfuscation compresses multiple forward slashes (/) into a single slash. For strings that commonly use double slashes, like “http://”, be sure to search for “http:/” instead.

Table 25-1 lists the metacharacters that have special meanings.

Table 25-1 regex Metacharacters

Character	Description	Notes
.	Dot	Matches any single character. For example, **d.g** matches dog, dag, dtg, and any word that contains those characters, such as doggonnit.
(*exp*)	Subexpression	A subexpression segregates characters from surrounding characters, so that you can use other metacharacters on the subexpression. For example, **d(o|a)g** matches dog and dag, but **do|ag** matches do and ag. A subexpression can also be used with repeat quantifiers to differentiate the characters meant for repetition. For example, **ab(xy){3}z** matches abxyxyxyz.
|	Alternation	Matches either expression it separates. For example, **dog|cat** matches dog or cat.
?	Question mark	A quantifier that indicates that there are 0 or 1 of the previous expression. For example, **lo?se** matches lse or lose. **Note** You must enter **Ctrl+V** and then the question mark or else the help function is invoked.
*	Asterisk	A quantifier that indicates that there are 0, 1 or any number of the previous expression. For example, **lo*se** matches lse, lose, loose, and so on.
+	Plus	A quantifier that indicates that there is at least 1 of the previous expression. For example, **lo+se** matches lose and loose, but not lse.
{*x*} or {*x*,}	Minimum repeat quantifier	Repeat at least *x* times. For example, **ab(xy){2,}z** matches abxyxyz, abxyxyxyz, and so on.
[*abc*]	Character class	Matches any character in the brackets. For example, **[abc]** matches a, b, or c.
[^*abc*]	Negated character class	Matches a single character that is not contained within the brackets. For example, **[^abc]** matches any character other than a, b, or c. **[^A-Z]** matches any single character that is not an uppercase letter.
[*a-c*]	Character range class	Matches any character in the range. **[a-z]** matches any lowercase letter. You can mix characters and ranges: **[abcq-z]** matches a, b, c, q, r, s, t, u, v, w, x, y, z, and so does [**a-cq-z]**. The dash (-) character is literal only if it is the last or the first character within the brackets: **[abc-]** or **[-abc]**.
“”	Quotation marks	Preserves trailing or leading spaces in the string. For example, **“ test”** preserves the leading space when it looks for a match.
^	Caret	Specifies the beginning of a line.

Table 25-1 regex Metacharacters (continued)

Character	Description	Notes
\	Escape character	When used with a metacharacter, matches a literal character. For example, \[matches the left square bracket.
char	Character	When character is not a metacharacter, matches the literal character.
\r	Carriage return	Matches a carriage return 0x0d.
\n	Newline	Matches a new line 0x0a.
\t	Tab	Matches a tab 0x09.
\f	Formfeed	Matches a form feed 0x0c.
\x*NN*	Escaped hexadecimal number	Matches an ASCII character using hexadecimal (exactly two digits).
NNN	Escaped octal number	Matches an ASCII character as octal (exactly three digits). For example, the character 040 represents a space.

Detailed Steps

Step 1 Choose **Configuration > Global Objects > Regular Expressions**.

Step 2 In the Regular Expressions area, click **Add**.

The Add Regular Expression dialog box appears.

Step 3 In the Name field, name the expression, up to 40 characters in length.

Step 4 (Optional) Click **Build** to use the Creating a Regular Expression Class Map dialog box. See Table 25-1 on page 25-11 for more information about metacharacters.

- Build Snippet—This area lets you build text snippets of regular text or lets you insert a metacharacter into the Regular Expression field.
- Starts at the beginning of the line (^)—Indicates that the snippet should start at the beginning of a line, using the caret (^) metacharacter. Be sure to insert any snippet with this option at the beginning of the regular expression.
- Specify Character String—Enter a text string manually.
  - Character String—Enter a text string.
  - Escape Special Characters—If you entered any metacharacters in your text string that you want to be used literally, check this box to add the backslash (\) escape character before them. for example, if you enter “example.com,” this option converts it to “example\.com”.
  - Ignore Case—If you want to match upper and lower case characters, this check box automatically adds text to match both upper and lower case. For example, entering “cats” is converted to “[cC][aA][tT][sS]”.
- Specify Character—Lets you specify a metacharacter to insert in the regular expression.
  - Negate the character—Specifies not to match the character you identify.
  - Any character (.)—Inserts the period (.) metacharacter to match any character. For example, **d.g** matches dog, dag, dtg, and any word that contains those characters, such as doggonnit.

  - Character set—Inserts a character set. Text can match any character in the set. Sets include:

    [0-9A-Za-z]

    [0-9]

    [A-Z]

    [a-z]

    [aeiou]

    [\n\f\r\t] (which matches a new line, form feed, carriage return, or a tab)

    For example, if you specify [0-9A-Za-z], then this snippet will match any character from A to Z (upper or lower case) or any digit 0 through 9.
  - Special character—Inserts a character that requires an escape, including \, ?, *, +, |, ., [, (, or ^. The escape character is the backslash (\), which is automatically entered when you choose this option.
  - Whitespace character—Whitespace characters include \n (new line), \f (form feed), \r (carriage return), or \t (tab).
  - Three digit octal number—Matches an ASCII character as octal (up to three digits). For example, the character \040 represents a space. The backslash (\) is entered automatically.
  - Two digit hexadecimal number—Matches an ASCII character using hexadecimal (exactly two digits). The backslash (\) is entered automatically.
  - Specified character—Enter any single character.

- Snippet Preview—*Display only.* Shows the snippet as it will be entered in the regular expression.
- Append Snippet—Adds the snippet to the end of the regular expression.
- Append Snippet as Alternate—Adds the snippet to the end of the regular expression separated by a pipe (|), which matches either expression it separates. For example, **dog|cat** matches dog or cat.
- Insert Snippet at Cursor—Inserts the snippet at the cursor.

Regular Expression—This area includes regular expression text that you can enter manually and build with snippets. You can then select text in the Regular Expression field and apply a quantifier to the selection.

- Selection Occurrences—Select text in the Regular Expression field, click one of the following options, and then click **Apply to Selection**. For example, if the regular expression is “test me,” and you select “me” and apply **One or more times**, then the regular expression changes to “test (me)+”.
  - Zero or one times (?)—A quantifier that indicates that there are 0 or 1 of the previous expression. For example, **lo?se** matches lse or lose.
  - One or more times (+)—A quantifier that indicates that there is at least 1 of the previous expression. For example, **lo+se** matches lose and loose, but not lse.
  - Any number of times (*)—A quantifier that indicates that there are 0, 1 or any number of the previous expression. For example, **lo*se** matches lse, lose, loose, etc.
  - At least—Repeat at least *x* times. For example, **ab(xy){2,}z** matches abxyxyz, abxyxyxyz, etc.
  - Exactly—Repeat exactly *x* times. For example, **ab(xy){3}z** matches abxyxyxyz.
  - Apply to Selection—Applies the quantifier to the selection.
- Test—Tests a regular expression against some sample text.

Step 5 If you do not use the Build tool, enter the regular expression manually in the Value field, up to 100 characters in length. Refer to the metacharacters in Table 25-1.

Step 6 To test the regular expression before adding it, click **Test**.

The Test Regular Expression dialog box appears.

- Regular Expression—Enter the regular expression you want to test. By default, the regular expression you entered in the Add/Edit Regular Expression or Build Regular Expression dialog box is input into this field. If you change the regular expression during your testing, and click **OK**, the changes are inherited by the Add/Edit Regular Expression or Build Regular Expression dialog boxes. Click **Cancel** to dismiss your changes.
- Test String—Enter a text string that you expect to match the regular expression.
- Test—Tests the Text String against the Regular Expression,
- Test Result—*Display only.* Shows if the test succeeded or failed.

Creating a Regular Expression Class Map

A regular expression class map identifies one or more regular expressions. You can use a regular expression class map to match the content of certain traffic; for example, you can match URL strings inside HTTP packets.

Prerequisites

Create one or more regular expressions according to the "Creating a Regular Expression" section on page 25-10.

Detailed Steps

Step 1 Choose **Configuration > Global Objects > Regular Expressions**.

Step 2 In the Regular Expression Classes area, click **Add**.

- Name—Enter a name for the class map, up to 40 characters in length. The name "class-default" is reserved. All types of class maps use the same name space, so you cannot reuse a name already used by another type of class map.
- Description—Enter a description, up to 200 characters in length.
- Available Regular Expressions—Lists the regular expressions that are not yet assigned to the class map.
  - Edit—Edits the selected regular expression.
  - New—Creates a new regular expression.
- Add—Adds the selected regular expression to the class map.
- Remove—Removes the selected regular expression from the class map.
- Configured Match Conditions—Shows the regular expressions in this class map, along with the match type.
  - Match Type—Shows the match type, which for regular expressions is always a positive match type (shown by the icon with the equal sign (=)) the criteria. (Inspection class maps allow you to create negative matches as well (shown by the icon with the red circle)). If more than one regular expression is in the class map, then each match type icon appears with "OR" next it, to indicate that this class map is a "match any" class map; traffic matches the class map if only one regular expression is matched.

– Regular Expression—Lists the regular expression names in this class map.

Configuring Time Ranges

Create a reusable component that defines starting and ending times that can be applied to various security features. Once you have defined a time range, you can select the time range and apply it to different options that require scheduling.

The time range feature lets you define a time range that you can attach to traffic rules, or an action. For example, you can attach an access list to a time range to restrict access to the ASA.

A time range consists of a start time, an end time, and optional recurring entries.

Guidelines

- Multiple periodic entries are allowed per time range. If a time range has both absolute and periodic values specified, then the periodic values are evaluated only after the absolute start time is reached, and they are not further evaluated after the absolute end time is reached.
- Creating a time range does not restrict access to the device. This procedure defines the time range only.

Detailed Steps

Step 1 Choose **Configuration > Global Objects > Time Ranges**.

Step 2 Click **Add**.

The Add Time Range window appears.

Step 3 In the Time Range Name field, enter a time range name, with no spaces.

Step 4 Choose the Start Time and the End Time by doing one of the following:

a. Allow the default settings, in which the Start Now and the Never End radio buttons are checked.

b. Apply a specific time range by clicking the **Start at** and **End at** radio buttons and selecting the specified start and stop times from the lists.

The time range is inclusive of the times that you enter.

Step 5 (Optional) To specify additional time constraints for the time range, such as specifying the days of the week or the recurring weekly interval in which the time range will be active, in the Recurring Time Ranges area, click **Add.**

The Add Recurring Time Range dialog box appears.

Step 6 Do one of the following:

- Click **Specify days of the week and times on which this recurring range will be active**, and choose the days and times from the lists, and click **OK**.
- Click **Specify a weekly interval when this recurring range will be active**, and choose the days and times from the lists, and click **OK**.

Step 7 Click **OK**, and then click **Apply**.

Monitoring Objects

To view which rules use a network object or group, in the Configuration > Firewall > Objects > Network Objects/Group pane, click the magnifying glass Find icon.

The Usages dialog box appears, listing all the rules currently using the network object or group. This dialog box also lists any network object groups that contain the object.

Feature History for Objects

Table 25-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 25-2 Feature History for Object Groups

Feature Name	Platform Releases	Feature Information
Object groups	7.0(1)	Object groups simplify access list creation and maintenance.
Objects	8.3(1)	Object support was introduced.
User Object Groups for Identity Firewall	8.4(2)	User object groups for identity firewall were introduced.
Mixed IPv4 and IPv6 network object groups	9.0(1)	Previously, network object groups could only contain all IPv4 addresses or all IPv6 addresses. Now network object groups can support a mix of both IPv4 and IPv6 addresses. **Note** You cannot use a mixed object group for NAT.
Security Group Object Groups for Cisco TrustSec	8.4(2)	Security group object groups for TrustSec were introduced.
Extended ACLand object enhancement to filter ICMP traffic by ICMP code	9.0(1)	ICMP traffic can now be permitted/denied based on ICMP code. We introduced or modified the following screens: Configuration > Firewall > Objects > Service Objects/Groups Configuration > Firewall > Access Rule

Using the ACL Manager

This chapter describes how to configure extended access lists (also known as access control lists), and it includes the following sections:

- Information About the ACL Manager, page 26-1
- Licensing Requirements for the ACL Manager, page 26-1
- Guidelines and Limitations, page 26-2
- Adding ACLs and ACEs, page 26-2
- Feature History for the ACL Manager, page 26-5

Information About the ACL Manager

Access control lists (ACLs) are used to control network access or to specify traffic for many features to act upon. An ACL is made up of one or more access control entries (ACEs) in which you can specify the line number to insert the ACE, the source and destination addresses, and, depending upon the ACE type, the protocol, the ports (for TCP or UDP), or the ICMP type.

The ACL Manager dialog box lets you define ACLs to control the access of a specific host or network to another host/network, including the protocol or port that can be used.

You can configure ACLs (access control lists) to apply to user sessions. These are filters that permit or deny user access to specific networks, subnets, hosts, and web servers.

- If you do not define any filters, all connections are permitted.
- The ASA supports only an inbound ACL on an interface.

At the end of each ACL, there is an implicit, unwritten rule that denies all traffic that is not permitted. If traffic is not explicitly permitted by an access control entry (ACE), the ASA denies it. ACEs are referred to as rules in this section.

For information about adding ACLs and ACEs, see the "Adding ACLs and ACEs" section on page 26-2.

For information about finding specific ACLs and ACEs in your configuration, see the "Using the Find Function in the ACL Manager Pane" section on page 4-15.

Licensing Requirements for the ACL Manager

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes only.

IPv6 Guidelines

IPv6 is supported.

Additional Guidelines and Limitations

The following guidelines and limitations apply to creating an extended access list:

- Enter the access list name in uppercase letters so that the name is easy to see in the configuration. You might want to name the access list for the interface (for example, INSIDE), or you can name it for the purpose for which it is created (for example, NO_NAT or VPN).
- You can specify the source and destination ports only for the TCP or UDP protocols. For a list of permitted keywords and well-known port assignments, see the "TCP and UDP Ports" section on page A-11. DNS, Discard, Echo, Ident, NTP, RPC, SUNRPC, and Talk each require one definition for TCP and one for UDP. TACACS+ requires one definition for port 49 on TCP.

Adding ACLs and ACEs

An access list (ACL) is made up of one or more access list entries (ACEs). To create an ACL, you start by creating an ACE and applying a list name. An ACL with one entry is still considered a list, although you can add multiple ACEs to the list.

To add an ACL and then add an ACE to that ACL, perform the following steps:

Step 1 Choose **Configuration > Firewall > Advanced > ACL Manager**.

Step 2 Select **Add > Add ACL**. Adds an ACL configurable for IPv4 or IPv6 traffic.

Step 3 In the ACL name field, add a descriptive name for the ACL, and click **OK**.

Your newly created ACL appears in the window.

Step 4 Select the newly created ACL, click **Add**, and from the drop-down list, choose **Add ACE**.

Step 5 In the Action field of the Add ACE window, click one of the following radio buttons to choose the action

- **Permit**—Permits access if the conditions are matched.

- **Deny**—Denies access if the conditions are matched.

Step 6 In the Source field, enter an IP address that specifies the network object group, interface IP, or any address from which traffic is permitted or denied.

IPv6 must be enabled on at least one interface before you can configure an ACE with an IPv6 address. For more information about enabling IPv6 on an interface, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 7 Select a destination to specify the IP addresses (host or network) that are permitted or denied to send traffic to the IP addresses listed in the Source section.

Step 8 Specify the service to which this ACE applies. You can type a known service into the window or click browse to select from a list of services.

Service groups let you identify multiple non-contiguous port numbers that you want to match.

For example, if you want to filter HTTP, FTP, and port numbers 5, 8, and 9, define a service group that includes all these ports.Without service groups, you would have to create a separate rule for each port

You can create service groups for TCP, UDP, TCP-UDP, ICMP, and other protocols. A service group with the TCP-UDP protocol contains services, ports, and ranges that might use either the TCP or UDP protocol.

- Protocol—Selects the protocol to which this rule applies. Possible values are ip, tcp, udp, icmp, and other. The remaining available fields in the Protocol and Service area depend upon the protocol you select. The next few bullets describe the consequences of each of these selections:
- Protocol: TCP and UDP—Selects the TCP/UDP protocol for the rule. The Source Port and Destination Port areas allow you to specify the ports that the ACL uses to match packets.
- Source Port/Destination Port—(*Available only for TCP and UDP protocols*) Specifies an operator and a port number, a range of ports, or a well-known service name from a list of services, such as HTTP or FTP. The operator list specifies how the ACL matches the port. Choose one of the following operators: = (equals the port number), not = (does not equal the port number), > (greater than the port number), < (less than the port number), range (equal to one of the port numbers in the range).
- Group—(*Available only for TCP and UDP protocols*) Selects a source port service group. The Browse (...) button opens the Browse Source Port or Browse Destination Port dialog box.
- Protocol: ICMP—Enables you to choose an ICMP type or ICMP group from a preconfigured list or browse (...) for an ICMP group. The Browse button opens the Browse ICMP dialog box.
- Protocol: IP—Specifies the IP protocol for the rule in the IP protocol box. No other fields are available when you make this selection.
- Protocol: Other—Enables you to choose a protocol from a drop-down list, choose a protocol group from a drop-down list, or browse for a protocol group. The Browse (...) button opens the Browse Other dialog box.

Step 9 (Optional) Add text that provides a brief description of this rule. A description line can be up to 100 characters long, yet you can break a description into multiple lines.

Note If you add remarks with non-English characters on one platform (such as Windows) then try to remove them from another platform (such as Linux), you might not be able to edit or delete them because the original characters might not be correctly recognized. This limitation is due to an underlying platform dependency that encodes different language characters in different ways.

Step 10 (Optional) Check the Enable Logging check box to enable or disable logging or specify the use of the default logging settings. If logging is enabled, the Syslog Level and Log Interval fields become available.

a. If logging is enables, choose a logging level to specify logging activity. The default is Informational. For information about logging levels, see the "Severity Levels" section on page 96-3.

b. Choose a logging interval to display the interval, in seconds, that is used to limit how many messages at this logging level can be sent.

Step 11 Set the source service (TCP, UDP, and TCP/UDP only).

Step 12 Set the logging interval to establish the number of seconds between log messages. The default is 300.

Step 13 Set the time range during which the rule is applied.

Step 14 Click **Apply** to save the ACL and ACE to the running configuration.

To see a condensed view of all ACLs in your configuration, click **Collapse All** below the ACL Manager window. To see a comprehensive view of all ACLs and ACEs in your configuration, click **Expand All**.

For information about finding specific ACLs and ACEs in your configuration, see the "Using the Find Function in the ACL Manager Pane" section on page 4-15.

Using Standard ACLs in the ACL Manager

Standard ACLs identify the destination IP addresses (not source addresses). Standard ACLs cannot be applied to interfaces to control traffic.

To add a standard ACL to your configuration, perform the following steps:

Step 1 Click **Add**, and from the drop-down list, choose **Add ACL**.

Step 2 In the Add ACL dialog box, add a name or number (without spaces) to identify the ACL.

Step 3 Click **OK**

The ACL name appears in the main pane.

Step 4 Select the newly created ACL, click **Add**, and from the drop-down list, choose **Add ACE**.

The Add ACE dialog box appears.

Step 5 (Optional) To specify the placement of the new ACE, select an existing ACE, and click Insert... to add the ACE before the selected ACE, or click Insert After... to add the ACE after the selected ACE.

Step 6 Click one of the following radio buttons to choose an action:

- **Permit**—Permits access if the conditions are matched.
- **Deny**—Denies access if the conditions are matched.

Step 7 In the Address field, enter the IP address of the destination to which you want to perform or deny access.

You can also browse for the address of a network object by clicking the ellipsis at the end of the Address field.

Step 8 (Optional) In the Description field, enter a description that makes an ACE easier to understand.

The description can contain multiple lines; however, each line can be no more than 100 characters in length.

Note If you add remarks with non-English characters on one platform (such as Windows) then try to remove them from another platform (such as Linux), you might not be able to edit or delete them because the original characters might not be correctly recognized. This limitation is due to an underlying platform dependency that encodes different language characters in different ways.

Step 9 Click **OK**.

The newly created ACE appears under the ACL.

Step 10 Click **Apply** to save the ACE to your configuration.

Feature History for the ACL Manager

Table 26-1 lists the release history for this feature.

Table 26-1 Feature History for Extended Access Lists

Feature Name	Releases	Feature Information
Extended access lists	7.0(1)	Access lists are used to control network access or to specify traffic for many features to act upon. An extended access control list is made up of one or more access control entries (ACEs) in which you can specify the line number to insert the ACE, the source and destination addresses, and, depending upon the ACE type, the protocol, the ports (for TCP or UDP), or the IPCMP type (for ICMP).

Adding a Standard Access Control List

This chapter describes how to configure a standard ACL and includes the following sections:

- Information About Standard ACLs, page 27-1
- Licensing Requirements for Standard ACLs, page 27-1
- Guidelines and Limitations, page 27-1
- Default Settings, page 27-2
- Adding Standard ACLs, page 27-3
- Feature History for Standard ACLs, page 27-4

Information About Standard ACLs

Standard access lists identify the destination IP addresses of OSPF routes and can be used in a route map for OSPF redistribution. Standard access lists cannot be applied to interfaces to control traffic.

Licensing Requirements for Standard ACLs

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

- Context Mode Guidelines, page 27-2
- Firewall Mode Guidelines, page 27-2
- IPv6 Guidelines, page 27-2
- Additional Guidelines and Limitations, page 27-2

Context Mode Guidelines

Supported in single context mode only.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines and Limitations

The following guidelines and limitations apply for standard ACLs:

- Standard ACLs identify the destination IP addresses (not source addresses) of OSPF routes and can be used in a route map for OSPF redistribution. Standard ACLs cannot be applied to interfaces to control traffic.
- When specifying a source, local, or destination address, use the following guidelines:
  - Use a 32-bit quantity in four-part, dotted-decimal format.
- If you add descriptive remarks to your ACL with non-English characters on one platform (such as Windows) then try to remove them from another platform (such as Linux), you might not be able to edit or delete them because the original characters might not be correctly recognized. This limitation is due to an underlying platform dependency that encodes different language characters in different ways.

Default Settings

Table 27-1 lists the default settings for standard ACL parameters.

Table 27-1 Default Standard Access List Parameters

Parameters	Default
deny	The ASA denies all packets on the originating interface unless you specifically permit access. Access list logging generates system log message 106023 for denied packets. Deny packets must be present to log denied packets.

Adding Standard ACLs

This section includes the following topics:

- Using Standard ACLs, page 27-3

Using Standard ACLs

Standard ACLs identify the destination IP addresses (not source addresses) of OSPF routes and can be used in a route map for OSPF redistribution. Standard ACLs cannot be applied to interfaces to control traffic.

This section includes the following topics:

- Adding a Standard ACL, page 27-3
- Adding an ACE to a Standard ACL, page 27-3
- Editing an ACE in a Standard ACL, page 27-4

Adding a Standard ACL

To add a standard ACL to your configuration, perform the following steps:

Step 1 Choose **Configuration > Firewall > Advanced > Standard ACL.**

Step 2 Click **Add**, and from the drop-down list, choose **Add ACL**.

Step 3 In the Add ACL dialog box, add a name or number (without spaces) to identify the ACL.

Step 4 Click **OK.**

The ACL name appears in the main pane.

You may add additional ACLs.

Step 5 Click **Apply** to save the ACLs to your configuration.

You can now add one or more ACEs to the newly created ACL.

To add an ACE, see the "Adding an ACE to a Standard ACL" section on page 27-3.

Adding an ACE to a Standard ACL

Before you can add an ACE to a configuration, you must first add an ACL. For information about adding a standard ACL, see the "Adding a Standard ACL" section on page 27-3. For information about editing ACEs, see the "Editing an ACE in a Standard ACL" section on page 27-4

To add an ACE to an ACL that exists in your configuration, perform the following steps:

Step 1 Choose **Configuration > Firewall > Advanced > Standard ACL.**

Step 2 In the main pane, select the ACL for which you want to add an ACE.

Step 3 Click **Add**, and choose **Add ACE** from the drop-down list.

The Add ACE dialog box appears.

Step 4 (Optional) To specify the placement of the new ACE, select an existing ACE, and click Insert... to add the ACE before the selected ACE, or click Insert After... to add the ACE after the selected ACE.

Step 5 Click one of the following radio buttons to choose an action:

- **Permit**—Permits access if the conditions are matched.
- **Deny**—Denies access if the conditions are matched.

Step 6 In the Address field, enter the IP address of the destination to which you want to perform or deny access.

You can also browse for the address of a network object by clicking the ellipsis at the end of the Address field.

Step 7 (Optional) In the Description field, enter a description that makes an ACE easier to understand.

The description can contain multiple lines; however, each line can be no more than 100 characters in length.

Step 8 Click **OK**.

The newly created ACE appears under the ACL.

Step 9 Click Apply to save the ACE to your configuration.

Editing an ACE in a Standard ACL

To edit an ACE in a standard ACL, perform the following steps:

Step 1 Choose **Configuration > Firewall > Advanced > Standard ACL.**

Step 2 In the main pane, select the existing ACE that you want to edit.

Step 3 Click **Edit.**

The Edit ACE dialog box appears.

Step 4 Enter the desired changes.

Step 5 Click **OK**.

Feature History for Standard ACLs

Table 27-2 lists the release history for this feature.

Table 27-2 Feature History for Standard Access Lists

Feature Name	Releases	Feature Information
Standard ACLs	7.0(1)	Standard ACLs identify the destination IP addresses of OSPF routes, which can be used in a route map for OSPF redistribution. The feature was introduced.

Adding a Webtype Access Control List

Webtype ACLs are added to a configuration that supports filtering for clientless SSL VPN. This chapter describes how to add an ACLto the configuration that supports filtering for WebVPN.

This chapter includes the following sections:

- Licensing Requirements for Webtype ACLs, page 28-1
- Guidelines and Limitations, page 28-1
- Default Settings, page 28-2
- Using Webtype ACLs, page 28-2
- Feature History for Webtype Access Lists, page 28-6
- Feature History for Webtype Access Lists, page 28-6

Licensing Requirements for Webtype ACLs

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature:

- Context Mode Guidelines, page 28-1
- Firewall Mode Guidelines, page 28-1
- Additional Guidelines and Limitations, page 28-2

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines and Limitations

The following guidelines and limitations apply to Webtype ACLs:

- Smart tunnel ACEs filter on a per-server basis only, so you cannot create smart tunnel ACEs to permit or deny access to directories or to permit or deny access to specific smart tunnel-enabled applications.
- If you add descriptive remarks about your ACL with non-English characters on one platform (such as Windows) then try to remove them from another platform (such as Linux), you might not be able to edit or delete them because the original characters might not be correctly recognized. This limitation is due to an underlying platform dependency that encodes different language characters in different ways.

Default Settings

Table 28-1 lists the default settings for Webtype access lists parameters.

Table 28-1 Default Webtype Access List Parameters

Parameters	Default
deny	The ASA denies all packets on the originating interface unless you specifically permit access.
log	Access list logging generates system log message 106023 for denied packets. Deny packets must be present to log denied packets.

Using Webtype ACLs

This section includes the following topics:

- Adding a Webtype ACL and ACE, page 28-3
- Editing Webtype ACLs and ACEs, page 28-4
- Deleting Webtype ACLs and ACEs, page 28-5

Task Flow for Configuring Webtype ACLs

Use the following guidelines to create and implement an ACL:

- Create an ACL by adding an ACE and applying an ACL name. See the "Using Webtype ACLs" section on page 28-2.
- Apply the ACL to an interface. See the "Configuring Access Rules" section on page 51-7 for more information.

Adding a Webtype ACL and ACE

You must first create the webtype ACL and then add an ACE to the ACL.

Note Smart tunnel ACEs filter on a per-server basis only, so you cannot create smart tunnel ACEs to permit or deny access to directories or to permit or deny access to specific smart tunnel-enabled applications.

To configure a webtype ACL, perform the following steps:

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Web ACLs**.

Step 2 Click **Add**, and choose one of the following ACL types to add:

- **Add ACL**
- **Add IPv6 ACL**

The Add ACL dialog box appears.

Step 3 Enter a name for the ACL (with no spaces), and click **OK**.

Step 4 To add an entry to the list that you just created, click **Add**, and choose **Add ACE** from the drop-down list.

Step 5 In the Action field, click the radio button next to the desired action:

- Permit—Permits access if the conditions are matched.
- Deny—Denies access if the conditions are matched.

Note The end of every ACL has an implicit deny rule.

Step 6 In the filter field, you can either filter on a URL or filter on an address and Service.

a. To filter on a URL, choose the URL prefix from the drop-down list, and enter the URL>

Wildcard characters can be used in the URL field:

- An asterisk * matches none or any number of characters.
- A question mark ? matches any one character exactly.
- Square brackets [] are range operators, matching any character in the range. For example, to match both http://www.cisco.com:80/ and http://www.cisco.com:81/, enter the following: **http://www.cisco.com:8[01]/**

b. To filter on an address and service, click the **Filter address and service** radio button, and enter the appropriate values.

Wildcard characters can be used in the with regular expression in the address field:

- An asterisk * matches none or any number of characters.
- A question mark ? matches any one character exactly.
- Square brackets [] are range operators, matching any character in the range. For example to permit a range of IP addresses from 10.2.2.20 through 10.2.2.31, enter the following: **10.2.2.[20-31]**

You can also browse for the address and service by clicking the browse buttons at the end of the fields.

Step 7 (Optional) Logging is enabled by default. You can disable logging by unchecking the check box, or you can change the logging level from the drop-down list. The default logging level is Informational.

For more information about logging options, see the Log Options section on page 21-29.

Step 8 (Optional) If you changed the logging level from the default setting, you can specify the logging interval by clicking **More Options** to expand the list.

Valid values are from 1 through 6000 seconds. The default is 300 seconds.

Step 9 (Optional) To add a time range to your access rule that specifies when traffic can be allowed or denied, click **More Options** to expand the list.

a. To the right of the Time Range drop-down list, click the browse button.

b. The Browse Time Range dialog box appears.

c. Click **Add**.

d. The Add Time Range dialog box appears.

e. In the Time Range Name field, enter a time range name, with no spaces.

f. Enter the Start Time and the End Time.

g. To specify additional time constraints for the time range, such as specifying the days of the week or the recurring weekly interval in which the time range will be active, click **Add**, and specify the desired values.

Step 10 Click **OK** to apply the optional time range specifications.

Step 11 Click **Apply** to save the configuration.

Note After you add ACLs, you can click the following radio buttons to filter which ACLs appear in the main pane: IPv4 andIPv6, IPv4 only, or IPv6 Only.

Editing Webtype ACLs and ACEs

To edit a webtype ACL or ACT, perform the following steps:

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Web ACLs**.

Step 2 Choose the ACL type to edit by clicking one of the following radio buttons:

- **IPv4 and IPv6**— Shows ACLs that have both IPv4 and IPv6 addresses only.
- **IPv4 Only**—Shows ACLs that have IPv4 type addresses only.
- **IPv6 Only**—Shows access rules that have IPv6 type addresses only.

The main Access Rule Pane displays the available interfaces for the chosen rule type.

Step 3 Select the ACE to edit, and make any changes to the values.

For more information about specific values, see the "Adding a Webtype ACL and ACE" section on page 28-3.

Step 4 Click **OK**.

Step 5 Click **Apply** to save the changes to your configuration.

Deleting Webtype ACLs and ACEs

To delete a webtype ACE, perform the following steps:

Step 1 Choose **Configuration > Remote Access VPN > Clientless SSL VPN Access > Advanced > Web ACLs**.

Step 2 Choose the ACL type to edit by clicking one of the following radio buttons:

- **IPv4 and IPv6**— Shows ACLs that have both IPv4 and IPv6 addresses only.
- **IPv4 Only**—Shows ACLs that have IPv4 type addresses only.
- **IPv6 Only**—Shows access rules that have IPv6 type addresses only.

The main Access Rule Pane displays the available interfaces for the chosen rule type.

Step 3 Select the ACE to delete.

If you select a specific ACE, only that ACE is deleted. If you select an ACL, that ACL and all of the ACEs under it are deleted.

Step 4 Click **Delete**.

The selected items are removed from the viewing pane.

Note If you deleted an item in error and want to restore it to your configuration, click **Reset** before you click Apply. The deleted item reappears in the viewing pane.

Step 5 Click **Apply** to save the change to the configuration.

Feature History for Webtype Access Lists

Table 28-2 lists the release history for this feature.

Table 28-2 Feature History for Webtype Access Lists

Feature Name	Releases	Feature Information
Webtype access lists	7.0(1)	Webtype ACLs are access lists that are added to a configuration that supports filtering for clientless SSL VPN. We introduced the feature.
Unified ACL for IPv4 and IPv6	9.0(1)	ACLs now support IPv4 and IPv6 addresses. You can even specify a mix of IPv4 and IPv6 addresses for the source and destination. The IPv6-specific ACLs are deprecated. Existing IPv6 ACLs are migrated to extended ACLs. See the release notes for more information about migration. We modified the following screens: Configuration > Firewall > Access Rules Configuration > Remote Access VPN > Network (Client) Access > Group Policies > General > More Options

PART 5

Configuring IP Routing

Routing Overview

This chapter describes underlying concepts of how routing behaves within the ASA, and the routing protocols that are supported.

This chapter includes the following sections:

- Information About Routing, page 30-1
- How Routing Behaves Within the ASA, page 30-4
- Supported Internet Protocols for Routing, page 30-5
- Information About the Routing Table, page 30-5
- Disabling Proxy ARPs, page 30-11

Information About Routing

Routing is the act of moving information across an internetwork from a source to a destination. Along the way, at least one intermediate node typically is encountered. Routing involves two basic activities: determining optimal routing paths and transporting information groups (typically called packets) through an internetwork. In the context of the routing process, the latter of these is referred to as packet switching. Although packet switching is relatively straightforward, path determination can be very complex.

This section includes the following topics:

- Switching, page 30-1
- Path Determination, page 30-2
- Supported Route Types, page 30-2

Switching

Switching algorithms is relatively simple; it is the same for most routing protocols. In most cases, a host determines that it must send a packet to another host. Having acquired a router address by some means, the source host sends a packet addressed specifically to a router physical (Media Access Control [MAC]-layer) address, this time with the protocol (network layer) address of the destination host.

As it examines the packet destination protocol address, the router determines that it either knows or does not know how to forward the packet to the next hop. If the router does not know how to forward the packet, it typically drops the packet. If the router knows how to forward the packet, however, it changes the destination physical address to that of the next hop and transmits the packet.

The next hop may be the ultimate destination host. If not, the next hop is usually another router, which executes the same switching decision process. As the packet moves through the internetwork, its physical address changes, but its protocol address remains constant.

Path Determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

Note Asymmetric routing is only supported for Active/Active failover in multiple context mode. For more information, see the "Configuring Active/Active Failover" section on page 13-8.

Supported Route Types

There are several route types that a router can use. The ASA uses the following route types:

- Static Versus Dynamic, page 30-3
- Single-Path Versus Multipath, page 30-3
- Flat Versus Hierarchical, page 30-3
- Link-State Versus Distance Vector, page 30-3

Static Versus Dynamic

Static routing algorithms are hardly algorithms at all, but are table mappings established by the network administrator before the beginning of routing. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a router to which all unroutable packets are sent), for example, can be designated to act as a repository for all unroutable packets, ensuring that all messages are at least handled in some way.

Single-Path Versus Multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

Flat Versus Hierarchical

Some routing algorithms operate in a flat space, while others use routing hierarchies. In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from nonbackbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more nonbackbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas. In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

Link-State Versus Distance Vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables. Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state

algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

How Routing Behaves Within the ASA

The ASA uses both routing table and XLATE tables for routing decisions. To handle destination IP translated traffic, that is, untranslated traffic, the ASA searches for existing XLATE, or static translation to select the egress interface.

This section includes the following topics:

- Egress Interface Selection Process, page 30-4
- Next Hop Selection Process, page 30-4

Egress Interface Selection Process

The selection process follows these steps:

1. If a destination IP translating XLATE already exists, the egress interface for the packet is determined from the XLATE table, but not from the routing table.
2. If a destination IP translating XLATE does not exist, but a matching static translation exists, then the egress interface is determined from the static route and an XLATE is created, and the routing table is not used.
3. If a destination IP translating XLATE does not exist and no matching static translation exists, the packet is not destination IP translated. The ASA processes this packet by looking up the route to select the egress interface, then source IP translation is performed (if necessary).

   For regular dynamic outbound NAT, initial outgoing packets are routed using the route table and then creating the XLATE. Incoming return packets are forwarded using existing XLATE only. For static NAT, destination translated incoming packets are always forwarded using existing XLATE or static translation rules.

Next Hop Selection Process

After selecting the egress interface using any method described previously, an additional route lookup is performed to find out suitable next hop(s) that belong to a previously selected egress interface. If there are no routes in the routing table that explicitly belong to a selected interface, the packet is dropped with a level 6 syslog message 110001 generated (no route to host), even if there is another route for a given destination network that belongs to a different egress interface. If the route that belongs to a selected egress interface is found, the packet is forwarded to the corresponding next hop.

Load sharing on the ASA is possible only for multiple next hops available using a single egress interface. Load sharing cannot share multiple egress interfaces.

If dynamic routing is in use on the ASA and the route table changes after XLATE creation (for example, route flap), then destination translated traffic is still forwarded using the old XLATE, not via the route table, until XLATE times out. It may be either forwarded to the wrong interface or dropped with a level 6 syslog message 110001 generated (no route to host), if the old route was removed from the old interface and attached to another one by the routing process.

The same problem may happen when there are no route flaps on the ASA itself, but some routing process is flapping around it, sending source-translated packets that belong to the same flow through the ASA using different interfaces. Destination-translated return packets may be forwarded back using the wrong egress interface.

This issue has a high probability in some security traffic configurations, where virtually any traffic may be either source-translated or destination-translated, depending on the direction of the initial packet in the flow. When this issue occurs after a route flap, it can be resolved manually by using the **clear xlate** command, or automatically resolved by an XLATE timeout. The XLATE timeout may be decreased if necessary. To ensure that this issue rarely occurs, make sure that there are no route flaps on the ASA and around it. That is, ensure that destination-translated packets that belong to the same flow are always forwarded the same way through the ASA.

Supported Internet Protocols for Routing

The ASA supports several Internet protocols for routing. Each protocol is briefly described in this section.

- Enhanced Interior Gateway Routing Protocol (EIGRP)

  EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperation with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

  For more information about configuring EIGRP, see the "Configuring EIGRP" section on page 36-4.

- Open Shortest Path First (OSPF)

  OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

  For more information about configuring OSPF, see the "Configuring OSPFv2" section on page 33-5.

- Routing Information Protocol (RIP)

  RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

  For more information about configuring RIP, see the "Configuring RIP" section on page 34-4.

Information About the Routing Table

This section includes the following topics:

- Displaying the Routing Table, page 30-6
- How the Routing Table Is Populated, page 30-6
- How Forwarding Decisions Are Made, page 30-8
- Dynamic Routing and Failover, page 30-8
- Dynamic Routing and Clustering, page 30-9

- Dynamic Routing in Multiple Context Mode, page 30-10

Displaying the Routing Table

To show all routes in ASDM that are in the routing table, choose **Monitoring > Routing > Routes**.

In this pane, each row represents one route.

How the Routing Table Is Populated

The ASA routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the RIP, EIGRP, and OSPF routing protocols. Because the ASA can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

  For example, if the RIP and OSPF processes discovered the following routes:

  - RIP: 192.168.32.0/24
  - OSPF: 192.168.32.0/19

  Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the ASA learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

  Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the ASA learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the ASA uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. Table 30-1 shows the default administrative distance values for the routing protocols supported by the ASA.

Table 30-1 Default Administrative Distance for Supported Routing Protocols

Route Source	Default Administrative Distance
Connected interface	0
Static route	1
EIGRP Summary Route	5
Internal EIGRP	90
OSPF	110
RIP	120
EIGRP external route	170
Unknown	255

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the ASA receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the ASA chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the ASA would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you use the **distance-ospf** command to change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the ASA on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The EIGRP, OSPF, and RIP routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the ASA routing table.

Backup Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the ASA. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

How Forwarding Decisions Are Made

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, and the entries all have the same network prefix length, the two entries with identical network prefixes and different interfaces cannot coexist in the routing table.
- If the destination matches more than one entry in the routing table, and the entries have different network prefix lengths, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface of an ASA with the following routes in the routing table:

```
hostname# show route
        ....
        R   192.168.32.0/24 [120/4] via 10.1.1.2
        O   192.168.32.0/19 [110/229840] via 10.1.1.3
        ....
```

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but the 192.168.32.0/24 has the longest prefix within the routing table (24 bits verses 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

Dynamic Routing and Failover

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update

messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a router to which all unroutable packets are sent), for example, can be designated to act as a repository for all unroutable packets, ensuring that all messages are at least handled in some way.

Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit, which means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active after the primary unit has been active for a period of time, routes become synchronized as a part of the failover bulk synchronization process, so the routing table on the active/standby failover pair should appear the same.

For more information about static routes and how to configure them, see the "Configuring Static and Default Routes" section on page 31-2.

Dynamic Routing and Clustering

Dynamic routing is fully integrated in a cluster, and routes are shared across units (up to eight units are allowed in a cluster). Routing table entries are also replicated across units in a cluster.

When one unit transitions from the slave to the master, the epoch number (32-bit sequence number) for the RIB table is incremented. After the transition, the new master unit initially has RIB table entries that are the mirror image of the previous master unit. In addition, the reconvergence timer starts on the new master unit. When the epoch number for the RIB table is incremented, all existing entries are considered stale. Forwarding of IP packets continues as normal. On the new master unit, dynamic routing protocols start to either update existing route entries or create new route entries with the new epoch number. These modified or new entries with the current epoch number indicate that they have been refreshed and are synchronized to all slave units. After the reconvergence timer has expired, old entries from the RIB table are removed. RIB table entries for OSPF routes, RIP routes, and EIGRP routes are synchronized to the slave units.

Bulk synchronization occurs only when a unit joins a cluster and is from the master unit to a joining unit.

For dynamic routing updates, when the master unit learns a new route through OSPF, RIP or EIGRP, the master unit sends those updates to all slave units through reliable message transmission. Slave units update their RIB tables after they receive a cluster route update message.

For the supported dynamic routing protocols (OSPF, RIP, and EIGRP), routing packets from layer 2 load balancing interfaces on the slave units are forwarded to the master unit. Only the master unit sees and processes dynamic routing protocol packets. When the slave unit requests a bulk synchronization, all routing entries learned through layer 2 load balancing interfaces are replicated.

When new routing entries are learned through layer 2 load balancing interfaces on the master unit, the new entries are broadcast to all slave units. When existing routing entries are modified because of a network topology change, the modified entries are also synchronized to all slave units. When existing routing entries are removed because of a network topology change, the removed entries are also synchronized to all slave units.

When a combination of layer 2 and layer 3 load balancing interfaces are deployed and configured for dynamic routing, the slave units only have partial topology and neighbor information (including details that were obtained through layer 3 load balancing interfaces) in the routing process because only RIB table entries are synchronized from the master unit for layer 2 load balancing interfaces. You must configure the network to have layer 2 and layer 3 belong to different routing processes and redistribute the load from each routing process.

Table 30-2 provides a summary of the supported configurations. Yes indicates that the combination of two processes (one process to layer 2 and one process to layer 3) work, No indicates that the combination of two processes does not work.

Table 30-2 Summary of Supported Configurations

Layer 2 or Layer 3	OSPF (Layer 3)	EIGRP (Layer 3)	RIP (Layer 3)
OSPF (layer 2)	Yes	Yes	Yes
EIGRP (layer 2)	Yes	No	Yes
RIP (layer 2)	Yes	Yes	No

All the units in a cluster must be in the same mode: either single or multiple context mode. In multiple context mode, the master-slave synchronization includes all the contexts and the RIB table entries of all the contexts in the synchronization message.

In clustering, if you have configured a layer 3 interface, you must also configure the router-id pool setting.

For more information about dynamic routing and clustering, see Chapter 10, "Configuring a Cluster of ASAs."

Dynamic Routing in Multiple Context Mode

In multiple context mode, each context maintains a separate routing table and routing protocol databases. This enables you to configure OSPFv2 and EIGRP independently in each context. You can configure EIGRP in some contexts and OSPFv2 in the same or different contexts. In mixed context mode, you can enable any of the dynamic routing protocols in contexts that are in routed mode. RIP and OSPFv3 are not supported in multiple context mode.

The following table lists the attributes for EIGRP, OSPFv2, route maps used for distributing routes into OSPFv2 and EIGRP processes, and prefix lists used in OSPFv2 to filter the routing updates entering or leaving an area when they are used in multiple context mode:

EIGRP	OSPFv2	Route Maps and Prefix Lists
One instance is supported per context.	Two instances are supported per context.	N/A
It is disabled in the system context.		N/A
Two contexts may use the same or different autonomous system numbers.	Two contexts may use the same or different area IDs.	N/A
Shared interfaces in two contexts may have multiple EIGRP instances running on them.	Shared interfaces in two contexts may have multiple OSPF instances running on them.	N/A
The interaction of EIGRP instances across shared interfaces is supported.	The interaction of OSPFv2 instances across shared interfaces is supported.	N/A

EIGRP (continued)	OSPFv2 (continued)	Route Maps and Prefix Lists (continued)
All CLIs that are available in single mode are also available in multiple context mode.		
Each CLI has an effect only in the context in which it is used.		

Route Resource Management

A resource class called *routes* has been introduced, which specifies the maximum number of routing table entries that can exist in a context. This resolves the problem of one context affecting the available routing table entries in another context and also allows you greater control over the maximum route entries per context.

Because there is no definitive system limit, you can only specify an absolute value for this resource limit; you may not use a percentage limit. Also, there are no minimum and maximum limits per context, so the default class does not change. If you add a new route for any of the static or dynamic routing protocols (connected, static, OSPF, EIGRP, and RIP) in a context and the resource limit for that context is exhausted, then the route addition fails and a syslog message is generated.

Disabling Proxy ARPs

When a host sends IP traffic to another device on the same Ethernet network, the host needs to know the MAC address of the device. ARP is a Layer 2 protocol that resolves an IP address to a MAC address. A host sends an ARP request asking "Who is this IP address?" The device owning the IP address replies, "I own that IP address; here is my MAC address."

Proxy ARP is used when a device responds to an ARP request with its own MAC address, even though the device does not own the IP address. The ASA uses proxy ARP when you configure NAT and specify a mapped address that is on the same network as the ASA interface. The only way traffic can reach the hosts is if the ASA uses proxy ARP to claim that the MAC address is assigned to destination mapped addresses.

Under rare circumstances, you might want to disable proxy ARP for NAT addresses.

If you have a VPN client address pool that overlaps with an existing network, the ASA by default sends proxy ARPs on all interfaces. If you have another interface that is on the same Layer 2 domain, it will see the ARP requests and will answer with the MAC address of its interface. The result of this is that the return traffic of the VPN clients towards the internal hosts will go to the wrong interface and will get dropped. In this case, you need to disable proxy ARPs for the interface on which you do not want proxy ARPs.

To disable proxy ARPs,perform the following steps:

Step 1 Choose **Configuration > Device Setup > Routing > Proxy ARPs**.

The Interface field lists the interface names. The Proxy ARP Enabled field shows whether or not proxy ARP is enabled (Yes) or disabled (No) for NAT global addresses.

Step 2 To enable proxy ARP for the selected interface, click **Enable**. By default, proxy ARP is enabled for all interfaces.

Step 3 To disable proxy ARP for the selected interface, click **Disable**.

Step 4 Click **Apply** to save your settings to the running configuration.

Configuring Static and Default Routes

This chapter describes how to configure static and default routes on the ASA and includes the following sections:

- Information About Static and Default Routes, page 31-1
- Licensing Requirements for Static and Default Routes, page 31-2
- Guidelines and Limitations, page 31-2
- Configuring Static and Default Routes, page 31-2
- Monitoring a Static or Default Route, page 31-8
- Configuration Examples for Static or Default Routes, page 31-8
- Feature History for Static and Default Routes, page 31-9

Information About Static and Default Routes

To route traffic to a nonconnected host or network, you must define a static route to the host or network or, at a minimum, a default route for any networks to which the ASA is not directly connected; for example, when there is a router between a network and the ASA.

Without a static or default route defined, traffic to nonconnected hosts or networks generates the following syslog message:

```
%ASA-6-110001: No route to dest_address from source_address
```

You might want to use static routes in single context mode in the following cases:

- Your networks use a different router discovery protocol from EIGRP, RIP, or OSPF.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.

The simplest option is to configure a default route to send all traffic to an upstream router, relying on the router to route the traffic for you. However, in some cases the default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the ASA.

In transparent firewall mode, for traffic that originates on the ASA and is destined for a nondirectly connected network, you need to configure either a default route or static routes so the ASA knows out of which interface to send traffic. Traffic that originates on the ASA might include communications to a

syslog server, Websense or N2H2 server, or AAA server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. Additionally, the ASA supports up to three equal cost routes on the same interface for load balancing.

Licensing Requirements for Static and Default Routes

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Failover Guidelines

Supports Stateful Failover of dynamic routing protocols.

Additional Guidelines

- IPv6 static routes are not supported in transparent mode in ASDM.
- In clustering, static route monitoring is only supported on the master unit. For information about clustering, see Chapter 10, “Configuring a Cluster of ASAs.”

Configuring Static and Default Routes

This section explains how to configure a static route and a static default route and includes the following topics:

- Configuring a Static Route, page 31-3
- Configuring a Default Static Route, page 31-6
- Configuring IPv6 Default and Static Routes, page 31-7

Configuring a Static Route

Static routing algorithms are basically table mappings established by the network administrator before the beginning of routing. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple. Because of this fact, static routing systems cannot react to network changes.

Static routes remain in the routing table even if the specified gateway becomes unavailable. If the specified gateway becomes unavailable, you need to remove the static route from the routing table manually. However, static routes are removed from the routing table if the specified interface goes down, and are reinstated when the interface comes back up.

Note If you create a static route with an administrative distance greater than the administrative distance of the routing protocol running on the ASA, then a route to the specified destination discovered by the routing protocol takes precedence over the static route. The static route is used only if the dynamically discovered route is removed from the routing table.

You can define up to three equal cost routes to the same destination per interface. Equal-cost multi-path (ECMP) is not supported across multiple interfaces. With ECMP, the traffic is not necessarily divided evenly between the routes; traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses.

To configure a static route, choose one of the following:

- Adding or Editing a Static Route, page 31-3
- Configuring Static Route Tracking, page 31-5
- Deleting Static Routes, page 31-6

Adding or Editing a Static Route

To add or edit a static route in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Static Routes**.

Step 2 Choose which route to filter by clicking one of the following radio buttons:

- **Both** (filters both IPv4 and IPv6)
- **IPv4 only**
- **IPv6 only**

By default, the Both radio button is selected, and both IPv4 and IPv6 addresses appear in the pane. To limit your viewed choices to routes configured with IPv4 addresses, click the **IPv4** radio button. To limit your viewed choices to routes configured with IPv6 addresses, click the **IPv6** radio button.

Step 3 Click **Add** or **Edit**.

The Add or Edit Static Route dialog box appears.

Step 4 From the Interface drop-down list, choose the internal or external network interface name enabled in the Interface field:

- **management** (internal interface)
- **outside** (external interface)

Step 5 In the IP Address field, type an internal or external network IP address for the destination network.

For IPv4 addresses, enter **0.0.0.0** to specify a default route. The 0.0.0.0 IP address can be abbreviated as 0. Optionally, click the ellipsis to browse for an address.

For IPv6 addresses, enter two colons (**::**) to specify a default route. Optionally, click the ellipsis to browse for an address.

Step 6 In the Gateway IP field, enter the IP address of the gateway router, which is the next hop address for this route.

To enter a default route, set the IP address and mask to **0.0.0.0**, or the shortened form of **0**.

Optionally, click the ellipsis to browse for an address.

Note If an IP address from one ASA interface is used as the gateway IP address, the ASA will ARP the designated IP address in the packet instead of ARPing the gateway IP address.

The addresses you specify for the static route are the addresses that are in the packet before entering the ASA and performing NAT.

Step 7 Choose the netmask from the drop-down list for the destination network. Depending upon which route you chose to filter (IPv4, IPv6, or both), do one of the following:

- For IPv4 static routes (or for both IPv4 and IPv6 static routes), enter the network mask address that applies to the IP address. Enter **0.0.0.0** to specify a default route. The **0.0.0.0** netmask can be abbreviated as **0**.
- For IPv6 static routes only, enter a prefix length.

Step 8 In the Metric field, type the metric, or administrative distance.

The metric or distance is the administrative distance for the route. The default is 1 if you do not specify a value. Administrative distance is a parameter used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols, but not directly connected routes.

The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static routes take precedence. Connected routes always take precedence over static or dynamically discovered routes.

Step 9 (Optional) In the Options area, choose one of the following options for a static route:

- **None** to have no options specified for the static route. This setting is the default.
- **Tunneled** to specify the route as the default tunnel gateway for VPN traffic. This setting is used for the default route only. You can configure only one tunneled route per device. The tunneled option is not supported in transparent mode.
- **Tracked** to specify that the route is tracked. The tracking object ID and the address of the tracking target also appear. The tracked option is supported in single, routed mode only. Specify the following settings for the tracked option:
  - In the Track ID field, enter a unique identifier for the route tracking process.
  - In the Track IP Address/DNS Name field, enter the IP address or hostname of the target being tracked. Typically, this would be the IP address of the next hop gateway for the route, but it could be any network object available from that interface.
  - In the SLA ID field, enter a unique identifier for the SLA monitoring process.

Note The Tracked option is not supported for IPv6.

Step 10 (Optional) Click **Monitoring Options**.

The Route Monitoring Options dialog box appears. From here, you change the following tracking object monitoring properties:

- Frequency, which allows you to modify how often, in seconds, the ASA should test for the presence of the tracking target. Valid values range from 1 to 604800 seconds. The default value is 60 seconds.
- Threshold, which allows you to enter the amount of time, in milliseconds, that indicates an over-threshold event. This value cannot be more than the timeout value.
- Timeout, which allows you to modify the amount of time, in milliseconds, that the route monitoring operation should wait for a response from the request packets. Valid values range from 0 to 604800000 milliseconds. The default value is 5000 milliseconds.
- Data Size, which allows you to modify the size of data payload to use in the echo request packets. The default value is 28. Valid values range from 0 to 16384.

Note This setting specifies the size of the payload only; it does not specify the size of the entire packet.

- ToS, which allows you to choose a value for the type of service byte in the IP header of the echo request. Valid values are from 0 to 255. The default value is 0.
- Number of Packets, which allows you to choose the number of echo requests to send for each test. Valid values range from 1 to 100. The default value is 1.

Step 11 Click **OK**.

Step 12 Click **Apply** to save the configuration.

The added or edited route information appears in the Static Routes pane. The monitoring process begins as soon as you save the newly configured route.

Configuring Static Route Tracking

To configure tracking for a static route, perform the following steps:

Note Static route tracking is available for IPv4 routes only.

Step 1 Choose a target of interest. Make sure that the target responds to echo requests.

Step 2 Open the Static Routes pane by choosing **Configuration > Device Setup > Routing > Static Routes**.

Step 3 Click **Add** to configure a static route that is to be used based on the availability of your selected target of interest. You must enter the Interface, IP Address, Mask, Gateway, and Metric settings for this route.

Step 4 Click the **Tracked** radio button in the Options area for this route.

Step 5 Configure the tracking properties. You must enter a unique Track ID, a unique SLA ID, and the IP address of your target of interest.

Step 6 (Optional) To configure the monitoring properties, click **Monitoring Options** in the Add Static Route dialog box.

Step 7 Click **OK** to save your changes.

The monitoring process begins as soon as you save the tracked route.

Step 8 Create a secondary route by repeating Steps 1 through 7.

The secondary route is a static route to the same destination as the tracked route, but through a different interface or gateway. You must assign this route a higher administrative distance (metric) than your tracked route.

Step 9 Click **OK** to save your changes.

Deleting Static Routes

To delete a static route, perform the following steps:

Step 1 Choose **Configuration > Device Setup > Routing > Static Routes**.

Step 2 On the Static Routes pane, choose which route to delete.

By default, the Both radio button is checked, and both IPv4 and IPv6 addresses appear in the pane.

- To limit your viewed choices to routes configured with IPv4 addresses, click the **IPv4** radio button.
- To limit your viewed choices to routes configured with IPv6 addresses, click the **IPv6** radio button.

Step 3 Click **Delete**.

The deleted route is removed from list of routes on in the main Static Routes pane.

Step 4 Click **Apply** to save the changes to your configuration.

Configuring a Default Static Route

A default route identifies the gateway IP address to which the ASA sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 as the destination IP address. Routes that identify a specific destination take precedence over the default route.

Note In Versions 7.0(1) and later, if you have two default routes configured on different interfaces that have different metrics, the connection to the ASA that is made from the higher metric interface fails, but connections to the ASA from the lower metric interface succeed as expected.

You can define up to three equal cost default route entries per device. Defining more than one equal cost default route entry causes the traffic sent to the default route to be distributed among the specified gateways. When defining more than one default route, you must specify the same interface for each entry.

If you attempt to define more than three equal cost default routes or a default route with a different interface than a previously defined default route, you receive the following message:

```
"ERROR: Cannot add route entry, possible conflict with existing routes."
```

You can define a separate default route for tunneled traffic along with the standard default route. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the ASA that cannot be routed using learned or static routes is sent to this route. For traffic emerging from a tunnel, this route overrides any other configured or learned default routes.

Limitations on Configuring a Default Static Route

The following restrictions apply to default routes with the tunneled option:

- Do not enable unicast RPF (**ip verify reverse-path** command) on the egress interface of a tunneled route, because this setting causes the session to fail.
- Do not enable TCP intercept on the egress interface of the tunneled route, because this setting causes the session to fail.
- Do not use the VoIP inspection engines (CTIQBE, H.323, GTP, MGCP, RTSP, SIP, SKINNY), the DNS inspect engine, or the DCE RPC inspection engine with tunneled routes, because these inspection engines ignore the tunneled route.
- You cannot define more than one default route with the tunneled option.
- ECMP for tunneled traffic is not supported.

To add or edit a tunneled default static route in ASDM, perform the following steps:

Step 1 On the main ASDM window, choose **Configuration > Device Setup > Routing > Static Routes**.

Step 2 Click **Add** or **Edit**.

Step 3 In the Options area, choose **Tunneled**.

Step 4 Click **OK**.

Configuring IPv6 Default and Static Routes

The ASA automatically routes IPv6 traffic between directly connected hosts if the interfaces to which the hosts are attached are enabled for IPv6 and the IPv6 ACLs allow the traffic.

To add or edit a default static route in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Static Routes**.

Step 2 Click the **IPv6 only** radio button.

Step 3 Click **Add** or **Edit**.

Step 4 Click **OK**.

Monitoring a Static or Default Route

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the ASA goes down.

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

The ASA implements this feature by associating a static route with a monitoring target that you define, and monitors the target using ICMP echo requests. If an echo reply is not received within a specified time period, the object is considered down and the associated route is removed from the routing table. A previously configured backup route is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. The target can be any network object that you choose, but you should consider using the following:

- The ISP gateway (for dual ISP support) address
- The next hop gateway address (if you are concerned about the availability of the gateway)
- A server on the target network, such as a AAA server, that the ASA needs to communicate with
- A persistent network object on the destination network

Note A desktop or notebook computer that may be shut down at night is not a good choice.

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

To monitor the state of a route in ASDM, in the main ASDM window, perform the following steps:

Step 1 Choose **Monitoring > Routing > Routes**.

In the Routes pane, each row represents one route. You can filter by IPv4 connections, IPv6 connections, or both. The routing information includes the protocol, the route type, the destination IP address, the netmask or prefix length, the gateway IP address, the interface through which the route is connected, and the administrative distance.

Step 2 To update the current list, click **Refresh**.

Configuration Examples for Static or Default Routes

The following example shows how to create a static route that sends all traffic destined for 10.1.1.0/24 to the router 10.1.2.45, which is connected to the inside interface, defines three equal cost static routes that direct traffic to three different gateways on the outside interface, and adds a default route for tunneled traffic. The ASA then distributes the traffic among the specified gateways:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Static Routes**.

Step 2 Choose **Management** from the Interfaces drop-down list.

Step 3 Enter **10.1.1.0** in the IP Address field.

Step 4 Choose **255.255.255.0** from the Mask drop-down list.

Step 5 Enter **10.1.2.45 1** in the Gateway IP field.

A static route is created that sends all traffic destined for 10.1.1.0/24 to the router 10.1.2.45, which is connected to the inside interface.

Step 6 Click **OK**.

Step 7 Choose **Configuration > Device Setup > Routing > Static Routes**.

Step 8 Click **Add**.

Step 9 Enter the IP Address in the IP Address field for the destination network.

In this case, the route IP addresses are: 192.168.2.1, 192.168.2.2, 192.168.2.3, and 192.168.2.4. When adding 192.168.2.4, click the **Tunneled** radio button in the Options area.

Step 10 Enter the Gateway IP Address in the Gateway IP Address field for the address of the next hop router.

The addresses you specify for the static route are the addresses that are in the packet before entering the ASA and performing NAT.

Step 11 Choose the netmask for the destination network from the NetMask drop-down list.

Step 12 Click **OK**.

Feature History for Static and Default Routes

Table 31-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 31-1 Feature History for Static and Default Routes

Feature Name	Platform Releases	Feature Information
Routing	7.0(1)	Static and default routing were introduced. We introduced the following screen: Configuration > Device Setup > Routing.
Clustering	9.0(1)	Supports static route monitoring on the master unit only.

Defining Route Maps

This chapter describes route maps and includes the following sections:

- Information About Route Maps, page 32-1
- Licensing Requirements for Route Maps, page 32-3
- Guidelines and Limitations, page 32-3
- Defining a Route Map, page 32-4
- Customizing a Route Map, page 32-5
- Configuration Example for Route Maps, page 32-8
- Feature History for Route Maps, page 32-8

Information About Route Maps

Route maps are used when redistributing routes into an OSPF, RIP, or EIGRP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, each has a permit or deny result. Evaluation of ACL or route maps consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms—Criteria matches and match interpretation are dictated by the way that they are applied. The same route map applied to different tasks might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps frequently use ACLs as matching criteria.
- The main result from the evaluation of an access list is a yes or no answer—An ACL either permits or denies input data. Applied to redistribution, an ACL determines if a particular route can (route matches ACLs permit statement) or can not (matches deny statement) be redistributed. Typical route maps not only permit (some) redistributed routes but also modify information associated with the route, when it is redistributed into another protocol.
- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.

- Each ACL ends with an implicit deny statement, by design convention; there is no similar convention for route maps. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Fortunately, route maps that are applied to redistribution behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained deny statement at the end.

The dynamic protocol **redistribute** command allows you to apply a route map. In ASDM, this capability for redistribution can be found when you add or edit a new route map (see the "Defining a Route Map" section on page 32-4). Route maps are preferred if you intend to either modify route information during redistribution or if you need more powerful matching capability than an ACL can provide. If you simply need to selectively permit some routes based on their prefix or mask, we recommends that you use a route map to map to an ACL (or equivalent prefix list) directly in the **redistribute** command. If you use a route map to selectively permit some routes based on their prefix or mask, you typically use more configuration commands to achieve the same goal.

Note You must use a standard ACL as the match criterion for your route map. Using an extended ACL will not work, and your routes will never be redistributed. We recommend that you number clauses in intervals of 10, to reserve numbering space in case you need to insert clauses in the future.

This section includes the following topics:

- Permit and Deny Clauses, page 32-2
- Match and Set Clause Values, page 32-2

Permit and Deny Clauses

Route maps can have permit and deny clauses. In the **route-map ospf-to-eigrp** command, there is one deny clause (with sequence number 10) and two permit clauses. The deny clause rejects route matches from redistribution. Therefore, the following rules apply:

- If you use an ACL in a route map using a permit clause, routes that are permitted by the ACL are redistributed.
- If you use an ACL in a route map deny clause, routes that are permitted by the ACL are not redistributed.
- If you use an ACL in a route map permit or deny clause, and the ACL denies a route, then the route map clause match is not found and the next route-map clause is evaluated.

Match and Set Clause Values

Each route map clause has two types of values:

- A match value **s**elects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeed, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the Set Value tab in ASDM or from the **set** commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found whose **match** command(s), or Match Clause as set from the Match Clause tab in ASDM, match the route or until the end of the route map is reached.

A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several **match** commands or Match Clause values in ASDM are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a **match** command or Match Clause value in ASDM refers to several objects in one command, either of them should match (the logical OR algorithm is applied). For example, in the **match ip address 101 121** command, a route is permitted if access list 101 or access list 121 permits it.
- If a **match** command or Match Clause value in ASDM is not present, all routes match the clause. In the previous example, all routes that reach clause 30 match; therefore, the end of the route map is never reached.
- If a **set** command, or Set Value in ASDM, is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

Note Do not configure a **set** command in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

A route map clause without a **match** or **set** command, or Match or Set Value as set on the Match or Set Value tab in ASDM, performs an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allows a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

Licensing Requirements for Route Maps

The following table shows the licensing requirements for route maps:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single context mode and multiple context mode.

Firewall Mode Guidelines

Supported only in routed firewall mode. Transparent firewall mode is not supported.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

Route maps do not support access lists that include a user, user group, or fully qualified domain name objects.

Defining a Route Map

You must define a route map when specifying which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Adding or Editing a Route Map

In ASDM, you can define a route map by adding, editing, or deleting a route map name, sequence number, or redistribution.

To add or edit a route map, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Route Maps**.

Step 2 Click **Add**.

The Add Route Map or Edit Route Map dialog box appears.

Step 3 Enter the route map name and sequence number. The route map name is the name that you assign to a particular route. The sequence number is the order in which you add or delete the route map entries into the ASA.

Note If you are editing an existing route map, the fields for Route Map name and sequence number are already filled in.

Step 4 To reject route matches from redistribution, click **Deny**. If you use an ACL in a route map Deny clause, routes that are permitted by the ACL are not redistributed. To allow route matches for redistribution. click **Permit**. If you use an ACL in a route map Permit clause, routes that are permitted by the ACL are redistributed.

In addition, if you use an ACL in a route map Permit or Deny clause, and the ACL denies a route, then the route map clause match is not found and the next route map clause is evaluated.

Step 5 Click the **Match Clause** tab to choose routes to which this clause should be applied, and set the following parameters:

- Check the **Match first hop interface of route** check box to enable or disable matching the first hop interface of a route or to match any routes with the specified next hop interface. If you specify more than one interface, then the route can match either interface.
  - Enter the interface name in the Interface field, or click the ellipses to display the Browse Interface dialog box.
  - Choose the interface type (**inside** or **outside**), click **Selected Interface**, then click **OK**.
  - Check the **Match IP Address** check box to enable or disable the Match address of a route or match packet.
  - Check the **Match Next Hop** check box to enable or disable the Match next hop address of a route.

  - Check the **Match Route Source** check box to enable or disable the Match advertising source address of the route.
  - Choose Access List to Prefix List from the drop-down list to match the IP address.
  - According to the previous selection, click the ellipses to display the Browse Access List or Browse Prefix List dialog box.
  - Choose the ACL or prefix list that you want.
- Check the **Match metric of route** check box to enable or disable matching the metric of a route.
  - In the Metric Value field, type the metric values. You can enter multiple values, separated by commas. This setting allows you to match any routes that have a specified metric. The metric value can range from 0 to 4294967295.
- Check the **Match Route Type** check box to enable or disable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. When enabled, you can choose more than one route type from the list.

Step 6 Click the **Set Clause** tab to modify the following information, which will be redistributed to the target protocol:

- Check the **Set Metric Clause** check box to enable or disable the metric value for the destination routing protocol, and type the value in the Value field.
- Check the **Set Metric Type** check box to enable or disable the type of metric for the destination routing protocol, and choose the metric type from the drop-down list.

Customizing a Route Map

This section describes how to customize the route map and includes the following topics:

- Defining a Route to Match a Specific Destination Address, page 32-5
- Configuring Prefix Lists, page 32-6
- Configuring Prefix Rules, page 32-7
- Configuring the Metric Values for a Route Action, page 32-7

Defining a Route to Match a Specific Destination Address

To define a route to match a specified destination address, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Route Maps**.

Step 2 Click **Add**.

The Add Route Map dialog box appears. From this dialog box you can assign or choose the route map name, the sequence number and its redistribution access (that is, permit or deny). Route map entries are read in order. You can identify the order using the sequence number, or the ASA uses the order in which you add the entries.

Step 3 Click the **Match Clause** tab to choose routes to which this clause should be applied, and set the following parameters:

- Check the **Match first hop interface of route** check box to enable or disable matching the first hop interface of a route or to match any routes with the specified next hop interface. If you specify more than one interface, then the route can match either interface.
  - Enter the interface name in the Interface field, or click the ellipses to display the Browse Interface dialog box.
  - Choose the interface type (**inside** or **outside**), click **Selected Interface**, then click **OK**.
  - Check the **Match IP Address** check box to enable or disable the Match address of a route or match packet.
  - Check the **Match Next Hop** check box to enable or disable the Match next hop address of a route.
  - Check the **Match Route Source** check box to enable or disable the Match advertising source address of the route.
  - Choose Access List to Prefix List from the drop-down list to match the IP address.
  - According to the previous selection, click the ellipses to display the Browse Access List or Browse Prefix List dialog box.
  - Choose the ACL or prefix list that you want.
- Check the **Match metric of route** check box to enable or disable matching the metric of a route.
  - In the Metric Value field, type the metric values. You can enter multiple values, separated by commas. This setting allows you to match any routes that have a specified metric. The metric value can range from 0 to 4294967295.
- Check the **Match Route Type** check box to enable or disable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. When enabled, you can choose more than one route type from the list.

Configuring Prefix Lists

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

To add prefix lists, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Prefix Rules**.

Step 2 From the Add drop-down list, choose **Add Prefix List**.

The Add Prefix List dialog box appears.

Step 3 Enter the prefix name and description, then click **OK**.

Configuring Prefix Rules

Note You must configure a prefix list before you may configure a prefix rule.

To configure prefix rules, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Prefix Rules**.

Step 2 Click **Add**.

The Add Prefix Rule dialog box appears. From this dialog box, you can add a sequence number, specify a prefix for the network, its redistribution access (that is, permit or deny), the minimum and maximum prefix length.

Step 3 Enter an optional sequence number or accept the default value.

Step 4 Specify the prefix number in the format of IP address/mask length.

Step 5 Click the **Permit** or **Deny** radio button to indicate the redistribution access.

Step 6 Enter the optional minimum and maximum prefix lengths.

Step 7 Click **OK** when you are done.

The new or revised prefix rule appears in the list.

Step 8 Check the **Enable Prefix list sequence numbering** check box if you want to use automatically generated sequence numbers.

Step 9 Click **Apply** to save your changes.

Configuring the Metric Values for a Route Action

To configure the metric value for a route action, perform the following steps:

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Route Maps**.

Step 2 Click **Add**.

The Add Route Map or Edit Route Map dialog box appears. From this dialog box, you can assign or select the route map name, the sequence number and its redistribution access (that is, permit or deny). Route map entries are read in order. You can identify the order using the sequence number, or the ASA uses the order in which you add route map entries.

Step 3 Click the **Set Clause** tab to modify the following information, which will be redistributed to the target protocol:

- Check the **Set Metric Clause** check box to enable or disable the metric value for the destination routing protocol, and enter the value in the Value field.
- Check the **Set Metric Type** check box to enable or disable the type of metric for the destination routing protocol, and choose the metric type from the drop-down list.

Configuration Example for Route Maps

The following example shows how to redistribute routes with a hop count equal to 1 into OSPF.

Step 1 In ASDM, choose **Configuration > Device Setup > Routing > Route Maps**.

Step 2 Click **Add**.

Step 3 Enter **1-to-2** in the Route Map Name field.

Step 4 Enter the routing sequence number in the Sequence Number field.

Step 5 Click the **Permit** radio button.

By default this tab is on top.

Step 6 Click the **Match Clause** tab.

Step 7 Check the **Match Metric of Route** check box and type **1** for the metric value.

Step 8 Click the **Set Clause** tab.

Step 9 Check the **Set Metric Value** check box, and type **5** for the metric value.

Step 10 Check the **Set Metric-Type** check box, and choose **Type-1**.

Feature History for Route Maps

Table 26-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 32-1 Feature History for Route Maps

Feature Name	Platform Releases	Feature Information
Route maps	7.0(1)	We introduced this feature. We introduced the following screen: Configuration > Device Setup > Routing > Route Maps.
Enhanced support for static and dynamic route maps	8.0(2)	Enhanced support for dynamic and static route maps was added.
Dynamic Routing in Multiple Context Mode	9.0(1)	Route maps are supported in multiple context mode.

Configuring OSPF

This chapter describes how to configure the ASA to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

The chapter includes the following sections:

- Information About OSPF, page 33-1
- Licensing Requirements for OSPF, page 33-3
- Guidelines and Limitations, page 33-3
- Configuring OSPFv2, page 33-5
- Customizing OSPFv2, page 33-6
- Configuring OSPFv3, page 33-21
- Removing the OSPF Configuration, page 33-32
- Configuration Example for OSPFv2, page 33-32
- Configuration Example for OSPFv3, page 33-34
- Monitoring OSPF, page 33-35
- Additional References, page 33-36
- Feature History for OSPF, page 33-37

Information About OSPF

OSPF is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements rather than routing table updates. Because only LSAs are exchanged instead of the entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include the following:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, as stale information is timed out.

- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The ASA calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The ASA can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The ASA supports the following OSPF features:

- Intra-area, interarea, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the ASA as a designated router or a designated backup router. The ASA also can be set up as an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such as RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting as an ABR. Type 3 LSAs (interarea routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

Note Only Type 3 LSAs can be filtered. If you configure the ASA as an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either as default or Type 5 AS external LSAs. However, you need to configure static routes for the private networks protected by the ASA. Also, you should not mix public and private networks on the same ASA interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the ASA at the same time.

Implementation Differences Between OSPFv2 and OSPFv3

OSPFv3 is not backward compatible with OSPFv2. To use OSPF to route both IPv4 and IPv6 traffic, you must run both OSPFv2 and OSPFv3 at the same time. They coexist with each other, but do not interact with each other.

The additional features that OSPFv3 provides include the following:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.
- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

Using Clustering

For more information about dynamic routing and clustering, see the "Dynamic Routing and Clustering" section on page 30-9.

For more information about using clustering, see Chapter 10, "Configuring a Cluster of ASAs."

Licensing Requirements for OSPF

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

OSPFv2 supports single and multiple context mode.

OSPFv3 supports single mode only.

Firewall Mode Guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

Failover Guidelines

OSPFv3 supports Stateful Failover.

IPv6 Guidelines

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The ASA installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.
- OSPFv3 packets can be filtered out using IPv6 ACLs in the **capture** command.

Clustering Guidelines

- OSPFv2 and OSPFv3 support clustering.
- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In the spanned interface mode, dynamic routing is not supported on management-only interfaces.
- In individual interface mode, make sure that you establish the master and slave units as either OSPFv2 or OSPFv3 neighbors.
- When you configure both OSPFv2 and EIGRP, you can use either spanned interface mode or individual interface mode; you cannot use the two modes at the same time.
- In individual interface mode, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the master unit. Configuring static neighbors is supported only on point-to point-links; therefore, only one neighbor statement is allowed on an interface.
- The router ID is optional in the OSPFv2, OSPFv3, and EIGRP router configuration mode. If you do not explicitly set a router ID, then a router ID is automatically generated and set to the highest IPv4 address on any data interface in each of the cluster units.
- If the cluster interface mode has not been configured, then only a single, dotted-decimal IPv4 address is allowed as the router ID, and the **cluster pool** option is disabled.
- If the cluster interface mode is set to a spanned configuration, then only a single, dotted-decimal IPv4 address is allowed as the router ID, and the **cluster pool** option is disabled.
- If the cluster interface mode is set to an individual configuration, then the **cluster pool** option is mandatory, and a single, dotted-decimal IPv4 address is not allowed as the router ID.
- When the cluster interface mode is changed from a spanned to an individual configuration and vice versa without specifying the **check-detail** or **nocheck** options, then the entire configuration including the router ID is removed.
- If any of the dynamic routing protocol router ID configurations are incompatible with the new interface mode, then an error message appears on the console and the interface mode CLI fails. The error message has one line per dynamic routing protocol (OSPFv2, OSPFv3, and EIGRP) and lists the names of each context in which the incompatible configuration occurs.
- If the **nocheck** option is specified for the **cluster interface mode** command, then the interface mode is allowed to change although all the router ID configurations may not be compatible with the new mode.
- When the cluster is enabled, the router ID compatibility checks are repeated. If any incompatibility is detected, then the **cluster enable** command fails. The administrator needs to correct the incompatible router ID configuration before the cluster can be enabled.

- When a unit enters a cluster as a slave, then we recommend that you specify the **nocheck** option for the **cluster interface mode** command to avoid any router ID compatibility check failures. The slave unit still inherits the router configuration from the master unit.
- When a mastership role change occurs in the cluster, the following behavior occurs:
  - In spanned interface mode, the router process is active only on the master unit and is in a suspended state on the slave units. Each cluster unit has the same router ID because the configuration has been synchronized from the master unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change.
  - In individual interface mode, the router process is active on all the individual cluster units. Each cluster unit chooses its own distinct router ID from the configured cluster pool. A mastership role change in the cluster does not change the routing topology in any way.

Additional Guidelines

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.

Configuring OSPFv2

This section describes how to enable an OSPFv2 process on the ASA.

After you enable OSPFv2, you need to define a route map. For more information, see the "Defining a Route Map" section on page 32-4. Then you generate a default route. For more information, see the "Configuring Static and Default Routes" section on page 31-2.

After you have defined a route map for the OSPFv2 process, you can customize it for your particular needs, To learn how to customize the OSPFv2 process on the ASA, see the "Customizing OSPFv2" section on page 33-6.

To enable OSPFv2, you need to create an OSPFv2 routing process, specify the range of IP addresses associated with the routing process, then assign area IDs associated with that range of IP addresses.

You can enable up to two OSPFv2 process instances. Each OSPFv2 process has its own associated areas and networks.

To enable OSPFv2, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

In the OSPF Setup pane, you can enable OSPF processes, configure OSPF areas and networks, and define OSPF route summarization.

Step 2 The three tabs in ASDM used to enable OSPF are as follows:

- The Process Instances tab allows you to enable up to two OSPF process instances for each context. Single context mode and multiple context mode are both supported. After you check the **Enable Each OSPF Process** check box, you can enter a unique identifier numeric identifier for that OSPF process. This process ID is used internally and does not need to match the OSPF process ID on any other OSPF devices; valid values range from 1 to 65535. Each OSPF process has its own associated areas and networks.

If you click **Advanced**, the Edit OSPF Process Advanced Properties dialog box appears. From here, you can configure the Router ID, cluster IP address pools in Layer 2 or Layer 3 clustering, Adjacency Changes, Administrative Route Distances, Timers, and Default Information Originate settings for each OSPF process.

- The Area/Networks tab allows you to display the areas and the networks that they include for each OSPF process on the ASA. From this tab you can display the area ID, the area type, and the type of authentication set for the area. To add or edit the OSPF area or network, see the "Configuring OSPFv2 Area Parameters" section on page 33-13 for more information.
- The Route Summarization tab allows you to configure an ABR. In OSPF, an ABR will advertise networks in one area into another area. If the network numbers in an area are assigned in a way so that they are contiguous, you can configure the ABR to advertise a summary route that includes all the individual networks within the area that fall into the specified range. See the "Configuring Route Summarization Between OSPFv2 Areas" section on page 33-10 for more information.

Customizing OSPFv2

This section explains how to customize the OSPFv2 processes and includes the following topics:

- Redistributing Routes Into OSPFv2, page 33-6
- Configuring Route Summarization When Redistributing Routes Into OSPFv2, page 33-8
- Configuring Route Summarization Between OSPFv2 Areas, page 33-10
- Configuring OSPFv2 Interface Parameters, page 33-11
- Configuring OSPFv2 Area Parameters, page 33-13
- Configuring an OSPFv2 NSSA, page 33-14
- Configuring an IP Address Pool for Clustering (OSPFv2 and OSPFv3), page 33-15
- Defining Static OSPFv2 Neighbors, page 33-17
- Configuring Route Calculation Timers, page 33-18
- Logging Neighbors Going Up or Down, page 33-18
- Configuring Filtering in OSPF, page 33-19
- Configuring a Virtual Link in OSPF, page 33-20

Redistributing Routes Into OSPFv2

The ASA can control the redistribution of routes between OSPFv2 routing processes.

Note If you want to redistribute a route by defining which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process, you must first generate a default route. See the "Configuring Static and Default Routes" section on page 31-2, and then define a route map according to the "Defining a Route Map" section on page 32-4.

To redistribute static, connected, RIP, or OSPFv2 routes into an OSPFv2 process, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Redistribution**.

The Redistribution pane displays the rules for redistributing routes from one routing process into an OSPF routing process. You can redistribute routes discovered by RIP and OSPF into the EIGRP routing process. You can also redistribute static and connected routes into the EIGRP routing process. You do not need to redistribute static or connected routes if they fall within the range of a network that has been configured through the Setup > Networks tab.

Step 2 Click **Add** or **Edit**.

Alternatively, double-clicking a table entry in the Redistribution pane (if any) opens the Add/Edit OSPF Redistribution Entry dialog box for the selected entry.

Note All steps that follow are optional.

The Add/Edit OSPF Redistribution Entry dialog box lets you add a new redistribution rule or edit an existing redistribution rule in the Redistribution table. Some of the redistribution rule information cannot be changed when you are editing an existing redistribution rule.

Step 3 Choose the OSPF process associated with the route redistribution entry. If you are editing an existing redistribution rule, you cannot change this setting.

Step 4 Choose the source protocol from which the routes are being redistributed. You can choose one of the following options:

- Static—Redistributes static routes to the OSPF routing process.
- Connected—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the AS.
- OSPF—Redistributes routes from another OSPF routing process. Choose the OSPF process ID from the list. If you choose this protocol, the Match options on this dialog box become visible. These options are not available when redistributing static, connected, RIP, or EIGRP routes. Skip to Step 5.
- RIP—Redistributes routes from the RIP routing process.
- EIGRP—Redistributes routes from the EIGRP routing process. Choose the autonomous system number of the EIGRP routing process from the list.

Step 5 If you have chosen OSPF for the source protocol, choose the conditions used for redistributing routes from another OSPF routing process into the selected OSPF routing process. These options are not available when redistributing static, connected, RIP, or EIGRP routes. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions:

- Internal—The route is internal to a specific AS.
- External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 1 external routes.
- External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 external routes.
- NSSA External 1—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.

- NSSA External 2—Routes that are external to the autonomous system, but are imported into OSPF as Type 2 NSSA routes.

Step 6 In the Metric Value field, enter the metric value for the routes being redistributed. Valid values range from 1 to 16777214.

When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

Step 7 Choose one of the following options for the Metric Type.

- If the metric is a Type 1 external route, choose **1**.
- If the metric is a Type 2 external route, choose **2**.

Step 8 Enter the tag value in the Tag Value field.

The tag value is a 32-bit decimal value attached to each external route that is not used by OSPF itself, but may be used to communicate information between ASBRs. Valid values range from 0 to 4294967295.

Step 9 Check the **Use Subnets** check box to enable the redistribution of subnetted routes. Uncheck this check box to cause only routes that are not subnetted to be redistributed.

Step 10 Choose the name of the route map to apply to the redistribution entry from the Route Map drop-down list.

Step 11 If you need to add or configure a route map, click **Manage**.

The Configure Route Map dialog box appears.

Step 12 Click **Add** or **Edit** to define which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process. For more information, see the "Defining a Route Map" section on page 32-4.

Step 13 Click **OK**.

Configuring Route Summarization When Redistributing Routes Into OSPFv2

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the ASA to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database.

Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

There are two areas that you can configure for route summarization:

- Adding a Route Summary Address, page 33-9
- Adding or Editing an OSPF Summary Address, page 33-9

Adding a Route Summary Address

The Summary Address pane displays information about the summary addresses configured for each OSPF routing process.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

Note OSPF does not support summary-address 0.0.0.0 0.0.0.0.

To configure the software advertisement on one summary route for all redistributed routes included for a network address and mask, perform the following steps:

Step 1 In the main ASDM home page, choose **Configuration > Device Setup > Routing > OSPF > Summary Address**.

Step 2 Click **Add**.

The Add OSPF Summary Address Entry dialog box appears. You can add new entries to existing entries in the Summary Address table. Some of the summary address information cannot be changed when editing an existing entry.

Step 3 Choose the specified OSPF Process ID associated with the summary address from the OSPF Process drop-down list. You cannot change this information when editing an existing entry.

Step 4 Enter the IP address of the summary address in the IP Address field. You cannot change this information when editing an existing entry.

Step 5 Choose the network mask for the summary address from the Netmask drop-down list. You cannot change this information when editing an existing entry.

Step 6 Check the **Advertise** check box to advertise the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

The Tag value displays a 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.

Step 7 Click **OK**.

Adding or Editing an OSPF Summary Address

To add or edit OSPF summary address setting, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Route Summarization** tab.

The Add/Edit a Route Summarization Entry dialog box appears.

The Add/Edit a Route Summarization Entry dialog box allows you to add new entries to or modify existing entries in the Summary Address table. Some of the summary address information cannot be changed when editing an existing entry.

Step 3 Choose the specified OSPF Process ID associated with the summary address from the OSPF Process drop-down list. You cannot change this information when editing an existing entry.

Step 4 Enter the IP address of the summary address in the IP Address field. You cannot change this information when editing an existing entry.

Step 5 Enter the network mask for the summary address from the Netmask drop-down list. You cannot change this information when editing an existing entry.

Step 6 Check the **Advertise** check box to advertise the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

Configuring Route Summarization Between OSPFv2 Areas

Route summarization is the consolidation of advertised addresses. This feature causes a single summary route to be advertised to other areas by an area boundary router. In OSPF, an area boundary router advertises networks in one area into another area. If the network numbers in an area are assigned in a way so that they are contiguous, you can configure the area boundary router to advertise a summary route that includes all the individual networks within the area that fall into the specified range.

To define an address range for route summarization, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Route Summarization** tab.

The Add/Edit a Route Summarization Entry dialog box appears.

The Add/Edit a Route Summarization Entry dialog box allows you to add new entries to or modify existing entries in the Summary Address table. Some of the summary address information cannot be changed when editing an existing entry.

Step 3 Enter the OSPF Area ID in the Area ID field. You cannot change this information when editing an existing entry.

Step 4 Enter the IP address of the summary address in the IP Address field. You cannot change this information when editing an existing entry.

Configuring OSPFv2 Interface Parameters

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the Hello interval, the Dead interval, and the Authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

To configure OSPFv2 interface parameters, perform the following steps:

In ASDM, the Interface pane lets you configure interface-specific OSPF routing properties, such as OSPF message authentication and properties. There are two tabs that help you configure interfaces in OSPF:

- The Authentication tab displays the OSPF authentication information for the ASA interfaces.
- The Properties tab displays the OSPF properties defined for each interface in a table format.

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Interface.**

Step 2 Click the **Authentication** tab to display the authentication information for the ASA interfaces. Double-clicking a row in the table opens the Edit OSPF Authentication Interface dialog box for the selected interface.

Step 3 Click **Edit**.

The Edit OSPF Authentication Interface dialog box appears. The Edit OSPF Interface Authentication dialog box lets you configure the OSPF authentication type and parameters for the selected interface.

Step 4 Choose the Authentication type from the Authentication drop-down list according to the following options:

- **None** to disable OSPF authentication.
- **Authentication Password** to use clear text password authentication (not recommended where security is a concern).
- **MD5** to use MD5 authentication (recommended).
- **Area** (Default) to use the authentication type specified for the area. See the "Configuring OSPFv2 Area Parameters" section on page 33-13 for information about configuring area authentication. Area authentication is disabled by default. Therefore, unless you have previously specified an area authentication type, interfaces set to area authentication have authentication disabled until you configure this setting.

Step 5 Click the radio button in the Authentication Password area, which includes the settings for entering the password when password authentication is enabled.

a. In the Enter Password field, type a text string of up to eight characters.

b. In the Re-enter Password field, retype the password.

Step 6 Choose the settings for MD5 IDs and keys in the ID area, which includes the settings for entering the MD5 keys and parameters when MD5 authentication is enabled. All devices on the interface using OSPF authentication must use the same MD5 key and ID.

a. In the Key ID field, enter a numerical key identifier. Valid values range from 1 to 255. The Key ID displays for the selected interface.

b. In the Key field, enter an alphanumeric character string of up to 16 bytes. The key displays for the selected interface.

c. Click **Add** or **Delete** to add or delete the specified MD5 key to the MD5 ID and Key table.

Step 7 Click **OK.**

Step 8 Click the **Properties** tab.

Step 9 Choose the interface that you want to edit. Double-clicking a row in the table opens the Properties tab dialog box for the selected interface.

Step 10 Click **Edit**.

The Edit OSPF Interface Properties dialog box appears. The Interface field displays the name of the interface for which you are configuring OSPF properties. You cannot edit this field.

Step 11 Check or uncheck the **Broadcast** check box to specify that the interface is a broadcast interface.

By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.

When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:

- You can define only one neighbor for the interface.
- You need to manually configure the neighbor. See the "Defining Static OSPFv2 Neighbors" section on page 33-17 for more information.
- You need to define a static route pointing to the crypto endpoint. See the "Configuring Static and Default Routes" section on page 31-2 for more information.
- If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
- You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.

Step 12 Configure the following options:

- Enter a value in the Cost field, which determines the cost of sending a packet through the interface. The default value is 10.
- In the Priority field, enter the OSPF router priority value.

  When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.

  Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.
- Check or uncheck the **MTU Ignore** check box.

  OSPF checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency will not be established.
- Check or uncheck the **Database filter** check box.

  Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.

Step 13 (Optional) Click **Advanced** to display the Edit OSPF Advanced Interface Properties dialog box, which lets you change the values for the OSPF hello interval, retransmit interval, transmit delay, and dead interval.

Typically, you only need to change these values from the defaults if you are experiencing OSPF problems on your network.

Step 14 Enter values for the following:

- The Hello Interval, which specifies the interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds. The default value is 10 seconds.
- The Retransmit Interval, which specifies the time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgement message. If the router receives no acknowledgement, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
- The Transmit Delay, which specifies the estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds. The default value is 1 second.
- The Dead Interval, which specifies the interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535. The default value of this setting is four times the interval that was set in the Hello Interval field.

Configuring OSPFv2 Area Parameters

You can configure several OSPF area parameters. These area parameters (shown in the following task list) include setting authentication, defining stub areas, and assigning specific costs to the default summary route. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

To specify OSPFv2 area parameters for your network, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Area/Networks** tab.

The Add OSPF Area dialog box appears.

Step 3 Choose one of the following Area Type options:

- **Normal** to make the area a standard OSPF area. This option is selected by default when you first create an area.

- **Stub** to make the area a stub area. Stub areas do not have any routers or areas beyond it. Stub areas prevent AS External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you have the option of preventing summary LSAs (Types 3 and 4) from being flooded into the area by unchecking the Summary check box.
- **Summary** to prevent LSAs from being sent into the stub area when the area being defined is a stub area, uncheck this check box. By default, this check box is checked for stub areas.
- **NSSA** to make the area a not-so-stubby area. NSSAs accept Type 7 LSAs. When you create the NSSA, you have the option of preventing summary LSAs from being flooded into the area by unchecking the Summary check box. You can also disable route redistribution by unchecking the Redistribute check box and checking the Default Information Originate check box.

Step 4 Enter the IP address in the IP Address field of the network or host to be added to the area. Use **0.0.0.0** with a netmask of **0.0.0.0** to create the default area. You can only enter **0.0.0.0** in one area.

Step 5 Enter the network mask in the Network Mask field for the IP address or host to be added to the area. If adding a host, choose the **255.255.255.255** mask.

Step 6 Choose the OSPF Authentication type from the following options:

- **None** to disable OSPF area authentication. This is the default setting.
- **Password** to provide a clears text password for area authentication, which is not recommended where security is a concern.
- **MD5** to allow MD5 authentication.

Step 7 Enter a value in the Default Cost field to specify a default cost for the OSPF area.

Valid values range from 0 to 65535. The default value is 1.

Step 8 Click **OK**.

Configuring an OSPFv2 NSSA

The OSPFv2 implementation of an NSSA is similar to an OSPFv2 stub area. NSSA does not flood Type 5 external LSAs from the core into the area, but it can import autonomous system external routes in a limited way within the area.

NSSA imports Type 7 autonomous system external routes within an NSSA area by redistribution. These Type 7 LSAs are translated into Type 5 LSAs by NSSA ABRs, which are flooded throughout the whole routing domain. Summarization and filtering are supported during the translation.

You can simplify administration if you are an ISP or a network administrator that must connect a central site using OSPFv2 to a remote site that is using a different routing protocol with NSSA.

Before the implementation of NSSA, the connection between the corporate site border router and the remote router could not be run as an OSPFv2 stub area because routes for the remote site could not be redistributed into the stub area, and two routing protocols needed to be maintained. A simple protocol such as RIP was usually run and handled the redistribution. With NSSA, you can extend OSPFv2 to cover the remote connection by defining the area between the corporate router and the remote router as an NSSA.

Before you use this feature, consider these guidelines:

- You can set a Type 7 default route that can be used to reach external destinations. When configured, the router generates a Type 7 default into the NSSA or the NSSA area boundary router.

- Every router within the same area must agree that the area is NSSA; otherwise, the routers cannot communicate with each other.

To specify area parameters for your network to configure an OSPFv2 NSSA, perform the following steps:

Step 1 From the main ASDM home page, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Area/Networks** tab.

Step 3 Click **Add**.

The Add OSPF Area dialog box appears.

Step 4 Click the **NSSA** radio button in the Area Type area.

Choose this option to make the area a not-so-stubby area. NSSAs accept Type 7 LSAs. When you create the NSSA, you have the option of preventing summary LSAs from being flooded into the area by unchecking the Summary check box. You can also disable route redistribution by unchecking the Redistribute check box and checking the Default Information Originate check box.

Step 5 Enter the IP address in the IP Address field of the network or host to be added to the area. Use **0.0.0.0** with a netmask of **0.0.0.0** to create the default area. You can only enter **0.0.0.0** in one area.

Step 6 Enter the network mask in the Network Mask field for the IP address or host to be added to the area. If adding a host, choose the **255.255.255.255** mask.

Step 7 In the Authentication area, click the **None** radio button to disable OSPF area authentication.

Step 8 Enter a value in the Default Cost field to specify a default cost for the OSPF area.

Valid values range from 0 to 65535. The default value is 1.

Step 9 Click **OK**.

Configuring an IP Address Pool for Clustering (OSPFv2 and OSPFv3)

You can assign a range of IPv4 addresses for the router ID cluster pool if you are using Layer 3 clustering.

To assign a range of IPv4 addresses for the router ID cluster pool in Layer 3 clustering for OSPFv2, perform the following steps:

Step 1 From the main ASDM home page, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPF Process Advanced Properties dialog box appears.

Step 4 Click the **Cluster Pool** radio button. If you are using clustering, then you do not need to specify an IP address pool for the router ID (that is, leave the field blank). If you do not enter an IP address pool, then the ASA uses the automatically generated router ID.

Step 5 Enter the name of the IP address pool, or click the ellipses to display the Select IP Address Pool dialog box.

Step 6 Double-click an existing IP address pool name to add it to the Assign field. Alternatively, click **Add** to create a new IP address pool.

The Add IPv4 Pool dialog box appears.

Step 7 Enter the new IP address pool name in the Name field.

Step 8 Enter the starting IP address or click the ellipses to display the Browse Starting IP Address dialog box.

Step 9 Double-click an entry to add it to the Starting IP Address field, then click **OK**.

Step 10 Enter the ending IP address or click the ellipses to display the Browse Ending IP Address dialog box.

Step 11 Double-click an entry to add it to the Ending IP Address field, then click **OK**.

Step 12 Choose the subnet mask from the drop-down list, then click **OK**.

The new IP address pool appears in the Select IP Address Pool list.

Step 13 Double-click the new IP address pool name to add it to the Assign field, then click **OK**.

The new IP address pool name appears in the Cluster Pool field of the Edit OSPF Process Advanced Properties dialog box.

Step 14 Click **OK**.

Step 15 If you want to change the newly added IP address pool settings, click **Edit**.

The Edit IPv4 Pool dialog box appears.

Step 16 Repeat Steps 4 through 14.

Note You cannot edit or delete an existing IP address pool that has been assigned and is already being used by one or more connection profiles.

Step 17 Click **OK**.

To assign a range of IPv4 addresses for the router ID cluster pool in Layer 3 clustering for OSPFv3, perform the following steps:

Step 1 From the main ASDM home page, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 Choose the Cluster Pool option from the Router ID drop-down list. If you do not need to specify an IP address pool for the router ID, choose the Automatic option. If you do not configure an IP address pool, then the ASA uses the automatically generated router ID.

Step 5 Enter the IP address pool name. Alternatively, click the ellipses to display the Select IP Address Pool dialog box.

Step 6 Double-click an existing IP address pool name to add it to the Assign field. Alternatively, click **Add** to create a new IP address pool.

The Add IPv4 Pool dialog box appears.

Step 7 Enter the new IP address pool name in the Name field.

Step 8 Enter the starting IP address or click the ellipses to display the Browse Starting IP Address dialog box.

Step 9 Double-click an entry to add it to the Starting IP Address field, then click **OK**.

Step 10 Enter the ending IP address or click the ellipses to display the Browse Ending IP Address dialog box.

Step 11 Double-click an entry to add it to the Ending IP Address field, then click **OK**.

Step 12 Choose the subnet mask from the drop-down list, then click **OK**.

The new IP address pool appears in the Select IP Address Pool list.

Step 13 Double-click the new IP address pool name to add it to the Assign field, then click **OK**.

The new IP address pool name appears in the Cluster Pool field of the Edit OSPF Process Advanced Properties dialog box.

Step 14 Click **OK**.

Step 15 If you want to change the newly added cluster pool settings, click **Edit**.

The Edit IPv4 Pool dialog box appears.

Step 16 Repeat Steps 4 through 14.

Note You cannot edit or delete an existing IP address pool that has been assigned and is already being used by another OSPFv3 process.

Step 17 Click **OK**.

Defining Static OSPFv2 Neighbors

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Before you begin, you must create a static route to the OSPFv2 neighbor. See Chapter 31, "Configuring Static and Default Routes," for more information about creating static routes.

To define a static OSPFv2 neighbor, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Static Neighbor**.

Step 2 Click **Add** or **Edit**.

The Add/Edit OSPF Neighbor Entry dialog box appears. This dialog box lets you define a new static neighbor or change information for an existing static neighbor. You must define a static neighbor for each point-to-point, nonbroadcast interface. Note the following restrictions:

- You cannot define the same static neighbor for two different OSPF processes.
- You need to define a static route for each static neighbor.

Step 3 From the OSPF Process drop-down list, choose the OSPF process associated with the static neighbor. If you are editing an existing static neighbor, you cannot change this value.

Step 4 In the Neighbor field, enter the IP address of the static neighbor.

Step 5 In the Interface field, choose the interface associated with the static neighbor. If you are editing an existing static neighbor, you cannot change this value.

Step 6 Click **OK**.

Configuring Route Calculation Timers

You can configure the delay time between when OSPFv2 receives a topology change and when it starts an SPF calculation. You also can configure the hold time between two consecutive SPF calculations.

To configure route calculation timers, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPF Process Advanced Properties dialog box appears.

Step 4 The Timers area allows you to modify the settings that are used to configure LSA pacing and SPF calculation timers. In the Timers area, enter the following values:

- The SPF Delay Time, which specifies the time between when OSPF receives a topology change and when the SPF calculation starts. Valid values range from 0 to 65535. The default value is 5.
- The SPF Hold Time, which specifies the hold time between consecutive SPF calculations.Valid values range from 1 to 65534. The default value is 10.
- The LSA Group Pacing, which specifies the interval at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.

Step 5 Click **OK**.

Logging Neighbors Going Up or Down

By default, a syslog message is generated when an OSPFv2 neighbor goes up or down.

To log OSPFv2 neighbors going up or down, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Click **Advanced**.

The Edit OSPF Process Advanced Properties dialog box appears.

Step 4 The Adjacency Changes area includes settings that define the adjacency changes that cause syslog messages to be sent. In the Adjacency Changes area, enter the following values:

- Check the **Log Adjacency Changes** check box to cause the ASA to send a syslog message whenever an OSPFv2 neighbor goes up or down. This setting is checked by default.
- Check the **Log Adjacency Changes Detail** check box to cause the ASA to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.

Step 5 Click **OK**.

Note Logging must be enabled for the neighbor up or down messages to be sent.

Configuring Filtering in OSPF

The Filtering pane displays the ABR Type 3 LSA filters that have been configured for each OSPF process.

ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. This type of area filtering can be applied out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF areas at the same time.

OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

Note Only Type 3 LSAs that originate from an ABR are filtered.

To configure filtering in OSPF, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Filtering**.

Step 2 Click **Add** or **Edit**.

The Add or Edit OSPF Filtering Entry dialog box lets you add new filters to the Filter table or modify an existing filter. Some of the filtering information cannot be changed when you edit an existing filter.

Step 3 Choose the OSPF process that is associated with the filter entry from the OSPF Process drop-down list.

Step 4 Choose the Area ID that is associated with the filter entry from the Area ID drop-down list. If you are editing an existing filter entry, you cannot modify this setting.

Step 5 Choose a prefix list from the Prefix List drop-down list.

Step 6 Choose the traffic direction being filtered from the Traffic Direction drop-down list.

Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

Step 7 Click **Manage** to display the Configure Prefix Lists dialog box, from which you can add, edit, or delete prefix lists and prefix rules. For more information, see the "Configuring Prefix Lists" section on page 32-6 and the "Configuring Prefix Rules" section on page 32-7.

Step 8 Click **OK**.

Configuring a Virtual Link in OSPF

If you add an area to an OSPF network, and it is not possible to connect the area directly to the backbone area, you need to create a virtual link. A virtual link connects two OSPF devices that have a common area, called the transit area. One of the OSPF devices must be connected to the backbone area.

To define new virtual links or change the properties of existing virtual links, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Virtual Link**.

Step 2 Click **Add** or **Edit**.

The Add or Edit OSPF Virtual Link dialog box appears, which allows you to define new virtual links or change the properties of existing virtual links.

Step 3 Choose the OSPF process ID that is associated with the virtual link from the OSPF Process drop-down list. If you are editing an existing virtual link entry, you cannot modify this setting.

Step 4 Choose the Area ID that is associated with the virtual link from the Area ID drop-down list.

Choose the area shared by the neighbor OSPF devices. The selected area cannot be an NSSA or a Stub area. If you are editing an existing virtual link entry, you cannot modify this setting.

Step 5 In the Peer Router ID field, enter the router ID of the virtual link neighbor.

If you are editing an existing virtual link entry, you cannot modify this setting.

Step 6 Click **Advanced** to edit advanced virtual link properties,

The Advanced OSPF Virtual Link Properties dialog box appears. You can configure the OSPF properties for the virtual link in this area. These properties include authentication and packet interval settings.

Step 7 In the Authentication area, choose the Authentication type by clicking the radio button next to one of the following options:

- **None** to disable OSPF authentication.
- **Authentication Password** to use clear text password authentication. This is not recommended where security is a concern.
- **MD5** to use MD5 authentication (recommended).
- **Area** (Default) to use the authentication type specified for the area. See the "Configuring OSPFv2 Area Parameters" section on page 33-13 for information about configuring area authentication. Area authentication is disabled by default. Therefore, unless you have previously specified an area authentication type, interfaces set to area authentication have authentication disabled until you configure this setting.

Step 8 In the Authentication Password area, enter and re-enter a password when password authentication is enabled. Passwords must be a text string of up to 8 characters.

Step 9 In the MD5 IDs and Key area, enter the MD5 keys and parameters when MD5 authentication is enabled. All devices on the interface using OSPF authentication must use the same MD5 key and ID. Specify the following settings:

a. In the Key ID field, enter a numerical key identifier. Valid values range from 1 to 255. The Key ID displays for the selected interface.

b. In the Key field, enter an alphanumeric character string of up to 16 bytes. The Key ID displays for the selected interface.

c. Click **Add** or **Delete** to add or delete the specified MD5 key to the MD5 ID and Key table.

Step 10 In the Interval area, specify the interval timing for the packet by choosing from the following options:

- **Hello Interval** to specify the interval, in seconds, between hello packets sent on an interface. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface. Valid values range from 1 to 65535 seconds. The default value is 10 seconds.
- **Retransmit Interval** to specify the time, in seconds, between LSA retransmissions for adjacencies belonging to the interface. When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgement message. If the router receives no acknowledgement, it will resend the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links. Valid values range from 1 to 65535 seconds. The default value is 5 seconds.
- **Transmit Delay** to specify the estimated time, in seconds, required to send an LSA packet on the interface. LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links. Valid values range from 1 to 65535 seconds. The default value is 1 second.
- **Dead Interval** to specify the interval, in seconds, in which no hello packets are received, causing neighbors to declare a router down. Valid values range from 1 to 65535. The default value of this field is four times the interval set by the Hello Interval field.

Step 11 Click **OK**.

Configuring OSPFv3

This section describes how to configure OSPFv3 routing processes and includes the following topics:

- Enabling OSPFv3, page 33-22
- Configuring OSPFv3 Interface Parameters, page 33-22
- Configuring OSPFv3 Area Parameters, page 33-23
- Configuring a Virtual Link Neighbor, page 33-24
- Configuring OSPFv3 Passive Interfaces, page 33-25
- Configuring OSPFv3 Administrative Distance, page 33-26
- Configuring OSPFv3 Timers, page 33-27
- Defining Static OSPFv3 Neighbors, page 33-28
- Sending Syslog Messages, page 33-29
- Suppressing Syslog Messages, page 33-29
- Calculating Summary Route Costs, page 33-29
- Generating a Default External Route into an OSPFv3 Routing Domain, page 33-30
- Configuring an IPv6 Summary Prefix, page 33-30
- Redistributing IPv6 Routes, page 33-31

Enabling OSPFv3

To enable OSPFv3, you need to create an OSPFv3 routing process, create an area for OSPFv3, enable an interface for OSPFv3, then redistribute the route into the targeted OSPFv3 routing processes.

To enable OSPFv3, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 On the Process Instances tab, check the **Enable OSPFv3 Process** check box. You can enable up to two OSPF process instances. Only single context mode is supported.

Step 3 Enter a process ID in the Process ID field. The ID can be any positive integer.

Step 4 Click **Apply** to save your changes.

Step 5 To continue, see the "Configuring OSPFv3 Area Parameters" section on page 33-23.

Configuring OSPFv3 Interface Parameters

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

To configure OSPFv3 interface parameters for IPv6, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Interfaces**.

Step 2 Click the **Authentication** tab.

Step 3 To specify the authentication parameters for an interface, select the interface and click **Edit**.

The Edit OSPFv3 Interface Authentication dialog box appears.

Step 4 Choose the authentication type from the Authentication Type drop-down list. The available options are Area, Interface, and None. The None option indicates that no authentication is used.

Step 5 Choose the authentication algorithm from the Authentication Algorithm drop-down list. Supported values are SHA-1 and MD5.

Step 6 Enter the authentication key in the Authentication Key field. When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.

Step 7 Choose the encryption algorithm from the Encryption Algorithm drop-down list. Supported values are AES-CDC, 3DES, and DES. The NULL entry indicates no encryption.

Step 8 Enter the encryption key in the Encryption Key field.

Step 9 Click **OK**.

Step 10 Click the **Properties** tab.

Step 11 Select the interface whose properties you want to modify, and click **Edit**.

The Edit OSPFv3 Interface Properties dialog box appears.

Step 12 Check the **Enable OSPFv3 on this interface** check box.

Step 13 Choose the process ID from the drop-down list.

Step 14 Choose the area ID from the drop-down list.

Step 15 (Optional) Specify the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

Step 16 Choose the network type from the drop-down list. Supported options are Default, Broadcast, and Point-to-Point.

Step 17 Enter the cost of sending a packet on an interface in the Cost field.

Step 18 Enter the router priority, which helps determine the designated router for a network. in the Priority field. Valid values range from 0 to 255.

Step 19 Check the **Disable MTU mismatch detection** check box to disable the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.

Step 20 Check the **Filter outgoing link state advertisements** check box to filter outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.

Step 21 In the Timers area, in the Dead Interval field, enter the time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.

Step 22 In the Hello Interval field, enter the interval in seconds between hello packets sent on the interface. The value must be the same for all nodes on a specific network and can range from 1 to 65535. The default interval is 10 seconds for Ethernet interfaces and 30 seconds for non-broadcast interfaces.

Step 23 In the Retransmit Interval field, enter the time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

Step 24 In the Transmit Delay field, enter the estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.

Step 25 Click **OK**.

Step 26 Click **Apply** to save your changes.

Configuring OSPFv3 Area Parameters

To configure OSPFv3 area parameters, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Areas** tab.

Step 3 To add a new area, click **Add**. To modify an existing area, click **Edit**. To remove a selected area, click **Delete**.

The Add OSPFv3 Area dialog box or Edit OSPFv3 Area dialog box appears.

Step 4 From the OSPFv3 Process ID drop-down list, choose the process ID.

Step 5 Enter the area ID, which specifies the area for which routes are to be summarized, in the Area ID field.

Step 6 Choose the area type from the Area Type drop-down list. Available options are Normal, NSSA, and Stub.

Step 7 To allow the sending of summary LSAs into the area, check the **Allow sending of summary LSAs into the area** check box.

Step 8 To allow redistribution to import routes to normal and not so stubby areas, check the **Redistribution imports routes to normal and NSSA areas** check box.

Step 9 To generate a default external route into an OSPFv3 routing domain, check the **Default information originate** check box.

Step 10 Enter the metric used for generating the default route in the Metric field. The default value is 10. Valid metric values range from 0 to 16777214.

Step 11 Choose the metric type from the Metric Type drop-down list. The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

Step 12 Enter the cost in the Default Cost field.

Step 13 Click **OK**.

Step 14 Click the **Route Summarization** tab.

Step 15 To specify a new range for consolidating and summarizing routes, click **Add**. To modify an existing range for consolidating and summarizing routes, click **Edit**.

The Add Route Summarization dialog box or Edit Route Summarization dialog box appears.

Step 16 Choose the process ID from the Process ID drop-down list.

Step 17 Choose the area ID from the Area ID drop-down list.

Step 18 Enter the IPv6 prefix and prefix length in the IPv6 Prefix/Prefix Length field.

Step 19 (Optional) Enter the metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.

Step 20 Check the **Advertised** check box to set the address range status to advertised and generate a Type 3 summary LSA.

Step 21 Click **OK**.

Step 22 To continue, see the "Configuring a Virtual Link Neighbor" section on page 33-24.

Configuring a Virtual Link Neighbor

To configure a virtual link neighbor, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Virtual Link**.

Step 2 To add a new virtual link neighbor, click **Add**. To modify an existing virtual link neighbor, click **Edit**. To remove a selected virtual link neighbor, click **Delete**.

The Add Virtual Link dialog box or Edit Virtual Link dialog box appears.

Step 3 Choose the process ID from the Process ID drop-down list.

Step 4 Choose the area ID from the Area ID drop-down list.

Step 5 Enter the peer router ID (that is, the IP address) in the Peer Router ID field.

Step 6 (Optional) Enter the time-to-live (TTL) security hop count on a virtual link in the TTL Security field. The hop count value can range from 1 to 254.

Step 7 In the Timers area, enter the time in seconds that hello packets are not seen before a neighbor indicates that the router is down in the Dead Interval field. The dead interval is an unsigned integer. The default is four times the hello interval, or 40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 to 8192.

Step 8 Enter the time in seconds between the hello packets that are sent on an interface in the Hello Interval field. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 to 8192. The default is 10.

Step 9 Enter the time in seconds between LSA retransmissions for adjacencies that belong to the interface in the Retransmit Interval field. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 8192. The default is 5.

Step 10 Enter the estimated time in seconds that is required to send a link-state update packet on the interface in the Transmit Delay field. The integer value must be greater than zero. LSAs in the update packet have their own ages incremented by this amount before transmission. The range of values can be from 1 to 8192. The default is 1.

Step 11 In the Authentication area, check the **Enable Authentication** check box to enable authentication.

Step 12 Enter the security policy index, which must be a number from 256 to 4294967295, in the Security Policy Index field.

Step 13 Choose the authentication algorithm from the Authentication Algorithm drop-down list. Supported values are SHA-1 and MD5. When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.

Step 14 Enter the authentication key in the Authentication Key field. The key must include 32 hexadecimal characters.

Step 15 Choose the encryption algorithm from the Encryption Algorithm drop-down list. Supported values are AES-CDC, 3DES, and DES. The NULL entry indicates no encryption.

Step 16 Enter the encryption key in the Encryption Key field.

Step 17 Click **OK**.

Step 18 Click **Apply** to save your changes.

Configuring OSPFv3 Passive Interfaces

To configure OSPFv3 passive interfaces, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPFv3 process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 The Passive Interfaces area allows you to enable passive OSPFv3 routing on an interface. Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface. In the Passive Interfaces area, choose the following settings:

- Check the **Global passive** check box to make all of the interfaces listed in the table passive. Uncheck individual interfaces to make them non-passive.
- Uncheck the **Global passive** check box to make all of the interfaces non-passive. Check individual interfaces to make them passive.

Step 5 Click **OK**.

Step 6 Click **Apply** to save your changes.

Configuring OSPFv3 Administrative Distance

To configure OSPFv3 administrative distance for IPv6 routes, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

The Administrative Route Distances area allows you to modify the settings that were used to configure administrative route distances. The administrative route distance is an integer from 10 to 254. In the Administrative Route Distances area, enter the following values:

- The Inter Area, which specifies the inter-area routes for OSPV for IPv6 routes.
- The Intra Area, which specifies the intra-area routes for OSPF for IPv6 routes.
- The External, which specifies the external type 5 and type 7 routes for OSPF for IP6 routes.

Step 4 Click **OK**.

Step 5 Click **Apply** to save your changes.

Configuring OSPFv3 Timers

You can set LSA arrival, LSA pacing, and throttling timers for OSPFv3.

To set the minimum interval at which the ASA accepts the same LSA from OSPFv3 neighbors, perform the following steps:

To configure LSA flood packet pacing, perform the following steps:

To change the interval at which OSPFv3 LSAs are collected into a group and refreshed, check summed, or aged, perform the following steps:

To configure LSA retransmission packet pacing, perform the following steps:

LSA and SPF throttling provide a dynamic mechanism to slow down LSA updates in OSPFv3 during times of network instability and allow faster OSPFv3 convergence by providing LSA rate limiting in milliseconds.

To configure LSA and SPF throttling timers, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPFv3 process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 The Timers area allows you to modify the settings that are used to configure LSA arrival, LSA pacing, LSA retransmission, LSA throttle, and SPF throttle times. In the Timers area, enter the following values:

- The LSA Arrival, which specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- The LSA Flood Pacing, which specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- The LSA Group Pacing, which specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- The LSA Retransmission Pacing, which specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- The LSA Throttle Initial, which specifies the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 milliseconds.
- The LSA Throttle Min Hold, which specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.
- The LSA Throttle Max Wait, which specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

Note For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- The SPF Throttle Initial, specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds.
- The SPF Throttle Min Hold, which specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds.
- The SPF Throttle Max Wait, which specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

Note For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

Step 5 Click **OK**.

Step 6 Click **Apply** to save your changes.

Defining Static OSPFv3 Neighbors

You need to define static OSPFv3 neighbors to advertise OSPF routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv3 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

Before you begin, you must create a static route to the OSPFv3 neighbor. See Chapter 31, "Configuring Static and Default Routes," for more information about creating static routes.

To define a static OSPFv3 neighbor, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Static Neighbor**.

Step 2 Click **Add** or **Edit**.

The Add or Edit Static Neighbor dialog box appears. This dialog box lets you define a new static neighbor or change information for an existing static neighbor. You must define a static neighbor for each point-to-point, nonbroadcast interface. Note the following restrictions:

- You cannot define the same static neighbor for two different OSPFv3 processes.
- You need to define a static route for each static neighbor.

Step 3 From the Interface drop-down list, choose the interface associated with the static neighbor. If you are editing an existing static neighbor, you cannot change this value.

Step 4 In the Link-local Address field, enter the IPv6 address of the static neighbor.

Step 5 (Optional) In the Priority field, enter the priority level.

Step 6 (Optional) In the Poll Interval field, enter the poll interval in seconds.

Step 7 Click **OK**.

Sending Syslog Messages

To configure the router to send a syslog message when an OSPFv3 neighbor goes up or down, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

The Adjacency Changes area allows you to modify the settings for sending syslog messages when an OSPFv3 neighbor goes up or down. In the Adjacency Changes area, do the following:

- To send a syslog message when an OSPFv3 neighbor goes up or down, check the **Log Adjacency Changes** check box.
- To sends a syslog message for each state, not only when an OSPFv3 neighbor goes up or down, check the **Include Details** check box.

Step 4 Click **OK**.

Step 5 Click **Apply** to save your changes.

Suppressing Syslog Messages

To suppress the sending of syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPFv3 process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 Check the **Ignore LSA MOSPF** check box, then click **OK**.

Calculating Summary Route Costs

To calculate summary route costs according to RFC 1583, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPF process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 Check the **RFC1583 Compatible** check box, then click **OK**.

Generating a Default External Route into an OSPFv3 Routing Domain

To generate a default route into an OSPFv3 routing domain, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Click the **Process Instances** tab.

Step 3 Choose the OSPFv3 process that you want to edit, then click **Advanced**.

The Edit OSPFv3 Process Advanced Properties dialog box appears.

Step 4 In the Default Information Originate Area, do the following:

a. Check the **Enable** check box to enable the OSPFv3 routing process.

b. Check the **Always advertise** check box to always advertise the default route, whether or not one exists.

c. Enter the metric used for generating the default route in the Metric field. Valid metric values range from 0 to 16777214. The default value is 10.

d. From the Metric Type drop-down list, choose the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are the following:

- 1—Type 1 external route
- 2—Type 2 external route

The default is the Type 2 external route.

e. From the Route Map drop-down list, choose the routing process that generates the default route if the route map is satisfied.

Step 5 Click **OK**.

Step 6 Click **Apply** to save your changes.

Configuring an IPv6 Summary Prefix

To configure an IPv6 summary prefix, perform the following steps:

Step 1 In the ASDM main window, choose **Configuration > Device Setup > Routing > OSPFv3 > Summary Prefix**.

Step 2 To add a new summary prefix, click **Add**. To modify an existing summary prefix, click **Edit**. To remove a summary prefix, click **Delete**.

The Add Summary Prefix dialog box or Edit Summary Prefix dialog box appears.

Step 3 Choose the process ID from the Process ID drop-down list.

Step 4 Enter the IPv6 prefix and prefix length in the IPv6 Prefix/Prefix Length field.

Step 5 Check the **Advertise** check box to advertise routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.

Step 6 Enter the tag value that you can use as a match value for controlling redistribution through route maps in the Tag field.

Step 7 Click **OK**.

Step 8 Click **Apply** to save your changes.

Redistributing IPv6 Routes

To redistribute connected routes into an OSPFv3 process, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Redistribution**.

Step 2 To add new parameters for redistributing connected routes into an OSPFv3 process, click **Add**. To modify existing parameters for redistributing connected routes into an OSPFv3 process, click **Edit**. To remove a selected set of parameters, click **Delete**.

The Add Redistribution dialog box or Edit Redistribution dialog box appears.

Step 3 Choose the process ID from the Process ID drop-down list.

Step 4 Choose the source protocol from which routes are being redistributed from the Source Protocol drop-down list. The supported protocols are connected, static, and OSPF.

Step 5 Enter the metric value in the Metric field. When redistributing routes from one OSPF process into another OSPF process on the same router, the metric is carried through from one process to the other if no metric value is specified. When redistributing other processes into an OSPF process, the default metric is 20 when no metric value is specified.

Step 6 Choose the metric type from the Metric Type drop-down list. The available options are None, 1, and 2.

Step 7 (Optional) Enter the tag value in the Tag field. This parameter specifies the 32-bit decimal value attached to each external route, which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.

Step 8 Choose the route map from the Route Map drop-down list to check for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported.

Step 9 To include connected routes in the redistribution, check the **Include connected** check box.

Step 10 Check the **Match** check box to redistribute routes into other routing domains, then check one of the following check boxes:

- **Internal** for routes that are internal to a specific autonomous system
- **External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 1 external routes
- **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 2 external routes

- **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 1 external routes
- **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 2 external routes

Step 11 Click **OK**.

Step 12 Click **Apply** to save your changes.

Removing the OSPF Configuration

To remove the entire OSPFv2 configuration that you have already enabled, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Uncheck the **Enable this OSPF Process** check box.

Step 3 Click **Apply**.

To remove the entire OSPFv3 configuration that you have already enabled, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 Uncheck the **Enable OSPFv3 Process** check box.

Step 3 Click **Apply**.

Configuration Example for OSPFv2

The following example shows how to enable and configure OSPFv2 with various optional processes:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 2 Click the **Process Instances** tab and in the OSPF Process 1 field, type **2**.

Step 3 Click the **Area/Networks** tab, and click **Add**.

Step 4 Enter **0** in the Area ID field.

Step 5 In the Area Networks area, enter **10.0.0.0** in the IP Address field.

Step 6 Choose 255.0.0.0 from the Netmask drop-down list.

Step 7 Click **OK**.

Step 8 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Redistribution**.

Step 9 Click **Add**.

The Add/Edit OSPF Redistribution Entry dialog box appears.

Step 10 In the Protocol area, click the **OSPF** radio button to choose the source protocol from which the routes are being redistributed. Choosing OSPF redistributes routes from another OSPF routing process.

Step 11 Choose the OSPF process ID from the OSPF Process drop-down list.

Step 12 In the Match area, check the **Internal** check box.

Step 13 In the Metric Value field, enter **5** for the metric value for the routes being redistributed.

Step 14 From the Metric Type drop-down list, choose 1 for the Metric Type value.

Step 15 From the Route Map drop-down list, choose 1.

Step 16 Click **OK**.

Step 17 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Interface**.

Step 18 From the Properties tab, choose the **inside** interface and click **Edit.**

The Edit OSPF Properties dialog box appears.

Step 19 In the Cost field, enter **20**.

Step 20 Click **Advanced**.

Step 21 In the Retransmit Interval field, enter **15**.

Step 22 In the Transmit Delay field, enter **20**.

Step 23 In the Hello Interval field, enter **10**.

Step 24 In the Dead Interval field, enter **40**.

Step 25 Click **OK**.

Step 26 In the Edit OSPF Properties dialog box, enter **20** in the Priorities field, and click **OK**.

Step 27 Click the **Authentication** tab.

The Edit OSPF Authentication dialog box appears.

Step 28 In the Authentication area, click the **MD5** radio button.

Step 29 In the MD5 and Key ID area, enter **cisco** in the MD5 Key field, and **1** in the MD5 Key ID field.

Step 30 Click **OK**.

Step 31 Choose **Configuration > Device Setup > Routing > OSPF > Setup,** and click the **Area/Networks** tab.

Step 32 Choose the **OSPF 2** process and click **Edit**.

The Edit OSPF Area dialog box appears.

Step 33 In the Area Type area, choose **Stub**.

Step 34 In the Authentication area, choose **None**, and enter **20** in the Default Cost field.

Step 35 Click **OK**.

Step 36 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPF > Setup**.

Step 37 Click the **Process Instances** tab and check the **OSPF process 2** check box.

Step 38 Click **Advanced**.

The Edit OSPF Area dialog box appears.

Step 39 In the Timers area, enter **10** in the SPF Delay Time field and **20** in the SPF Hold Time field.

Step 40 In the Adjacency Changes area, check the **Log Adjacency Change Details** check box.

Step 41 Click **OK**.

Step 42 Click **Reset**.

Configuration Example for OSPFv3

The following example shows how to configure OSPFv3 routing in ASDM:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Setup**.

Step 2 On the Process Instances tab, do the following:

a. Check the **Enable OSPFv3 Process** check box.

b. Enter **1** in the Process ID field.

Step 3 Click the **Areas** tab. then click **Add** to display the Add OSPFv3 Area dialog box.

Step 4 From the OSPFv3 Process ID drop-down list, choose **1**.

Step 5 Enter **22** in the Area ID field.

Step 6 Choose **Normal** from the Area Type drop-down list.

Step 7 Enter **10** in the Default Cost field.

Step 8 Check the **Redistribution imports routes to normal and NSSA areas** check box.

Step 9 Enter **20** in the Metric field.

Step 10 Choose **1** from the Metric Type drop-down list.

Step 11 Check the **inside** check box as the specified interface being used.

Step 12 Check the **Enable Authentication** check box.

Step 13 Enter **300** in the Security Policy Index field.

Step 14 Choose **SHA-1** from the Authentication Algorithm drop-down list.

Step 15 Enter **12345ABCDE** in the Authentication Key field.

Step 16 Choose **DES** from the Encryption Algorithm drop-down list.

Step 17 Enter **1122334455aabbccddee** in the Encryption Key field.

Step 18 Click **OK**.

Step 19 Click the **Route Summarization** tab, then click **Add** to display the Add Route Summarization dialog box.

Step 20 Choose **1** from the Process ID drop-down list.

Step 21 Choose **22** from the Area ID drop-down list.

Step 22 Enter **2000:122::/64** in the IPv6 Prefix/Prefix Length field.

Step 23 (Optional) Enter **100** in the Cost field.

Step 24 Check the **Advertised** check box.

Step 25 Click **OK**.

Step 26 In the main ASDM window, choose **Configuration > Device Setup > Routing > OSPFv3 > Interface**.

Step 27 Click the **Properties** tab.

Step 28 Check the **inside** check box and click **Edit** to display the Edit OSPF Properties dialog box.

Step 29 In the Cost field, enter **20**.

Step 30 Enter **1** in the Priority field.

Step 31 Check the **point-to-point** check box.

Step 32 In the Dead Interval field, enter **40**.

Step 33 In the Hello Interval field, enter **10**.

Step 34 In the Retransmit Interval field, enter **15**.

Step 35 In the Transmit Delay field, enter **20**.

Step 36 Click **OK**.

Step 37 In the main ASDM window, choose **Configuration > Device Setup > Routing > Redistribution**.

Step 38 Choose **1** from the Process ID drop-down list.

Step 39 Choose **OSPF** from the Source Protocol drop-down list.

Step 40 Enter **50** in the Metric field.

Step 41 Choose **1** from the Metric Type drop-down list.

Step 42 Click **OK**.

Step 43 Click **Apply** to save your changes.

Monitoring OSPF

You can display specific statistics such as the contents of IP routing tables, caches, and databases. You can also use the information provided to determine resource utilization and solve network problems. You can also display information about node reachability and discover the routing path that your device packets are taking through the network.

To monitor or display various OSPFv2 routing statistics in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Monitoring > Routing > OSPF LSAs**.

Step 2 You can select and monitor OSPF LSAs, Types 1 through 5 and 7. Each pane shows one LSA type, as follows:

- Type 1 LSAs represent the routes in an area under a process.
- Type 2 LSAs show the IP address of the designated router that advertises the routers.
- Type 3 LSAs show the IP address of the destination network.
- Type 4 LSAs show the IP address of the AS boundary router.
- Type 5 LSAs and Type 7 LSAs show the IP address of the AS external network.

Step 3 Click **Refresh** to update each LSA type pane.

Step 4 In the main ASDM window, choose **Monitoring > Routing > OSPF Neighbors**.

In the OSPF Neighbors pane, each row represents one OSPF neighbor. In addition, the OSPF Neighbors pane shows the network on which the neighbor is running, the priority, the state, the amount of dead time in seconds, the IP address of the neighbor, and the interface on which it is running. For a list of possible states for an OSPF neighbor, see RFC 2328.

Step 5 Click **Refresh** to update the OSPF Neighbors pane.

To monitor or display various OSPFv3 routing statistics in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Monitoring > Routing > OSPFv3 LSAs**.

Step 2 You can select and monitor OSPFv3 LSAs. Choose a link-state type to display its status according to specified parameters from the Link State type drop-down list. The supported link-state types are router, network, inter-area prefix, inter-area router, AS external, NSSA, link, and intra-area prefix.

Step 3 Click **Refresh** to update each link-state type.

Step 4 In the main ASDM window, choose **Monitoring > Routing > OSPFv3 Neighbors**.

In the OSPFv3 Neighbors pane, each row represents one OSPFv3 neighbor. In addition, the OSPFv3 Neighbors pane shows the IP address of the neighbor, the priority, the state, the amount of dead time in seconds, and the interface on which it is running. For a list of possible states for an OSPFv3 neighbor, see RFC 5340.

Step 5 Click **Refresh** to update the OSPFv3 Neighbors pane.

Additional References

For additional information related to implementing OSPF, see the following section:

RFCs

RFC	Title
2328	OSPFv2
4552	OSPFv3 Authentication
5340	OSPF for IPv6

Feature History for OSPF

Table 33-1 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 33-1 Feature History for OSPF

Feature Name	Platform Releases	Feature Information
OSPF Support	7.0(1)	Support was added for route data, authentication, and redistribution and monitoring of routing information using the Open Shortest Path First (OSPF) routing protocol. We introduced the following screen: Configuration > Device Setup > Routing > OSPF.
Dynamic Routing in Multiple Context Mode	9.0(1)	OSPFv2 routing is supported in multiple context mode. We modified the following screen: Configuration > Device Setup > Routing > OSPF > Setup
Clustering		For OSPFv2 and OSPFv3, bulk synchronization, route synchronization, and Layer 2 load balancing are supported in the clustering environment.
OSPFv3 Support for IPv6		OSPFv3 routing is supported for IPv6. We introduced the following screens: Configuration > Device Setup > Routing > OSPFv3 > Setup, Configuration > Device Setup > Routing > OSPFv3 > Interface, Configuration > Device Setup > Routing > OSPFv3 > Redistribution, Configuration > Device Setup > Routing > OSPFv3 > Summary Prefix, Configuration > Device Setup > Routing > OSPFv3 > Virtual Link, Monitoring > Routing > OSPFv3 LSAs, Monitoring > Routing > OSPFv3 Neighbors.

Configuring RIP

This chapter describes how to configure the ASA to route data, perform authentication, and redistribute routing information, using the Routing Information Protocol (RIP).

This chapter includes the following sections:

- Information About RIP, page 34-1
- Licensing Requirements for RIP, page 34-3
- Guidelines and Limitations, page 34-3
- Configuring RIP, page 34-4
- Customizing RIP, page 34-5
- Monitoring RIP, page 34-12
- Configuration Example for RIP, page 34-12
- Feature History for RIP, page 34-13

Information About RIP

This section includes the following topics:

- Routing Update Process, page 34-2
- RIP Routing Metric, page 34-2
- RIP Stability Features, page 34-2
- RIP Timers, page 34-2
- Using Clustering, page 34-3

The Routing Information Protocol, or RIP, as it is more commonly called, is one of the most enduring of all routing protocols. RIP has four basic components: routing update process, RIP routing metrics, routing stability, and routing timers. Devices that support RIP send routing-update messages at regular intervals and when the network topology changes. These RIP packets include information about the networks that the devices can reach, as well as the number of routers or gateways that a packet must travel through to reach the destination address. RIP generates more traffic than OSPF, but is easier to configure.

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcasts with neighboring devices to dynamically learn about and advertise routes.

The ASA supports both RIP Version 1 and RIP Version 2. RIP Version 1 does not send the subnet mask with the routing update. RIP Version 2 sends the subnet mask with the routing update and supports variable-length subnet masks. Additionally, RIP Version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the ASA receives reliable routing information from a trusted source.

RIP has advantages over static routes because the initial configuration is simple, and you do not need to update the configuration when the topology changes. The disadvantage to RIP is that there is more network and processing overhead than in static routing.

Routing Update Process

RIP sends routing-update messages at regular intervals and when the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP routers maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates are sent independently of the regularly scheduled updates that RIP routers send.

RIP Routing Metric

RIP uses a single routing metric (hop count) to measure the distance between the source and a destination network. Each hop in a path from source to destination is assigned a hop count value, which is typically 1. When a router receives a routing update that contains a new or changed destination network entry, the router adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop.

RIP Stability Features

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. If a router receives a routing update that contains a new or changed entry, and if increasing the metric value by 1 causes the metric to be infinity (that is, 16), the network destination is considered unreachable. The downside of this stability feature is that it limits the maximum diameter of a RIP network to less than 16 hops.

RIP includes a number of other stability features that are common to many routing protocols. These features are designed to provide stability despite potentially rapid changes in network topology. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

RIP Timers

RIP uses numerous timers to regulate its performance. These include a routing-update timer, a route-timeout timer, and a route-flush timer. The routing-update timer clocks the interval between periodic routing updates. Generally, it is set to 30 seconds, with a small random amount of time added whenever the timer is reset. This is done to help prevent congestion, which could result from all routers

simultaneously attempting to update their neighbors. Each routing table entry has a route-timeout timer associated with it. When the route-timeout timer expires, the route is marked invalid but is retained in the table until the route-flush timer expires.

Using Clustering

For information about using clustering with RIP, see the "Dynamic Routing and Clustering" section on page 30-9.

Licensing Requirements for RIP

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single context mode only.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the ASA transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

Limitations

RIP has the following limitations:

- The ASA cannot pass RIP updates between interfaces.

- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.
- You can only enable a single RIP process on the ASA.

Configuring RIP

This section describes how to enable and restart the RIP process on the ASA.

After you have enabled RIP, see the "Customizing RIP" section on page 34-5 to learn how to customize the RIP process on the ASA.

Note If you want to redistribute a route by defining which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process, you must first generate a default route. For information, see the "Configuring a Default Static Route" section on page 31-6 and then define a route map. For information, see the "Defining a Route Map" section on page 32-4.

Enabling RIP

You can only enable one RIP routing process on the ASA. After you enable the RIP routing process, you must define the interfaces that will participate in that routing process using the **network** command. By default, the ASA sends RIP Version 1 updates and accepts RIP Version 1 and Version 2 updates.

In ASDM, to enable a RIP process, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

The main RIP Setup pane appears.

From this pane, you can perform the following tasks:

- Enable Auto-summarization. See the "Configuring Route Summarization" section on page 34-8.
- Enable RIP version. See the "Configuring the RIP Version" section on page 34-5.
- Enable default information origination.
- Define an IP Address for a Network to Add. See the "Filtering Networks in RIP" section on page 34-8.
- Configure an Interface. See the "Configuring Interfaces for RIP" section on page 34-5.

Step 2 Check the **Enable RIP routing** check box.

After the Enable RIP routing box has been checked, you can enable RIP on the ASA and configure global RIP protocol parameters. You can only enable a single RIP process on the ASA. When you enable RIP, it is enabled on all interfaces. Checking this check box also enables the other fields in this pane. Uncheck this check box to disable RIP routing on the ASA.

Step 3 Click **Apply**.

Step 4 To customize the RIP process, see the "Configuring RIP" section on page 34-4.

Customizing RIP

This section describes how to configure RIP and includes the following topics:

- Configuring the RIP Version, page 34-5
- Configuring Interfaces for RIP, page 34-5
- Configuring the RIP Send and Receive Version on an Interface, page 34-7
- Configuring Route Summarization, page 34-8
- Filtering Networks in RIP, page 34-8
- Redistributing Routes into the RIP Routing Process, page 34-10
- Enabling RIP Authentication, page 34-11
- Restarting the RIP Process, page 34-12

Configuring the RIP Version

In ASDM, you can specify the version of RIP used by the ASA by performing the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box, and click **Apply**.

Step 3 Check the **Enable RIP version** check box.

Checking this check box specifies the version of RIP used by the ASA. If this check box is unchecked, then the ASA sends RIP Version 1 updates and accepts RIP Version 1 and Version 2 updates. This setting can be overridden on a per-interface basis in the Interface pane. For more information about configuring interfaces, see the "Configuring Interfaces for RIP" section on page 34-5. Indicate the version of RIP to be used by choosing one of the following:

- Version 1, which specifies that the ASA only sends and receives RIP Version 1 updates. Any Version 2 updates received are dropped.
- Version 2, which specifies that the ASA only sends and receives RIP Version 2 updates. Any Version 1 updates received are dropped.

Step 4 Click **Apply**.

Configuring Interfaces for RIP

If you have an interface that you do not want to have participate in RIP routing, but that is attached to a network that you want advertised, you can configure the network that includes the network to which the interface is attached, and configure the passive interfaces to prevent that interface from using RIP. Additionally, you can specify the version of RIP that is used by the ASA for updates.

In ASDM, you can configure an interface in RIP used by the ASA so that all interfaces on the ASA are set to passive RIP mode. The ASA listens for RIP routing broadcasts on all interfaces and uses that information to populate the routing tables but do not broadcast routing updates.

To set specific interfaces to passive RIP, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box.

Step 3 In the Passive Interfaces area, check the check box in the Passive column for those interfaces that you want to have operate in passive mode. The other interfaces will still send and receive RIP broadcasts.

Step 4 Click **Apply**.

Note Individual interfaces can be made passive only if the global passive mode is not enabled. Uncheck the **Global Passive** check box to make individual interfaces passive using the Passive Interfaces table.

You can override this setting on a per-interface basis in the Interface pane. For more information, see the "Editing a RIP Interface" section on page 34-6.

Editing a RIP Interface

In ASDM, the Interface pane allows you to configure interface-specific RIP settings, such as the version of RIP that the interface sends and receives and the authentication method, if any, that are used for the RIP broadcasts.

To edit an interface that you have previously set up and configured, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box and click **Apply**.

Step 3 Choose **Configuration > Device Setup > Routing > RIP > Interfaces**.

Step 4 Click **Add** or **Edit**.

The Add or Edit RIP Interface Entry dialog box appears and allows you to configure the interface-specific RIP settings.

Step 5 (Optional) Choose the following options according to your preferences:

- **Override Global Send Version**—Check this check box to specify the RIP version sent by the interface. Choose one of the following options:
  - Version 1
  - Version 2
  - Version 1 & 2

  Unchecking this check box restores the global setting.
- **Override Global Receive Version**—Check this check box to specify the RIP version accepted by the interface. If a RIP updated from an unsupported version of RIP is received by the interface, it is dropped. Choose one of the following options:
  - Version 1
  - Version 2
  - Version 1 & 2

  Unchecking this check box restores the global setting.

- **Enable Authentication**—Check this check box to enable RIP authentication. Uncheck this check box to disable RIP authentication. Specify the following settings:
  - Key, which is the key used by the authentication method, and can be up to 16 characters long.
  - Key ID, which is the key ID used by the authentication method. Valid values range from 0 to 255.
  - Authentication Mode—You can choose one of the following authentication modes:

    MD5 to use MD5 for RIP message authentication.

    Use clear text for RIP message authentication (not recommended).

Step 6 Click **Apply**.

Configuring the RIP Send and Receive Version on an Interface

You can override the globally-set version of RIP that the ASA uses to send and receive RIP updates on a per-interface basis.

To configure the RIP version for sending and receiving updates, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** box, and click **Apply**.

Step 3 Choose **Configuration > Device Setup > Routing > RIP > Interfaces**.

Step 4 Click **Edit**.

The Edit RIP Interface Entry dialog box appears, which allows you to configure the interface-specific RIP settings for sending and receiving.

Step 5 In the Send Version area, check the **Override global send version** check box to specify the RIP version sent by the interface. Choose one of the following:

- Version 1
- Version 2
- Version 1 & 2

  Unchecking this check box restores the global setting.

Step 6 In the Receive Version area, check the **Override global receive version** check box to specify the RIP version accepted by the interface. If a RIP updated from an unsupported version of RIP is received by the interface, it is dropped. Choose one of from the following:

- Version 1
- Version 2
- Version 1 & 2

  Unchecking this check box restores the global setting.

Step 7 Click **Apply**.

Configuring Route Summarization

Note RIP Version 1 always uses automatic route summarization. You cannot disable this feature for RIP Version 1. RIP Version 2 uses automatic route summarization by default.

The RIP routing process summarizes on network number boundaries, which can cause routing problems if you have noncontiguous networks.

For example, if you have a router with the networks 192.168.1.0, 192.168.2.0, and 192.168.3.0 connected to it, and those networks all participate in RIP, the RIP routing process creates the summary address 192.168.0.0 for those routes. If an additional router is added to the network with the networks 192.168.10.0 and 192.168.11.0, and those networks participate in RIP, they will also be summarized as 192.168.0.0. To prevent the possibility of traffic being routed to the wrong location, you should disable automatic route summarization on the routers that are creating conflicting summary addresses.

Because RIP Version 1 always uses automatic route summarization, and RIP Version 2 always uses automatic route summarization by default, when configuring automatic route summarization, you only need to disable it.

In ASDM, you can enable or disable automatic route summarization in a RIP process by performing the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box, and click **Apply**.

Step 3 Check the **Enable Auto-Summarization** check box.

Uncheck this check box to disable automatic route summarization. Check this check box to reenable automatic route summarization. RIP Version 1 always uses automatic summarization. You cannot disable automatic route summarization for RIP Version 1. If you are using RIP Version 2, you can turn off automatic route summarization by unchecking this check box. Disable automatic route summarization if you must perform routing between disconnected subnets. When automatic route summarization is disabled, subnets are advertised.

Step 4 Click **Apply**.

Filtering Networks in RIP

To filter the networks received in updates, perform the following steps:

Note Before you begin, you must create a standard access list that permits the networks that you want the RIP process to allow in the routing table and denies the networks that you want the RIP process to discard.

In ASDM, you can configure filter rules that allow you to filter the network received in RIP routing updates or sent in RIP routing updates. Each filter rule consists of one or more network rules.

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box, and click **Apply**.

Step 3 Choose **Configuration > Device Setup > Routing > RIP > Filter Rules**.

Step 4 Click **Add** or **Edit**.

The Add or Edit Filter Rule dialog box appears, which allows you to create or edit filter rules that apply to all interfaces or to a specific interface.

Step 5 From the Direction drop-down list, choose the direction in which the filter should act.

Choosing In filters networks on incoming RIP updates. Additionally, only the Interface drop-down list is visible.

If you choose Out as the filter direction, skip to Step 8.

Step 6 Choose the Interface type from the Interface drop-down list.

This setting allows you to choose a specific interface for the filter rule, or you can choose the All Interfaces option to apply the filter to all interfaces.

Step 7 (Optional) Add a network rule by clicking **Add**. Skip to the "Adding or Editing a Filter Rule" section on page 34-9.

Step 8 Choose Out to filter networks from outgoing RIP updates. Additionally, the Interface and Routing Process drop-down list becomes visible.

- Click the **Interface** radio button to choose a specific interface for the filter rule from the Interface drop-down list, or click the **All Interfaces** option to apply the filter to all interfaces.
- Click the **Routing Process** radio button to activate the Routing process drop-down list. Choose from the following routing process types:
  - connected
  - static
  - OSPF
  - RIP
  - EIGRP

Step 9 (Optional) Add a network rule by clicking **Add**. Continue to the "Adding or Editing a Filter Rule" section on page 34-9.

Adding or Editing a Filter Rule

After you have configured a filter rule (see the "Filtering Networks in RIP" section on page 34-8), you can add or edit a network rule below the selected rule in the list by performing the following steps:

Step 1 After you have selected the direction or Interface type from Step 5 or Step 8 of the previous procedure, click **Add** or **Edit** in the Filtering Networks in RIP area.

The Network Rule dialog box appears.

Step 2 Choose the action from the Action drop-down list. The default is Permit.

- Choose Permit if the specified network is not filtered from incoming or outgoing RIP advertisements.
- Choose Deny if the specified network is to be filtered from incoming or outgoing RIP advertisements.

Step 3 Enter the IP address for the network being filtered, if different than what is displayed, in the IP Address field.

By default, the IP Address field displays the IP Address for the network being filtered.

Step 4 Enter the netmask, if different than what is displayed, in the Netmask field.

By default, the Netmask field displays the network mask applied to the IP address.

Step 5 Click **OK**.

Redistributing Routes into the RIP Routing Process

You can redistribute routes from the OSPF, EIGRP, static, and connected routing processes into the RIP routing process.

Note Before you begin this procedure, you must create a route map to further define which routes from the specified routing protocol are redistributed in to the RIP routing process. See Chapter 32, "Defining a Route Map," for more information about creating a route map.

In ASDM, you can display the routes that are being redistributed from other routing processes into the RIP routing process by performing the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Redistribution**.

The Redistribution pane displays the routes that are being redistributed from other routing processes into the RIP routing process.

Step 2 Click **Add** or **Edit**.

If you clicked **Add**, the Add Route Redistribution dialog box allows you to add a new redistribution rule. If you clicked **Edit**, the Edit Route Redistribution dialog box allows you to change an existing rule.

Step 3 In the Protocol area, choose the routing protocol to redistribute into the RIP routing process:

- Static, for static routes.
- Connected, for directly connected networks.
- OSPF and OSPF ID, for routes discovered by the OSPF routing process. If you choose OSPF, you must also enter the OSPF process ID. Additionally, you can select the specific types of OSPF routes to redistribute from the Match area.
- EIGRP and EIGRP ID, for routes discovered by the EIGRP routing process. If you choose EIGRP, you must also specify the autonomous system number of the EIGRP routing process in the EIGRP ID field.

Step 4 In the Metrics area, check the **Configure Metric Type** check box to specify a metric for the redistributed routes. If not specified, the routes are assigned a default metric of 0. When the check box is checked, choose from one of the following available values:

- **Transparent** to cause the current route metric to be used.
- **Value** to assign a specific metric value. Valid values range from 0 to 16.

Step 5 In the Optional area, choose the route map from the Route Map drop-down list. This route map specifies the name of a route map that must be specified before the route can be redistributed into the RIP routing process. Click **Manage** to configure a specific route map. For more information about configuring route maps, see the "Adding or Editing a Route Map" section on page 32-4.

Step 6 In the Match area, choose specific types of OSPF routes to redistribute by checking the check box next to the route type. This area is not active unless OSPF has been chosen in the Protocol area.

If you do not check any route types, Internal, External 1, and External 2 routes are redistributed by default. The Match types are:

- Internal, in which routes internal to the AS are redistributed.
- External 1, in which Type 1 routes external to the AS are redistributed.
- External 2, in which Type 2 routes external to the AS are redistributed.
- NSSA External 1, in which Type 1 routes external to an NSSA are redistributed.
- NSSA External 2, in which Type 2 routes external to an NSSA are redistributed.

Step 7 Click **OK**.

Enabling RIP Authentication

Note The ASA supports RIP message authentication for RIP Version 2 messages.

RIP route authentication provides MD5 authentication of routing updates from the RIP routing protocol. The MD5 keyed digest in each RIP packet prevents the introduction of unauthorized or false routing messages from unapproved sources.

RIP route authentication is configured on a per-interface basis. All RIP neighbors on interfaces configured for RIP message authentication must be configured with the same authentication mode and key for adjacencies to be established.

Note Before you can enable RIP route authentication, you must enable RIP.

To enable RIP authentication on an interface, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box, and click **Apply**. If you uncheck this check box, the ASA sends RIP Version 1 updates and accepts RIP Version 1 and Version 2 updates. You can override this setting on a per-interface basis in the Interface pane. Version 1 specifies that the ASA only sends and receives RIP Version 1 updates. Any Version 2 updates received are dropped. Version 2 specifies that the ASA only sends and receives RIP Version 2 updates. Any Version 1 updates received are dropped.

Step 3 Choose **Configuration > Device Setup > Routing > RIP > Interface**.

Step 4 Click **Edit**.

The Edit RIP Interface Entry dialog box appears, which allows you to configure the interface-specific RIP settings.

Step 5 In the Authentication area, check the **Enable Authentication** check box to enable RIP authentication. Uncheck this check box to disable RIP authentication.

Step 6 In the Key field, enter the key used by the authentication method. This entry can include up to 16 characters.

Step 7 In the Key ID field, enter the key ID. Valid values range from 0 to 255.

Step 8 Choose the type of authentication mode that you want to use by clicking the radio button next to one of the following:

- **MD5** to use MD5 for RIP message authentication.
- **cleartext** to use cleartext for RIP message authentication (not recommended).

Step 9 Click **Apply**.

Restarting the RIP Process

To remove the entire RIP configuration, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Click **Reset**.

Monitoring RIP

To monitor or display various RIP routing statistics in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Monitoring > Routing > Routes**.

Step 2 From this pane, you can choose to monitor the following:

- **IPv4**
- **IPv6**
- **Both**

Configuration Example for RIP

The following example shows how to enable and configure RIP with various optional processes:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > RIP > Setup**.

Step 2 Check the **Enable RIP routing** check box and click **Apply**.

Step 3 Check the **Enable default information originate** check box.

For more information about defining a route map, see the "Defining a Route Map" section on page 32-4.

Step 4 Check the **Enable RIP version** check box and choose **Version 1**.

Step 5 In the Networks area, enter **225.25.24.225** in the IP Network to Add field.

Step 6 In the Passive Interface area, click the check box next to the interface that you want to be passive in the Passive Interfaces table.

Step 7 Click **Apply**.

Step 8 Choose **Configuration > Device Setup > Routing > RIP > Redistribution**.

Step 9 Click **Edit**.

Step 10 In the Protocol area, choose **Connected**.

Step 11 In the Metric area, check the **Configure Metric Type** check box and choose **Transparent Mode** (default).

Step 12 In the Optional area, choose a route map from the Route Map drop-down list.

Step 13 Click **Manage** to configure a specific route map. For more information about configuring route maps, see the "Adding or Editing a Route Map" section on page 32-4.

Step 14 Click **OK**.

Feature History for RIP

Table 34-1 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 34-1 Feature History for RIP

Feature Name	Releases	Feature Information
RIP support	7.0(1)	Support was added for routing data, performing authentication, and redistributing and monitoring routing information using the Routing Information Protocol (RIP). We introduced the following screen: Configuration > Device Setup > Routing > RIP.
Clustering	9.0(1)	For RIP, bulk synchronization, route synchronization, and layer 2 load balancing are supported in the clustering environment.

Configuring Multicast Routing

This chapter describes how to configure the ASA to use the multicast routing protocol and includes the following sections:

- Information About Multicast Routing, page 35-1
- Licensing Requirements for Multicast Routing, page 35-3
- Guidelines and Limitations, page 35-3
- Enabling Multicast Routing, page 35-3
- Customizing Multicast Routing, page 35-4
- Configuration Example for Multicast Routing, page 35-17
- Additional References, page 35-18
- Feature History for Multicast Routing, page 35-19

Information About Multicast Routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications that take advantage of multicast routing include videoconferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

Multicast routing protocols delivers source traffic to multiple receivers without adding any additional burden on the source or the receivers while using the least network bandwidth of any competing technology. Multicast packets are replicated in the network by Cisco routers enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols resulting in the most efficient delivery of data to multiple receivers possible.

The ASA supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single ASA.

Note The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

This section includes the following topics:

- Stub Multicast Routing, page 35-2
- PIM Multicast Routing, page 35-2

- Multicast Group Concept, page 35-2
- Clustering, page 35-2

Stub Multicast Routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing. When configured for stub multicast routing, the ASA acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the ASA forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the ASA cannot be configured for PIM.

The ASA supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees rooted at a single Rendezvous Point per multicast group and optionally creates shortest-path trees per multicast source.

PIM Multicast Routing

Bi-directional PIM is a variant of PIM-SM that builds bi-directional shared trees connecting multicast sources and receivers. Bi-directional trees are built using a DF election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point, and therefore along the shared tree to receivers, without requiring source-specific state. The DF election takes place during Rendezvous Point discovery and provides a default route to the Rendezvous Point.

Note If the ASA is the PIM RP, use the untranslated outside address of the ASA as the RP address.

Multicast Group Concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries—the hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream. For information about how to configure multicast groups, see the "Configuring a Multicast Group" section on page 35-14.

Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

Clustering

Multicast routing supports clustering. In Layer 2 clustering, the master unit sends all multicast routing packets and data packets until fast-path forwarding is established. After fast-path forwarding is established, slave units may forward multicast data packets. All data flows are full flows. Stub

forwarding flows are also supported. Because only one unit receives multicast packets in Layer 2 clustering, redirection to the master unit is common. In Layer 3 clustering, units do not act independently. All data and routing packets are processed and forwarded by the master unit. Slave units drop all packets that have been sent.

For more information about clustering, see Chapter 10, "Configuring a Cluster of ASAs."

Licensing Requirements for Multicast Routing

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single context mode. In multiple context mode, unshared interfaces and shared interfaces are not supported.

Firewall Mode Guidelines

Supported only in routed firewall mode. Transparent firewall mode is not supported.

IPv6 Guidelines

Does not support IPv6.

Additional Guidelines

In clustering, for IGMP and PIM, this feature is only supported on the master unit.

Enabling Multicast Routing

Enabling multicast routing lets you enable multicast routing on the ASA. Enabling multicast routing enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

Note Only the UDP transport layer is supported for multicast routing.

To enable multicast routing, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast**.

Step 2 In the Multicast pane, check the **Enable Multicast** routing check box.

Checking this check box enables IP multicast routing on the ASA. Unchecking this check box disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces. You can disable multicast on a per-interface basis.

Table 35-1 lists the maximum number of entries for specific multicast tables based on the amount of RAM on the ASA. Once these limits are reached, any new entries are discarded.

Table 35-1 Entry Limits for Multicast Tables

Table	16 MB	128 MB	128+ MB
MFIB	1000	3000	5000
IGMP Groups	1000	3000	5000
PIM Routes	3000	7000	12000

Customizing Multicast Routing

This section describes how to customize multicast routing and includes the following topics:

- Configuring Stub Multicast Routing and Forwarding IGMP Messages, page 35-4
- Configuring a Static Multicast Route, page 35-5
- Configuring IGMP Features, page 35-6
- Configuring PIM Features, page 35-10
- Configuring a Multicast Group, page 35-14
- Configuring a Bidirectional Neighbor Filter, page 35-15
- Configuring a Multicast Boundary, page 35-16

Configuring Stub Multicast Routing and Forwarding IGMP Messages

Note Stub multicast routing and PIM are not supported concurrently.

An ASA acting as the gateway to the stub area does not need to participate in PIM. Instead, you can configure it to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface. To configure the ASA as an IGMP proxy agent, forward the host join and leave messages from the stub area interface to an upstream interface.

To forward the host join and leave messages, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast**.

Step 2 In the Multicast pane, check the **Enable Multicast routing** check box.

Step 3 Click **Apply** to save your changes.

Step 4 Choose **Configuration > Device Setup > Routing > Multicast > IGMP > Protocol**.

Step 5 To modify the specific interface from which you want to forward IGMP messages, select the interface and click **Edit**.

The Configure IGMP Parameters dialog box appears.

Step 6 From the **Forward Interface** drop-down list, choose the specific interface from which you want to forward IGMP messages.

Step 7 Click **OK** to close this dialog box, then click **Apply** to save your changes.

Configuring a Static Multicast Route

Configuring static multicast routes lets you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the ASA expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

To configure a static multicast route or a static multicast route for a stub area, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > MRoute**.

Step 2 Choose **Add** or **Edit**.

The Add or Edit Multicast Route dialog box appears.

Use the Add Multicast Route dialog box to add a new static multicast route to the ASA. Use the Edit Multicast Route dialog box to change an existing static multicast route.

Step 3 In the Source Address field, enter the IP address of the multicast source. You cannot change this value when editing an existing static multicast route.

Step 4 Choose the network mask for the IP address of the multicast source from the Source Mask drop-down list.

Step 5 In the Incoming Interface area, click either the **RPF Interface** radio button to choose RPF to forward the route or the **Interface Name** radio button, then enter the following:

- In the Source Interface field, choose the incoming interface for the multicast route from the drop-down list.
- In the Destination Interface field, choose the destination interface that the route is forwarded through from the drop-down list.

Note You can specify the interface or the RPF neighbor, but not both at the same time.

Step 6 In the Administrative Distance field, choose the administrative distance of the static multicast route. If the static multicast route has the same administrative distance as the unicast route, then the static multicast route takes precedence.

Step 7 Click **OK**.

Configuring IGMP Features

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly connected multicast routers.

IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

When you enable multicast routing on the ASA, IGMP Version 2 is automatically enabled on all interfaces.

Note Only the **no igmp** command appears in the interface configuration when you use the **show run** command. If the **multicast-routing** command appears in the device configuration, then IGMP is automatically enabled on all interfaces.

This section describes how to configure optional IGMP setting on a per-interface basis and includes the following topics:

- Disabling IGMP on an Interface, page 35-6
- Configuring IGMP Group Membership, page 35-7
- Configuring a Statically Joined IGMP Group, page 35-7
- Controlling Access to Multicast Groups, page 35-8
- Limiting the Number of IGMP States on an Interface, page 35-9
- Modifying the Query Messages to Multicast Groups, page 35-9
- Changing the IGMP Version, page 35-10

Disabling IGMP on an Interface

You can disable IGMP on specific interfaces. This information is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the ASA from sending host query messages on that interface.

To disable IGMP on an interface, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Protocol**.

The Protocol pane displays the IGMP parameters for each interface on the ASA.

Step 2 Choose the interface that you want to disable and click **Edit**.

Step 3 To disable the specified interface, uncheck the **Enable IGMP** check box.

Step 4 Click **OK**.

The Protocol pane displays Yes if IGMP is enabled on the interface, or No if IGMP is disabled on the interface.

Configuring IGMP Group Membership

You can configure the ASA to be a member of a multicast group. Configuring the ASA to join a multicast group causes upstream routers to maintain multicast routing table information for that group and keep the paths for that group active.

Note If you want to forward multicast packets for a specific group to an interface without the ASA accepting those packets as part of the group, see the "Configuring a Statically Joined IGMP Group" section on page 35-7.

To have the ASA join a multicast group, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Join Group**.

The Join Group pane appears.

Step 2 Click **Add** or **Edit**.

The Add IGMP Join Group dialog box allows you to configure an interface to be a member of a multicast group. The Edit IGMP Join Group dialog box allows you to change existing membership information.

Step 3 In the Interface Name field, choose the interface name from the drop-down list. If you are editing an existing entry, you cannot change this value.

Step 4 In the Multicast Group Address field, enter the address of a multicast group to which the interface belongs. Valid group addresses range from 224.0.0.0 to 239.255.255.255.

Step 5 Click **OK**.

Configuring a Statically Joined IGMP Group

Sometimes a group member cannot report its membership in the group because of some configuration, or there may be no members of a group on the network segment. However, you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group.

In the main ASDM window, choose **Configuration > Routing > Multicast > IGMP > Static Group** to configure the ASA to be a statically connected member of a group. With this method, the ASA does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

To configure a statically joined multicast group on an interface, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Static Group**.

The Static Group pane appears.

Step 2 Click **Add** or **Edit**.

Use the Add IGMP Static Group dialog box to statically assign a multicast group to an interface. Use the Edit IGMP Static Group dialog box to change existing static group assignments.

Step 3 In the Interface Name field, choose the interface name from the drop-down list. If you are editing an existing entry, you cannot change this value.

Step 4 In the Multicast Group Address field, enter the address of a multicast group to which the interface belongs. Valid group addresses range from 224.0.0.0 to 239.255.255.255.

Step 5 Click **OK**.

Controlling Access to Multicast Groups

To control the multicast groups that hosts on the ASA interface can join, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Access Group**.

The Access Group pane appears. The table entries in the Access Group pane are processed from the top down. Place more specific entries near the top of the table and more generic entries further down. For example, place an access group entry that permits a specific multicast group near the top of the table and an access group entry below that denies a range of multicast groups, including the group in the permit rule. The group is permitted because the permit rule is enforced before the deny rule.

Double-clicking an entry in the table opens the Add or Edit Access Group dialog box for the selected entry.

Step 2 Click **Add** or **Edit**.

The Add Access Group or Edit Access Group dialog box appears. The Add Access Group dialog box lets you add a new access group to the Access Group Table. The Edit Access Group dialog box lets you change information for an existing access group entry. Some fields may be dimmed when editing existing entries.

Step 3 Choose the interface name with which the access group is associated from the Interface drop-down list. You cannot change the associated interface when you are editing an existing access group.

Step 4 Choose permit from the Action drop-down list to allow the multicast group on the selected interface. Choose deny from the Action drop-down list to filter the multicast group from the selected interface.

Step 5 In the Multicast Group Address field, enter the address of the multicast group to which the access group applies.

Step 6 Enter the network mask for the multicast group address, or choose one of the common network masks from the Netmask drop-down list.

Step 7 Click **OK**.

Limiting the Number of IGMP States on an Interface

You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports exceeding the configured limits are not entered in the IGMP cache, and traffic for the excess membership reports is not forwarded.

To limit the number of IGMP states on an interface, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Protocol**.

Step 2 Choose the interface you want to limit from the table on the Protocol pane, and click **Edit**.

The Configure IGMP Parameters dialog box appears.

Step 3 In the Group Limit field, enter the maximum number of host that can join on an interface. Valid values range from 0 to 500. The default value is 500. Setting this value to 0 prevents learned groups from being added, but manually defined memberships are still permitted.

Step 4 Click **OK**.

Modifying the Query Messages to Multicast Groups

The ASA sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the ASA. If the ASA discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packet for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the ASA does not receive a response to a host query within this amount of time, it deletes the group.

To change the query interval, query response time, and query timeout value, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Protocol**.

Step 2 Choose the interface you want to limit from the table on the Protocol pane, and click **Edit**.

The Configure IGMP Parameters dialog box appears.

Step 3 In the Query Interval field, enter the interval, in seconds, at which the designated router sends IGMP host-query messages. Valid values range from 1 to 3600 seconds. The default value is 125 seconds.

```
If the ASA does not hear a query message on an interface for the specified timeout value,
then the ASA becomes the designated router and starts sending the query messages.
```

Step 4 In the Query Timeout field, enter the period of time, in seconds, before which the ASA takes over as the requester for the interface after the previous requester has stopped doing so. Valid values range from 60 to 300 seconds. The default value is 255 seconds.

Step 5 Click **OK**.

Changing the IGMP Version

By default, the ASA runs IGMP Version 2, which enables several additional features.

All multicast routers on a subnet must support the same version of IGMP. The ASA does not automatically detect Version 1 routers and switch to Version 1. However, a mix of IGMP Version 1 and 2 hosts on the subnet works; the ASA running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

To control which version of IGMP is running on an interface,perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Protocol**.

Step 2 Choose the interface whose version of IGMP you want to change from the table on the Protocol pane, and click **Edit**.

The Configure IGMP Interface dialog box appears.

Step 3 Choose the version number from the Version drop-down list.

Step 4 Click **OK**.

Configuring PIM Features

Routers use PIM to maintain forwarding tables for forwarding multicast diagrams. When you enable multicast routing on the ASA, PIM and IGMP are automatically enabled on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

This section describes how to configure optional PIM settings and includes the following topics:

- Enabling and Disabling PIM on an Interface, page 35-10
- Configuring a Static Rendezvous Point Address, page 35-11
- Configuring the Designated Router Priority, page 35-12
- Configuring and Filtering PIM Register Messages, page 35-12
- Configuring PIM Message Intervals, page 35-13
- Configuring a Route Tree, page 35-13
- Filtering PIM Neighbors, page 35-14

Enabling and Disabling PIM on an Interface

You can enable or disable PIM on specific interfaces. To enable or disable PIM on an interface, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Protocol**.

Step 2 Choose the interface on which you want to enable PIM from the table on the Protocol pane, and click **Edit**.

The Edit PIM Protocol dialog box appears.

Step 3 Check the **Enable PIM** check box. To disable PIM, uncheck this check box.

Step 4 Click **OK**.

Configuring a Static Rendezvous Point Address

All routers within a common PIM sparse mode or bidir domain require knowledge of the PIM RP address. The address is statically configured using the **pim rp-address** command.

Note The ASA does not support Auto-RP or PIM BSR

You can configure the ASA to serve as RP to more than one group. The group range specified in the access list determines the PIM RP group mapping. If an access list is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4).

To configure the address of the PIM PR, perform the following steps:

Note The ASA always advertises the bidirectional capability in the PIM hello messages, regardless of the actual bidirectional configuration.

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Rendezvous Points**.

Step 2 Click **Add** or **Edit**.

The Add or Edit Rendezvous Point dialog box appears. The Add Rendezvous Point dialog box lets you add a new entry to the Rendezvous Point table. The Edit Rendezvous Point dialog box lets you change an existing RP entry. Additionally, you can click **Delete** to remove the selected multicast group entry from the table.

These restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify All Groups for more than one RP.

Step 3 In the Rendezvous Point Address field, enter the IP address for the RP.

When editing an existing RP entry, you cannot change this value.

Step 4 Check the **Use bi-directional forwarding** check box if the specified multicast groups are to operate in bidirectional mode. The Rendezvous Point pane displays Yes if the specified multicast groups are to operate in bidirectional mode and displays No if the specified groups are to operate in sparse mode. In bidirectional mode, if the ASA receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.

Step 5 Click the **Use this RP for All Multicast Groups** radio button to use the specified RP for all multicast groups on the interface, or the **Use this RP for the Multicast Groups as specified below** radio button to designate the multicast groups to use with the specified RP.

For more information about multicast groups, see the "Configuring a Multicast Group" section on page 35-14.

Step 6 Click **OK**.

Configuring the Designated Router Priority

The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, selecting the DR is based on the DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR.

By default, the ASA has a DR priority of 1. To change this value, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Protocol**.

Step 2 Choose the interface that you want to enable for PIM from the table on the Protocol pane, and click **Edit**.

The Edit PIM Protocol dialog box appears.

Step 3 In the DR Priority field, type the value for the designated router priority for the selected interface. The router with the highest DR priority on the subnet becomes the designated router. Valid values range from 0 to 4294967294. The default DR priority is 1. Setting this value to 0 makes the ASA interface ineligible to become the default router.

Step 4 Click **OK**.

Configuring and Filtering PIM Register Messages

When the ASA is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. The Request Filter pane lets you define the multicast sources from which the ASA will accept PIM register messages.

To filter PIM register messages, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Request Filter**.

Step 2 Click **Add**.

The Request Filter Entry dialog box lets you define the multicast sources that are allowed to register with the ASA when the ASA acts as an RP. You create the filter rules based on the source IP address and the destination multicast address.

Step 3 From the Action drop-down list, choose Permit to create a rule that allows the specified source of the specified multicast traffic to register with the ASA, or choose Deny to create a rule that prevents the specified source of the specified multicast traffic from registering with the ASA.

Step 4 In the Source IP Address field, type the IP address for the source of the register message.

Step 5 In the Source Netmask field, type or choose the network mask from the drop-down list for the source of the register message.

Step 6 In the Destination IP Address field, type the multicast destination address.

Step 7 In the Destination Netmask field, type or choose the network mask from the drop-down list for the multicast destination address.

Step 8 Click **OK**.

Configuring PIM Message Intervals

Router query messages are used to select the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the ASA sends PIM join or prune messages.

To change these intervals, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Protocol**.

Step 2 Choose the interface that you want to enable for PIM from the table on the Protocol pane, and click **Edit**.

The Edit PIM Protocol dialog box appears.

Step 3 In the Hello Interval field, type the frequency, in seconds, at which the interface sends PIM hello messages.

Step 4 In the Prune Interval field, type the frequency, in seconds, at which the interface sends PIM join and prune advertisements.

Step 5 Click **OK**.

Configuring a Route Tree

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the ASA should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

To configure a PIM leaf router tree, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Route Tree**.

Step 2 Click one of the following radio buttons:

- **Use Shortest Path Tree for All Groups**—Choose this option to use the shortest-path tree for all multicast groups.
- **Use Shared Tree for All Groups**—Choose this option to use the shared tree for all multicast groups.
- **Use Shared Tree for the Groups specified below**—Choose this option to use the shared tree for the groups specified in the Multicast Groups table. The shortest-path tree is used for any group that is not specified in the Multicast Groups table.

The Multicast Groups table displays the multicast groups to use with the shared tree.

The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

To edit a multicast group, see the "Configuring a Multicast Group" section on page 35-14.

Configuring a Multicast Group

Multicast groups are lists of access rules that define which multicast addresses are part of a group. A multicast group can include a single multicast address or a range of multicast addresses. Use the Add Multicast Group dialog box to create a new multicast group rule. Use the Edit Multicast Group dialog box to modify an existing multicast group rule.

To configure a multicast group, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Rendezvous Points**.

Step 2 The Rendezvous Point pane appears. Click the group that you want to configure.

The Edit Rendezvous Point dialog box appears.

Step 3 Click the **Use this RP for the Multicast Groups as specified below** radio button to designate the multicast groups to use with the specified RP.

Step 4 Click **Add** or **Edit**.

The Add or Edit Multicast Group dialog box appears.

Step 5 From the Action drop-down list, choose Permit to create a group rule that allows the specified multicast addresses, or choose Deny to create a group rule that filters the specified multicast addresses.

Step 6 In the Multicast Group Address field, type the multicast address associated with the group.

Step 7 From the Netmask drop-down list, choose the network mask for the multicast group address.

Step 8 Click **OK**.

Filtering PIM Neighbors

You can define the routers that can become PIM neighbors. By filtering the routers that can become PIM neighbors, you can do the following:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

To define neighbors that can become a PIM neighbor, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Neighbor Filter**.

Step 2 Choose the PIM neighbor that you want to configure from the table by clicking **Add/Edit/Insert**.

The Add/Edit/Insert Neighbor Filter Entry dialog box appears. The Add/Edit/Insert Neighbor Filter Entry dialog box lets you create the ACL entries for the multicast boundary ACL. You can also delete a selected PIM neighbor entry.

Step 3 Choose the interface name from the Interface Name drop-down list.

Step 4 From the Action drop-down list, choose Permit or Deny for the neighbor filter ACL entry.

Choosing Permit allows the multicast group advertisements to pass through the interface. Choosing Deny prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

Step 5 In the IP Address text field, enter the IP address of the multicast PIM group being permitted or denied. Valid group addresses range from 224.0.0.0 to 239.255.255.255.

Step 6 From the Netmask drop-down list, choose the netmask for the multicast group address.

Step 7 Click **OK**.

Configuring a Bidirectional Neighbor Filter

The Bidirectional Neighbor Filter pane shows the PIM bidirectional neighbor filters, if any, that are configured on the ASA. A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the DF election. If a PIM bidirectional neighbor filter is not configured for an interface, then there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in the DF election process.

When a PIM bidirectional neighbor filter configuration is applied to the ASA, an ACL appears in the running configuration with the name *interface-name*_multicast, in which the *interface-name* is the name of the interface to which the multicast boundary filter is applied. If an ACL with that name already exists, a number is appended to the name (for example, inside_multicast_1). This ACL defines which devices can become PIM neighbors of the ASA.

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled for bidir to elect a DF.

The PIM bidirectional neighbor filters enable the transition from a sparse-mode-only network to a bidir network by letting you specify the routers that should participate in the DF election, while still allowing all routers to participate in the sparse-mode domain. The bidir-enabled routers can elect a DF from among themselves, even when there are non-bidir routers on the segment. Multicast boundaries on the non-bidir routers prevent PIM messages and data from the bidir groups from leaking in or out of the bidir subset cloud.

When a PIM bidirectional neighbor filter is enabled, the routers that are permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidir, then the DF election does not occur.
- If a denied neighbor supports bidir, then the DF election does not occur.
- If a denied neighbor does not support bidir, the DF election can occur.

To define the neighbors that can become a PIM bidirectional neighbor filter, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > PIM > Bidirectional Neighbor Filter**.

Step 2 Double-click an entry in the PIM Bidirectional Neighbor Filter table to open the Edit Bidirectional Neighbor Filter Entry dialog box for that entry.

Step 3 Choose the PIM neighbor that you want to configure from the table by clicking **Add/Edit/Insert**.

The Add/Edit/Insert Bidirectional Neighbor Filter Entry dialog box appears, which lets you create ACL entries for the PIM bidirectional neighbor filter ACL

Step 4 Choose the interface name from the Interface Name drop-down list. Select the interface for which you are configuring the PIM bidirectional neighbor filter ACL entry.

Step 5 From the Action drop-down list, choose Permit or Deny for the neighbor filter ACL entry.

Choose Permit to allow the specified devices to participate in the DF election process. Choose Deny to prevent the specified devices from participating in the DF election process.

Step 6 In the IP Address text field, enter the IP address of the multicast PIM group being permitted or denied. Valid group addresses range from 224.0.0.0 to 239.255.255.255.

Step 7 From the Netmask drop-down list, choose the netmask for the multicast group address.

Step 8 Click **OK**.

Configuring a Multicast Boundary

Address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary on an interface for multicast group addresses by choosing **Configuration > Routing > Multicast > MBoundary** in ASDM. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

A standard ACL defines the range of affected addresses. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

To configure a multicast boundary, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Routing > Multicast > MBoundary**.

The MBoundary pane lets you configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.

Step 2 Click **Edit**.

The Edit Boundary Filter dialog box appears and displays the multicast boundary filter ACL. You can add and remove boundary filter ACL entries using this dialog box.

When the boundary filter configuration is applied to the ASA, the ACL appears in the running configuration with the name *interface-name*_multicast, where the *interface-name* is the name of the interface to which the multicast boundary filter is applied. If an ACL with that name already exists, a number is appended to the name (for example, inside_multicast_1).

Step 3 Choose the interface for which you are configuring the multicast boundary filter ACL from the Interface drop-down list.

Step 4 Check the **Remove any Auto-RP group range** check box to filter Auto-RP messages from sources denied by the boundary ACL. If the **Remove any Auto-RP group range** check box is unchecked, all Auto-RP messages are passed.

Step 5 Click **OK**.

Configuration Example for Multicast Routing

The following example shows how to enable and configure multicast routing with various optional processes:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast**.

Step 2 In the Multicast pane, check the **Enable Multicast** routing check box, and click **Apply**.

Step 3 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > MRoute**.

Step 4 Click **Add** or **Edit**.

The Add or Edit Multicast Route dialog box appears.

Use the Add Multicast Route dialog box to add a new static multicast route to the ASA. Use the Edit Multicast Route dialog box to change an existing static multicast route.

Step 5 In the Source Address field, enter the IP address of the multicast source. You cannot change this value when editing an existing static multicast route.

Step 6 Choose the network mask for the IP address of the multicast source from the Source Mask drop-down list.

Step 7 In the Incoming Interface area, click either the **RPF Interface** radio button to choose RPF to forward the route or the **Interface Name** radio button, then enter the following:

- In the Source Interface field, choose the incoming interface for the multicast route from the drop-down list.
- In the Destination Interface field, choose the destination interface to which the route is forwarded through the selected interface from the drop-down list.

Note You can specify the interface or the RPF neighbor, but not both at the same time.

Step 8 In the Administrative Distance field, choose the administrative distance of the static multicast route. If the static multicast route has the same administrative distance as the unicast route, then the static multicast route takes precedence.

Step 9 Click **OK**.

Step 10 In the main ASDM window, choose **Configuration > Device Setup > Routing > Multicast > IGMP > Join Group**.

The Join Group pane appears.

Step 11 Click **Add** or **Edit**.

The Add IGMP Join Group dialog box allows you to configure an interface to be a member of a multicast group. The Edit IGMP Join Group dialog box allows you to change existing membership information.

Step 12 In the Interface Name field, choose the interface name from the drop-down list. If you are editing an existing entry, you cannot change this value.

Step 13 In the Multicast Group Address field, enter the address of a multicast group to which the interface belongs. Valid group addresses range from 224.0.0.0 to 239.255.255.255.

Step 14 Click **OK**.

Feature History for Multicast Routing

Table 35-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 35-2 Feature History for Multicast Routing

Feature Name	Platform Releases	Feature Information
Multicast routing support	7.0(1)	Support was added for multicast routing data, authentication, and redistribution and monitoring of routing information using the multicast routing protocol. We introduced the following screen: Configuration > Device Setup > Routing > Multicast.
Clustering support	9.0(1)	Support was added for clustering.

Configuring EIGRP

This chapter describes how to configure the ASA to route data, perform authentication, and redistribute routing information using the Enhanced Interior Gateway Routing Protocol (EIGRP).

This chapter includes the following sections:

- Information About EIGRP, page 36-1
- Licensing Requirements for EIGRP, page 36-2
- Guidelines and Limitations, page 36-3
- Task List to Configure an EIGRP Process, page 36-3
- Configuring EIGRP, page 36-4
- Customizing EIGRP, page 36-6
- Monitoring EIGRP, page 36-18
- Feature History for EIGRP, page 36-19

Information About EIGRP

EIGRP is an enhanced version of IGRP developed by Cisco. Unlike IGRP and RIP, EIGRP does not send out periodic route updates. EIGRP updates are sent out only when the network topology changes. Key capabilities that distinguish EIGRP from other routing protocols include fast convergence, support for variable-length subnet mask, support for partial updates, and support for multiple network layer protocols.

A router running EIGRP stores all the neighbor routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries propagate until an alternate route is found. Its support for variable-length subnet masks permits routes to be automatically summarized on a network number boundary. In addition, EIGRP can be configured to summarize on any bit boundary at any interface. EIGRP does not make periodic updates. Instead, it sends partial updates only when the metric for a route changes. Propagation of partial updates is automatically bounded so that only those routers that need the information are updated. As a result of these two capabilities, EIGRP consumes significantly less bandwidth than IGRP.

Neighbor discovery is the process that the ASA uses to dynamically learn of other routers on directly attached networks. EIGRP routers send out multicast hello packets to announce their presence on the network. When the ASA receives a hello packet from a new neighbor, it sends its topology table to the neighbor with an initialization bit set. When the neighbor receives the topology update with the initialization bit set, the neighbor sends its topology table back to the ASA.

The hello packets are sent out as multicast messages. No response is expected to a hello message. The exception to this is for statically defined neighbors. If you use the **neighbor** command, or configure the Hello Interval in ASDM, to configure a neighbor, the hello messages sent to that neighbor are sent as unicast messages. Routing updates and acknowledgements are sent out as unicast messages.

Once this neighbor relationship is established, routing updates are not exchanged unless there is a change in the network topology. The neighbor relationship is maintained through the hello packets. Each hello packet received from a neighbor includes a hold time. This is the time in which the ASA can expect to receive a hello packet from that neighbor. If the ASA does not receive a hello packet from that neighbor within the hold time advertised by that neighbor, the ASA considers that neighbor to be unavailable.

The EIGRP protocol uses four key algorithm technologies, four key technologies, including neighbor discovery/recovery, Reliable Transport Protocol (RTP), and DUAL, which is important for route computations. DUAL saves all routes to a destination in the topology table, not just the least-cost route. The least-cost route is inserted into the routing table. The other routes remain in the topology table. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router used for packet forwarding that has a least-cost path to a destination. The feasibility calculation guarantees that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation must occur. During route recomputation, DUAL queries the EIGRP neighbors for a route, who in turn query their neighbors. Routers that do no have a feasible successor for the route return an unreachable message.

During route recomputation, DUAL marks the route as active. By default, the ASA waits for three minutes to receive a response from its neighbors. If the ASA does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasibility successor are removed.

Note EIGRP neighbor relationships are not supported through the IPsec tunnel without a GRE tunnel.

Using Clustering

For information about using clustering with EIGRP, see the "Dynamic Routing and Clustering" section on page 30-9.

Licensing Requirements for EIGRP

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported only in routed firewall mode. Transparent firewall mode is not supported.

Failover Guidelines

Supports Stateful Failover in single and multiple context mode.

IPv6 Guidelines

Does not support IPv6.

Clustering Guidelines

- Supports Layer 2 and Layer 3 clustering when configured to use both EIGRP and OSPFv2.
- In a Layer 3 cluster setup, EIGRP adjacencies can only be established between two contexts on a shared interface on the master unit. You can manually configure multiple neighbor statements corresponding to each cluster node separately to work around this issue.

Additional Guidelines

EIGRP instances cannot form adjacencies with each other across shared interfaces because inter-context exchange of multicast traffic is not supported.

Task List to Configure an EIGRP Process

To configure EIGRP routing on the ASA, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP**.

Step 2 Enable the EIGRP routing process by checking the **Enable this EIGRP process** check box on the Process Instances tab. See the "Enabling EIGRP" section on page 36-4 or the "Enabling EIGRP Stub Routing" section on page 36-5.

Step 3 Define the networks and interfaces that will participate in EIGRP routing on the Setup > Networks tab. See the "Defining a Network for an EIGRP Routing Process" section on page 36-7 for more information.

Step 4 (Optional) Define route filters on the Filter Rules pane. Route filtering provides more control over the routes that are allowed to be sent or received in EIGRP updates. See the "Filtering Networks in EIGRP" section on page 36-13 for more information.

Step 5 (Optional) Define route redistribution in the Redistribution pane.

You can redistribute routes discovered by RIP and OSPF to the EIGRP routing process. You can also redistribute static and connected routes to the EIGRP routing process. See the "Redistributing Routes Into EIGRP" section on page 36-12 for more information.

Step 6 (Optional) Define static EIGRP neighbors on the Static Neighbor pane.

See the "Defining an EIGRP Neighbor" section on page 36-11 for more information.

Step 7 (Optional) Define summary addresses on the Summary Address pane.

See the "Configuring the Summary Aggregate Addresses on Interfaces" section on page 36-9 for more information about defining summary addresses.

Step 8 (Optional) Define interface-specific EIGRP parameters on the Interfaces pane. These parameters include EIGRP message authentication, hold time, hello interval, delay metric, and the use of split-horizon. See the "Configuring Interfaces for EIGRP" section on page 36-7 for more information.

Step 9 (Optional) Control the sending and receiving of default route information in EIGRP updates on the Default Information pane. By default, default routes are sent and accepted. See the "Configuring Default Information in EIGRP" section on page 36-16 for more information.

Configuring EIGRP

This section describes how to enable the EIGRP process on your system. After you have enabled EIGRP, see the following sections to learn how to customize the EIGRP process on your system.

- Enabling EIGRP, page 36-4
- Enabling EIGRP Stub Routing, page 36-5

Enabling EIGRP

You can only enable one EIGRP routing process on the ASA.

To enable EIGRP,perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

The three tabs on the main EIGRP Setup pane used to enable EIGRP are as follows:

- The Process Instances tab lets you enable an EIGRP routing process for each context. Single context mode and multiple context mode are both supported. See the "Enabling EIGRP" section on page 36-4 and the "Enabling EIGRP Stub Routing" section on page 36-5 for more information.
- The Networks tab lets you specify the networks used by the EIGRP routing process. For an interface to participate in EIGRP routing, it must fall within the range of addresses defined by the network entries. For directly connected and static networks to be advertised, they must also fall within the range of the network entries. See the "Defining a Network for an EIGRP Routing Process" section on page 36-7 for more information.
- The Passive Interfaces tab lets you configure one or more interfaces as passive interfaces. In EIGRP, a passive interface does not send or receive routing updates.The Passive Interface table lists each interface that is configured as a passive interface.

Step 2 Check the **Enable this EIGRP process** check box.

You can only enable one EIGRP routing process on the device. You must enter an autonomous system number (AS) for the routing process in the EIGRP Process field before you can save your changes.

Step 3 In the EIGRP Process field, enter the autonomous system (AS) number for the EIGRP process. The AS number can be from 1 to 65535.

Step 4 (Optional) Click **Advanced** to configure the EIGRP process settings, such as the router ID, default metrics, stub routing, neighbor changes, and the administrative distances for the EIGRP routes.

Step 5 Click the **Networks** tab.

Step 6 To add a new network entry, click **Add**.

The Add EIGRP Network dialog box appears. To remove a network entry, choose an entry in the table and click **Delete**.

Step 7 Choose the AS number of the EIGRP routing process from the drop-down list.

Step 8 Enter the IP address of the networks to participate in the EIGRP routing process in the IP Address field.

Note To change a network entry, you must first remove the entry and then add a new one. You cannot edit existing entries.

Step 9 Enter a network mask to apply to the IP address in the Network Mask field.

Step 10 Click **OK**.

Enabling EIGRP Stub Routing

You can enable, and configure the ASA as an EIGRP stub router. Stub routing decreases memory and processing requirements on the ASA. As a stub router, the ASA does not need to maintain a complete EIGRP routing table because it forwards all nonlocal traffic to a distribution router. Generally, the distribution router need not send anything more than a default route to the stub router.

Only specified routes are propagated from the stub router to the distribution router. As a stub router, the ASA responds to all queries for summaries, connected routes, redistributed static routes, external routes, and internal routes with the message “inaccessible.” When the ASA is configured as a stub, it sends a special peer information packet to all neighboring routers to report its status as a stub router. Any neighbor that receives a packet informing it of the stub status will not query the stub router for any routes, and a router that has a stub peer will not query that peer. The stub router depends on the distribution router to send the correct updates to all peers.

To enable the ASA as an EIGRP stub routing process, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the EIGRP Process field, enter the autonomous system (AS) number for the EIGRP process. The AS number can be from 1 to 65535.

Step 4 Click **Advanced** to configure the EIGRP stub routing process.

The Edit EIGRP Process Advanced Properties dialog box appears.

Step 5 In the Stub area on the Edit EIGRP Process Advanced Properties dialog box, choose one or more of the following EIGRP stub routing processes:

- Stub Receive only—Configures the EIGRP stub routing process to receive route information from the neighbor routers but does not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options.

- Stub Connected—Advertises connected routes.
- Stub Static—Advertises static routes.
- Stub Redistributed—Advertises redistributed routes.
- Stub Summary—Advertises summary routes.

Step 6 Click **OK**.

Step 7 Click the **Networks** tab.

Step 8 Click **Add** to add a new network entry.

The Add EIGRP Network dialog box appears. To remove a network entry, choose the entry in the table and click **Delete**.

Step 9 Choose the AS number of the EIGRP routing process from the drop-down list.

Step 10 Enter the IP address of the networks to participate in the EIGRP routing process in the IP Address field.

Note To change a network entry, you must first remove the entry and then add a new one. You cannot edit existing entries.

Step 11 Enter a network mask to apply to the IP address in the Network Mask field.

Step 12 Click **OK**.

Customizing EIGRP

This section describes how to customize the EIGRP routing and includes the following topics:

- Defining a Network for an EIGRP Routing Process, page 36-7
- Configuring Interfaces for EIGRP, page 36-7
- Configuring the Summary Aggregate Addresses on Interfaces, page 36-9
- Changing the Interface Delay Value, page 36-10
- Enabling EIGRP Authentication on an Interface, page 36-10
- Defining an EIGRP Neighbor, page 36-11
- Redistributing Routes Into EIGRP, page 36-12
- Filtering Networks in EIGRP, page 36-13
- Customizing the EIGRP Hello Interval and Hold Time, page 36-14
- Disabling Automatic Route Summarization, page 36-15
- Configuring Default Information in EIGRP, page 36-16
- Disabling EIGRP Split Horizon, page 36-17
- Restarting the EIGRP Process, page 36-17

Defining a Network for an EIGRP Routing Process

The Network table lets you specify the networks used by the EIGRP routing process. For an interface to participate in EIGRP routing, it must fall within the range of addresses defined by the network entries. For directly connected and static networks to be advertised, they must also fall within the range of the network entries.

The Network table displays the networks configured for the EIGRP routing process. Each row of the table displays the network address and associated mask configured for the specified EIGRP routing process.

To add or define a network, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the EIGRP Process field, enter the autonomous system (AS) number for the EIGRP process. The AS number can be from 1 to 65535.

Step 4 Click the **Networks** tab.

Step 5 Click **Add** to add a new network entry.

The Add EIGRP Network dialog box appears. To remove a network entry, choose the entry in the table and click **Delete**.

Step 6 Choose the AS number of the EIGRP routing process from the drop-down list.

Step 7 Enter the IP address of the networks to participate in the EIGRP routing process in the IP Address field.

Note To change a network entry, you must first remove the entry and then add a new one. You cannot edit existing entries.

Step 8 Enter a network mask to apply to the IP address in the Network Mask field.

Step 9 Click **OK**.

Configuring Interfaces for EIGRP

If you have an interface that you do not want to have participate in EIGRP routing, but that is attached to a network that you want advertised, you can configure the ASA that includes the network to which the interface is attached, and prevent that interface from sending or receiving EIGRP updates.

To configure interfaces for EIGRP, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 Click **OK**.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane appears and displays the EIGRP interface configurations. The Interface Parameters table displays all of the interfaces on the ASA and lets you modify the following settings on a per-interface basis:

- Authentication key and mode.
- The EIGRP hello interval and hold time.
- The interface delay metric used in EIGRP metric calculations.
- The use of split-horizon on the interface.

Step 5 Choose an interface entry by double-clicking an interface entry, or choose the entry and click **Edit**.

The Edit EIGRP Interface Entry dialog box appears.

Step 6 In the EIGRP Process field, enter the AS number for the EIGRP process. The AS number can range from 1 to 65535.

Step 7 In the Hello Interval field, enter the interval between EIGRP hello packets sent on an interface.

Valid values range from 1 to 65535 seconds. The default value is 5 seconds.

Step 8 In the Hold Time field, enter the hold time, in seconds. Valid values range from 1 to 65535 seconds. The default value is 15 seconds.

Step 9 Check the **Enable** check box for Split Horizon.

Step 10 In the Delay field, enter the delay value. The delay time is in tens of microseconds. Valid values range from 1 to 16777215.

Step 11 Check the **Enable MD5 Authentication** check box to enable MD5 authentication of EIGRP process messages.

Step 12 Enter the Key or Key ID values.

- In the Key field, enter the key to authenticate EIGRP updates. The key can contain up to 16 characters.
- In the Key ID field, enter the key identification value. Valid values range from 1 to 255.

Step 13 Click **OK**.

Configuring Passive Interfaces

You can configure one or more interfaces as passive interfaces. In EIGRP, a passive interface does not send or receive routing updates.

To configure passive interfaces, perform the following steps:

Note In ASDM, the Passive Interface table lists each interface that is configured as a passive interface.

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 Click **OK**.

Step 4 Click the **Passive Interfaces** tab.

Step 5 Choose the interface that you want to configure from the drop-down list.

Step 6 Check the **Suppress routing updates on all interfaces** check box to specify all interfaces as passive. Even if an interface is not shown in the Passive Interface table, it will be configured as passive when the check box is checked.

Step 7 Click **Add** to add a passive interface entry.

The Add EIGRP Passive Interface dialog box appears. Choose the interface that you want to make passive and click **Add**. To remove a passive interface, choose the interface in the table and click **Delete**.

Step 8 Click **OK**.

Configuring the Summary Aggregate Addresses on Interfaces

You can configure a summary addresses on a per-interface basis. You need to manually define summary addresses if you want to create summary addresses that do not occur at a network number boundary or if you want to use summary addresses on an ASA with automatic route summarization disabled. If any more specific routes are in the routing table, EIGRP will advertise the summary address out the interface with a metric equal to the minimum of all more specific routes.

To create a summary address, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane shows the EIGRP interface configurations. The Interface Parameters table shows all of the interfaces on the ASA and lets you modify the settings on a per-interface basis. For more information about these settings, see the "Configuring Interfaces for EIGRP" section on page 36-7.

Step 2 To configure the EIGRP parameters for an interface, double-click an interface entry or select the entry and click **Edit**.

Step 3 Click **OK**.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Summary Address**.

The Summary Address pane displays a table of the statically-defined EIGRP summary addresses. By default, EIGRP summarizes subnet routes to the network level. You can create statically defined EIGRP summary addresses to the subnet level from the Summary Address pane.

Step 5 Click **Add** to add a new EIGRP summary address, or to click **Edit** to edit an existing EIGRP summary address in the table.

The Add Summary Address or Edit Summary Address dialog box appears. You can also double-click an entry in the table to edit that entry.

Step 6 In the EIGRP Process field, enter the autonomous system (AS) number for the EIGRP process. The AS number can be from 1 to 65535.

Step 7 In the Interface drop-down list, choose the interface from which the summary address is advertised.

Step 8 In the IP Address field, enter the IP address of the summary route.

Step 9 In the Netmask field, choose or enter the network mask to apply to the IP address.

Step 10 Enter the administrative distance for the route in the Administrative Distance field. If left blank, the route has the default administrative distance of 5.

Step 11 Click **OK**.

Changing the Interface Delay Value

The interface delay value is used in EIGRP distance calculations. You can modify this value on a per-interface basis.

To change the interface delay value, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane shows the EIGRP interface configurations. The Interface Parameters table shows all of the interfaces on the ASA and lets you modify the settings on a per-interface basis. For more information about these settings, see the "Configuring Interfaces for EIGRP" section on page 36-7.

Step 2 Double-click an interface entry or choose the Interface entry and click **Edit** to configure the delay value in the EIGRP parameters for an interface.

The Edit EIGRP Interface Entry dialog box appears.

Step 3 In the Delay field, enter the delay time, which is in tens of microseconds. Valid values are from 1 to 16777215.

Step 4 Click **OK**.

Enabling EIGRP Authentication on an Interface

EIGRP route authentication provides MD5 authentication of routing updates from the EIGRP routing protocol. The MD5 keyed digest in each EIGRP packet prevents the introduction of unauthorized or false routing messages from unapproved sources.

EIGRP route authentication is configured on a per-interface basis. All EIGRP neighbors on interfaces configured for EIGRP message authentication must be configured with the same authentication mode and key for adjacencies to be established.

Note Before you can enable EIGRP route authentication, you must enable EIGRP.

To enable EIGRP authentication on an interface, perform the following steps:

Step 1 In the man ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the **EIGRP Process** field, enter the autonomous system (AS) number for the EIGRP process. The AS number can range from 1 to 65535.

Step 4 Click the **Networks** tab.

Step 5 Click **Add** to add a new network entry.

The Add EIGRP Network dialog box appears. To remove a network entry, choose the entry in the table and click **Delete**.

Step 6 Choose the AS number of the EIGRP routing process from the drop-down list.

Step 7 In the IP Address field, enter the IP address of the networks to participate in the EIGRP routing process.

Note To change a network entry, you must first remove the entry and then add a new one. You cannot edit existing entries.

Step 8 In the Network Mask field, choose or enter a network mask to apply to the IP address.

Step 9 Click **OK**.

Step 10 Choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane displays the EIGRP interface configurations. The Interface Parameters table displays all of the interfaces on the ASA and lets you modify the settings on a per-interface basis. For more information about these settings, see the "Configuring Interfaces for EIGRP" section on page 36-7.

Step 11 Check the **Enable MD5 Authentication** check box to enable MD5 authentication of EIGRP process messages. After you check this check box, provide one of the following:

- In the Key field, enter the key to authenticate EIGRP updates. The key can include up to 16 characters.
- In the Key ID field, enter the key identification value. Valid values range from 1 to 255.

Step 12 Click **OK**.

Defining an EIGRP Neighbor

EIGRP hello packets are sent as multicast packets. If an EIGRP neighbor is located across a non broadcast network, such as a tunnel, you must manually define that neighbor. When you manually define an EIGRP neighbor, hello packets are sent to that neighbor as unicast messages.

To manually define an EIGRP neighbor, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the EIGRP Process field, enter the AS number for the EIGRP process. The AS number can range from 1 to 65535.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Static Neighbor**.

The Static Neighbor pane appears and displays the statically-defined EIGRP neighbors. An EIGRP neighbor sends EIGRP routing information to and receives EIGRP routing information from the ASA. Normally, neighbors are dynamically discovered through the neighbor discovery process. However, on point-to-point, nonbroadcast networks, you must statically define the neighbors.

Each row of the Static Neighbor table displays the EIGRP autonomous system number for the neighbor, the neighbor IP address, and the interface through which the neighbor is available.

From the Static Neighbor pane, you can add or edit a static neighbor.

Step 5 Click **Add** or **Edit** to add or edit a EIGRP static neighbor.

The Add or Edit EIGRP Neighbor Entry dialog box appears.

Step 6 Choose the EIGRP AS number from the drop-down list for the EIGRP process for which the neighbor is being configured.

Step 7 Choose the Interface Name from the Interface Name drop-down list, which is the interface through which the neighbor is available.

Step 8 Enter the IP address of the neighbor in the Neighbor IP Address field.

Step 9 Click **OK**.

Redistributing Routes Into EIGRP

You can redistribute routes discovered by RIP and OSPF into the EIGRP routing process. You can also redistribute static and connected routes into the EIGRP routing process. You do not need to redistribute connected routes if they fall within the range of a **network** statement in the EIGRP configuration.

Note For RIP only: Before you begin this procedure, you must create a route map to further define which routes from the specified routing protocol are redistributed in to the RIP routing process. See Chapter 32, "Defining Route Maps," for more information about creating a route map.

To redistribute routes into the EIGRP routing process, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the EIGRP Process field, enter the AS number for the EIGRP process. The AS number can range from 1 to 65535.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Redistribution**.

The Redistribution pane displays the rules for redistributing routes from other routing protocols to the EIGRP routing process. When redistributing static and connected routes to the EIGRP routing process, metrics are not required to be configured, although this is recommended. Each row of the Redistribution pane table includes a route redistribution entry.

Step 5 Click **Add** to add a new redistribution rule. If you are editing an existing redistribution rule, go to Step 6.

The Add EIGRP Redistribution Entry dialog box appears.

Step 6 Choose the address in the table and click **Edit** to edit an existing EIGRP static neighbor, You can also double-click an entry in the table to edit that entry.

The Edit EIGRP Redistribution Entry dialog box appears.

Step 7 Choose the AS number of the EIGRP routing process to which the entry applies from the drop-down list.

Step 8 In the Protocol area, click the radio button next to one of the following protocols for the routing process:

- **Static** to redistribute static routes to the EIGRP routing process. Static routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them.

- **Connected** to redistribute connected routes into the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed into EIGRP; you do not need to define a redistribution rule for them.
- **RIP** to redistributes routes discovered by the RIP routing process to EIGRP.
- **OSPF** to redistribute routes discovered by the OSPF routing process to EIGRP.

Step 9 In the Optional Metrics area, choose one of the following metrics used for the redistributed route:

- **Bandwidth**, which is the EIGRP bandwidth metric in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay**, which is the EIGRP delay metric, in 10-microsecond units. Valid values range from 0 to 4294967295.
- **Reliability**, which is the EIGRP reliability metric. Valid values range from 0 to 255; 255 indicates 100 percent reliability.
- **Loading**, which is the EIGRP effective bandwidth (loading) metric. Valid values range from 1 to 255; 255 indicates 100 percent loaded.
- **MTU**, which is the MTU of the path. Valid values range from 1 to 65535.

Step 10 Choose the route map from the Route Map drop-down list to define which routes are redistributed into the EIGRP routing process. For more details about how to configure a route map, see Chapter 32, "Defining Route Maps."

Step 11 In the Optional OSPF Redistribution area, click one of the following OSPF radio buttons to further specify which OSPF routes are redistributed into the EIGRP routing process:

- **Match Internal** to match routes internal to the specified OSPF process.
- **Match External 1** to match type 1 routes external to the specified OSPF process.
- **Match External 2** to match type 2 routes external to the specified OSPF process.
- **Match NSSA-External 1** to match type 1 routes external to the specified OSPF NSSA.
- **Match NSSA-External 2** to match type 2 routes external to the specified OSPF NSSA.

Step 12 Click **OK**.

Filtering Networks in EIGRP

Note Before you begin this process, you must create a standard access list that defines the routes that you want to advertise. That is, create a standard access list that defines the routes that you want to filter from sending or receiving updates.

To filter networks in EIGRP, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 In the EIGRP Process field, enter the AS number for the EIGRP process. The AS number can range from 1 to 65535.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Filter Rules**.

The Filter Rules pane appears and displays the route filtering rules configured for the EIGRP routing process. Filter rules let you control which routes are accepted or advertised by the EIGRP routing process.

Each row of the Filter Rule table describes a filter rule for a specific interface or routing protocol. For example, a filter rule with a direction of in on the outside interface would apply filtering to any EIGRP updates received on the outside interface. A filter rule with a direction of out with OSPF 10 specified as the routing protocol would apply the filter rules to routes redistributed into the EIGRP routing process in outbound EIGRP updates.

Step 5 Click **Add** to add a filter rule. If you are editing an already existing filter rule, skip to Step 6.

The Add Filter Rules dialog box appears.

Step 6 To edit a filter rule, choose the filter rule in the table and click **Edit**.

The Edit Filter Rules dialog appears. You can also double-click a filter rule to edit the rule. To remove a filter rule, choose the filter rule in the table and click **Delete**.

Step 7 Choose the AS number from the drop-down list of the EIGRP routing process to which the entry applies.

Step 8 Choose the direction of the filter routes from the drop-down list.

Choose **in** for rules that filter routes from incoming EIGRP routing updates. Choose **out** to filter routes from EIGRP routing updates that are sent by the ASA.

If you choose **out**, the Routing process field becomes active. Choose the type of route to be filtered. You can filter routes redistributed from static, connected, RIP, and OSPF routing processes. Filters that specify a routing process filter those routes from updates sent on all interfaces.

Step 9 Enter the OSPF process ID in the ID field.

Step 10 Click the **Interface** radio button and choose the interface to which the filter applies.

Step 11 Click **Add** or **Edit** to define an access list for the filter rule. Clicking **Edit** opens the Network Rule dialog box for the selected network rule.

The Network Rule dialog box appears.

Step 12 In the Action drop-down list, choose Permit to allow the specified network to be advertised; choose Deny to prevent the specified network from being advertised.

Step 13 In the IP Address field, type IP address of the network being permitted or denied. To permit or deny all addresses, use the IP address **0.0.0.0** with a network mask of **0.0.0.0**.

Step 14 From the Netmask drop-down list, choose the network mask applied to the network IP address. You can type a network mask into this field or select one of the common masks from the list.

Step 15 Click **OK**.

Customizing the EIGRP Hello Interval and Hold Time

The ASA periodically sends hello packets to discover neighbors and to learn when neighbors become unreachable or inoperative. By default, hello packets are sent every 5 seconds.

The hello packet advertises the ASA hold time. The hold time indicates to EIGRP neighbors the length of time the neighbor should consider the ASA reachable. If the neighbor does not receive a hello packet within the advertised hold time, then the ASA is considered unreachable. By default, the advertised hold time is 15 seconds (three times the hello interval).

Both the hello interval and the advertised hold time are configured on a per-interface basis. We recommend setting the hold time to be at minimum three times the hello interval.

To configure the hello interval and advertised hold time, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 Click **OK**.

Step 4 Choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane appears and displays all of the EIGRP interface configurations.

Step 5 Double-click an interface entry or choose the entry and click **Edit**.

The Edit EIGRP Interface Entry dialog box appears.

Step 6 Choose the EIGRP AS number from the drop-down list, which is populated from system numbers that were set up when you enabled the EIGRP routing process.

Step 7 In the Hello Interval field, enter the interval between EIGRP hello packets sent on an interface.

Valid values range from 1 to 65535 seconds. The default value is 5 seconds.

Step 8 In the Hold Time field, specify the hold time, in seconds.

Valid values range from 1 to 65535 seconds. The default value is 15 seconds.

Step 9 Click **OK**.

Disabling Automatic Route Summarization

Automatic route summarization is enabled by default. The EIGRP routing process summarizes on network number boundaries. This can cause routing problems if you have noncontiguous networks.

For example, if you have a router with the networks 192.168.1.0, 192.168.2.0, and 192.168.3.0 connected to it, and those networks all participate in EIGRP, the EIGRP routing process creates the summary address 192.168.0.0 for those routes. If an additional router is added to the network with the networks 192.168.10.0 and 192.168.11.0, and those networks participate in EIGRP, they will also be summarized as 192.168.0.0. To prevent the possibility of traffic being routed to the wrong location, you should disable automatic route summarization on the routers creating the conflicting summary addresses.

To disable automatic route summarization in ASDM, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 Click the **Process Instance** tab.

Step 4 Click **Advanced**.

Step 5 In the Summary area, uncheck the **Auto-Summary** check box.

Note This setting is enabled by default.

Step 6 Click **OK**.

Configuring Default Information in EIGRP

You can control the sending and receiving of default route information in EIGRP updates. By default, default routes are sent and accepted. Configuring the ASA to disallow default information to be received causes the candidate default route bit to be blocked on received routes. Configuring the ASA to disallow default information to be sent disables the setting of the default route bit in advertised routes.

In ASDM, the Default Information pane displays a table of rules for controlling the sending and receiving of default route information in EIGRP updates. You can have one in and one out rule for each EIGRP routing process (only one process is currently supported).

By default, default routes are sent and accepted. To restrict or disable the sending and receiving of default route information, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The main EIGRP Setup pane appears.

Step 2 Check the **Enable EIGRP routing** check box.

Step 3 Click **OK**.

Step 4 Do one of the following:

- Click **Add** to create a new entry.
- To edit an entry, double-click the entry in the table or select an entry in the table and click **Edit**.

  The Add Default Information or Edit Default Information dialog box appears for that entry. The EIGRP AS number is automatically selected in the EIGRP field.

Step 5 In the Direction field, choose the direction for the rule from the following options:

- **in**—The rule filters default route information from incoming EIGRP updates.
- **out**—The rule filters default route information from outgoing EIGRP updates.

  You can have one in rule and one out rule for each EIGRP process.

Step 6 Add network rules to the network rule table. The network rules define which networks are allowed and which are not when receiving or sending default route information. Repeat the following steps for each network rule you are adding to the default information filter rule.

a. Click **Add** to add a network rule. Double-click an existing network rule to edit the rule.

b. In the Action field, click **Permit** to allow the network or **Deny** to block the network.

c. Enter the IP address and network mask of the network being permitted or denied by the rule in the IP Address and Network Mask fields.

To deny all default route information from being accepted or sent, enter **0.0.0.0** as the network address and choose **0.0.0.0** as the network mask.

d. Click **OK** to add the specified network rule to the default information filter rule.

Step 7 Click **OK** to accept the default information filter rule.

Disabling EIGRP Split Horizon

Split horizon controls the sending of EIGRP update and query packets. When split horizon is enabled on an interface, update and query packets are not sent for destinations for which this interface is the next hop. Controlling update and query packets in this manner reduces the possibility of routing loops.

By default, split horizon is enabled on all interfaces.

Split horizon blocks route information from being advertised by a router out of any interface from which that information originated. This behavior usually optimizes communications among multiple routing devices, particularly when links are broken. However, with nonbroadcast networks, there may be situations where this behavior is not desired. For these situations, including networks in which you have EIGRP configured, you may want to disable split horizon.

If you disable split horizon on an interface, you must disable it for all routers and access servers on that interface.

To disable EIGRP split horizon, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Interfaces**.

The Interface pane appears and displays the EIGRP interface configurations.

Step 2 Double-click an interface entry or choose the entry and click **Edit**.

The Edit EIGRP Interface Entry dialog box appears.

Step 3 Choose the EIGRP Autonomous system (AS) number from the drop-down list, which is populated from system numbers that were set up when you enabled the EIGRP routing process.

Step 4 Uncheck the **Split Horizon** check box.

Step 5 Click **OK**.

Restarting the EIGRP Process

To restart an EIGRP process or clear redistribution or counters, perform the following steps:

Step 1 In the main ASDM window, choose **Configuration > Device Setup > Routing > EIGRP > Setup**.

The EIGRP Setup pane appears.

Step 2 Click **Reset**.

Monitoring EIGRP

You can use the following commands to monitor the EIGRP routing process. For examples and descriptions of the command output, see the command reference. Additionally, you can disable the logging of neighbor change messages and neighbor warning messages.

To monitor or disable various EIGRP routing statistics, perform the following steps:

Step 1 In the main ASDM window, choose **Monitoring > Routing > EIGRP Neighbor**.

Each row represents one EIGRP neighbor. For each neighbor, the list includes its IP address, the interface to which the neighbor is connected, the holdtime, the uptime, the queue length, the sequence number, the smoothed round trip time, and the retransmission timeout. The list of possible state changes are the following:

- NEW ADJACENCY—A new neighbor has been established.
- PEER RESTARTED—The other neighbor initiates the reset of the neighbor relationship. The router getting the message is not the one resetting the neighbor.
- HOLD TIME EXPIRED—The router has not heard any EIGRP packets from the neighbor within the hold-time limit.
- RETRY LIMIT EXCEEDED—EIGRP did not receive the acknowledgement from the neighbor for EIGRP reliable packets, and EIGRP has already tried to retransmit the reliable packet 16 times without any success.
- ROUTE FILTER CHANGED—The EIGRP neighbor is resetting because there is a change in the route filter.
- INTERFACE DELAY CHANGED—The EIGRP neighbor is resetting because there is a manual configuration change in the delay parameter on the interface.
- INTERFACE BANDWIDTH CHANGED—The EIGRP neighbor is resetting because there is a manual configuration change in the interface bandwidth on the interface.
- STUCK IN ACTIVE—The EIGRP neighbor is resetting because EIGRP is stuck in active state. The neighbor getting reset is the result of the stuck-in-active state.

Step 2 Click the EIGRP neighbor that you want to monitor.

Step 3 To remove the current list of neighbors, click **Clear Neighbors**.

Step 4 To refresh the current list of neighbors, click **Refresh**.

Note By default, neighbor change and neighbor warning messages are logged.

Feature History for EIGRP

Table 36-1 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 36-1 Feature History for EIGRP

Feature Name	Platform Releases	Feature Information
EIGRP Support	7.0(1)	Support was added for routing data, performing authentication, and redistributing and monitoring routing information using the Enhanced Interior Gateway Routing Protocol (EIGRP). We introduced the following screen: Configuration > Device Setup > Routing > EIGRP.
Dynamic Routing in Multiple Context Mode	9.0(1)	EIGRP routing is supported in multiple context mode. We modified the following screen: Configuration > Device Setup > Routing > EIGRP > Setup.
Clustering	9.0(1)	For EIGRP, bulk synchronization, route synchronization, and layer 2 load balancing are supported in the clustering environment.

Configuring IPv6 Neighbor Discovery

This chapter describes how to enable and configure IPv6 neighbor discovery on the ASA and includes the following sections:

- Information About IPv6 Neighbor Discovery, page 37-1
- Licensing Requirements for IPv6 Neighbor Discovery, page 37-5
- Prerequisites for IPv6 Neighbor Discovery, page 37-5
- Guidelines and Limitations, page 37-5
- Default Settings for IPv6 Neighbor Discovery, page 37-7
- Configuring IPv6 Neighbor Discovery, page 37-7
- Viewing and Clearing Dynamically Discovered Neighbors, page 37-13
- Additional References, page 37-13
- Feature History for IPv6 Neighbor Discovery, page 37-14

Information About IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cashed values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

This section includes the following topics:

- Neighbor Solicitation Messages, page 37-2
- Neighbor Reachable Time, page 37-3
- Duplicate Address Detection, page 37-3
- Router Advertisement Messages, page 37-3
- Static IPv6 Neighbors, page 37-5

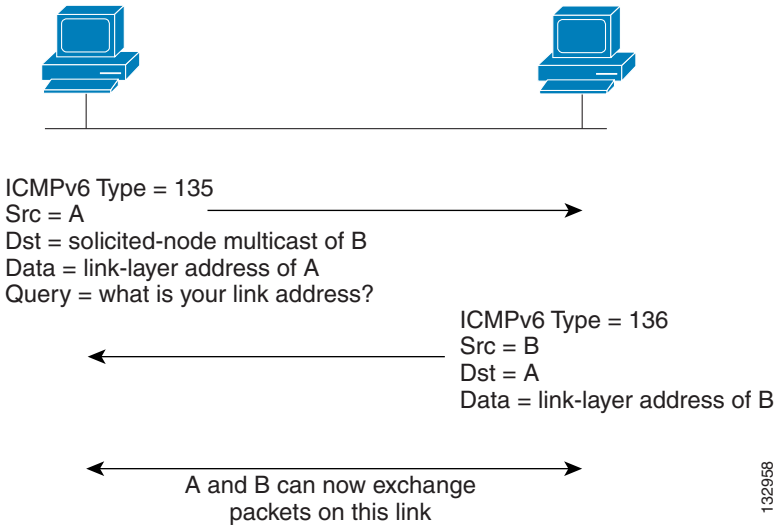
Neighbor Solicitation Messages

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. The neighbor solicitation message is sent to the solicited-node multicast address. The source address in the neighbor solicitation message is the IPv6 address of the node sending the neighbor solicitation message. The neighbor solicitation message also includes the link-layer address of the source node.

After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link. The source address in the neighbor advertisement message is the IPv6 address of the node sending the neighbor advertisement message; the destination address is the IPv6 address of the node that sent the neighbor solicitation message. The data portion of the neighbor advertisement message includes the link-layer address of the node sending the neighbor advertisement message.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Figure 37-1 shows the neighbor solicitation and response process.

Figure 37-1 IPv6 Neighbor Discovery—Neighbor Solicitation Message



Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link. When there is such a change, the destination address for the neighbor advertisement is the all-nodes multicast address.

Neighbor Reachable Time

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Duplicate Address Detection

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while Duplicate Address Detection is performed). Duplicate Address Detection is performed first on the new link-local address. When the link-local address is verified as unique, then Duplicate Address Detection is performed all the other IPv6 unicast addresses on the interface.

Duplicate Address Detection is suspended on interfaces that are administratively down. While an interface is administratively down, the unicast IPv6 addresses assigned to the interface are set to a pending state. An interface returning to an administratively up state restarts Duplicate Address Detection for all of the unicast IPv6 addresses on the interface.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
%ASA-4-325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used. However, all configuration commands associated with the duplicate address remain as configured while the state of the address is set to DUPLICATE.

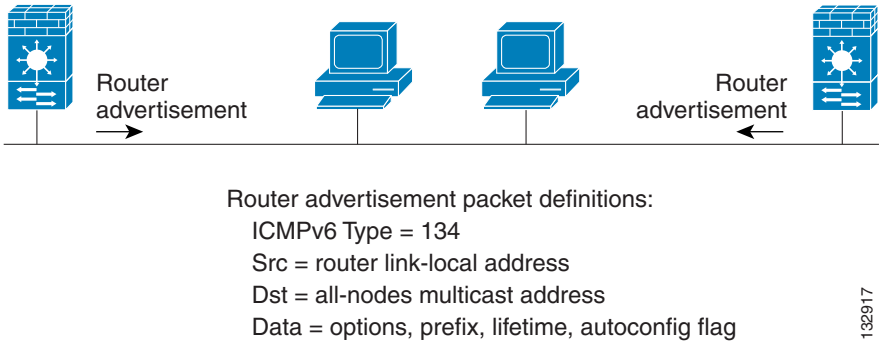
If the link-local address for an interface changes, Duplicate Address Detection is performed on the new link-local address and all of the other IPv6 address associated with the interface are regenerated (Duplicate Address Detection is performed only on the new link-local address).

The ASA uses neighbor solicitation messages to perform Duplicate Address Detection. By default, the number of times an interface performs Duplicate Address Detection is 1.

Router Advertisement Messages

An ASA can participate in router advertisements so that neighboring devices can dynamically learn a default router address. Router advertisement messages (ICMPv6 Type 134) are periodically sent out each IPv6 configured interface of the ASA. The router advertisement messages are sent to the all-nodes multicast address. Figure 37-2 shows an example of how to send router advertisement messages on an IPv6 configured interface.

Figure 37-2 IPv6 Neighbor Discovery—Router Advertisement Message



Router advertisement messages typically include the following information:

- One or more IPv6 prefix that nodes on the local link can use to automatically configure their IPv6 addresses.
- Lifetime information for each prefix included in the advertisement.
- Sets of flags that indicate the type of autoconfiguration (stateless or stateful) that can be completed.
- Default router information (whether the router sending the advertisement should be used as a default router and, if so, the amount of time (in seconds) the router should be used as a default router).
- Additional information for hosts, such as the hop limit and MTU a host should use in packets that it originates.
- The amount of time between neighbor solicitation message retransmissions on a given link.
- The amount of time a node considers a neighbor reachable.

Router advertisements are also sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message. Because router solicitation messages are usually sent by hosts at system startup, and the host does not have a configured unicast address, the source address in router solicitation messages is usually the unspecified IPv6 address (0:0:0:0:0:0:0:0). If the host has a configured unicast address, the unicast address of the interface sending the router solicitation message is used as the source address in the message. The destination address in router solicitation messages is the all-routers multicast address with a scope of the link. When a router advertisement is sent in response to a router solicitation, the destination address in the router advertisement message is the unicast address of the source of the router solicitation message.

You can configure the following settings for router advertisement messages:

- The time interval between periodic router advertisement messages.
- The router lifetime value, which indicates the amount of time IPv6 nodes should consider the ASA to be the default router.
- The IPv6 network prefixes in use on the link.
- Whether or not an interface transmits router advertisement messages.

Unless otherwise noted, the router advertisement message settings are specific to an interface and are entered in interface configuration mode.

Static IPv6 Neighbors

You can manually define a neighbor in the IPv6 neighbor cache. If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.

Licensing Requirements for IPv6 Neighbor Discovery

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Prerequisites for IPv6 Neighbor Discovery

Configure IPv6 addressing according to the "Configuring IPv6 Addressing" section on page 17-15.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed mode only. Transparent mode is not supported.

Additional Guidelines and Limitations

- The interval value is included in all IPv6 router advertisements that are sent out of this interface.
- The configured time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.
- The interval between transmissions should be less than or equal to the IPv6 router advertisement lifetime if the ASA is configured as a default router by using the **ipv6 nd ra-lifetime** command. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the specified value.
- The **ipv6 nd prefix** command allows control over the individual parameters per prefix, including whether or not the prefix should be advertised.

- By default, prefixes configured as addresses on an interface using the **ipv6 address** command are advertised in router advertisements. If you configure prefixes for advertisement using the **ipv6 nd prefix** command, then only these prefixes are advertised.
- The **default** keyword can be used to set default parameters for all prefixes.
- A date can be set to specify the expiration of a prefix. The valid and preferred lifetimes are counted down in real time. When the expiration date is reached, the prefix will no longer be advertised.
- When onlink is on (by default), the specified prefix is assigned to the link. Nodes sending traffic to such addresses that contain the specified prefix consider the destination to be locally reachable on the link.
- When autoconfig is on (by default), it indicates to hosts on the local link that the specified prefix can be used for IPv6 autoconfiguration.
- For stateless autoconfiguration to work correctly, the advertised prefix length in router advertisement messages must always be 64 bits.
- The router lifetime value is included in all IPv6 router advertisements sent out of the interface. The value indicates the usefulness of the ASA as a default router on this interface.
- Setting the value to a non-zero value indicates that the ASA should be considered a default router on this interface. The non-zero value for the router lifetime value should not be less than the router advertisement interval.

The following guidelines and limitations apply for configuring a static IPv6 neighbor:

- The **ipv6 neighbor** command is similar to the **arp** command. If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. These entries are stored in the configuration when the copy command is used to store the configuration.
- Use the **show ipv6 neighbor** command to view static entries in the IPv6 neighbor discovery cache.
- The **clear ipv6 neighbor** command deletes all entries in the IPv6 neighbor discovery cache except static entries. The **no ipv6 neighbor** command deletes a specified static entry from the neighbor discovery cache; the command does not remove dynamic entries—entries learned from the IPv6 neighbor discovery process—from the cache. Disabling IPv6 on an interface by using the **no ipv6 enable** command deletes all IPv6 neighbor discovery cache entries configured for that interface except static entries (the state of the entry changes to INCMP [Incomplete]).
- Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.
- The **clear ipv6 neighbor** command does not remove static entries from the IPv6 neighbor discovery cache; it only clears the dynamic entries.
- The ICMP syslogs generated are caused by a regular refresh of IPv6 neighbor entries. The ASA default timer for IPv6 neighbor entry is 30 seconds, so the ASA would generate ICMPv6 neighbor discovery and response packets about every 30 seconds. If the ASA has both failover LAN and state interfaces configured with IPv6 addresses, then every 30 seconds, ICMPv6 neighbor discovery and response packets will be generated by both ASAs for both configured and link-local IPv6 addresses. In addition, each packet will generate several syslogs (ICMP connection and local-host creation or teardown), so it may appear that constant ICMP syslogs are being generated. The refresh time for IPV6 neighbor entry is configurable on the regular data interface, but not configurable on the failover interface. However, the CPU impact for this ICMP neighbor discovery traffic is minimal.

Default Settings for IPv6 Neighbor Discovery

Table 37-1 lists the default settings for IPv6 Neighbor Discovery.

Table 37-1 Default IPv6 Neighbor Discovery Parameters

Parameters	Default
value for the neighbor solicitation transmission message interval	1000 seconds between neighbor solicitation transmissions.
value for the neighbor reachable time	The default is 0.
value for the router advertisement transmission interval	The default is 200 seconds.
value for the router lifetime	The default is 1800 seconds.
value for the number of consecutive neighbor solicitation messages sent during DAD	The default is one message.
prefix lifetime	The default lifetime is 2592000 seconds (30 days), and a preferred lifetime is 604800 seconds (7 days).
on-link flag	The flag is on by default, which means that the prefix is used on the advertising interface.
autoconfig flag	The flag is on by default, which means that the prefix is used for autoconfiguration.
static IPv6 neighbor	Static entries are not configured in the IPv6 neighbor discovery cache.

Configuring IPv6 Neighbor Discovery

- Configuring the Neighbor Solicitation Message Interval, page 37-8
- Configuring the Neighbor Reachable Time, page 37-8
- Configuring the Router Advertisement Transmission Interval, page 37-9
- Configuring the Router Lifetime Value, page 37-9
- Configuring DAD Settings, page 37-10
- Suppressing Router Advertisement Messages, page 37-10
- Configuring Address Config Flags for IPv6 DHCP Relay, page 37-11
- Configuring the IPv6 Prefix in Router Advertisements, page 37-11
- Configuring a Static IPv6 Neighbor, page 37-12

Configuring the Neighbor Solicitation Message Interval

To configure the interval between IPv6 neighbor solicitation retransmissions on an interface, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Choose the interface on which to configure the neighbor solicitation interval. The interface must have been configured with an IPv6 address. See the "Configuring IPv6 Addressing" section on page 17-15 for more information.

Step 3 Click **Edit**. The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 In the NS Interval field, enter the time interval.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the running configuration.

Configuring the Neighbor Reachable Time

To configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Choose the interface for which you want to configure the time. The interface must have been configured with an IPv6 address. For more information, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 3 Click **Edit**. The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 In the Reachable Time field, enter a valid value.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the running configuration.

Configuring the Router Advertisement Transmission Interval

To configure the interval between IPv6 router advertisement transmissions on an interface, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface for which you want to configure the time.

The interface must have been configured with an IPv6 address. For more information, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 3 Click **Edit**. The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 In the RA Interval field, enter a valid transmission interval value.

Note (Optional) To add a router advertisement transmission interval value in milliseconds instead, check the **RA Interval in Milliseconds** check box, and enter a value from 500 to 1800000.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the running configuration.

Configuring the Router Lifetime Value

To configure the router lifetime value in IPv6 router advertisements on an interface, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface you want to configure.

The interface must have been configured with an IPv6 address. For more information see the "Configuring IPv6 Addressing" section on page 17-15.

Step 3 Click **Edit**.

The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 In the RA Lifetime field, enter a valid lifetime value.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the running configuration.

Configuring DAD Settings

To specify DAD settings on the interface, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface you want to configure.

The interface must have been configured with an IPv6 address. For more information, see the "Configuring IPv6 Addressing" section on page 17-15.

Step 3 Click **Edit**.

The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 Enter the number of allowed DAD attempts. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. Valid values range from 0 to 600. A zero value disables DAD processing on the specified interface. The default is one message.

Suppressing Router Advertisement Messages

Router advertisement messages are automatically sent in response to router solicitation messages. You may want to disable these messages on any interface for which you do not want the ASA to supply the IPv6 prefix (for example, the outside interface).

To suppress the router lifetime value in IPv6 router advertisements on an interface, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface for which you want to suppress the router advertisement transmissions. The interface must have been configured with an IPv6 address.

Step 3 Click **Edit**.

The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 Check the **Suppress RA** check box.

Configuring Address Config Flags for IPv6 DHCP Relay

You can add a flag to IPv6 router advertisements to inform IPv6 autoconfigurtion clients to use DHCPv6 to obtain an IPv6 address and/or additional information such as the DNS server address.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface that you want to configure.

Step 3 Click **Edit**.

The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 Check the **Hosts should use DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet. This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

Check the **Hosts should use DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet. This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

Configuring the IPv6 Prefix in Router Advertisements

To configure the which IPv6 prefixes are included in IPv6 router advertisements, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Setup > Interfaces**.

Step 2 Select the interface for which you want to suppress the router advertisement transmissions. The interface must have been configured with an IPv6 address.

Step 3 Click **Edit**.

The Edit Interface dialog box appears with three tabs: General, Advanced, and IPv6.

Step 4 Click the **IPv6** tab.

Step 5 In the Interface IPv6 Prefixes area, click **Add**.

The Add IPv6 Prefix for Interface dialog box appears.

Step 6 Enter the IPv6 address with the prefix length.

Step 7 (Optional) To configure the IPv6 address manually, check the **No Auto-Configuration** check box. This setting indicates to hosts on the local link that the specified prefix cannot be used for IPv6 autoconfiguration.

Step 8 (Optional) To indicate that the IPv6 prefix is not advertised, check the **No Advertisements** check box.

Step 9 (Optional) The **Off Link** check box indicates that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.

Step 10 In the Prefix Lifetime area, click the **Lifetime Duration** radio button, and specify the following:

a. A valid lifetime for the prefix in seconds from the drop-down list. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days).

b. A preferred lifetime for the prefix from the drop-down list. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days).

Step 11 To define a prefix lifetime expiration date, click the **Lifetime Expiration Date** radio button, and specify the following:

a. Choose a valid month and day from the drop-down list, and then enter a time in hh:mm format.

b. Choose a preferred month and day from the drop-down list, and then enter a time in hh:mm format.

Step 12 Click **OK** to save your settings.

The Interface IPv6 Prefixes Address field appears with the preferred and valid dates.

Configuring a Static IPv6 Neighbor

Make sure that IPv6 is enabled on at least one interface before trying to add a neighbor, or ASDM returns an error message indicating that the configuration failed.

For information about configuring IPv6 addresses, see the "Configuring IPv6 Addressing" section on page 17-15.

To add an IPv6 static neighbor, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Management > Advanced > IPv6 Neighbor Discovery Cache**.

Step 2 Click **Add**.

The Add IPv6 Static Neighbor dialog box appears.

Step 3 From the Interface Name drop-down list, choose an interface on which to add the neighbor.

Step 4 In the IP Address field, enter the IPv6 address that corresponds to the local data-link address, or click the ellipsis (...) to browse for an address.

If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry.

Step 5 In the MAC address field, enter the local data-line (hardware) MAC address.

Step 6 Click **OK**.

Note Before you apply the changes and save the configuration, you can click **Reset** to cancel any changes and restore the original values.

Step 7 Click **Apply** to save the running configuration.

Viewing and Clearing Dynamically Discovered Neighbors

When a host or node communicates with a neighbor, the neighbor is added to the neighbor discovery cache. The neighbor is removed from the cache when there is no longer any communication with that neighbor.

To view dynamically discovered neighbors and clear these neighbors from the IPv6 neighbor discovery cache, perform the following steps:

Step 1 Choose **Monitoring > Interfaces > IPv6 Neighbor Discovery Cache**.

You can view all static and dynamically discovered neighbors from the IPv6 Neighbor Discovery Cache pane.

Step 2 To clear all dynamically discovered neighbors from the cache, click **Clear Dynamic Neighbor Entries**.

The dynamically discovered neighbor is removed from the cache.

Note This procedure clears only dynamically discovered neighbors from the cache; it does not clear static neighbors.

RFC 3849 specifies the requirements for using IPv6 address prefixes in documentation. The IPv6 unicast address prefix that has been reserved for use in documentation is 2001:DB8::/32.	IPv6 Address Prefix Reserved for Documentation

Feature History for IPv6 Neighbor Discovery

Table 37-2 lists each feature change and the platform release in which it was implemented. ASDM is backward-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 37-2 Feature History for IPv6 Neighbor Discovery

Feature Name	Releases	Feature Information
IPv6 Neighbor Discovery	7.0(1)	We introduced this feature. We introduced the following screens: Monitoring > Interfaces > IPv6 Neighbor Discovery Cache. Configuration > Device Management > Advanced > IPv6 Neighbor Discovery Cache. Configuration > Device Setup > Interfaces > IPv6.
Address Config Flags for IPv6 DHCP Relay	9.0(1)	We modified the following screen: Configuration > Device Device Setup > Interfaces > IPv6.

PART 6

Configuring Network Address Translation

Information About NAT (ASA 8.3 and Later)

This chapter provides an overview of how Network Address Translation (NAT) works on the ASA. This chapter includes the following sections:

- Why Use NAT?, page 39-1
- NAT Terminology, page 39-2
- NAT Types, page 39-3
- NAT in Routed and Transparent Mode, page 39-12
- NAT and IPv6, page 39-15
- How NAT is Implemented, page 39-15
- NAT Rule Order, page 39-20
- Routing NAT Packets, page 39-21
- NAT for VPN, page 39-24
- DNS and NAT, page 39-30
- Where to Go Next, page 39-34

Note To start configuring NAT, see Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)," or Chapter 41, "Configuring Twice NAT (ASA 8.3 and Later)."

Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise at a minimum only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.
- Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.
- Translating between IPv4 and IPv6 (Routed mode only) (Version 9.0(1) and later)—If you want to connect an IPv6 network to an IPv4 network, NAT lets you translate between the two types of addresses.

Note NAT is not required. If you do not configure NAT for a given set of traffic, that traffic will not be translated, but will have all of the security policies applied as normal.

NAT Terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the ASA, not just an inside network, Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.
- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

NAT Types

- NAT Types Overview, page 39-3
- Static NAT, page 39-3
- Dynamic NAT, page 39-8
- Dynamic PAT, page 39-10
- Identity NAT, page 39-12

NAT Types Overview

You can implement NAT using the following methods:

- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See the "Static NAT" section on page 39-3.
- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See the "Dynamic NAT" section on page 39-8.
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See the "Dynamic PAT" section on page 39-10.
- Identity NAT—A real address is statically transalted to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See the "Identity NAT" section on page 39-12.

Static NAT

This section describes static NAT and includes the following topics:

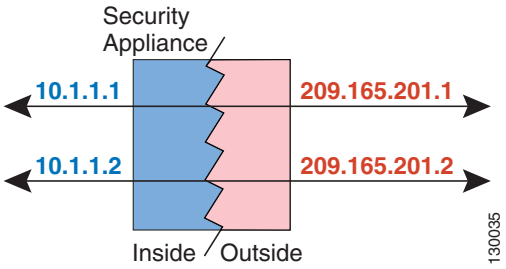
- Information About Static NAT, page 39-3
- Information About Static NAT with Port Translation, page 39-4
- Information About One-to-Many Static NAT, page 39-6
- Information About Other Mapping Scenarios (Not Recommended), page 39-7

Information About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

Figure 39-1 shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

Figure 39-1 Static NAT



Note You can disable bidirectionality if desired.

Information About Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol (TCP or UDP) and port.

This section includes the following topics:

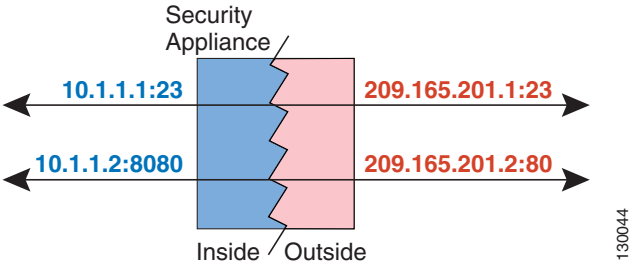
- Information About Static NAT with Port Address Translation, page 39-4
- Static NAT with Identity Port Translation, page 39-5
- Static NAT with Port Translation for Non-Standard Ports, page 39-5
- Static Interface NAT with Port Translation, page 39-6

Information About Static NAT with Port Address Translation

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

Figure 39-2 shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

Figure 39-2 Typical Static NAT with Port Translation Scenario

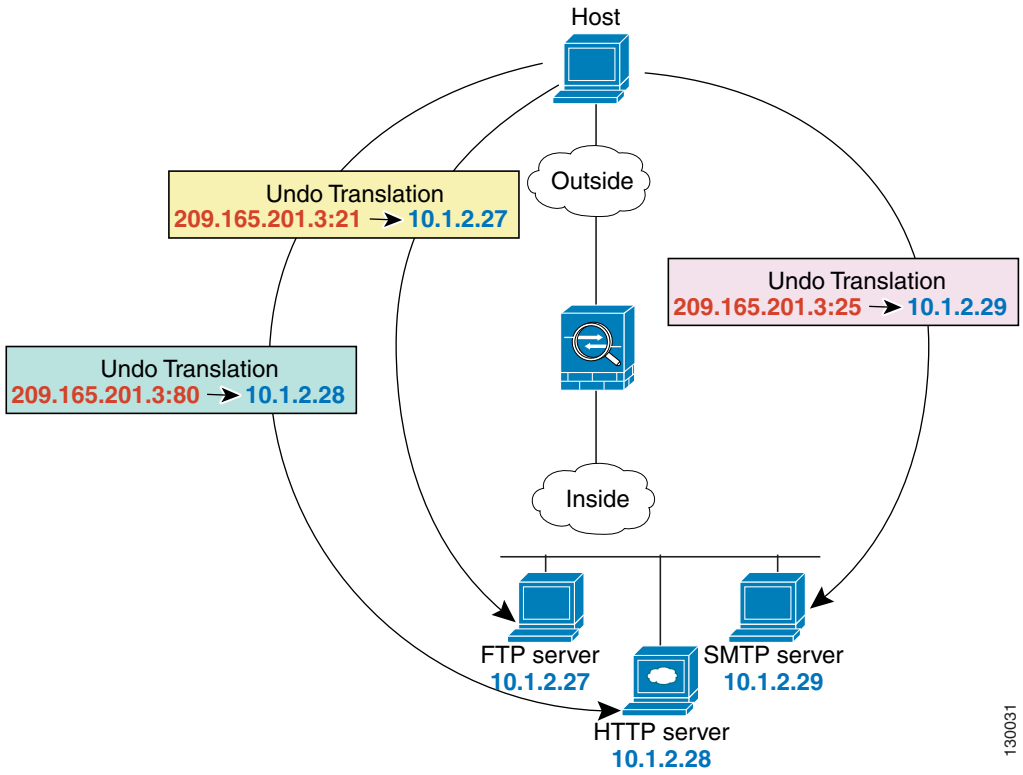


Note For applications that require application inspection for secondary channels (for example, FTP and VoIP), the ASA automatically translates the secondary ports.

Static NAT with Identity Port Translation

The following static NAT with port translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT with port translation rules that use the same mapped IP address, but different ports. (See Figure 39-3. See the "Single Address for FTP, HTTP, and SMTP (Static NAT-with-Port-Translation)" section on page 40-32 for details on how to configure this example.)

Figure 39-3 Static NAT with Port Translation



Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

Static Interface NAT with Port Translation

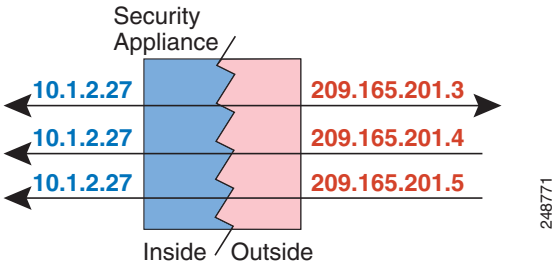
You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the ASA outside interface to an inside host, then you can map the inside host IP address/port 23 to the ASA interface address/port 23. (Note that although Telnet to the ASA is not allowed to the lowest security interface, static NAT with interface port translation redirects the Telnet session instead of denying it).

Information About One-to-Many Static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

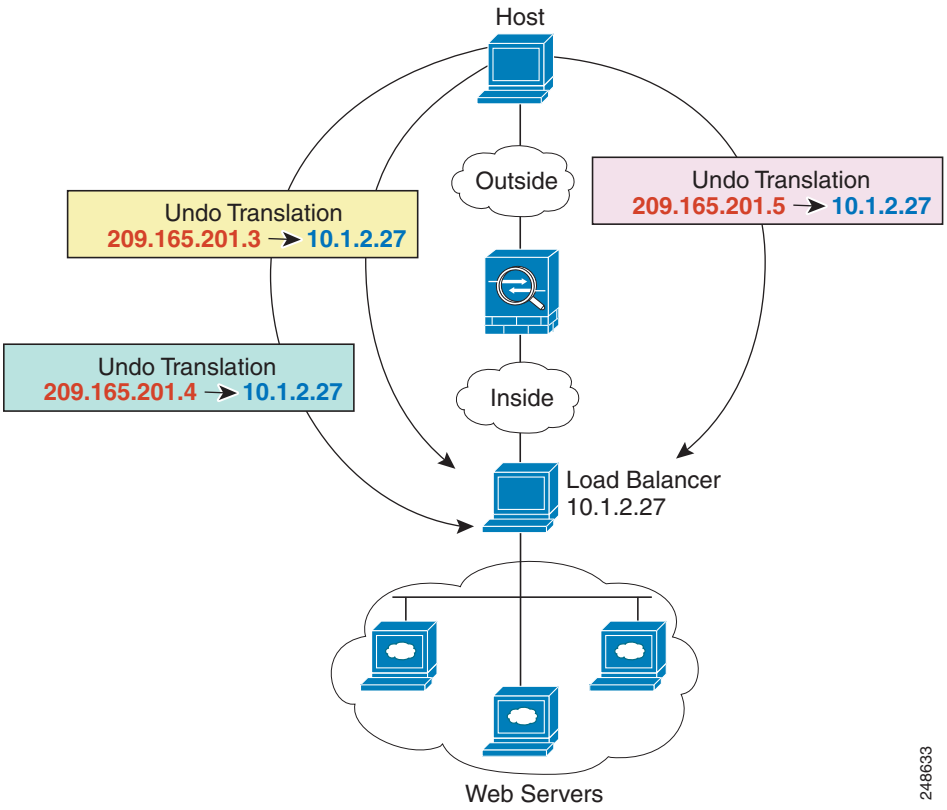
Figure 39-4 shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/1st mapped IP is technically the only bidirectional translation.

Figure 39-4 One-to-Many Static NAT



For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server (see Figure 39-5). (See the "Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many)" section on page 40-28 for details on how to configure this example.)

Figure 39-5 One-to-Many Static NAT



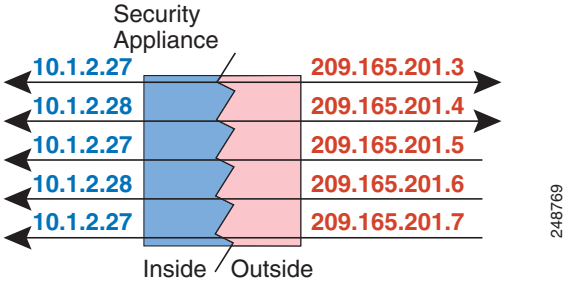
Information About Other Mapping Scenarios (Not Recommended)

The ASA has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

Figure 39-6 shows a typical few-to-many static NAT scenario.

Figure 39-6 Few-to-Many Static NAT

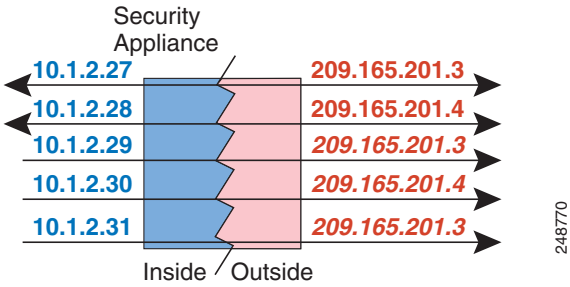


For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

Note Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

Figure 39-7 shows a typical many-to-few static NAT scenario.

Figure 39-7 Many-to-Few Static NAT



Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

Dynamic NAT

This section describes dynamic NAT and includes the following topics:

- Information About Dynamic NAT, page 39-9
- Dynamic NAT Disadvantages and Advantages, page 39-10

Information About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, the ASA assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

Figure 39-8 shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

Figure 39-8 Dynamic NAT

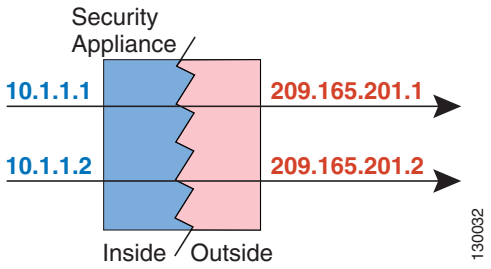


Figure 39-9 shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the ASA drops the packet.

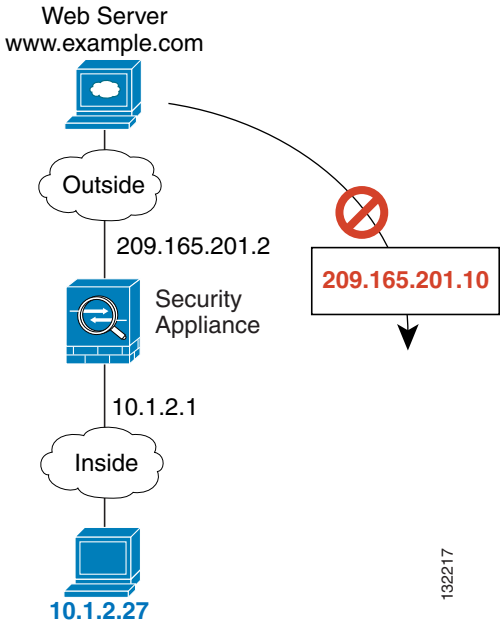
Figure 39-9 Remote Host Attempts to Initiate a Connection to a Mapped Address



Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT or a PAT fallback method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

See the "Default Settings" section on page 57-4 for more information about NAT and PAT support.

Dynamic PAT

This section describes dynamic PAT and includes the following topics:

- Information About Dynamic PAT, page 39-10
- Per-Session PAT vs. Multi-Session PAT (Version 9.0(1) and Later), page 39-11
- Dynamic PAT Disadvantages and Advantages, page 39-11

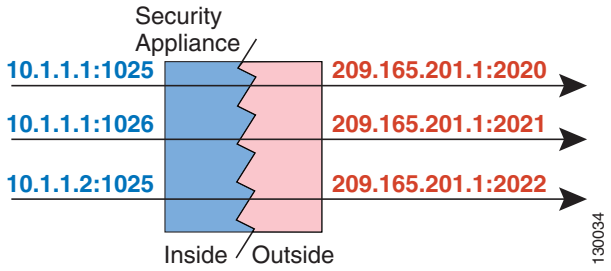
Information About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port. If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used. If you have a lot of traffic that uses the lower port ranges, you can specify a flat range of ports to be used instead of the three unequal-sized tiers.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

Figure 39-10 shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 39-10 Dynamic PAT



After the connection expires, the port translation also expires. For multi-session PAT, the PAT timeout is used, 30 seconds by default. For per-session PAT (9.0(1) and later), the xlate is immediately removed. Users on the destination network cannot reliably initiate a connection to a host that uses PAT (even if the connection is allowed by an access rule).

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

Per-Session PAT vs. Multi-Session PAT (Version 9.0(1) and Later)

The per-session PAT feature improves the scalability of PAT and, for clustering, allows each member unit to own PAT connections; multi-session PAT connections have to be forwarded to and owned by the master unit. At the end of a per-session PAT session, the ASA sends a reset and immediately removes the xlate. This reset causes the end node to immediately release the connection, avoiding the TIME_WAIT state. Multi-session PAT, on the other hand, uses the PAT timeout, by default 30 seconds. For "hit-and-run" traffic, such as HTTP or HTTPS, the per-session feature can dramatically increase the connection rate supported by one address. Without the per-session feature, the maximum connection rate for one address for an IP protocol is approximately 2000 per second. With the per-session feature, the connection rate for one address for an IP protocol is 65535/*average-lifetime*.

By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that can benefit from multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT be creating a per-session deny rule. See the "Configuring Per-Session PAT Rules" section on page 40-18.

Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the ASA interface IP address as the PAT address.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. See the "Default Settings" section on page 57-4 for more information about NAT and PAT support.

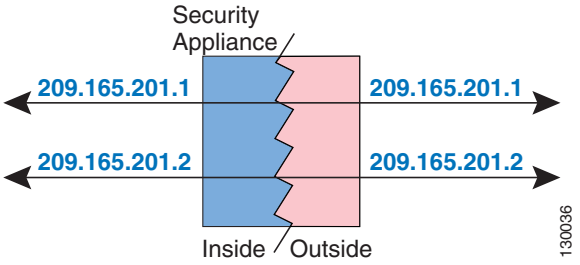
Dynamic PAT may also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. (8.4(2)/8.5(1) and later) You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself. Identity NAT is necessary for remote access VPN, where you need to exempt the client traffic from NAT.

Figure 39-11 shows a typical identity NAT scenario.

Figure 39-11 Identity NAT



NAT in Routed and Transparent Mode

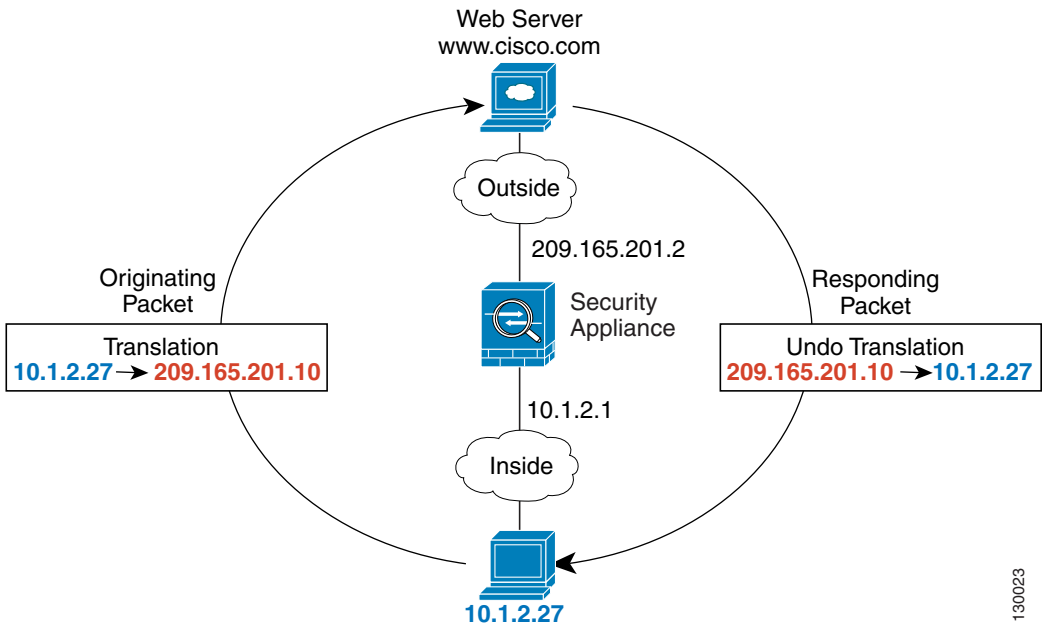
You can configure NAT in both routed and transparent firewall mode. This section describes typical usage for each firewall mode and includes the following topics:

- NAT in Routed Mode, page 39-13
- NAT in Transparent Mode, page 39-13

NAT in Routed Mode

Figure 39-12 shows a typical NAT example in routed mode, with a private network on the inside.

Figure 39-12 NAT Example: Routed Mode



1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is changed to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the ASA receives the packet because the ASA performs proxy ARP to claim the packet.
3. The ASA then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

NAT in Transparent Mode

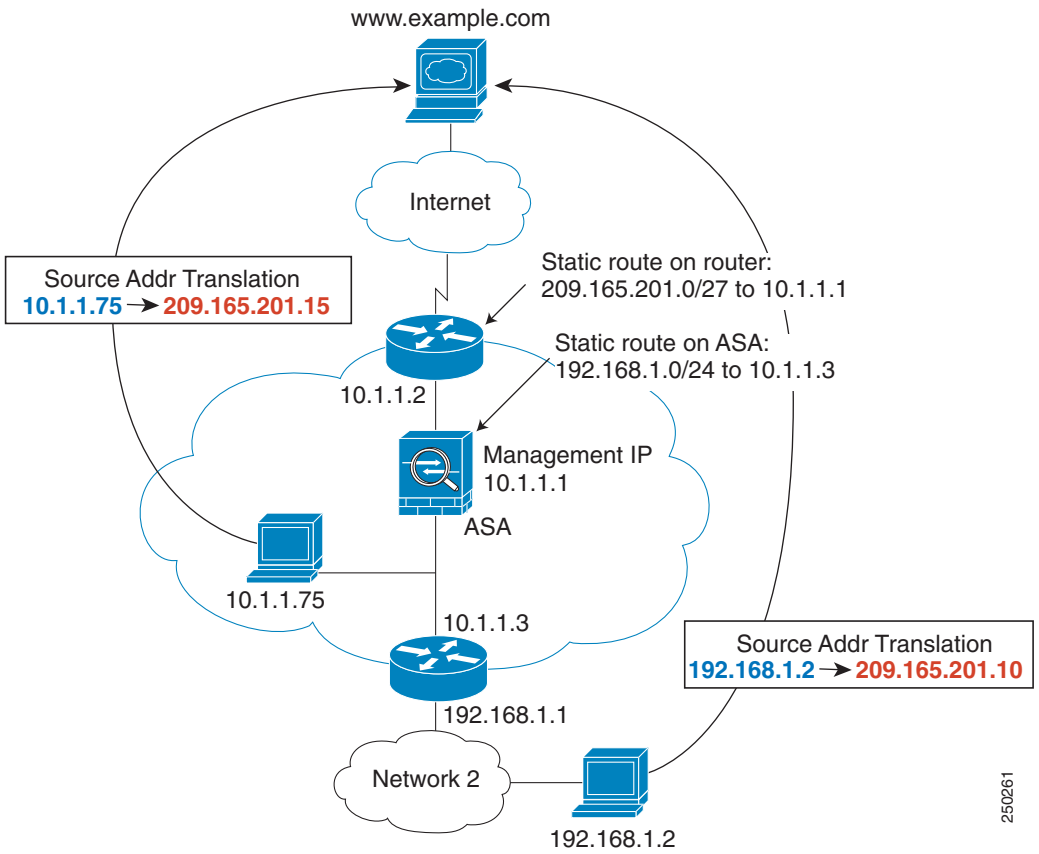
Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks.

NAT in transparent mode has the following requirements and limitations:

- Because the transparent firewall does not have any interface IP addresses, you cannot use interface PAT.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the ASA sends an ARP request to a host on the other side of the ASA, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

Figure 39-13 shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

Figure 39-13 NAT Example: Transparent Mode



1. When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.
2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the ASA receives the packet because the upstream router includes this mapped network in a static route directed to the ASA management IP address. See the "Mapped Addresses and Routing" section on page 39-22 for more information about required routes.
3. The ASA then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the ASA sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the ASA looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the ASA static route for 192.168.1.0/24. See the "Transparent Mode Routing Requirements for Remote Networks" section on page 39-24 for more information about required routes.

NAT and IPv6

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-tonet, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

For specific implementation guidelines and limitations, see the configuration chapters.

How NAT is Implemented

The ASA can implement address translation in two ways: *network object NAT* and *twice NAT*. This section includes the following topics:

- Main Differences Between Network Object NAT and Twice NAT, page 39-15
- Information About Network Object NAT, page 39-16
- Information About Twice NAT, page 39-16

Main Differences Between Network Object NAT and Twice NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Network object NAT—You define NAT as a parameter for a network object. A network object names an IP host, range, or subnet so you can then use the object in configuration instead of the actual IP addresses. The network object IP address serves as the real address. This method lets you easily add NAT to network objects that might already be used in other parts of your configuration.
  - Twice NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that twice NAT is more scalable.
- How source and destination NAT is implemented.

  - Network object NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Twice NAT—A single rule translates both the source and destination. A matching packet only matches the one rule, and further rules are not checked. Even if you do not configure the optional destination address for twice NAT, a matching packet still only matches one twice NAT rule. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.

- Order of NAT Rules.
  - Network object NAT—Automatically ordered in the NAT table.
  - Twice NAT—Manually ordered in the NAT table (before or after network object NAT rules).

  See the "NAT Rule Order" section on page 39-20 for more information.

We recommend using network object NAT unless you need the extra features that twice NAT provides. Network object NAT is easier to configure, and might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, because twice NAT is applicable only between two objects, you might see a failure in the translation of indirect addresses that do not belong to either of the objects.)

Information About Network Object NAT

All NAT rules that are configured as a parameter of a network object are considered to be *network object NAT* rules. Network object NAT is a quick and easy way to configure NAT for a network object, which can be a single IP address, a range of addresses, or a subnet.

After you configure the network object, you can then identify the mapped address for that object, either as an inline address or as another network object or network object group.

When a packet enters the ASA, both the source and destination IP addresses are checked against the network object NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use twice NAT for that kind of functionality (twice NAT lets you identify the source and destination address in a single rule).

To start configuring network object NAT, see Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)."

Information About Twice NAT

Twice NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Twice NAT also lets you use service objects for static NAT with port translation; network object NAT only accepts inline definition.

To start configuring twice NAT, see Chapter 41, "Configuring Twice NAT (ASA 8.3 and Later)."

Figure 39-14 shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130. (See the "Single Address for FTP, HTTP, and SMTP (Static NAT-with-Port-Translation)" section on page 40-32 for details on how to configure this example.)

Figure 39-14 Twice NAT with Different Destination Addresses

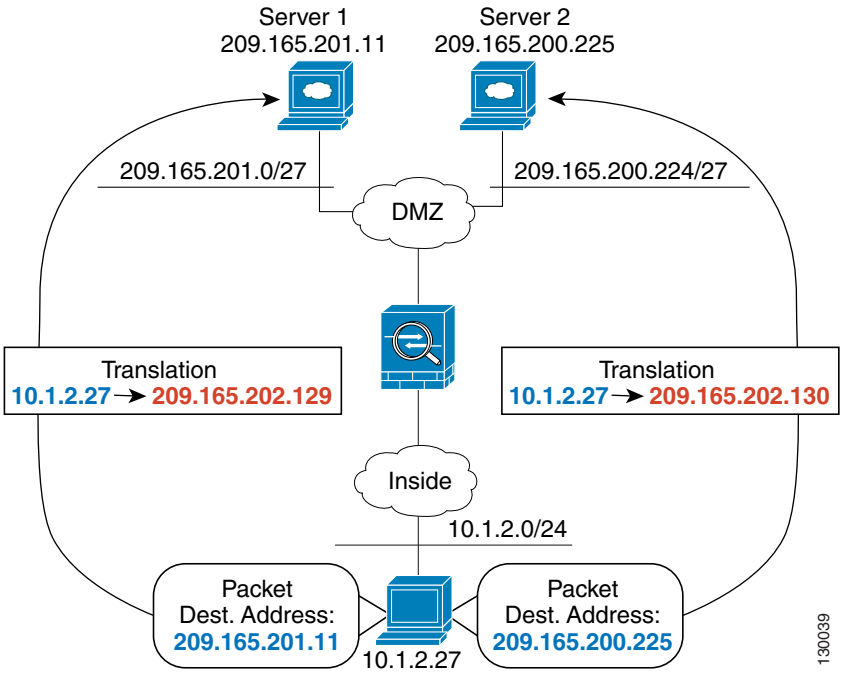


Figure 39-15 shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for web services, the real address is translated to 209.165.202.129. When the host accesses the same server for Telnet services, the real address is translated to 209.165.202.130.

Figure 39-15 Twice NAT with Different Destination Ports

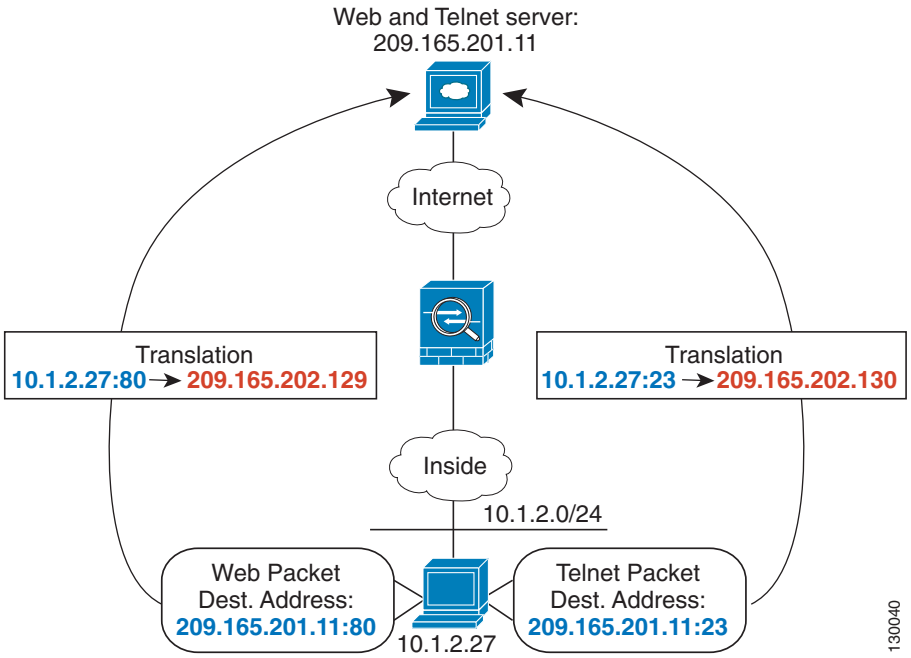

Figure 39-16 shows a remote host connecting to a mapped host. The mapped host has a twice static NAT translation that translates the real address only for traffic to and from the 209.165.201.0/27 network. A translation does not exist for the 209.165.200.224/27 network, so the translated host cannot connect to that network, nor can a host on that network connect to the translated host.

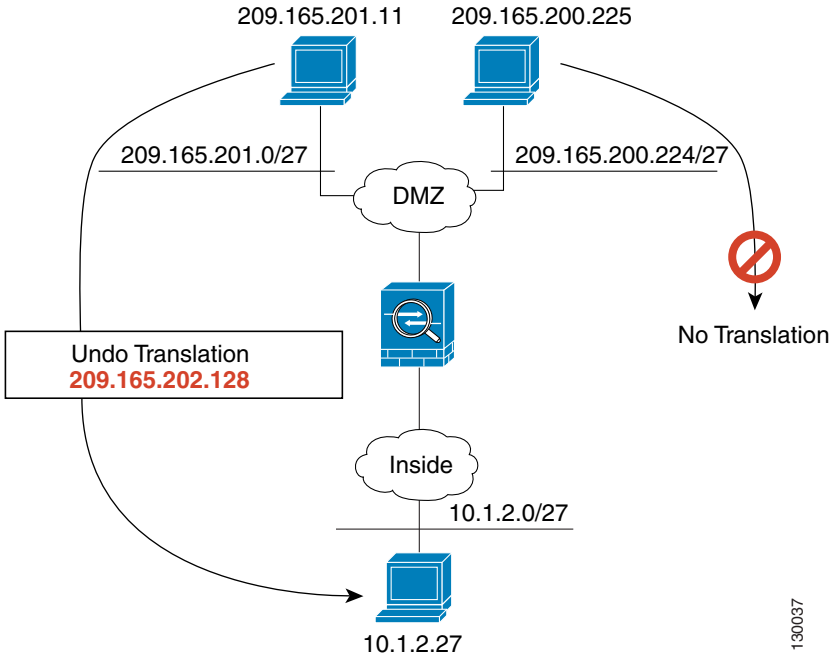
Figure 39-16 Twice Static NAT with Destination Address Translation



NAT Rule Order

Network object NAT rules and twice NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3. Table 39-1 shows the order of rules within each section.

Table 39-1 NAT Rule Table

Table Section	Rule Type	Order of Rules within the Section
Section 1	Twice NAT	Applied on a first match basis, in the order they appear in the configuration. By default, twice NAT rules are added to section 1. **Note** If you configure EasyVPN remote, the ASA dynamically adds invisible NAT rules to the end of this section. Be sure that you do not configure a twice NAT rule in this section that might match your VPN traffic, instead of matching the invisible rule. If VPN does not work due to NAT failure, consider adding twice NAT rules to section 3 instead.
Section 2	Network object NAT	Section 2 rules are applied in the following order, as automatically determined by the ASA: 1. Static rules. 2. Dynamic rules. Within each rule type, the following ordering guidelines are used: a. Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses. b. For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0. c. If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.
Section 3	Twice NAT	Section 3 rules are applied on a first match basis, in the order they appear in the configuration. You can specify whether to add a twice NAT rule to section 3 when you add the rule.

For section 2 rules, for example, you have the following IP addresses defined within network objects:

192.168.1.0/24 (static)

192.168.1.0/24 (dynamic)

10.1.1.0/24 (static)

192.168.1.1/32 (static)

172.16.1.0/24 (dynamic) (object def)

172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:

192.168.1.1/32 (static)

10.1.1.0/24 (static)

192.168.1.0/24 (static)

172.16.1.0/24 (dynamic) (object abc)

172.16.1.0/24 (dynamic) (object def)

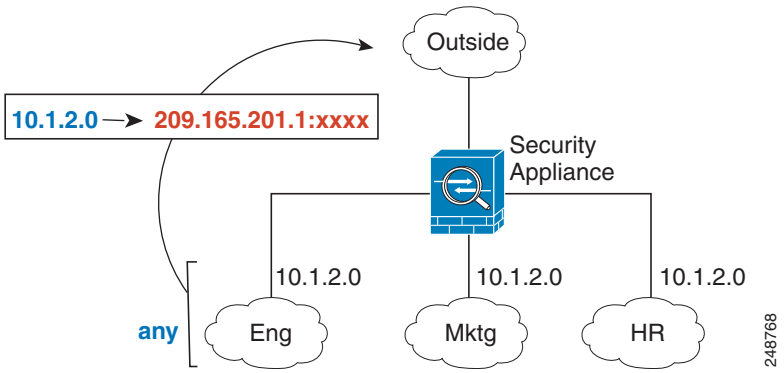
192.168.1.0/24 (dynamic)

NAT Interfaces

You can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside (Figure 39-17).

Figure 39-17 Specifying Any Interface



Note For transparent mode, you must choose specific source and destination interfaces.

Routing NAT Packets

The ASA needs to be the destination for any packets sent to the mapped address. The ASA also needs to determine the egress interface for translated packets. This section describes how the ASA handles accepting and delivering packets with NAT, and includes the following topics:

- Mapped Addresses and Routing, page 39-22
- Transparent Mode Routing Requirements for Remote Networks, page 39-24
- Determining the Egress Interface, page 39-24

Mapped Addresses and Routing

When you translate the real address to a mapped address, the mapped address you choose determines how to configure routing, if necessary, for the mapped address.

See additional guidelines about mapped IP addresses in Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)," and Chapter 41, "Configuring Twice NAT (ASA 8.3 and Later)."

See the following mapped address types:

- Addresses on the same network as the mapped interface.

  If you use addresses on the same network as the mapped interface, the ASA uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the ASA does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

  Note If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address (see Configuration > Device Management > Advanced > ARP > ARP Static Table). Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur.

- Addresses on a unique network.

  If you need more addresses than are available on the mapped interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the ASA. Alternatively for routed mode, you can configure a static route on the ASA for the mapped addresses, and then redistribute the route using your routing protocol. For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the ASA: in 8.3, specify the global management IP address; in 8.4(1) and later, specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

- The same address as the real address (identity NAT).

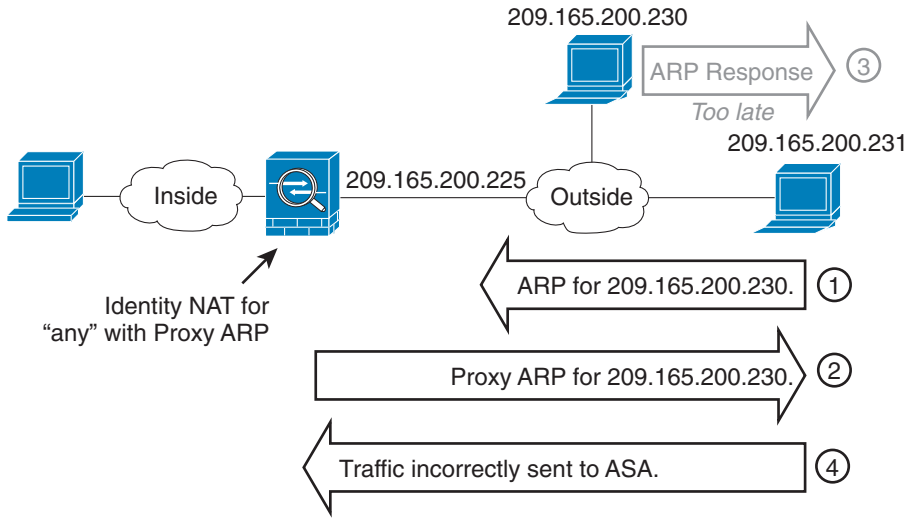
  (8.3(1), 8.3(2), and 8.4(1)) The default behavior for identity NAT has proxy ARP disabled. You cannot configure this setting.

  (8.4(2) and later) The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. **Note**: You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

  Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for "any" IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly-connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches "any" address). The ASA will then proxy ARP for the address, even though the packet is not actually destined for the ASA. (Note that this problem occurs even if you have a twice NAT rule; although

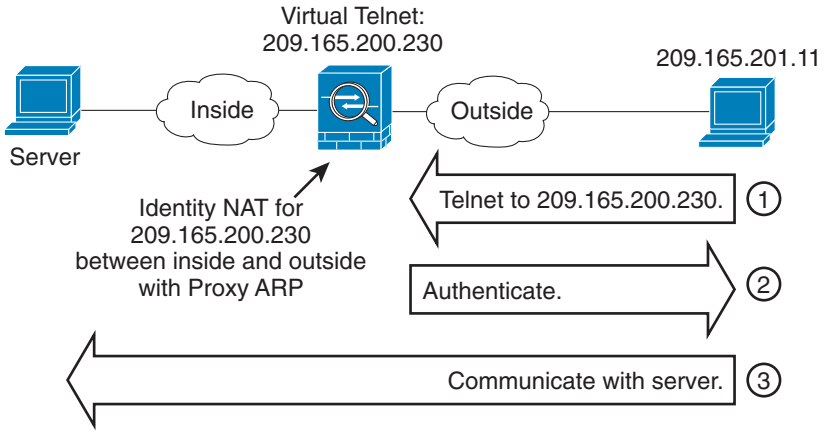
the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the "source" address). If the ASA ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the ASA (see Figure 39-18).

Figure 39-18 Proxy ARP Problems with Identity NAT



In rare cases, you need proxy ARP for identity NAT; for example for virtual Telnet. When using AAA for network access, a host needs to authenticate with the ASA using a service like Telnet before any other traffic can pass. You can configure a virtual Telnet server on the ASA to provide the necessary login. When accessing the virtual Telnet address from the outside, you must configure an identity NAT rule for the address specifically for the proxy ARP functionality. Due to internal processes for virtual Telnet, proxy ARP lets the ASA keep traffic destined for the virtual Telnet address rather than send the traffic out the source interface according to the NAT rule. (See Figure 39-19).

Figure 39-19 Proxy ARP and Virtual Telnet



Transparent Mode Routing Requirements for Remote Networks

If the ASA performs NAT for a host that is not on the directly-connected network, then you need to configure a static route on the ASA for that network. You also need to have a static route for embedded IP addresses that are at least one hop away from the ASA (such as in VoIP or DNS traffic) when you have inspection and NAT enabled.

Determining the Egress Interface

In transparent mode, the ASA determines the egress interface for a NAT packet by using the NAT configuration; you must specify the source and destination interfaces as part of the NAT configuration.

In routed mode, the ASA determines the egress interface for a NAT packet in the following way:

- If you specify an optional interface, then the ASA uses the NAT configuration to determine the egress interface. (8.3(1) through 8.4(1)) The only exception is for identity NAT, which always uses a route lookup, regardless of the NAT configuration. (8.4(2) and later) For identity NAT, the default behavior is to use the NAT configuration, but you have the option to always use a route lookup instead.
- If you do not specify a specific interface, then the ASA uses a route lookup to determine the egress interface.

NAT for VPN

- NAT and Remote Access VPN, page 39-24
- NAT and Site-to-Site VPN, page 39-26
- NAT and VPN Management Access, page 39-28
- Troubleshooting NAT and VPN, page 39-30

NAT and Remote Access VPN

Figure 39-20 shows both an inside server (10.1.1.6) and a VPN client (209.165.201.10) accessing the Internet. Unless you configure split tunnelling for the VPN client (where only specified traffic goes through the VPN tunnel), then Internet-bound VPN traffic must also go through the ASA. When the VPN traffic enters the ASA, the ASA decrypts the packet; the resulting packet includes the VPN client local address (10.3.3.10) as the source. For both inside and VPN client local networks, you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. To allow the VPN traffic to exit the same interface it entered, you also need to enable intra-interface communication (AKA “hairpin” networking).

Figure 39-20 Interface PAT for Internet-Bound VPN Traffic (Intra-Interface)

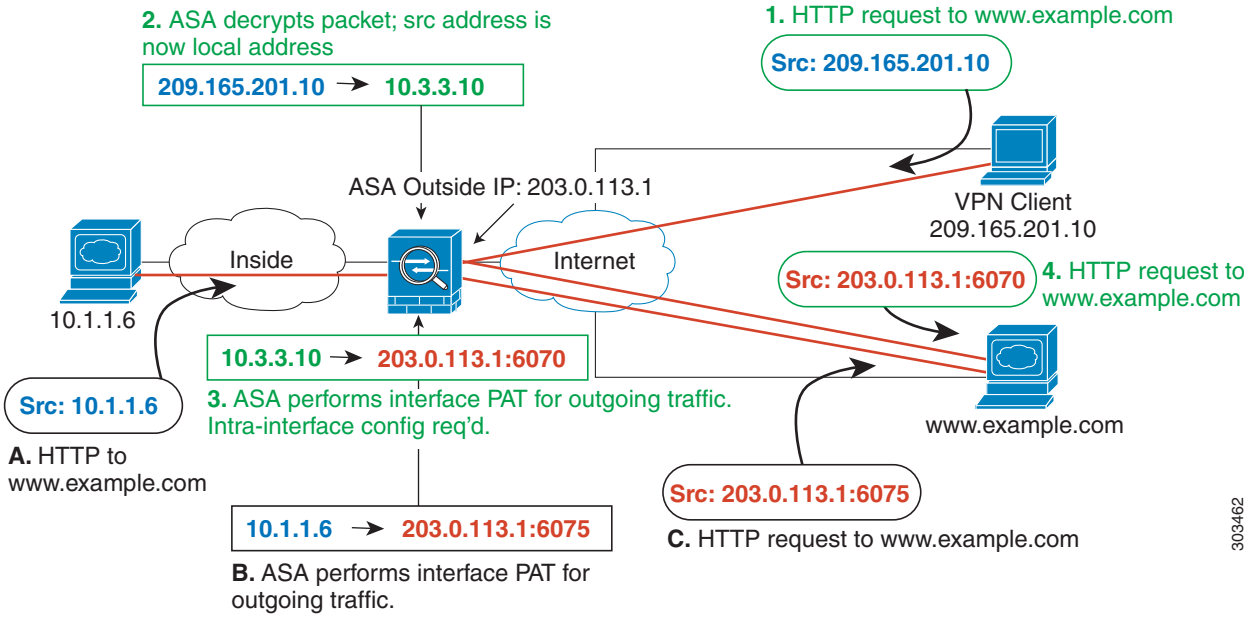


Figure 39-21 shows a VPN client that wants to access an inside mail server. Because the ASA expects traffic between the inside network and any outside network to match the interface PAT rule you set up for Internet access, traffic from the VPN client (10.3.3.10) to the SMTP server (10.1.1.6) will be dropped due to a reverse path failure: traffic from 10.3.3.10 to 10.1.1.6 does not match a NAT rule, but returning traffic from 10.1.1.6 to 10.3.3.10 *should* match the interface PAT rule for outgoing traffic. Because forward and reverse flows do not match, the ASA drops the packet when it is received. To avoid this failure, you need to exempt the inside-to-VPN client traffic from the interface PAT rule by using an identity NAT rule between those networks. Identity NAT simply translates an address to the same address.

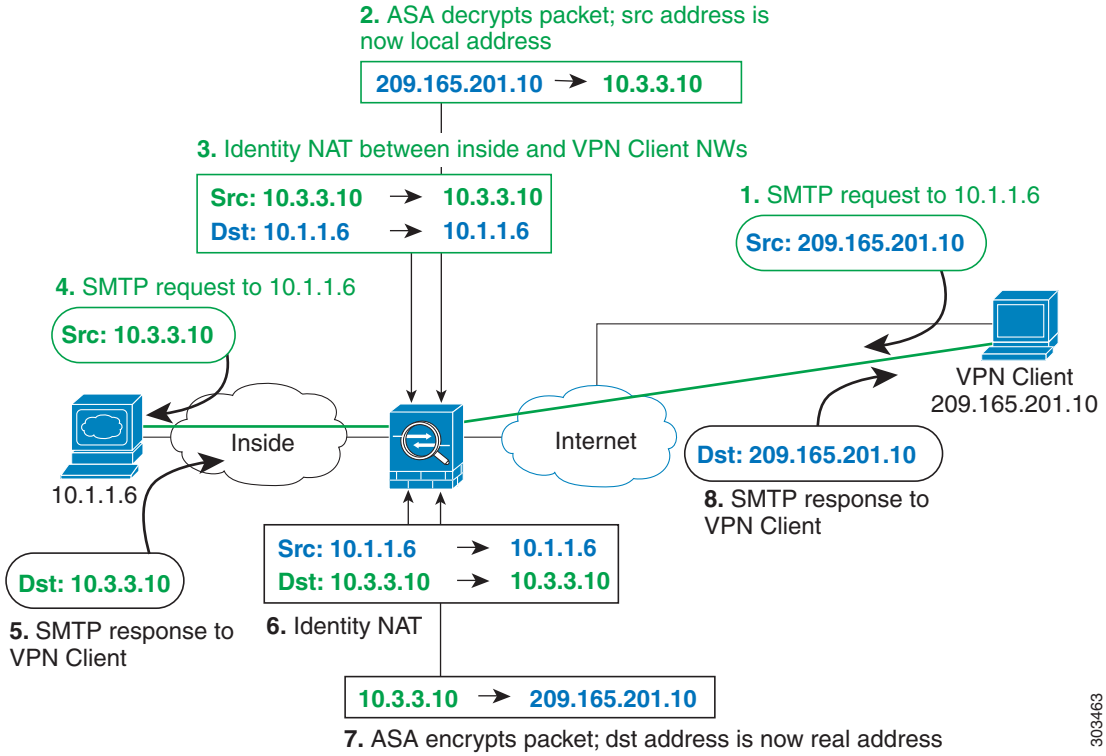
Figure 39-21 Identity NAT for VPN Clients



See the following sample NAT configuration for the above network:

```
! Enable hairpin for non-split-tunneled VPN client traffic:
same-security-traffic permit intra-interface

! Identify local VPN network, & perform object interface PAT when going to Internet:
object network vpn_local
    subnet 10.3.3.0 255.255.255.0
    nat (outside,outside) dynamic interface

! Identify inside network, & perform object interface PAT when going to Internet:
object network inside_nw
    subnet 10.1.1.0 255.255.255.0
    nat (inside,outside) dynamic interface

! Use twice NAT to pass traffic between the inside network and the VPN client without
! address translation (identity NAT):
nat (inside,outside) source static inside_nw inside_nw destination static vpn_local
vpn_local
```

NAT and Site-to-Site VPN

Figure 39-22 shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 39-22 Interface PAT and Identity NAT for Site-to-Site VPN

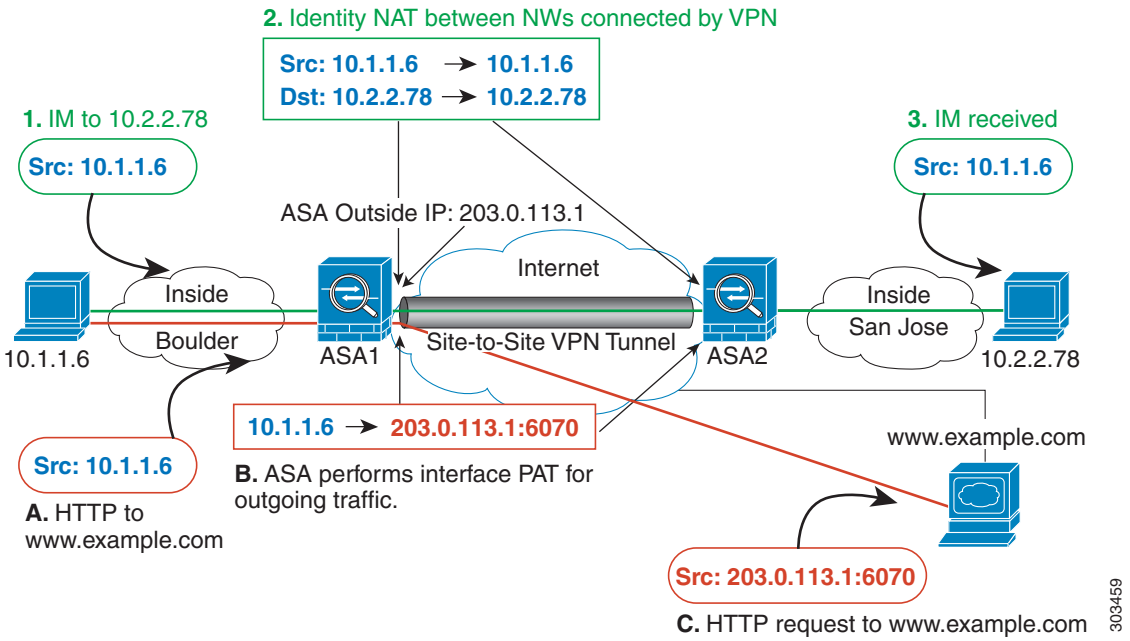


Figure 39-23 shows a VPN client connected to ASA1 (Boulder), with a Telnet request for a server (10.2.2.78) accessible over a site-to-site tunnel between ASA1 and ASA2 (San Jose). Because this is a hairpin connection, you need to enable intra-interface communication, which is also required for non-split-tunneled Internet-bound traffic from the VPN client. You also need to configure identity NAT between the VPN client and the Boulder & San Jose networks, just as you would between any networks connected by VPN to exempt this traffic from outbound NAT rules.

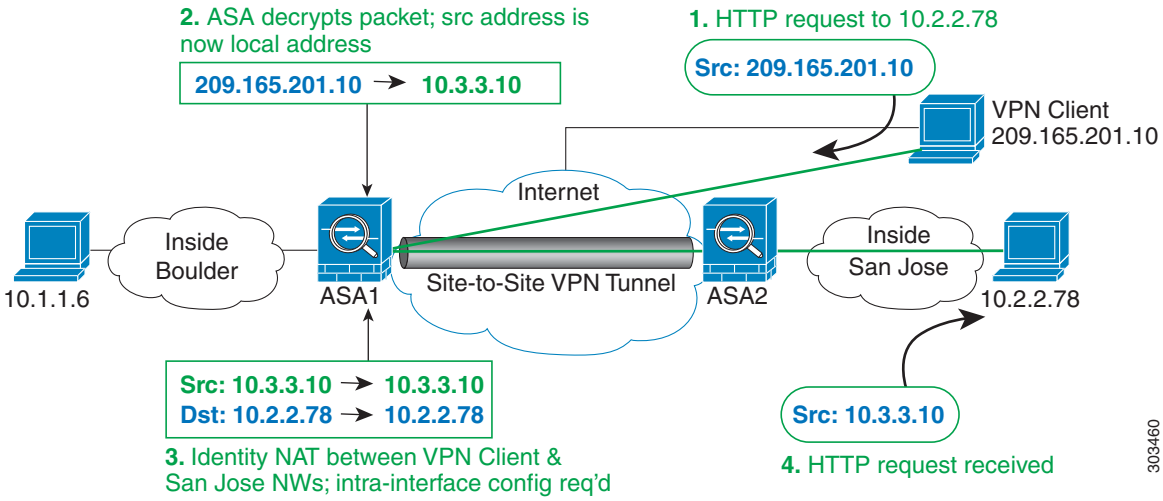
Figure 39-23 VPN Client Access to Site-to-Site VPN



See the following sample NAT configuration for ASA1 (Boulder):

```
! Enable hairpin for VPN client traffic:
same-security-traffic permit intra-interface

! Identify local VPN network, & perform object interface PAT when going to Internet:
```

```
object network vpn_local
    subnet 10.3.3.0 255.255.255.0
    nat (outside,outside) dynamic interface

! Identify inside Boulder network, & perform object interface PAT when going to Internet:
object network boulder_inside
    subnet 10.1.1.0 255.255.255.0
    nat (inside,outside) dynamic interface

! Identify inside San Jose network for use in twice NAT rule:
object network sanjose_inside
    subnet 10.2.2.0 255.255.255.0

! Use twice NAT to pass traffic between the Boulder network and the VPN client without
! address translation (identity NAT):
nat (inside,outside) source static boulder_inside boulder_inside destination static
vpn_local vpn_local

! Use twice NAT to pass traffic between the Boulder network and San Jose without
! address translation (identity NAT):
nat (inside,outside) source static boulder_inside boulder_inside destination static
sanjose_inside sanjose_inside

! Use twice NAT to pass traffic between the VPN client and San Jose without
! address translation (identity NAT):
nat (outside,outside) source static vpn_local vpn_local destination static sanjose_inside
sanjose_inside
```

See the following sample NAT configuration for ASA2 (San Jose):

```
! Identify inside San Jose network, & perform object interface PAT when going to Internet:
object network sanjose_inside
    subnet 10.2.2.0 255.255.255.0
    nat (inside,outside) dynamic interface

! Identify inside Boulder network for use in twice NAT rule:
object network boulder_inside
    subnet 10.1.1.0 255.255.255.0

! Identify local VPN network for use in twice NAT rule:
object network vpn_local
    subnet 10.3.3.0 255.255.255.0

! Use twice NAT to pass traffic between the San Jose network and Boulder without
! address translation (identity NAT):
nat (inside,outside) source static sanjose_inside sanjose_inside destination static
boulder_inside boulder_inside

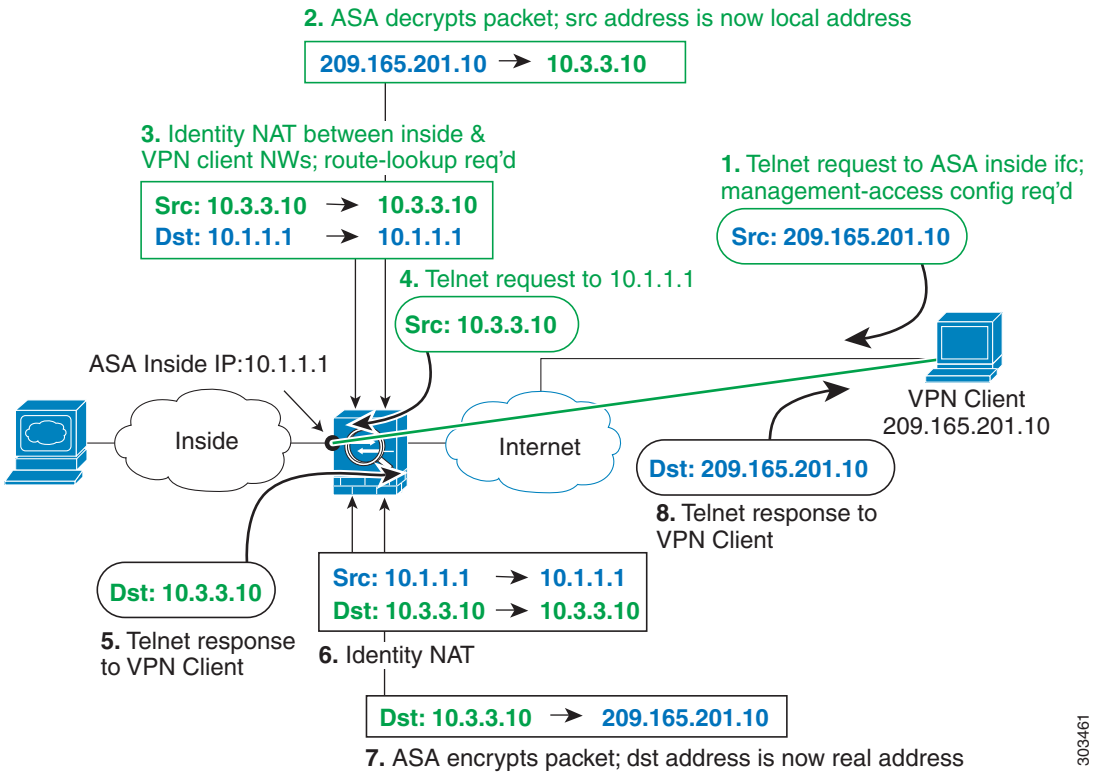
! Use twice NAT to pass traffic between the San Jose network and the VPN client without
! address translation (identity NAT):
nat (inside,outside) source static sanjose_inside sanjose_inside destination static
vpn_local vpn_local
```

NAT and VPN Management Access

When using VPN, you can allow management access to an interface other than the one from which you entered the ASA ("Configuring Management Access Over a VPN Tunnel" section on page 34-18). For example, if you enter the ASA from the outside interface, the management-access feature lets you connect to the inside interface using ASDM, SSH, Telnet, or SNMP; or you can ping the inside interface.

Figure 39-24 shows a VPN client Telnetting to the ASA inside interface. When you use a management-access interface, and you configure identity NAT according to the "NAT and Remote Access VPN" or "NAT and Site-to-Site VPN" section, you must configure NAT with the route lookup option. Without route lookup, the ASA sends traffic out the interface specified in the NAT command, regardless of what the routing table says; in the below example, the egress interface is the inside interface. You do not want the ASA to send the management traffic out to the inside network; it will never return to the inside interface IP address. The route lookup option lets the ASA send the traffic directly to the inside interface IP address instead of to the inside network. For traffic from the VPN client to a host on the inside network, the route lookup option will still result in the correct egress interface (inside), so normal traffic flow is not affected. See the "Determining the Egress Interface" section on page 39-24 for more information about the route lookup option.

Figure 39-24 VPN Management Access



See the following sample NAT configuration for the above network:

```
! Enable hairpin for non-split-tunneled VPN client traffic:
same-security-traffic permit intra-interface

! Enable management access on inside ifc:
management-access inside

! Identify local VPN network, & perform object interface PAT when going to Internet:
object network vpn_local
    subnet 10.3.3.0 255.255.255.0
    nat (outside,outside) dynamic interface

! Identify inside network, & perform object interface PAT when going to Internet:
object network inside_nw
    subnet 10.1.1.0 255.255.255.0
    nat (inside,outside) dynamic interface
```

```
! Use twice NAT to pass traffic between the inside network and the VPN client without
! address translation (identity NAT), w/route-lookup:
nat (outside,inside) source static vpn_local vpn_local destination static inside_nw
inside_nw route-lookup
```

Troubleshooting NAT and VPN

See the following monitoring tools for troubleshooting NAT issues with VPN:

- Packet tracer—When used correctly, a packet tracer shows which NAT rules a packet is hitting.
- **show nat detail**—Shows hit counts and untranslated traffic for a given NAT rule.
- **show conn all**—Lets you see active connections including to and from the box traffic.

To familiarize yourself with a non-working configuration vs. a working configuration, you can perform the following steps:

1. Configure VPN without identity NAT.
2. Enter **show nat detail** and **show conn all**.
3. Add the identity NAT configuration.
- Repeat **show nat detail** and **show conn all**.

DNS and NAT

You might need to configure the ASA to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation rule.

For IPv4, this feature rewrites the A record, or address record, in DNS replies that match a NAT rule. For IPv6, it rewrites the AAAA record. For NAT64, it converts between A and AAAA records. For DNS replies traversing from a mapped interface to any other interface, the address record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the address record is rewritten from the real value to the mapped value.

Note If you configure a twice NAT rule, you cannot configure DNS modification if you specify the source address as well as the destination address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, the ASA cannot accurately match the IP address inside the DNS reply to the correct twice NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.

Figure 39-25 shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure the ASA to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network. In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address. When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The ASA refers to the static rule for the inside server

and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

Figure 39-25 DNS Reply Modification, DNS Server on Outside

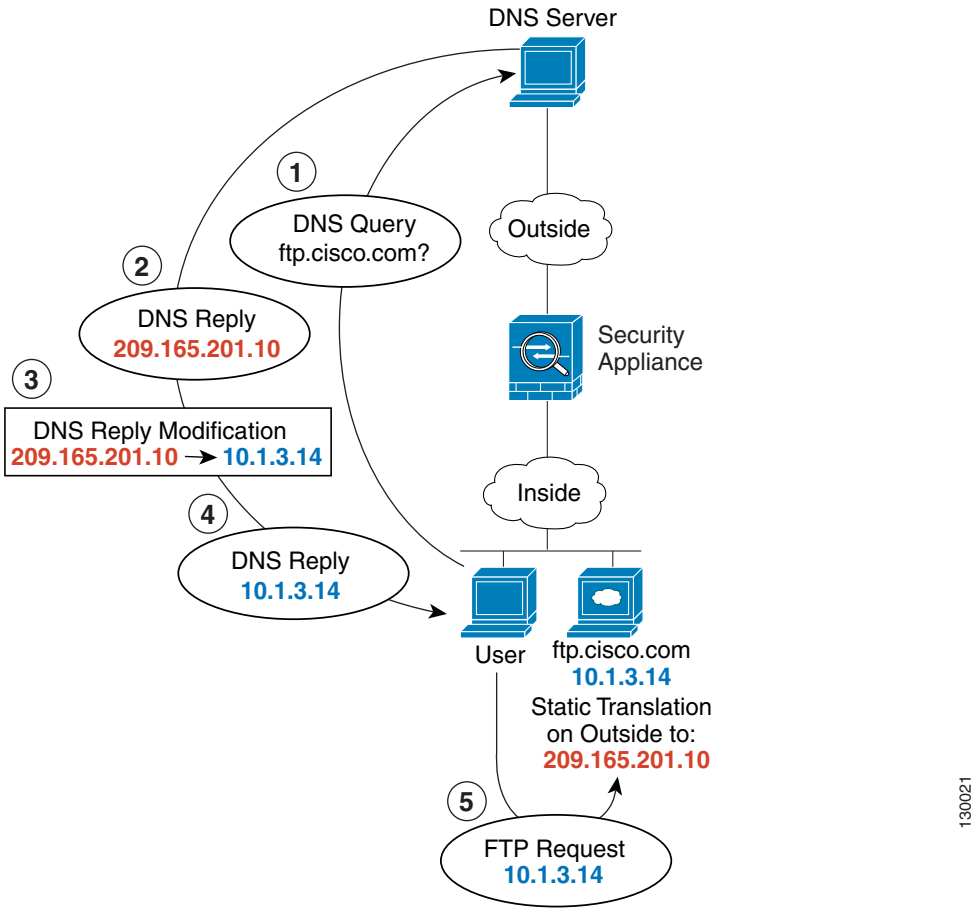


Figure 39-26 shows a user on the inside network requesting the IP address for ftp.cisco.com, which is on the DMZ network, from an outside DNS server. The DNS server replies with the mapped address (209.165.201.10) according to the static rule between outside and DMZ even though the user is not on the DMZ network. The ASA translates the address inside the DNS reply to 10.1.3.14. If the user needs to access ftp.cisco.com using the real address, then no further configuration is required. If there is also

a static rule between the inside and DMZ, then you also need to enable DNS reply modification on this rule. The DNS reply will then be modified two times.In this case, the ASA again translates the address inside the DNS reply to 192.168.1.10 according to the static rule between inside and DMZ.

Figure 39-26 DNS Reply Modification, DNS Server, Host, and Server on Separate Networks

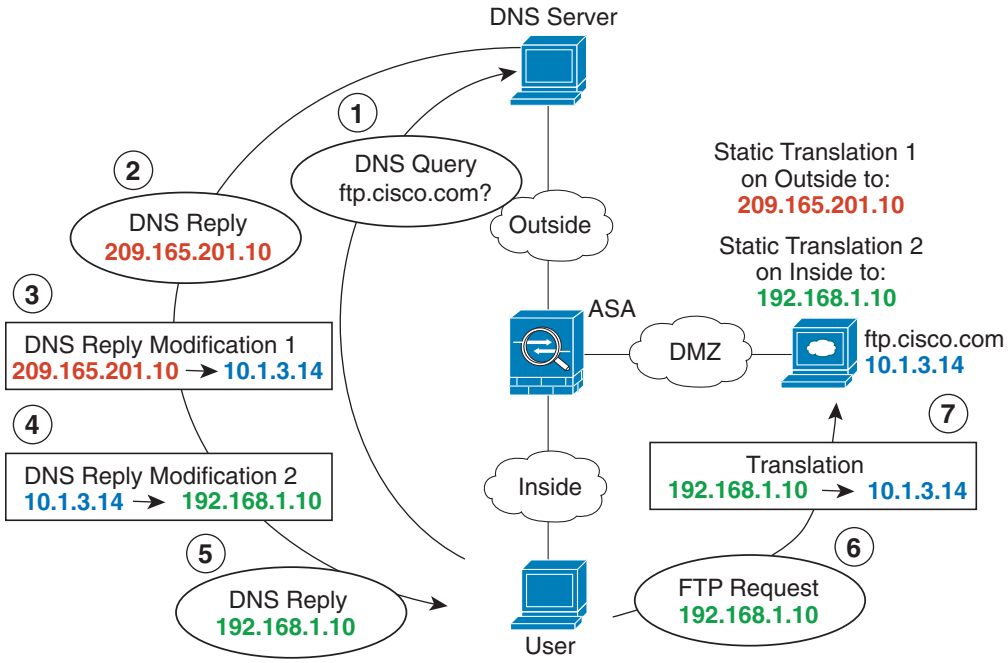

Figure 39-27 shows an FTP server and DNS server on the outside. The ASA has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Figure 39-27 DNS Reply Modification, DNS Server on Host Network

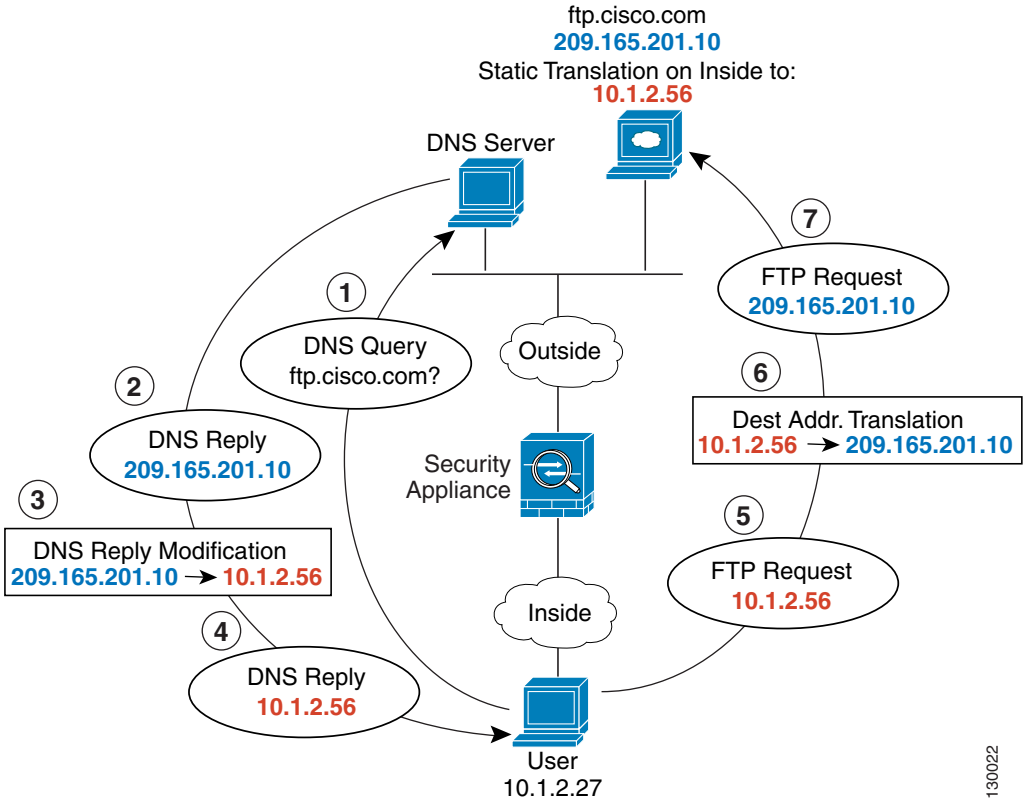

Figure 39-27 shows an FTP server and DNS server on the outside IPv4 network. The ASA has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

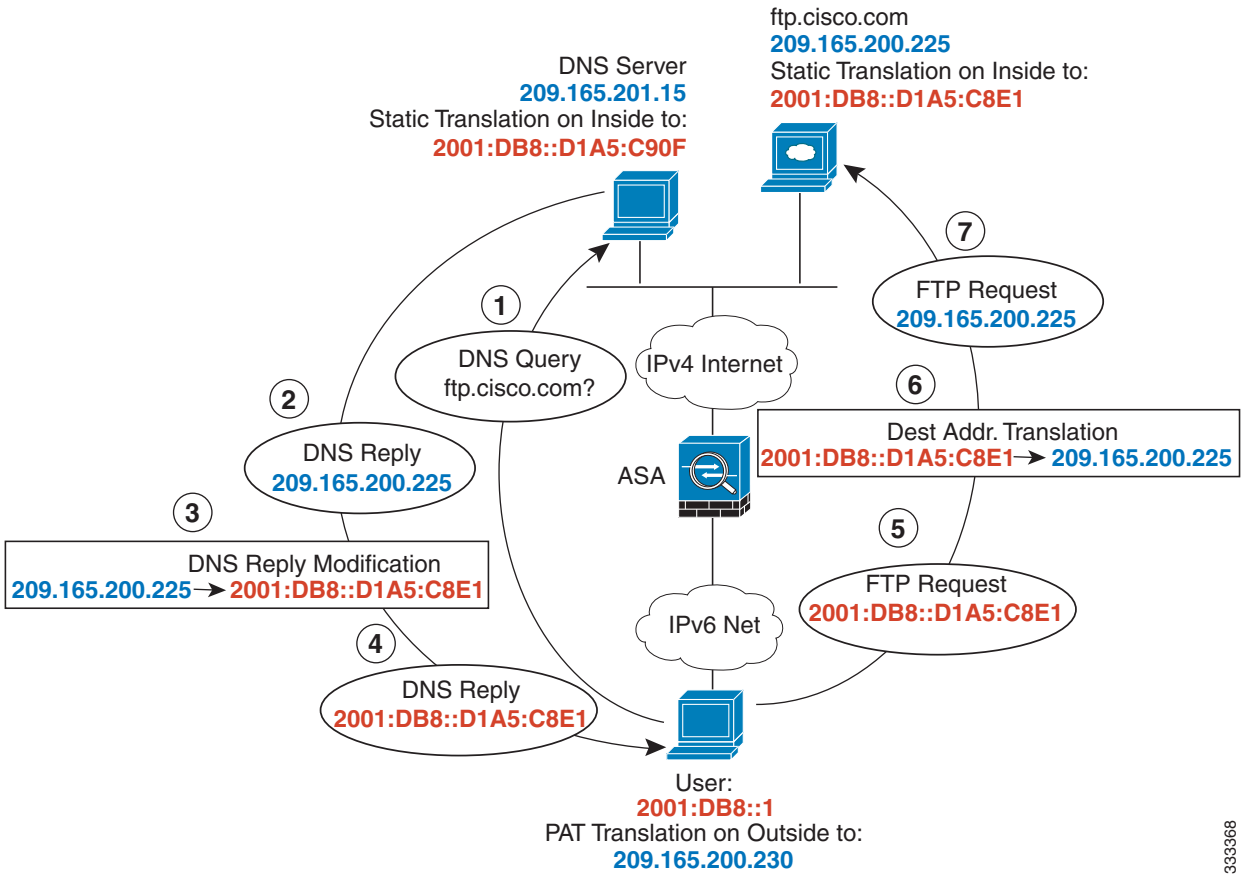
Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Figure 39-28 DNS64 Reply Modification Using Outside NAT



Where to Go Next

To configure network object NAT, see Chapter 40, "Configuring Network Object NAT (ASA 8.3 and Later)."

To configure twice NAT, see Chapter 41, "Configuring Twice NAT (ASA 8.3 and Later)."

Configuring Network Object NAT (ASA 8.3 and Later)

All NAT rules that are configured as a parameter of a network object are considered to be *network object NAT* rules. Network object NAT is a quick and easy way to configure NAT for a single IP address, a range of addresses, or a subnet. After you configure the network object, you can then identify the mapped address for that object.

This chapter describes how to configure network object NAT, and it includes the following sections:

- Information About Network Object NAT, page 40-1
- Licensing Requirements for Network Object NAT, page 40-2
- Prerequisites for Network Object NAT, page 40-2
- Guidelines and Limitations, page 40-2
- Default Settings, page 40-3
- Configuring Network Object NAT, page 40-4
- Monitoring Network Object NAT, page 40-19
- Configuration Examples for Network Object NAT, page 40-20
- Feature History for Network Object NAT, page 40-45

Note For detailed information about how NAT works, see Chapter 39, "Information About NAT (ASA 8.3 and Later)."

Information About Network Object NAT

When a packet enters the ASA, both the source and destination IP addresses are checked against the network object NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y. Use twice NAT for that kind of functionality (twice NAT lets you identify the source and destination address in a single rule).

For detailed information about the differences between twice NAT and network object NAT, see the "How NAT is Implemented" section on page 39-15.

Network object NAT rules are added to section 2 of the NAT rules table. For more information about NAT ordering, see the "NAT Rule Order" section on page 39-20.

Licensing Requirements for Network Object NAT

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Prerequisites for Network Object NAT

Depending on the configuration, you can configure the mapped address inline if desired or you can create a separate network object or network object group for the mapped address. Network object groups are particularly useful for creating a mapped address pool with discontinous IP address ranges or multiple hosts or subnets. To create a network object or group, see the "Configuring Network Objects and Groups" section on page 25-2.

For specific guidelines for objects and groups, see the configuration section for the NAT type you want to configure. See also the "Guidelines and Limitations" section.

Guidelines and Limitations

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

- Supported in routed and transparent firewall mode.
- In transparent mode, you must specify the real and mapped interfaces; you cannot use --Any--.
- In transparent mode, you cannot configure interface PAT, because the transparent mode interfaces do not have IP addresses. You also cannot use the management IP address as a mapped address.
- In transparent mode, translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

IPv6 Guidelines

- Supports IPv6. See also the "NAT and IPv6" section on page 39-15.
- For routed mode, you can also translate between IPv4 and IPv6.
- For transparent mode, translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.
- For transparent mode, a PAT pool is not supported for IPv6.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.

- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

Additional Guidelines

- You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address, for example, **object network obj-10.10.10.1-01**, **object network obj-10.10.10.1-02**, and so on.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command. However, clearing the translation table disconnects all current connections that use translations.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** command. This safeguard ensures that the same address is not assigned to multiple hosts.

- Objects and object groups used in NAT cannot be undefined; they must include IP addresses.
- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify --Any-- interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the interface name instead of the IP address.
  - (Transparent mode) The management IP address.
  - (Dynamic NAT) The standby interface IP address when VPN is enabled.
  - Existing VPN pool addresses.
- For application inspection limitations with NAT or PAT, see the "Default Settings" section on page 57-4 in Chapter 57, "Getting Started with Application Layer Protocol Inspection."

Default Settings

- (Routed mode) The default real and mapped interface is Any, which applies the rule to all interfaces.
- (8.3(1), 8.3(2), and 8.4(1)) The default behavior for identity NAT has proxy ARP disabled. You cannot configure this setting. (8.4(2) and later) The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. See the "Routing NAT Packets" section on page 39-21 for more information.
- If you specify an optional interface, then the ASA uses the NAT configuration to determine the egress interface. (8.3(1) through 8.4(1)) The only exception is for identity NAT, which always uses a route lookup, regardless of the NAT configuration. (8.4(2) and later) For identity NAT, the default behavior is to use the NAT configuration, but you have the option to always use a route lookup instead. See the "Routing NAT Packets" section on page 39-21 for more information.

Configuring Network Object NAT

This section describes how to configure network object NAT and includes the following topics:

- Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool, page 40-4
- Configuring Dynamic PAT (Hide), page 40-8
- Configuring Static NAT or Static NAT-with-Port-Translation, page 40-11
- Configuring Identity NAT, page 40-15
- Configuring Per-Session PAT Rules, page 40-18

Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool

This section describes how to configure network object NAT for dynamic NAT or for dynamic PAT using a PAT pool. For more information, see the "Dynamic NAT" section on page 39-8 or the "Dynamic PAT" section on page 39-10.

Guidelines

For a PAT pool:

- If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used. (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you have a lot of traffic that uses the lower port ranges, you can now specify for a PAT pool a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535.
- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT and a flat range, then the other rule must also specify extended PAT and a flat range.

For extended PAT for a PAT pool:

- Many application inspections do not support extended PAT. See the "Default Settings" section on page 57-4 in Chapter 57, "Getting Started with Application Layer Protocol Inspection," for a complete list of unsupported inspections.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.

For round robin for a PAT pool:

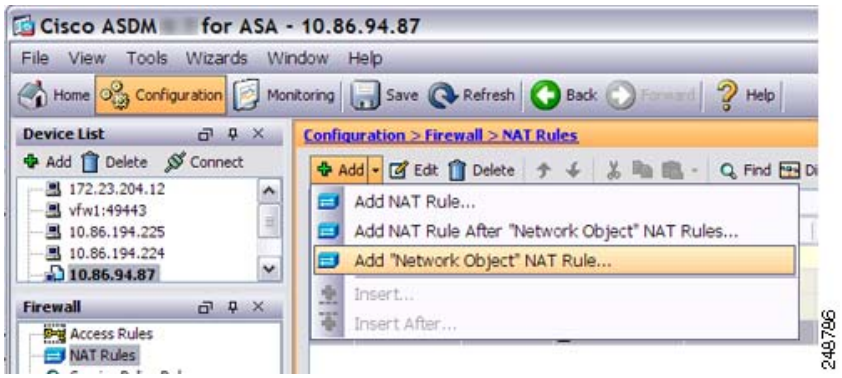
- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. **Note**: This "stickiness" does not survive a failover. If the ASA fails over, then subsequent connections from a host may not use the initial IP address.

- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

Detailed Steps

Step 1 Add NAT to a new or existing network object:

- To add a new network object, choose **Configuration > Firewall > NAT Rules**, then click **Add > Add Network Object NAT Rule**.



- To add NAT to an existing network object, choose **Configuration > Firewall > Objects > Network Objects/Groups**, and then double-click a network object.

For more information, see the "Configuring a Network Object" section on page 25-3.

The Add/Edit Network Object dialog box appears.

Step 2 For a new object, enter values for the following fields:

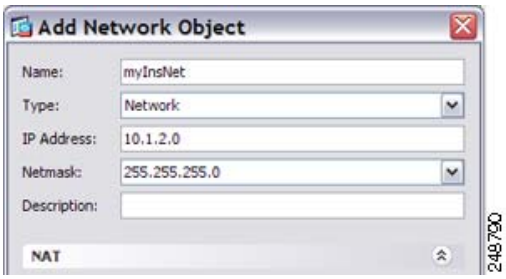
a. Name—The object name. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must be 64 characters or less.

b. Type—Host, Network, or Range.

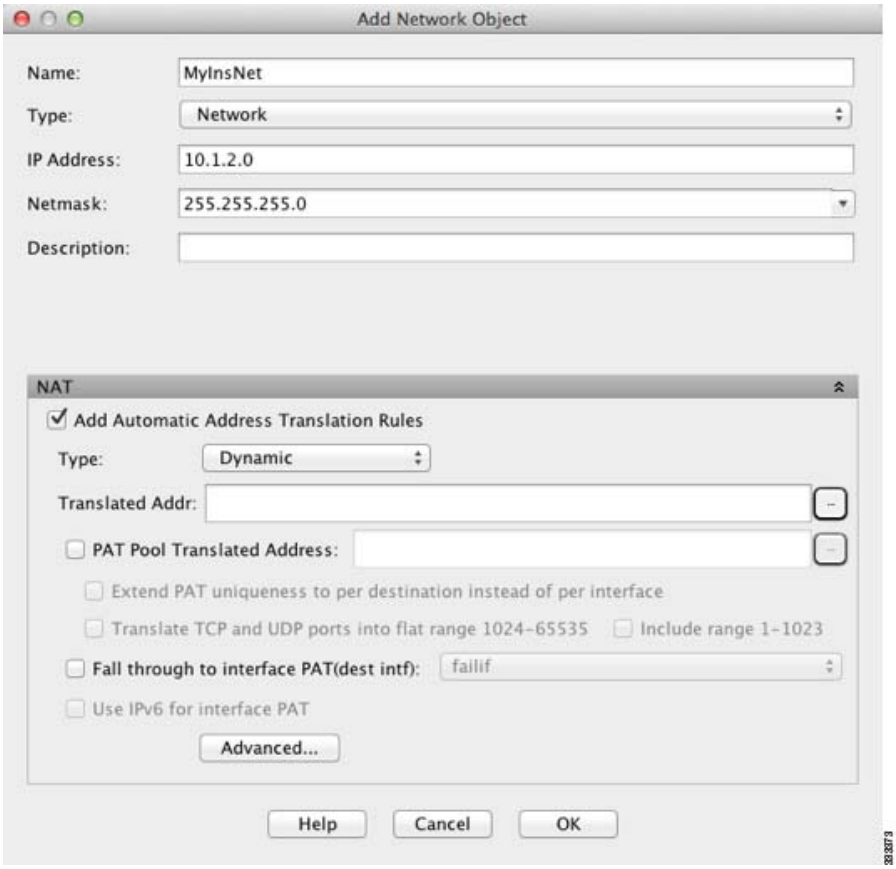
c. IP Address—An IPv4 or IPv6 address. If you select Range as the object type, the IP Address field changes to allow you to enter a Start Address and an End address.

d. Netmask/Prefix Length—Enter the subnet mask or prefix length.

e. Description—(Optional) The description of the network object (up to 200 characters in length).



Step 3 If the NAT section is hidden, click **NAT** to expand the section.

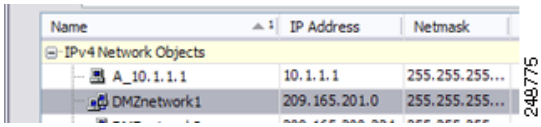


Step 4 Check the **Add Automatic Translation Rules** check box.

Step 5 From the Type drop-down list, choose **Dynamic**. Choose **Dynamic** even if you are configuring dynamic PAT with a PAT pool.

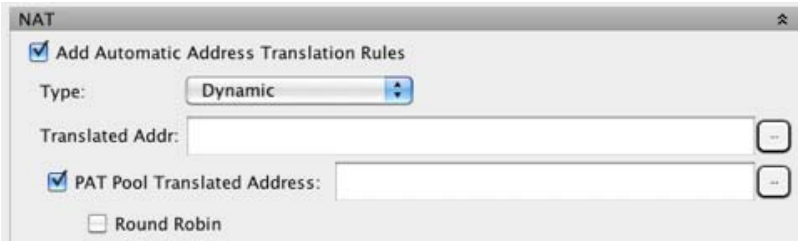
Step 6 Configure either dynamic NAT, or dynamic PAT with a PAT pool:

- Dynamic NAT—To the right of the Translated Addr field, click the browse button and choose an existing network object or create a new object from the Browse Translated Addr dialog box.



Note The object or group cannot contain a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

- Dynamic PAT using a PAT pool—Enable a PAT pool:



a. Do not enter a value for the Translated Addr. field; leave it blank.

b. Check the **PAT Pool Translated Address** check box, then click the browse button and choose an existing network object or create a new network object from the Browse Translated PAT Pool Address dialog box.

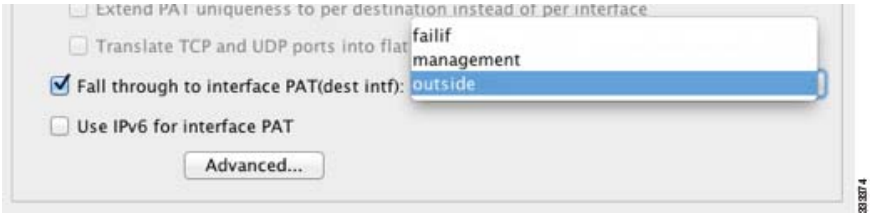
Note The PAT pool object or group cannot contain a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

c. (Optional) Check the **Round Robin** check box to assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

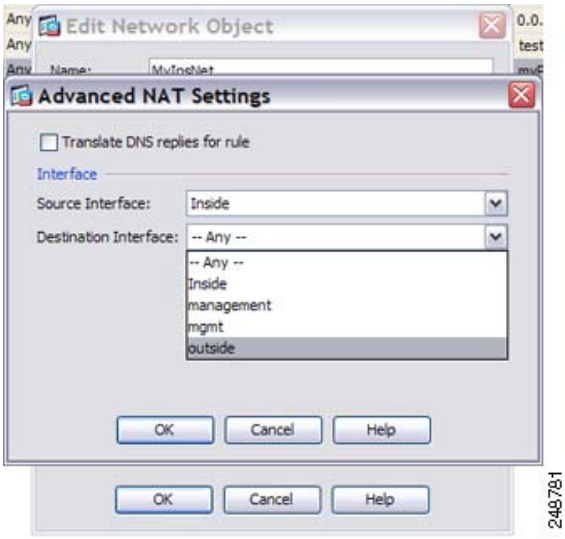
d. (Optional, 8.4(3) and later, not including 8.5(1) or 8.6(1)) Check the **Extend PAT uniqueness to per destination instead of per interface** check box to use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80.

e. (Optional, 8.4(3) and later, not including 8.5(1) or 8.6(1)) Check the **Translate TCP or UDP ports into flat range (1024-65535)** check box to use the 1024 to 65535 port range as a single flat range when allocating ports. When choosing the mapped port number for a translation, the ASA uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include range 1 to 1023** check box.

Step 7 (Optional, Routed Mode Only) To use the interface IP address as a backup method when the other mapped addresses are already allocated, check the **Fall through to interface PAT (dest intf)** check box, and choose the interface from the drop-down list. To use the IPv6 address of the interface, also check the **Use IPv6 for interface PAT** checkbox.



Step 8 (Optional) Click **Advanced**, and configure the following options in the Advanced NAT Settings dialog box.



- Translate DNS replies for rule—Translates the IP address in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the "DNS and NAT" section on page 39-30 for more information.
- (Required for Transparent Firewall Mode) Source Interface—Specifies the real interface where this NAT rule applies. By default, the rule applies to all interfaces.
- (Required for Transparent Firewall Mode) Destination Interface—Specifies the mapped interface where this NAT rule applies. By default, the rule applies to all interfaces.

When you are finished, click **OK**. You return to the Add/Edit Network Object dialog box.

Step 9 Click **OK**, and then **Apply**.

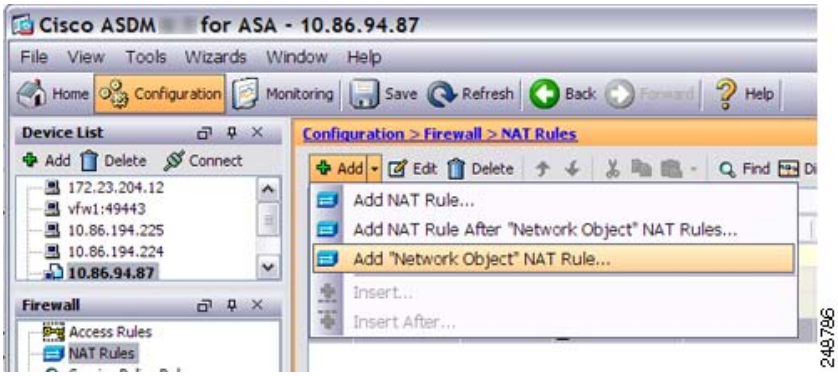
Configuring Dynamic PAT (Hide)

This section describes how to configure network object NAT for dynamic PAT (hide). For dynamic PAT using a PAT pool, see the "Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool" section on page 40-4 instead of using this section. For more information, see the "Dynamic PAT" section on page 39-10.

Detailed Steps

Step 1 Add NAT to a new or existing network object:

- To add a new network object, choose **Configuration > Firewall > NAT Rules**, then click **Add > Add Network Object NAT Rule**.



- To add NAT to an existing network object, choose **Configuration > Firewall > Objects > Network Objects/Groups**, and then double-click a network object.

For more information, see the "Configuring a Network Object" section on page 25-3.

The Add/Edit Network Object dialog box appears.

Step 2 For a new object, enter values for the following fields:

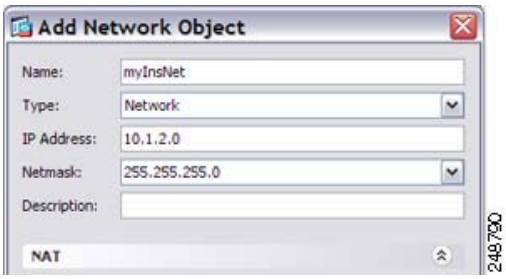
a. Name—The object name. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must be 64 characters or less.

b. Type—Host, Network, or Range.

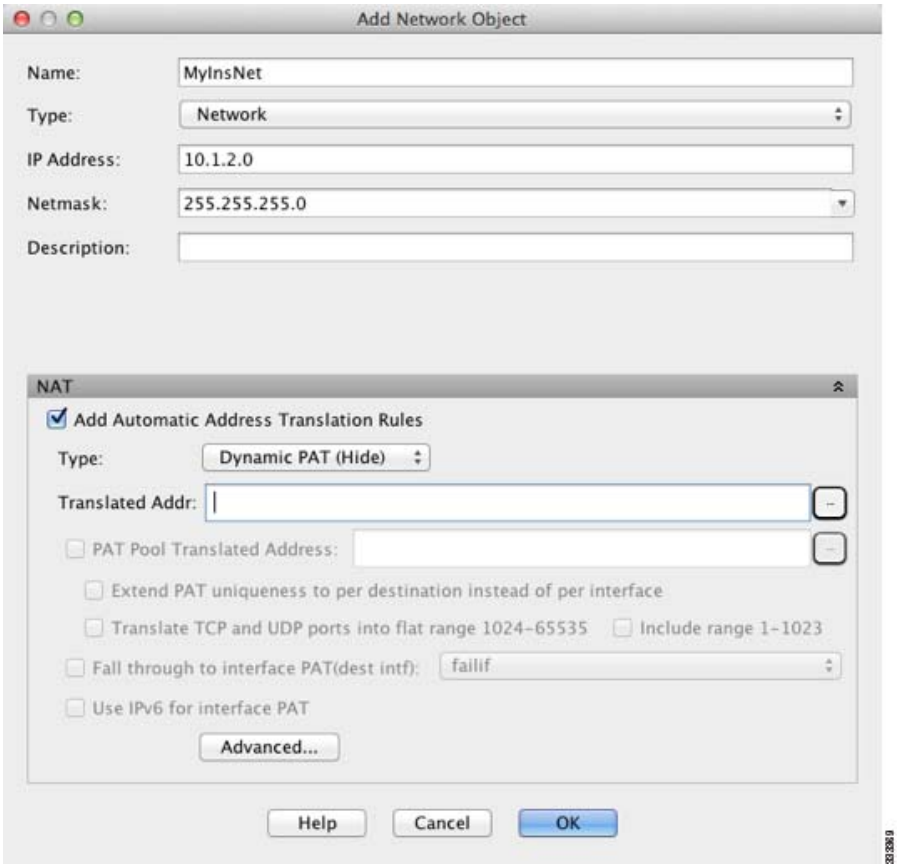
c. IP Address—An IPv4 or IPv6 address. If you select Range as the object type, the IP Address field changes to allow you to enter a Start Address and an End address.

d. Netmask/Prefix Length—Enter the subnet mask or prefix length.

e. Description—(Optional) The description of the network object (up to 200 characters in length).



Step 3 If the NAT section is hidden, click **NAT** to expand the section.



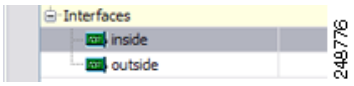
Step 4 Check the **Add Automatic Translation Rules** check box.

Step 5 From the Type drop-down list, choose **Dynamic PAT (Hide)**.

Note To configure dynamic PAT using a PAT pool instead of a single address, see the "Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool" section on page 40-4.

Step 6 Specify a single mapped address. In the Translated Addr. field, specify the mapped IP address by doing one of the following:

- Type a host IP address.
- Type an interface name or click the browse button, and choose an interface from the Browse Translated Addr dialog box.

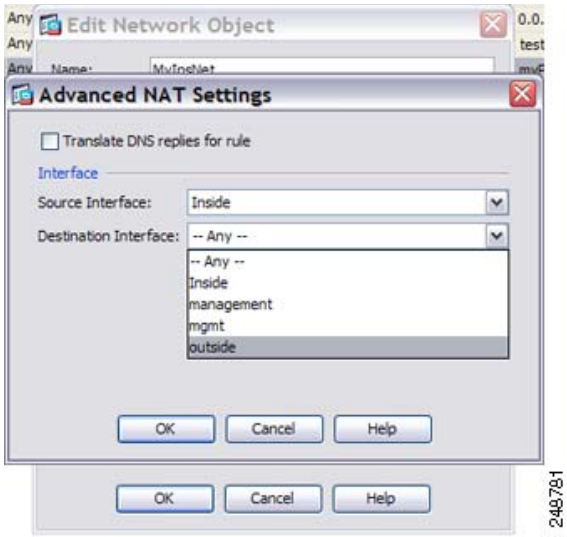


If you specify an interface name, then you enable *interface PAT*, where the specified interface IP address is used as the mapped address. To use the IPv6 interface address, you must also check the **Use IPv6 for interface PAT** checkbox. With interface PAT, the NAT rule only applies to the specified mapped interface. (If you do not use interface PAT, then the rule applies to all interfaces by default.) See Step 7 to optionally also configure the real interface to be a specific interface instead of --Any--.

Note You cannot specify an interface in transparent mode.

- Click the browse button, and choose an existing host address from the Browse Translated Addr dialog box.
- Click the browse button, and create a new named object from the Browse Translated Addr dialog box.

Step 7 (Optional) Click **Advanced**, and configure the following options in the Advanced NAT Settings dialog box.



- Translate DNS replies for rule—Translates the IP address in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the "DNS and NAT" section on page 39-30 for more information.
- (Required for Transparent Firewall Mode) Source Interface—Specifies the real interface where this NAT rule applies. By default, the rule applies to all interfaces.
- (Required for Transparent Firewall Mode) Destination Interface—Specifies the mapped interface where this NAT rule applies. By default, the rule applies to all interfaces.

When you are finished, click **OK**. You return to the Add/Edit Network Object dialog box.

Step 8 Click **OK**, and then **Apply**.

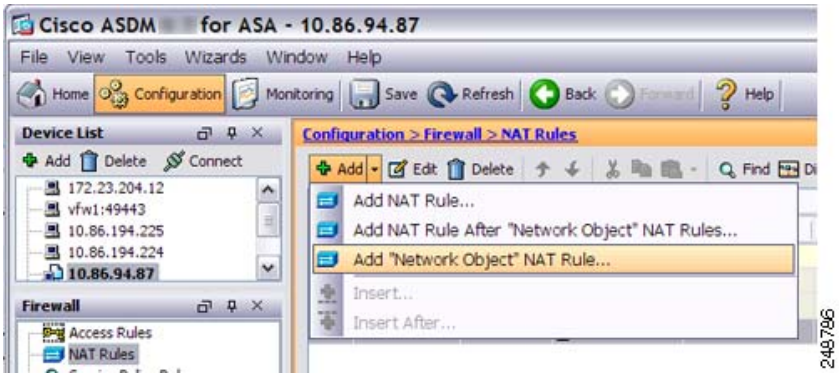
Configuring Static NAT or Static NAT-with-Port-Translation

This section describes how to configure a static NAT rule using network object NAT. For more information, see the "Static NAT" section on page 39-3.

Detailed Steps

Step 1 Add NAT to a new or existing network object:

- To add a new network object, choose **Configuration > Firewall > NAT Rules**, then click **Add > Add Network Object NAT Rule**.



- To add NAT to an existing network object, choose **Configuration > Firewall > Objects > Network Objects/Groups**, and then double-click a network object.

For more information, see the "Configuring a Network Object" section on page 25-3.

The Add/Edit Network Object dialog box appears.

Step 2 For a new object, enter values for the following fields:

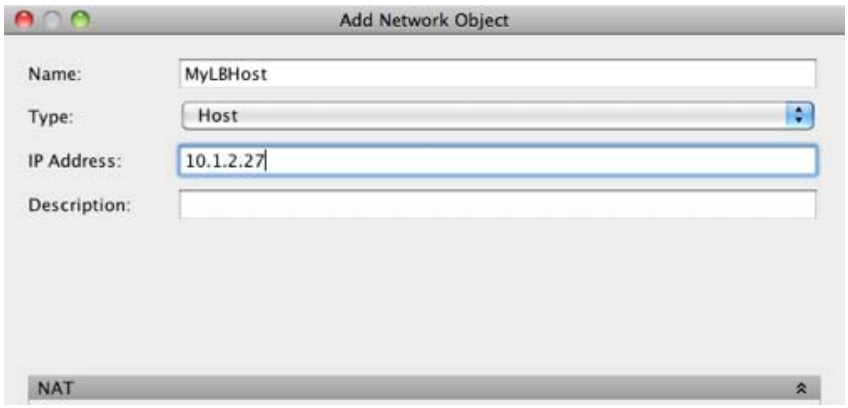
a. Name—The object name. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must be 64 characters or less.

b. Type—Network, Host, or Range.

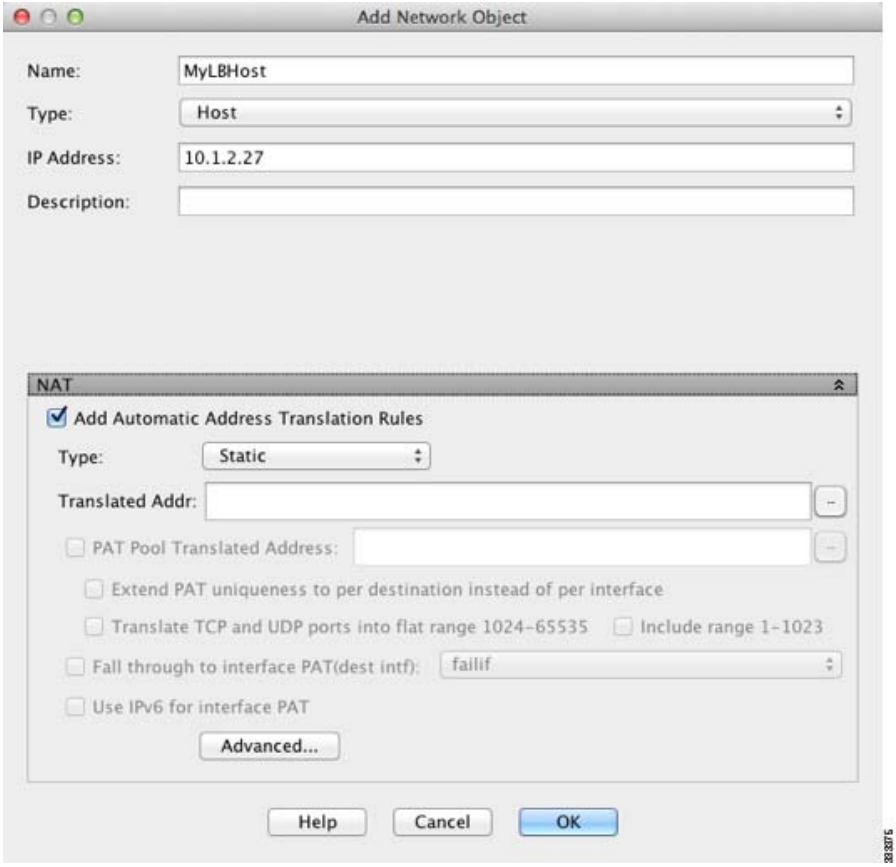
c. IP Address—An IPv4 or IPv6 address. If you select Range as the object type, the IP Address field changes to allow you to enter a Start Address and an End address.

d. Netmask/Prefix Length—Enter the subnet mask or prefix length.

e. Description—(Optional) The description of the network object (up to 200 characters in length).



Step 3 If the NAT section is hidden, click **NAT** to expand the section.



Step 4 Check the **Add Automatic Translation Rules** check box.

Step 5 From the Type drop-down list, choose **Static**.

Step 6 In the Translated Addr. field, do one of the following:

- Type an IP address.

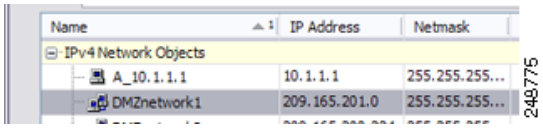
  When you type an IP address, the netmask or range for the mapped network is the same as that of the real network. For example, if the real network is a host, then this address will be a host address. In the case of a range, then the mapped addresses include the same number of addresses as the real range. For example, if the real address is defined as a range from 10.1.1.1 through 10.1.1.6, and you specify 172.20.1.1 as the mapped address, then the mapped range will include 172.20.1.1 through 172.20.1.6.

- (For static NAT-with-port-translation only) Type an interface name or click the browse button, and choose an interface from the Browse Translated Addr dialog box.

  To use the IPv6 interface address, you must also check the **Use IPv6 for interface PAT** checkbox. Be sure to also configure a service on the Advanced NAT Settings dialog box (see Step 8). (You cannot specify an interface in transparent mode).

- Click the browse button, and choose an existing address from the Browse Translated Addr dialog box.

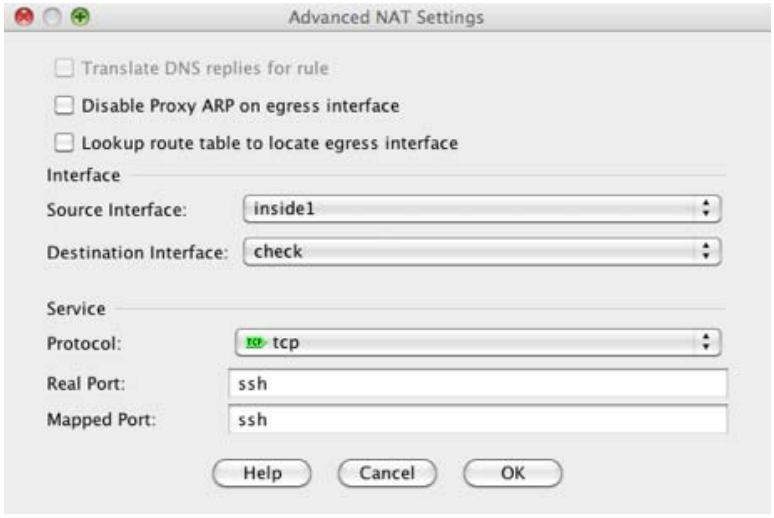
- Click the browse button, and create a new address from the Browse Translated Addr dialog box.



Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses. For more information, see the "Static NAT" section on page 39-3.

Step 7 (Optional) For NAT46, check **Use one-to-one address translation**. For NAT 46, specify one-to-one to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this keyword.

Step 8 (Optional) Click **Advanced**, and configure the following options in the Advanced NAT Settings dialog box.

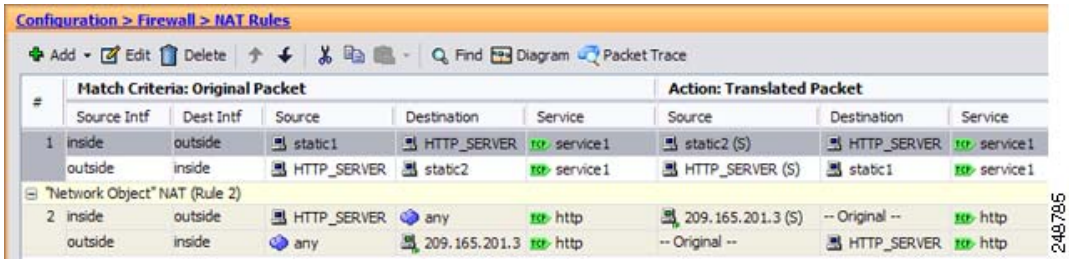


- Translate DNS replies for rule—Translates the IP address in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). See the "DNS and NAT" section on page 39-30 for more information.
- Disable Proxy ARP on egress interface—Disables proxy ARP for incoming packets to the mapped IP addresses. See the "Mapped Addresses and Routing" section on page 39-22 for more information.
- (Required for Transparent Firewall Mode) Interface:
  - Source Interface—Specifies the real interface where this NAT rule applies. By default, the rule applies to all interfaces.
  - Destination Interface—Specifies the mapped interface where this NAT rule applies. By default, the rule applies to all interfaces.
- Service:
  - Protocol—Configures static NAT-with-port-translation. Choose **tcp** or **udp**.
  - Real Port—You can type either a port number or a well-known port name (such as "ftp").
  - Mapped Port—You can type either a port number or a well-known port name (such as "ftp").

When you are finished, click **OK**. You return to the Add/Edit Network Object dialog box.

Step 9 Click **OK**, and then **Apply**.

Because static rules are bidirectional (allowing initiation to and from the real host), the NAT Rules table show two rows for each static rule, one for each direction.



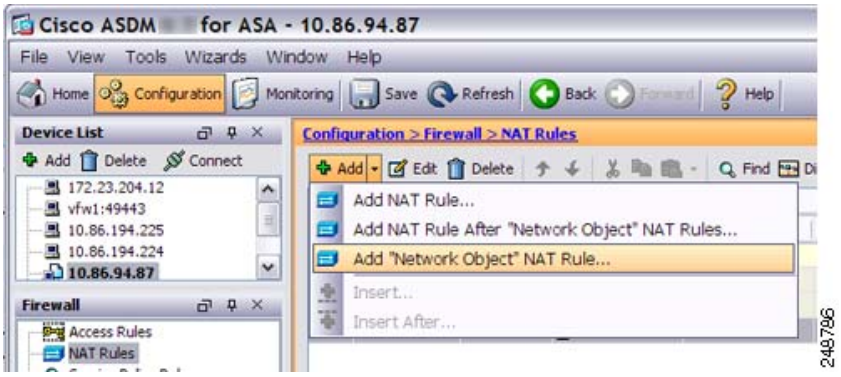
Configuring Identity NAT

This section describes how to configure an identity NAT rule using network object NAT. For more information, see the "Identity NAT" section on page 39-12.

Detailed Steps

Step 1 Add NAT to a new or existing network object:

- To add a new network object, choose **Configuration > Firewall > NAT Rules**, then click **Add > Add Network Object NAT Rule**.



- To add NAT to an existing network object, choose **Configuration > Firewall > Objects > Network Objects/Groups**, and then double-click a network object.

For more information, see the "Configuring a Network Object" section on page 25-3.

The Add/Edit Network Object dialog box appears.

Step 2 For a new object, enter values for the following fields:

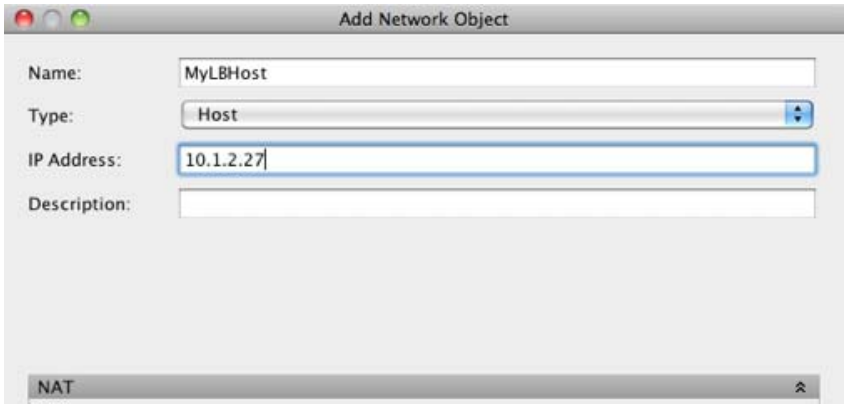
a. Name—The object name. Use characters a to z, A to Z, 0 to 9, a period, a dash, a comma, or an underscore. The name must be 64 characters or less.

b. Type—Network, Host, or Range.

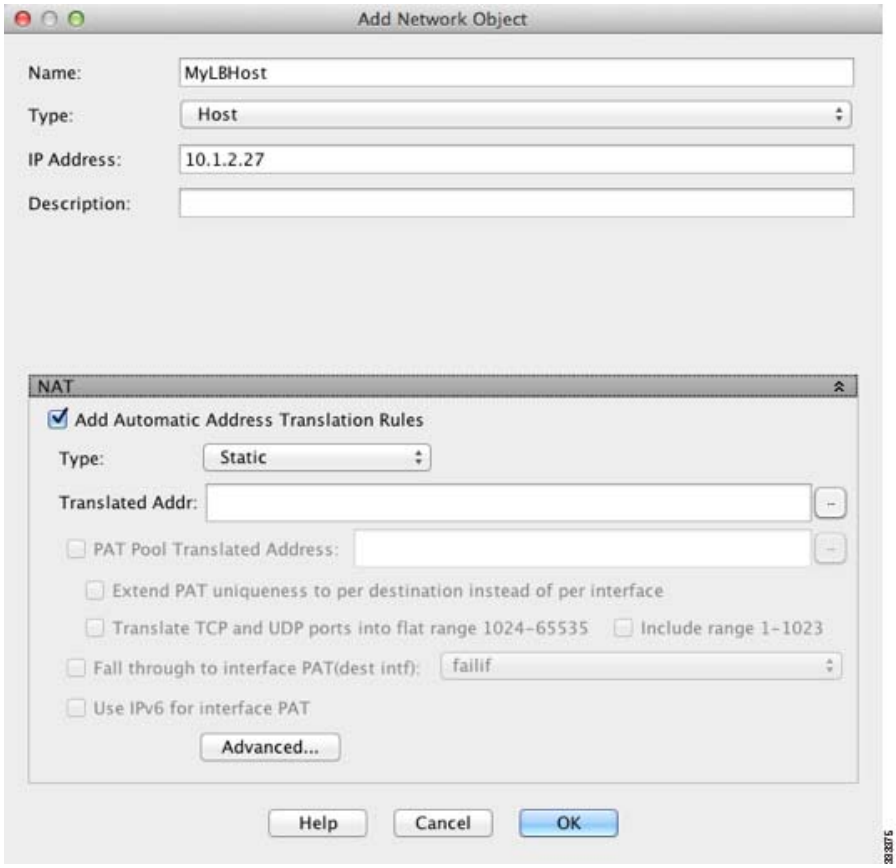
c. IP Address—An IPv4 or IPv6 address. If you select Range as the object type, the IP Address field changes to allow you to enter a Start Address and an End address.

d. Netmask/Prefix Length—Enter the subnet mask or prefix length.

e. Description—(Optional) The description of the network object (up to 200 characters in length).



Step 3 If the NAT section is hidden, click **NAT** to expand the section.

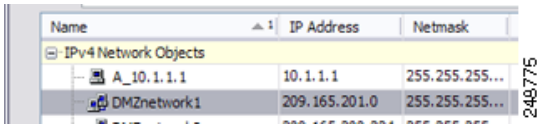


Step 4 Check the **Add Automatic Translation Rules** check box.

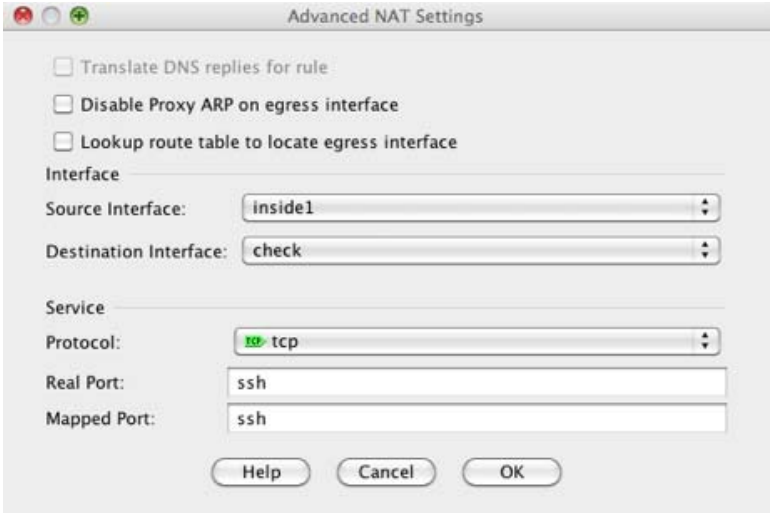
Step 5 From the Type drop-down list, choose **Static**.

Step 6 In the Translated Addr. field, do one of the following:

- Type the same IP address that you used for the real address.
- Click the browse button, and choose a network object with a matching IP address definition from the Browse Translated Addr dialog box.
- Click the browse button, and create a new network object with a matching IP address definition from the Browse Translated Addr dialog box.



Step 7 (Optional) Click **Advanced**, and configure the following options in the Advanced NAT Settings dialog box.

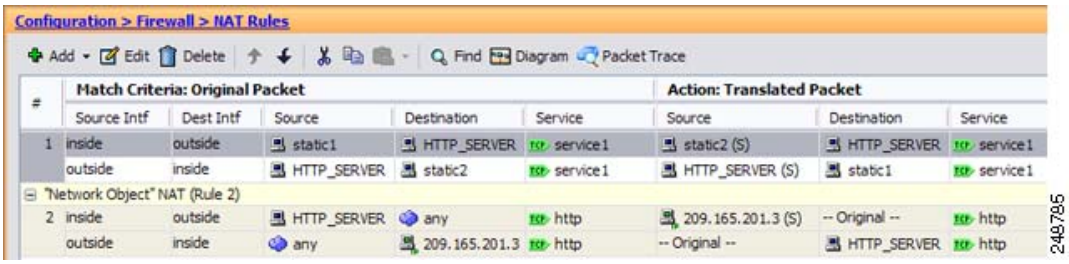


- Disable Proxy ARP on egress interface—Disables proxy ARP for incoming packets to the mapped IP addresses. See the "Mapped Addresses and Routing" section on page 39-22 for more information.
- (Routed mode; interface(s) specified) Lookup route table to locate egress interface—Determines the egress interface using a route lookup instead of using the interface specified in the NAT command. See the "Determining the Egress Interface" section on page 39-24 for more information.
- (Required for Transparent Firewall Mode) Interface:
  - Source Interface—Specifies the real interface where this NAT rule applies. By default, the rule applies to all interfaces.
  - Destination Interface—Specifies the mapped interface where this NAT rule applies. By default, the rule applies to all interfaces.

Do not configure any other options on this dialog box. When you are finished, click **OK**. You return to the Add/Edit Network Object dialog box.

Step 8 Click **OK**, and then **Apply**.

Because static rules are bidirectional (allowing initiation to and from the real host), the NAT Rules table show two rows for each static rule, one for each direction.



Configuring Per-Session PAT Rules

By default, all TCP PAT traffic and all UDP DNS traffic uses per-session PAT. To use multi-session PAT for traffic, you can configure per-session PAT rules: a permit rule uses per-session PAT, and a deny rule uses multi-session PAT. For more information about per-session vs. multi-session PAT, see the "Per-Session PAT vs. Multi-Session PAT (Version 9.0(1) and Later)" section on page 39-11.

Defaults

By default, the following rules are installed:

- Permit TCP from any (IPv4 and IPv6) to any (IPv4 and IPv6)
- Permit UDP from any (IPv4 and IPv6) to domain

These rules do not appear in the rule table.

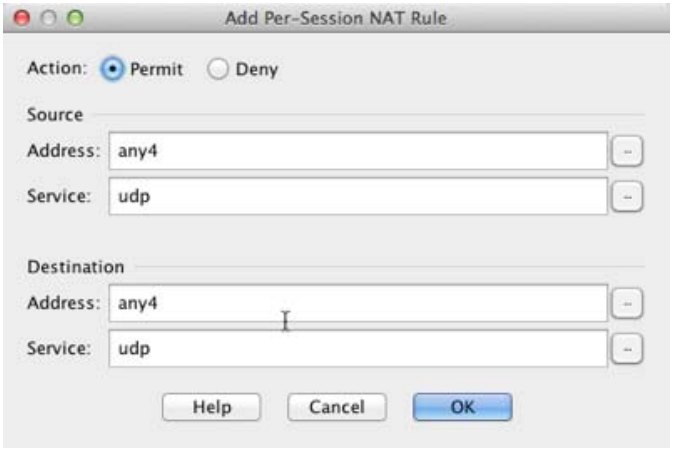
Note You cannot remove these rules, and they always exist after any manually-created rules. Because rules are evaluated in order, you can override the default rules. For example, to completely negate these rules, you could add the following:

- Deny TCP from any (IPv4 and IPv6) to any (IPv4 and IPv6)
- Deny UDP from any (IPv4 and IPv6) to domain

Detailed Steps

Step 1 Choose **Configuration > Firewall > Advanced > Per-Session NAT Rules**, and click **Add > Add Per-Session NAT Rule**.

Step 2 Click **Permit** or **Deny**.



A permit rule uses per-session PAT; a deny rule uses multi-session PAT.

Step 3 Specify the Source Address either by typing an address or clicking the **...** button to choose an object.

Step 4 Specify the Source Service, UDP or TCP. You can optionally specify a source port, although normally you only specify the destination port. Either type in UDP/*port* or TCP/*port*, or click the **...** button to select a common value or object.

Step 5 Specify the Destination Address either by typing an address or clicking the **...** button to choose an object.

Step 6 Specify the Destination Service, UDP or TCP; this must match the source service. You can optionally specify a destination port. Either type in UDP/*port* or TCP/*port*, or click the **...** button to select a common value or object.

Step 7 Click **OK**.

Step 8 Click **Apply**.

Monitoring Network Object NAT

The Monitoring > Properties > Connection Graphs > Xlates pane lets you view the active Network Address Translations in a graphical format. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Fields

- Available Graphs—Lists the components you can graph.
  - Xlate Utilization—Displays the ASA NAT utilization.
- Graph Window Title—Shows the graph window name to which you want to add a graph type. To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title.
- Add—Click to move the selected entries in the Available Graphs list to the Selected Graphs list.
- Remove—Click to remove the selected entry from the Selected Graphs list.
- Show Graphs—Click to display a new or updated graph window.

The Monitoring > Properties > Connection Graphs > Perfmon pane lets you view the performance information in a graphical format. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Fields

- Available Graphs—Lists the components you can graph.
  - AAA Perfmon—Displays the ASA AAA performance information.
  - Inspection Perfmon—Displays the ASA inspection performance information.
  - Web Perfmon—Displays the ASA web performance information, including URL access and URL server requests.
  - Connections Perfmon—Displays the ASA connections performance information.
  - Xlate Perfmon—Displays the ASA NAT performance information.
- Graph Window Title—Shows the graph window name to which you want to add a graph type. To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title.
- Add—Click to move the selected entries in the Available Graphs list to the Selected Graphs list.
- Remove—Click to remove the selected statistic type from the Selected Graphs list.
- Show Graphs—Click to display a new or updated graph window.

Configuration Examples for Network Object NAT

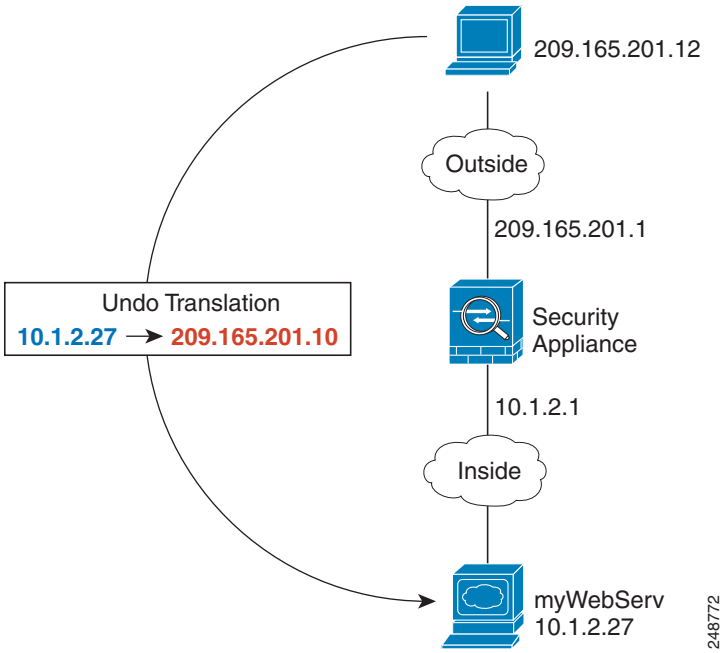
This section includes the following configuration examples:

- Providing Access to an Inside Web Server (Static NAT), page 40-21
- NAT for Inside Hosts (Dynamic NAT) and NAT for an Outside Web Server (Static NAT), page 40-23
- Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many), page 40-28
- Single Address for FTP, HTTP, and SMTP (Static NAT-with-Port-Translation), page 40-32
- DNS Server on Mapped Interface, Web Server on Real Interface (Static NAT with DNS Modification), page 40-35
- DNS Server and FTP Server on Mapped Interface, FTP Server is Translated (Static NAT with DNS Modification), page 40-38
- IPv4 DNS Server and FTP Server on Mapped Interface, IPv6 Host on Real Interface (Static NAT64 with DNS64 Modification), page 40-40

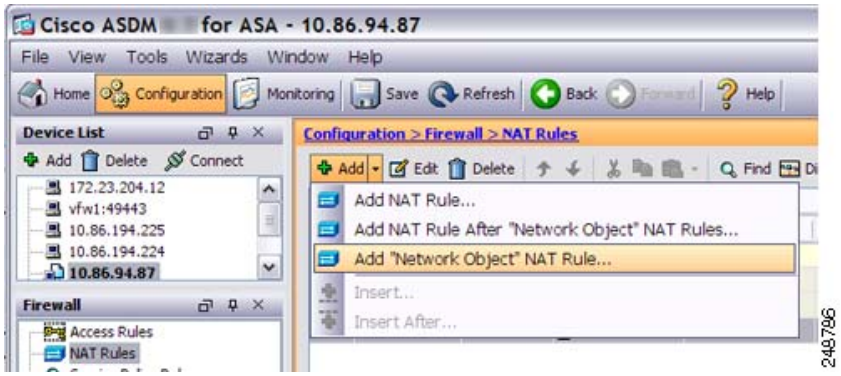
Providing Access to an Inside Web Server (Static NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address. (See Figure 40-1).

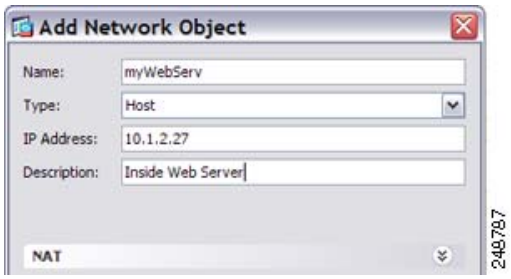
Figure 40-1 Static NAT for an Inside Web Server



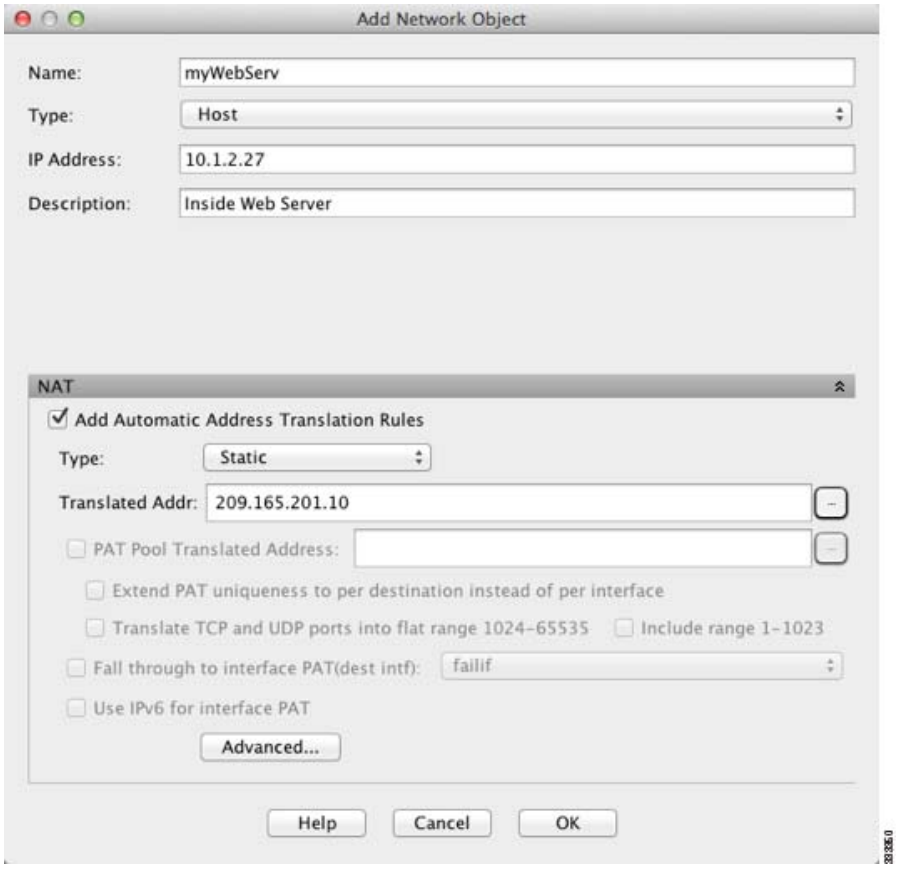
Step 1 Create a network object for the internal web server:



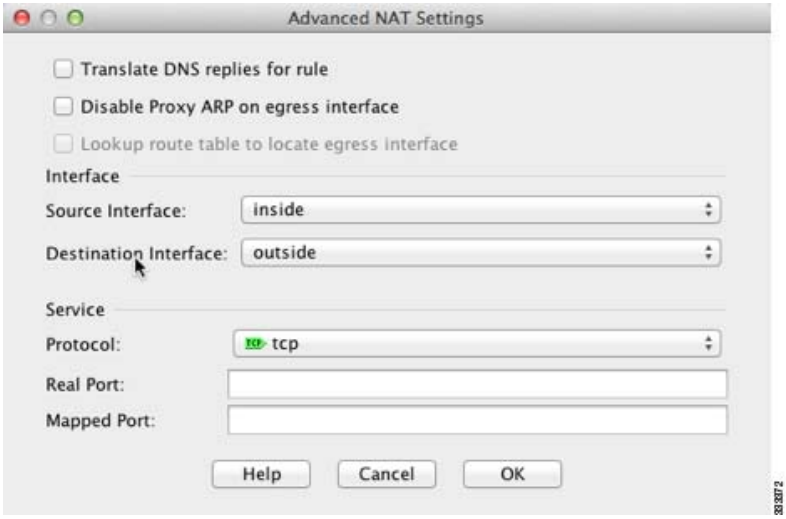
Step 2 Define the web server address:



Step 3 Configure static NAT for the object:



Step 4 Configure the real and mapped interfaces by clicking **Advanced**:

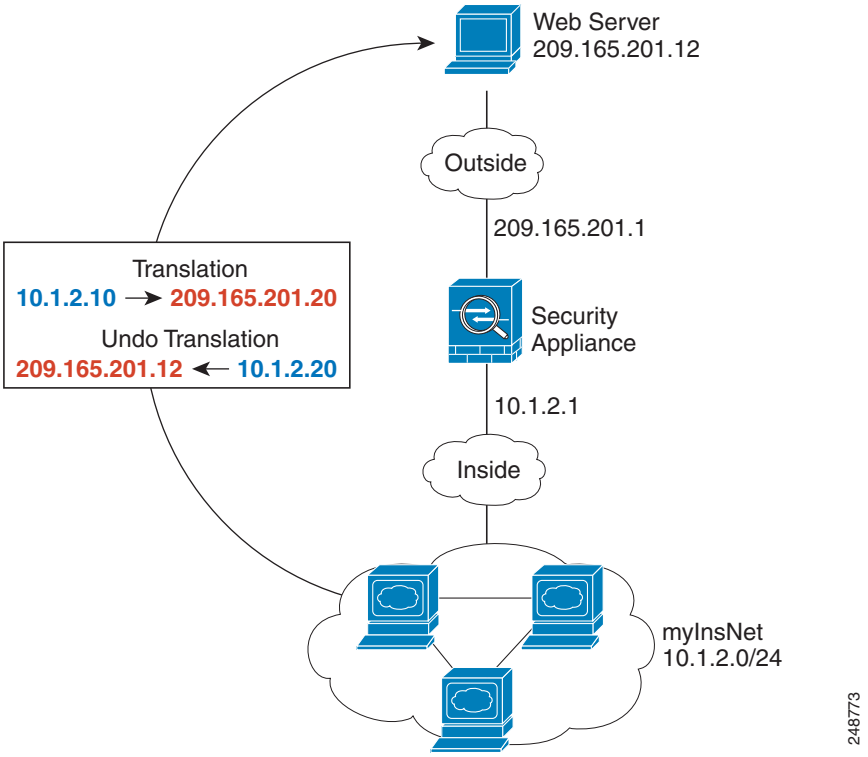


Step 5 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

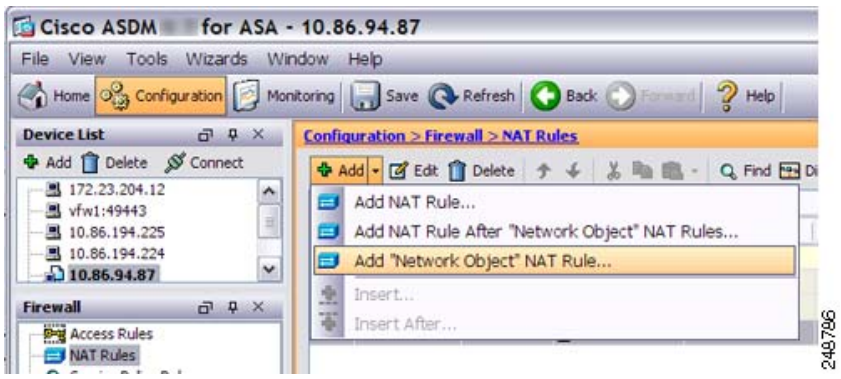
NAT for Inside Hosts (Dynamic NAT) and NAT for an Outside Web Server (Static NAT)

The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network. (See Figure 40-2).

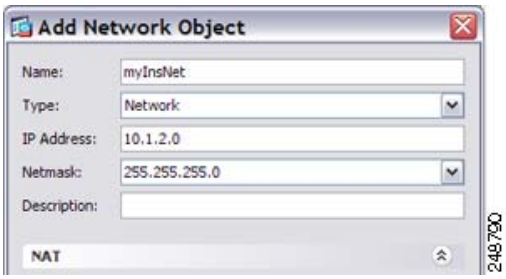
Figure 40-2 Dynamic NAT for Inside, Static NAT for Outside Web Server



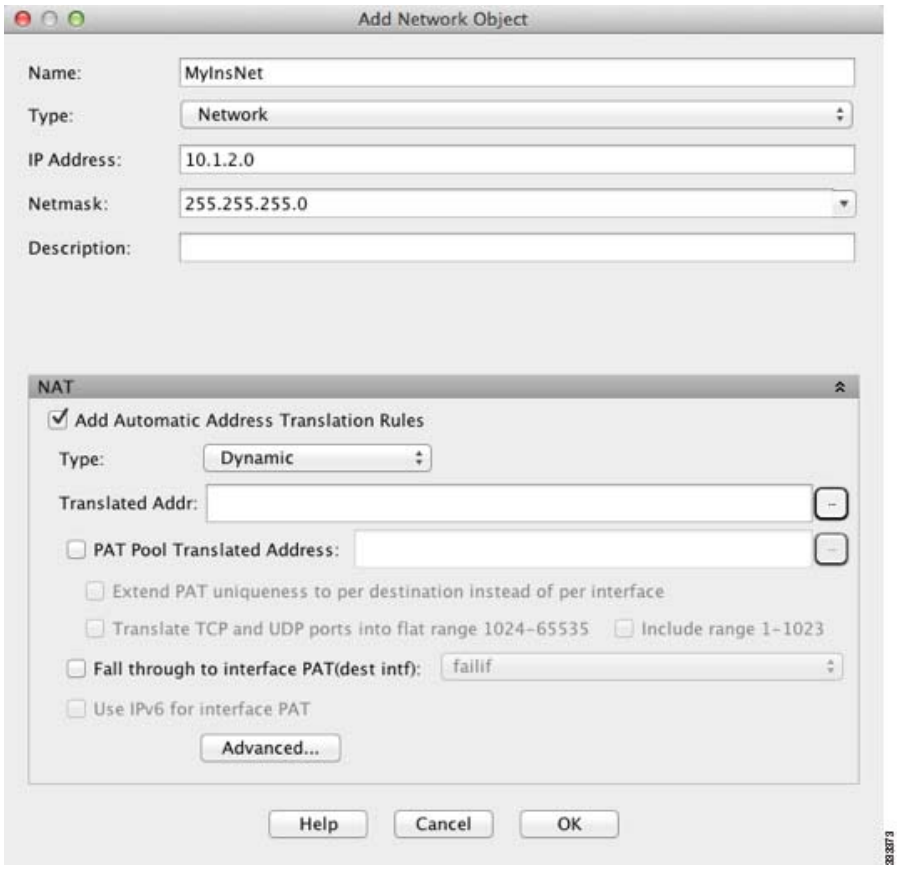
Step 1 Create a network object for the inside network:



Step 2 Define the addresses for the inside network:

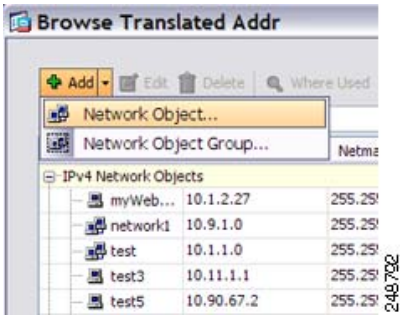


Step 3 Enable dynamic NAT for the inside network:



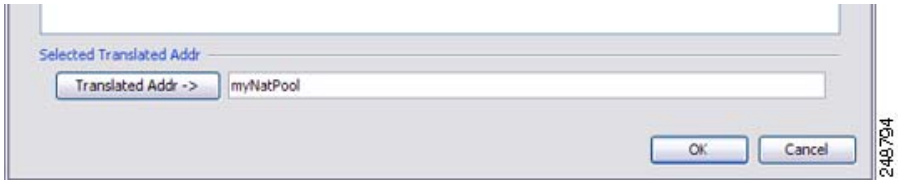
Step 4 For the Translated Addr field, add a new network object for the dynamic NAT pool to which you want to translate the inside addresses by clicking the browse button.

a. Add the new network object.

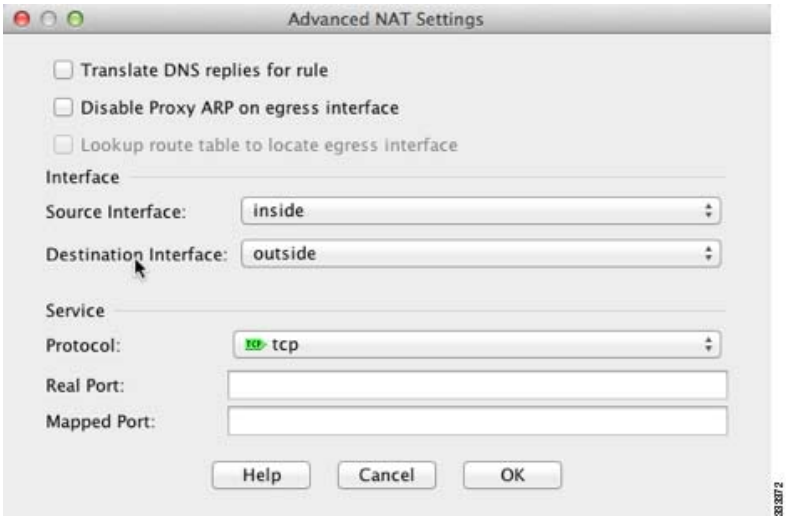


b. Define the NAT pool addresses, and click **OK**.

c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

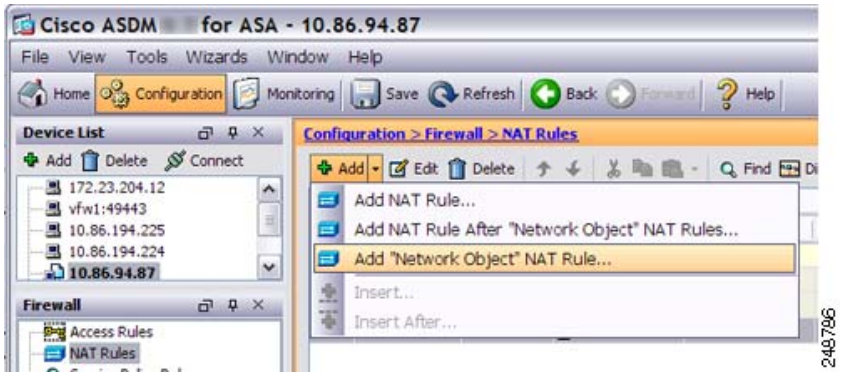


Step 5 Configure the real and mapped interfaces by clicking **Advanced**:

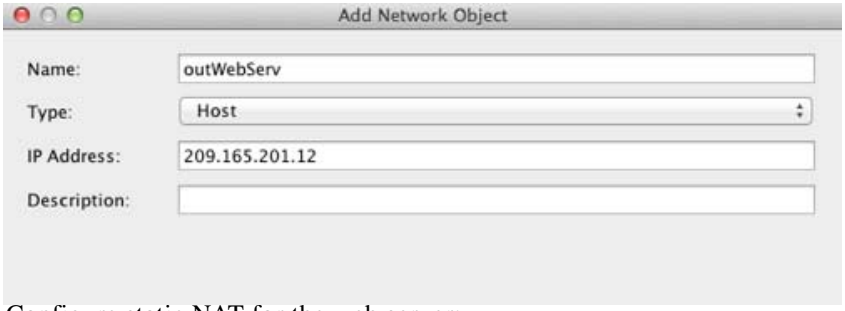


Step 6 Click **OK** to return to the Edit Network Object dialog box, click then click **OK** again to return to the NAT Rules table.

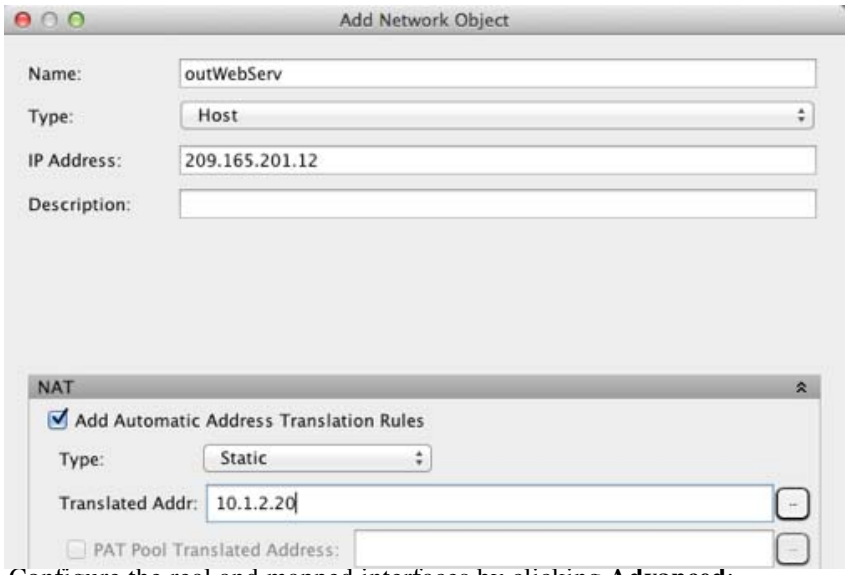
Step 7 Create a network object for the outside web server:



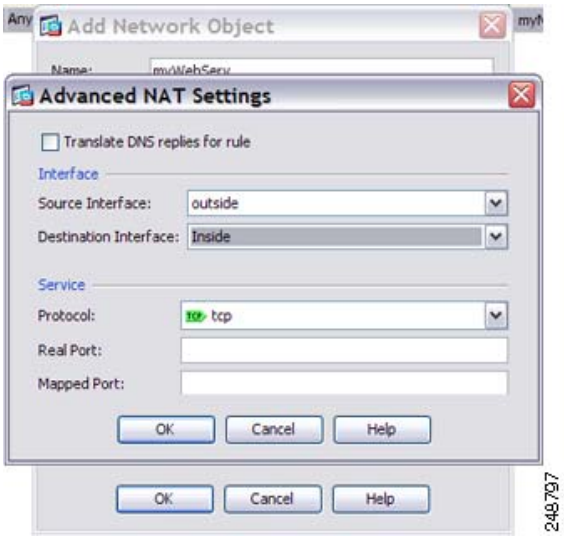
Step 8 Define the web server address:



Step 9 Configure static NAT for the web server:



Step 10 Configure the real and mapped interfaces by clicking **Advanced**:

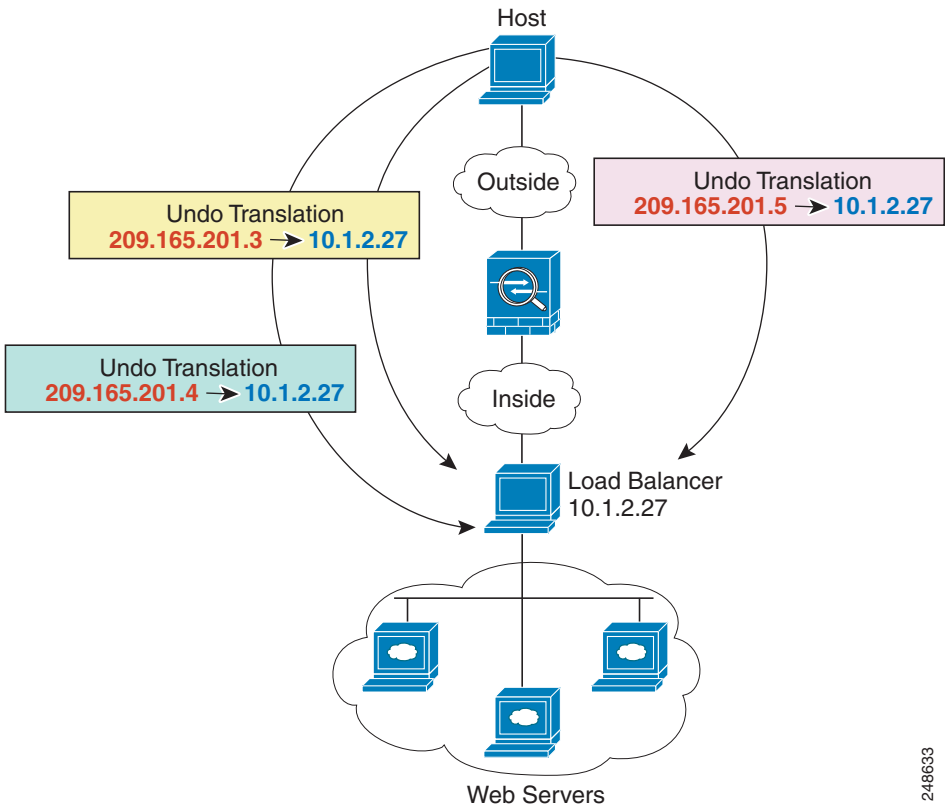


Step 11 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

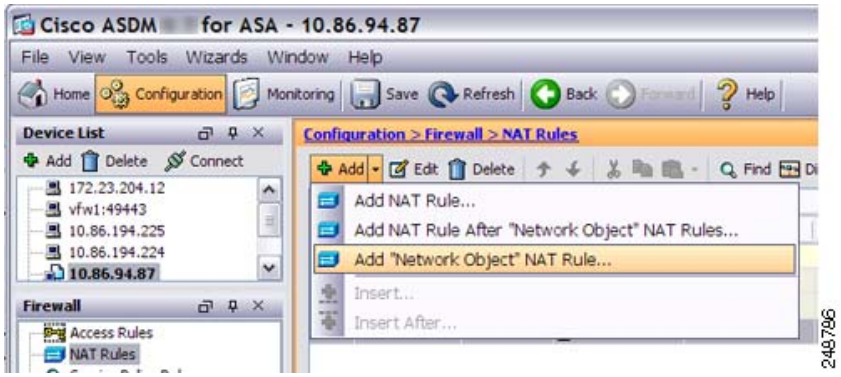
Inside Load Balancer with Multiple Mapped Addresses (Static NAT, One-to-Many)

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server. (See Figure 40-3).

Figure 40-3 Static NAT with One-to-Many for an Inside Load Balancer



Step 1 Create a network object for the load balancer:

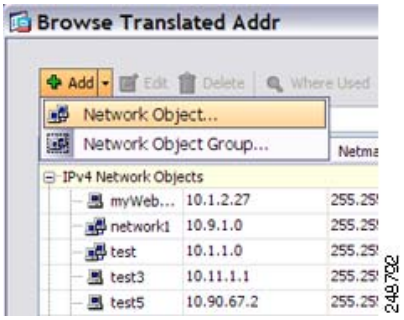


Step 2 Define the load balancer address:

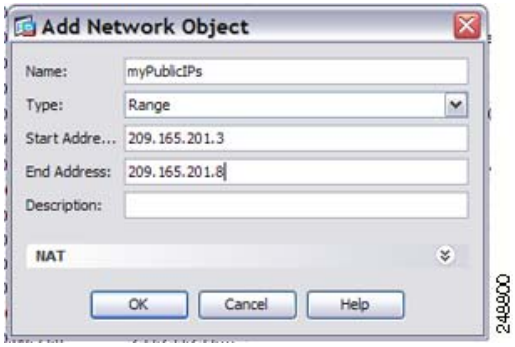
Step 3 Configure static NAT for the load balancer:

Step 4 For the Translated Addr field, add a new network object for the static NAT group of addresses to which you want to translate the load balancer address by clicking the browse button.

a. Add the new network object.

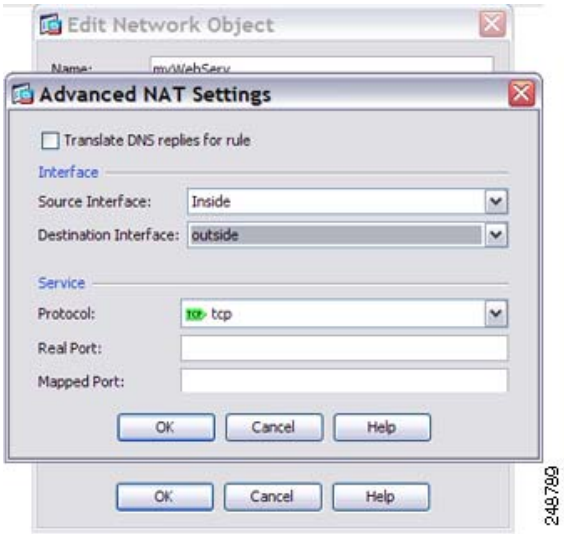


b. Define the static NAT group of addresses, and click **OK**.



c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 5 Configure the real and mapped interfaces by clicking **Advanced**:

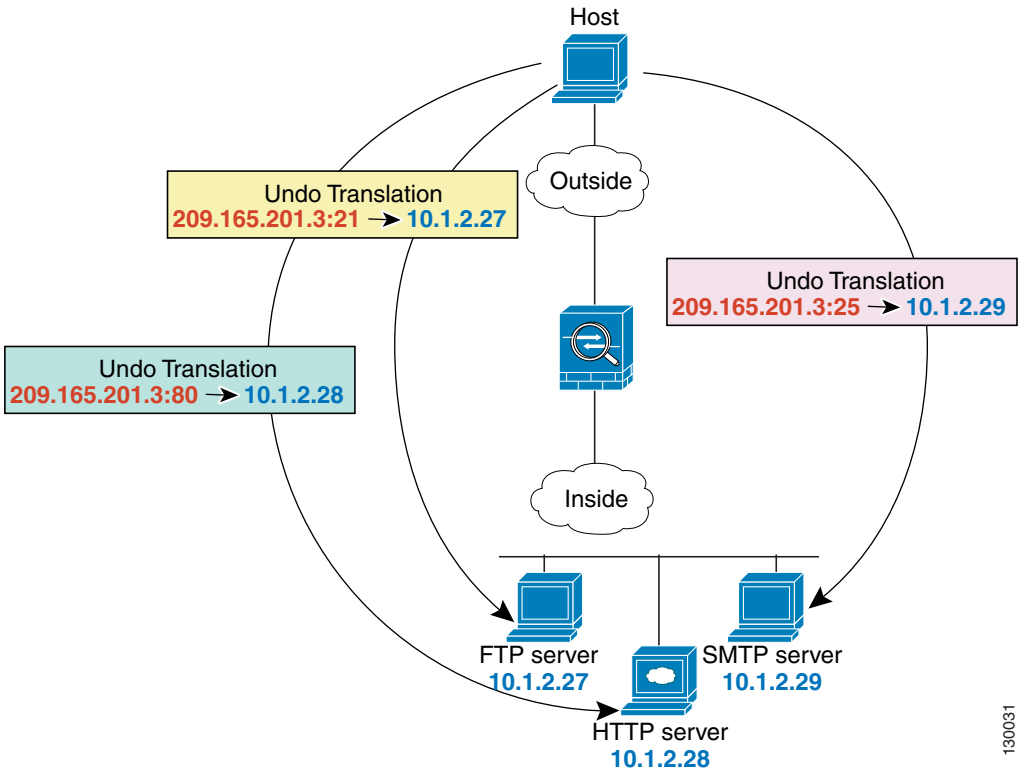


Step 6 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

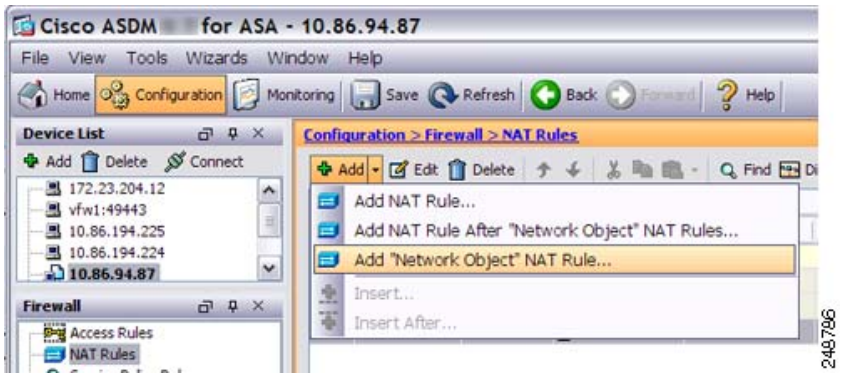
Single Address for FTP, HTTP, and SMTP (Static NAT-with-Port-Translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports. (See Figure 40-4.)

Figure 40-4 Static NAT-with-Port-Translation

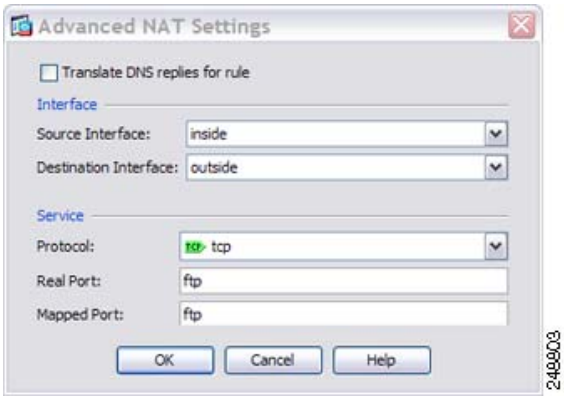


Step 1 Create a network object for the FTP server address:

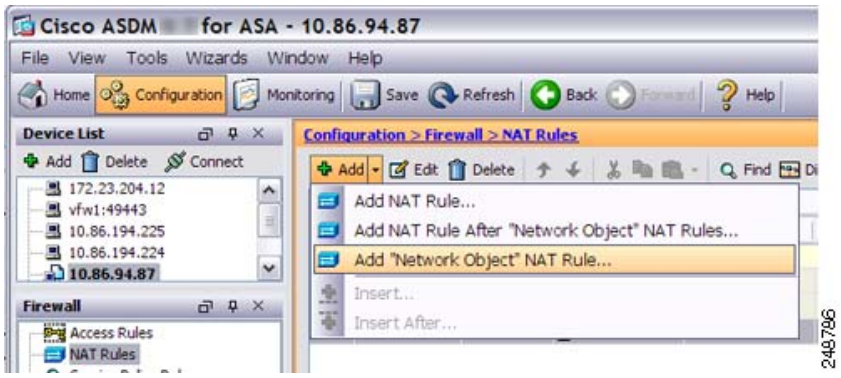


Step 2 Define the FTP server address, and configure static NAT with identity port translation for the FTP server:

Step 3 Click **Advanced** to configure the real and mapped interfaces and port translation for FTP.

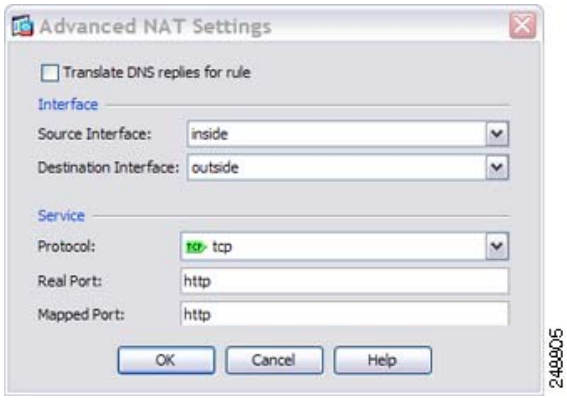


Step 4 Create a network object for the HTTP server address:

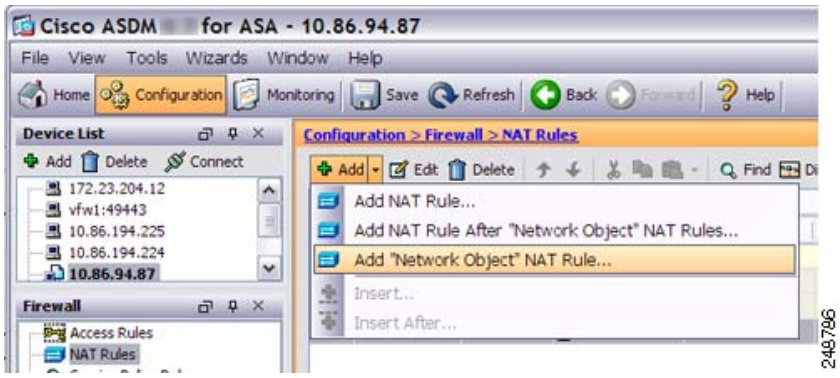


Step 5 Define the HTTP server address, and configure static NAT with identity port translation for the HTTP server:

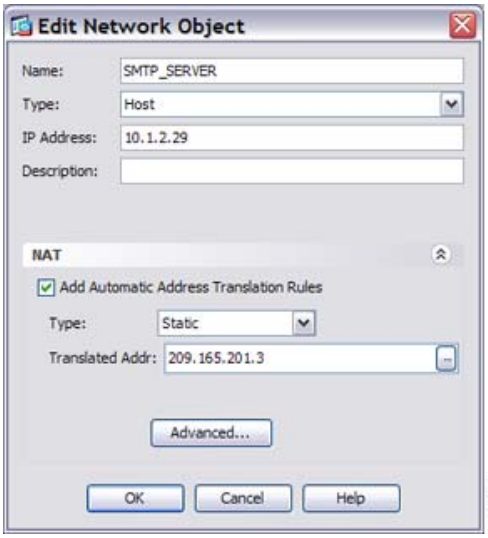
Step 6 Click **Advanced** to configure the real and mapped interfaces and port translation for HTTP.



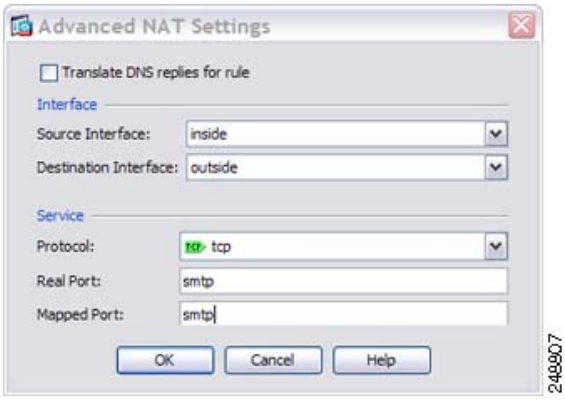
Step 7 Create a network object for the SMTP server address:



Step 8 Define the SMTP server address, and configure static NAT with identity port translation for the SMTP server:



Step 9 Click **Advanced** to configure the real and mapped interfaces and port translation for SMTP.



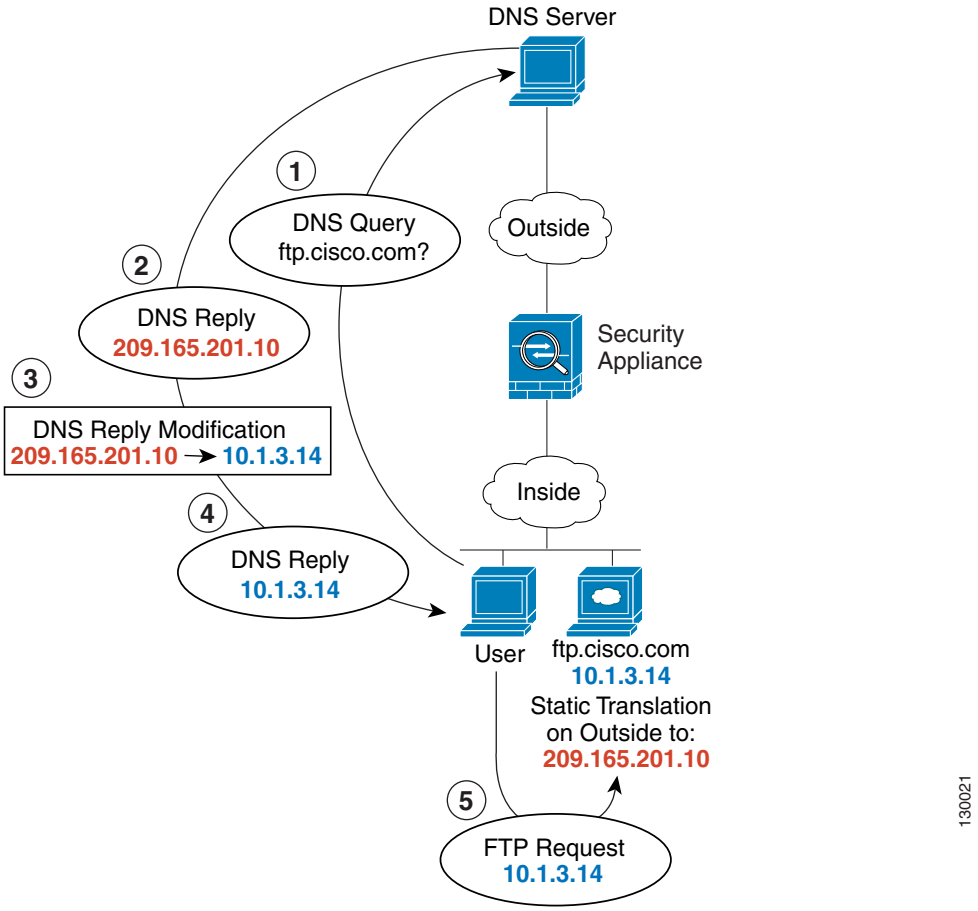
Step 10 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

DNS Server on Mapped Interface, Web Server on Real Interface (Static NAT with DNS Modification)

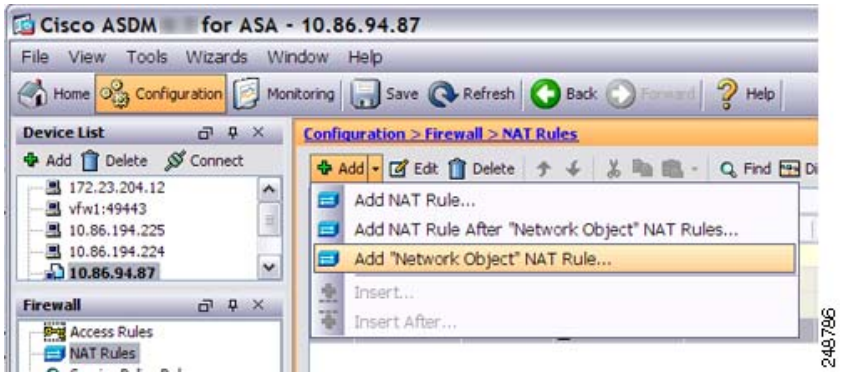
For example, a DNS server is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure the ASA to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network. (See Figure 40-5.) In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The ASA refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

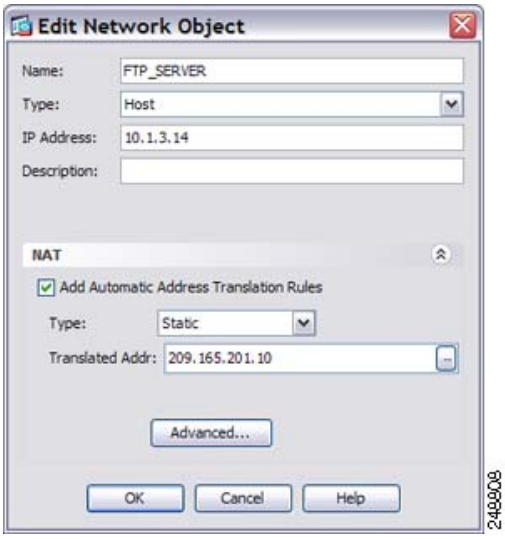
Figure 40-5 DNS Reply Modification



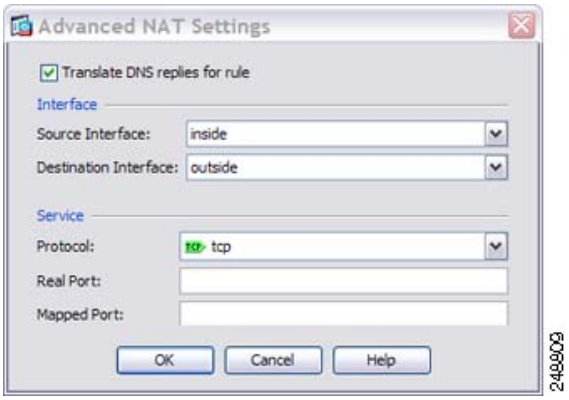
Step 1 Create a network object for the FTP server address:



Step 2 Define the FTP server address, and configure static NAT with DNS modification:



Step 3 Click **Advanced** to configure the real and mapped interfaces and DNS modification.

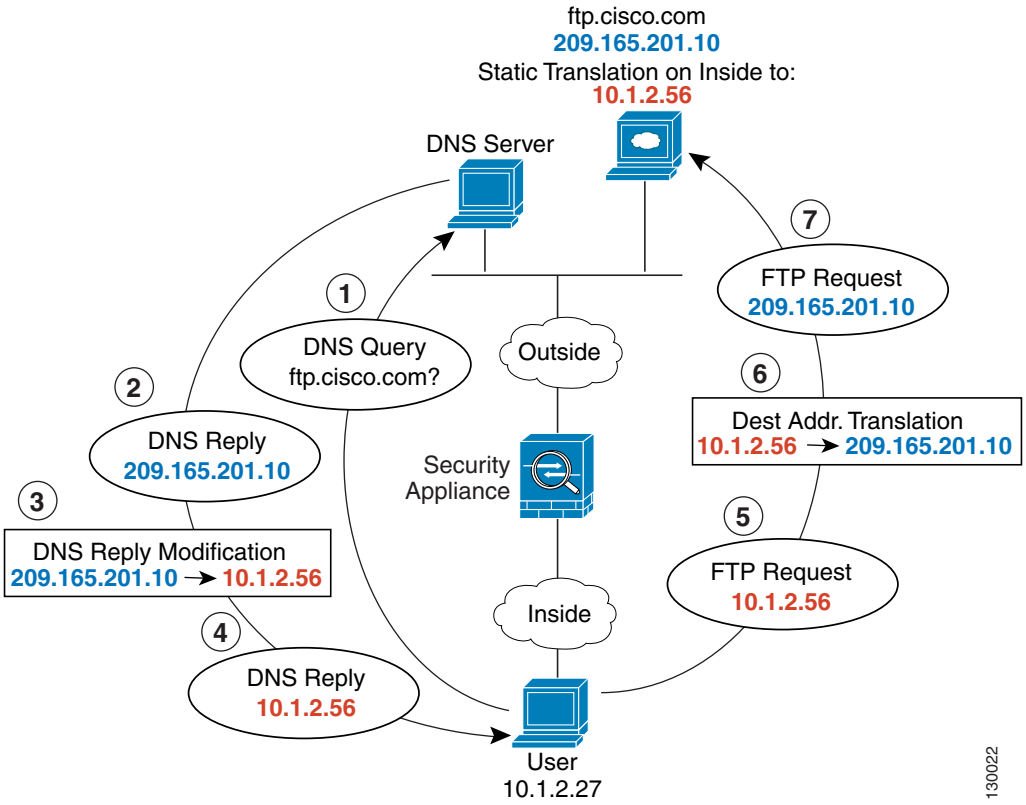


Step 4 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

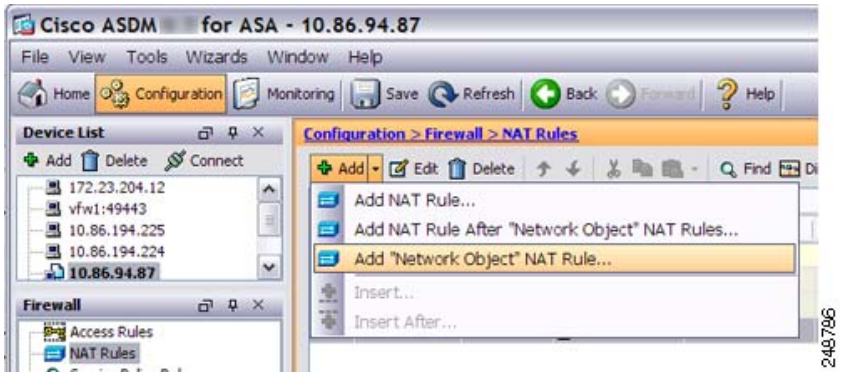
DNS Server and FTP Server on Mapped Interface, FTP Server is Translated (Static NAT with DNS Modification)

Figure 40-6 shows an FTP server and DNS server on the outside. The ASA has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.201.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

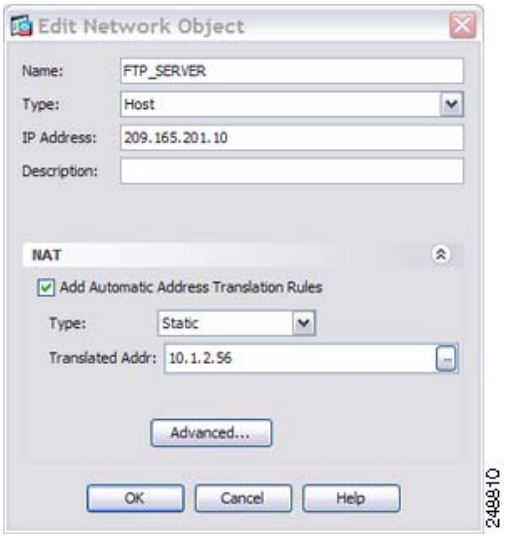
Figure 40-6 DNS Reply Modification Using Outside NAT



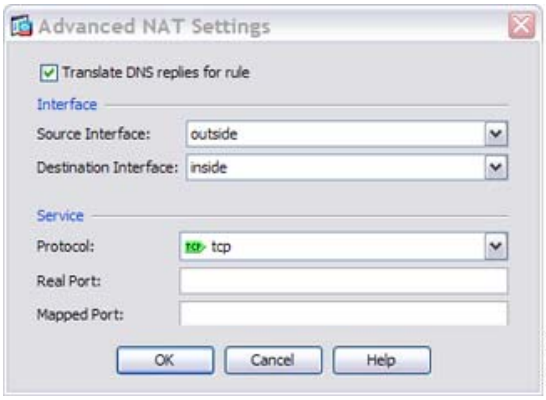
Step 1 Create a network object for the FTP server address:



Step 2 Define the FTP server address, and configure static NAT with DNS modification:



Step 3 Click **Advanced** to configure the real and mapped interfaces and DNS modification.

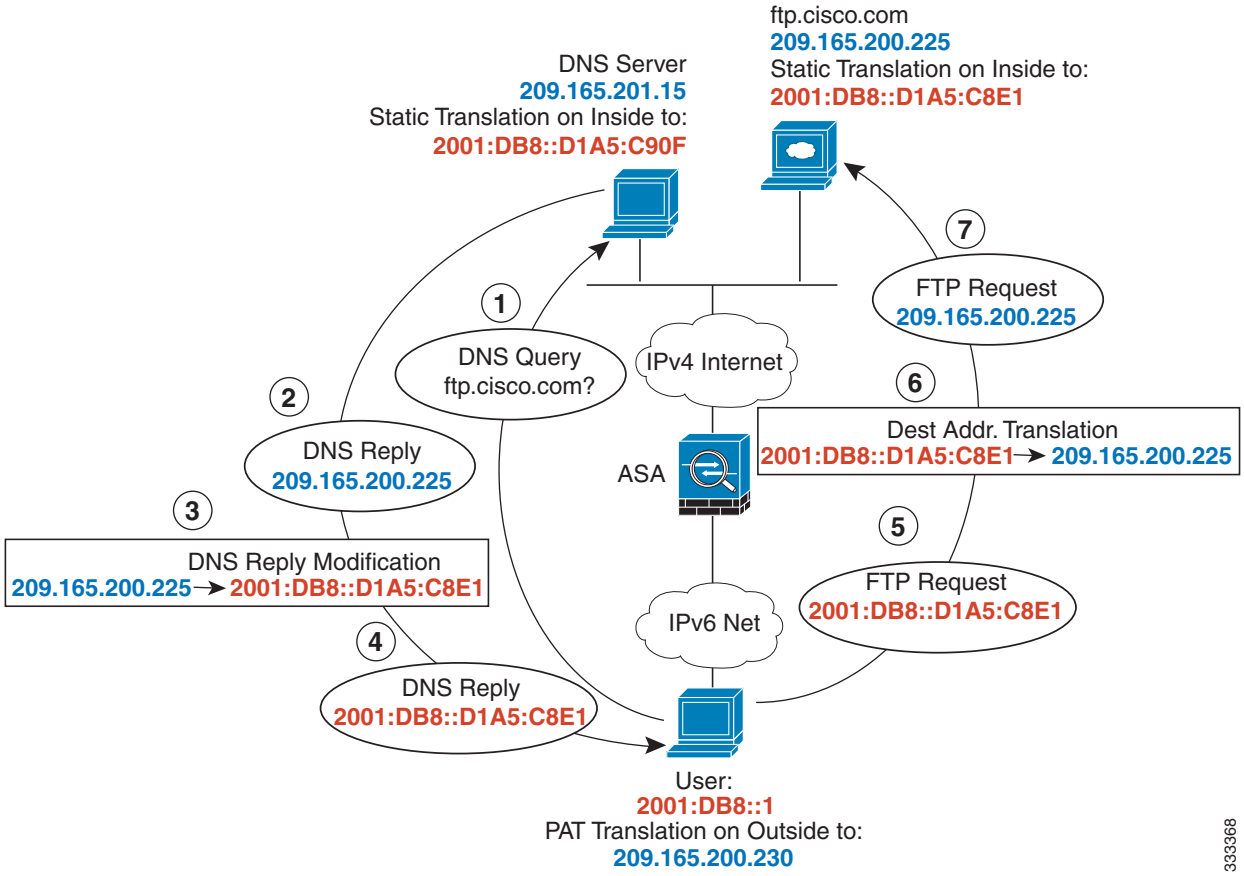


Step 4 Click **OK** to return to the Edit Network Object dialog box, click **OK** again, and then click **Apply**.

IPv4 DNS Server and FTP Server on Mapped Interface, IPv6 Host on Real Interface (Static NAT64 with DNS64 Modification)

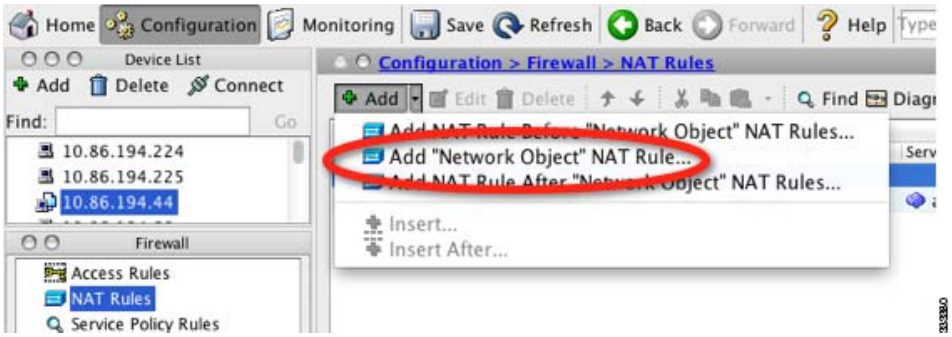
Figure 40-6 shows an FTP server and DNS server on the outside IPv4 network. The ASA has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225. Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

Figure 40-7 DNS Reply Modification Using Outside NAT

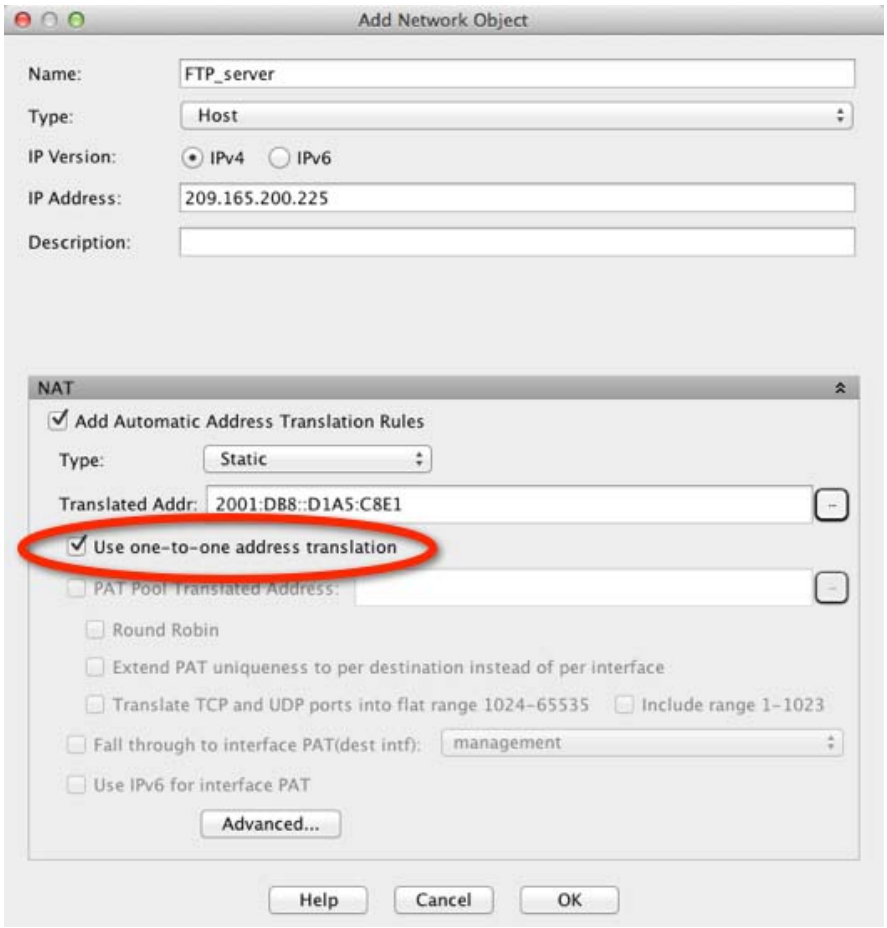


Step 1 Configure static NAT with DNS modification for the FTP server.

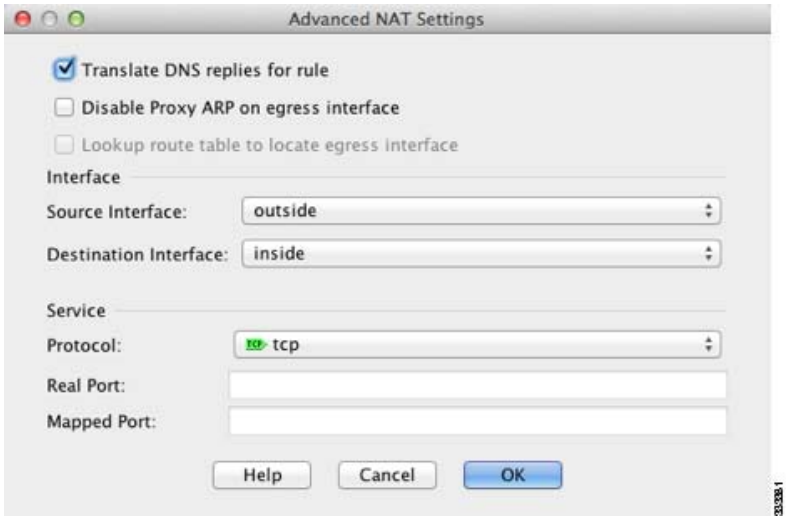
a. Create a network object for the FTP server address.



b. Define the FTP server address, and configure static NAT with DNS modification and, because this is a one-to-one translation, configure the one-to-one method for NAT46.



c. Click **Advanced** to configure the real and mapped interfaces and DNS modification.

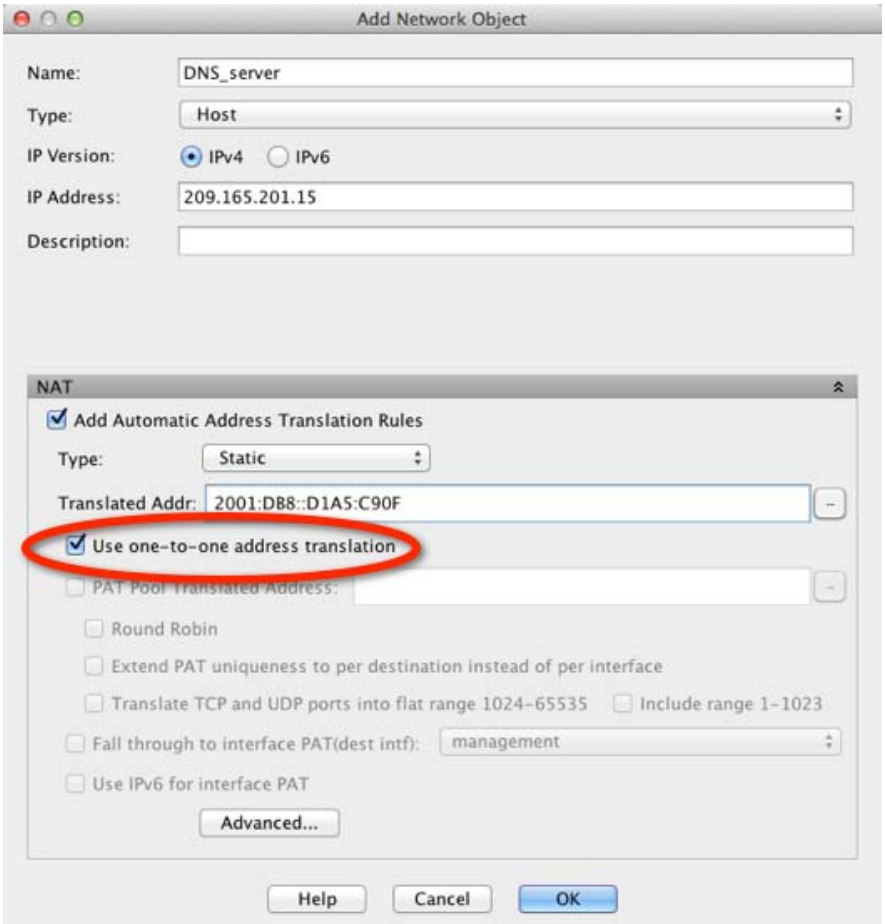


d. Click **OK** to return to the Edit Network Object dialog box.

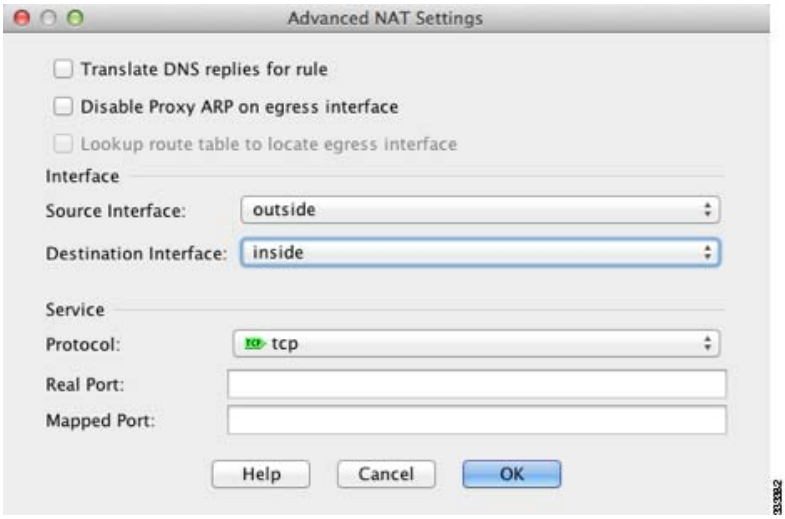
Step 2 Configure NAT for the DNS server.

a. Create a network object for the DNS server address.

b. Define the DNS server address, and configure static NAT using the one-to-one method.

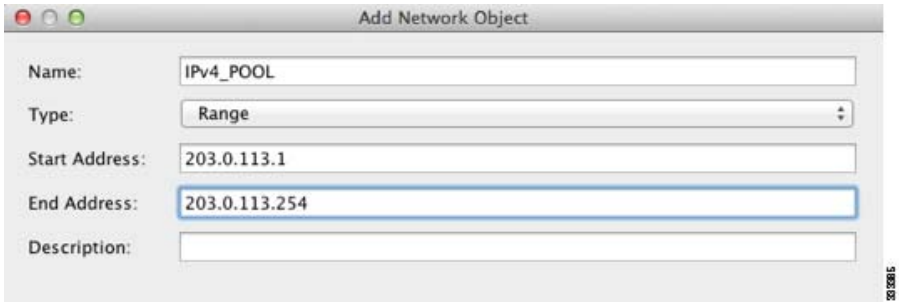


c. Click **Advanced** to configure the real and mapped interfaces.



d. Click **OK** to return to the Edit Network Object dialog box.

Step 3 Configure an IPv4 PAT pool for translating the inside IPv6 network.

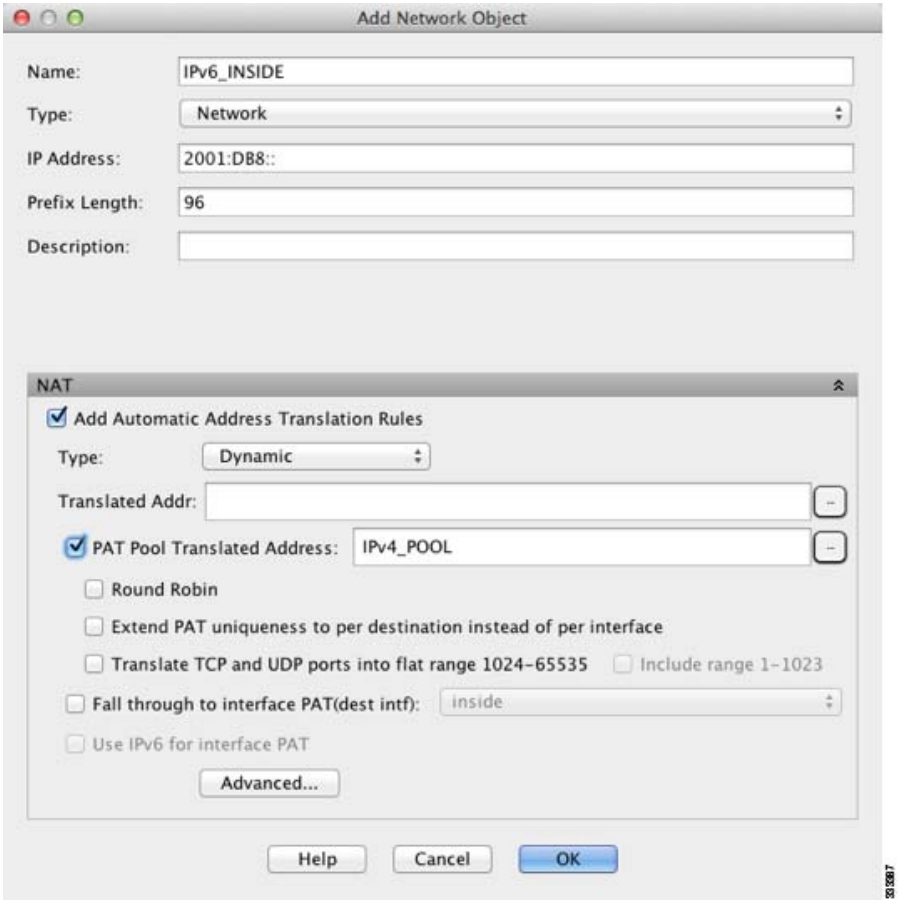


Under NAT, uncheck the **Add Automatic Address Translation Rules** check box.

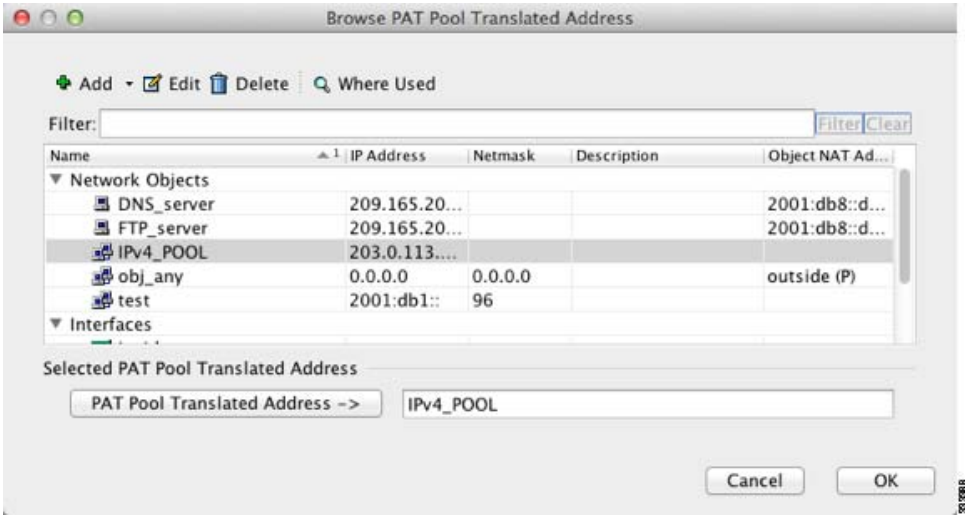
Step 4 Configure PAT for the inside IPv6 network.

a. Create a network object for the inside IPv6 network.

b. Define the IPv6 network address, and configure dynamic NAT using a PAT pool.



c. Next to the PAT Pool Translated Address field, click the **...** button to choose the PAT pool you created earlier, and click **OK**.



d. Click **Advanced** to configure the real and mapped interfaces.

e. Click **OK** to return to the Edit Network Object dialog box.

Step 5 Click **OK**, and then click **Apply**.

Feature History for Network Object NAT

Table 40-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 40-1 Feature History for Network Object NAT

Feature Name	Platform Releases	Feature Information
Network Object NAT	8.3(1)	Configures NAT for a network object IP address(es). We introduced or modified the following screens: Configuration > Firewall > NAT Rules Configuration > Firewall > Objects > Network Objects/Groups
Identity NAT configurable proxy ARP and route lookup	8.4(2)/8.5(1)	In earlier releases for identity NAT, proxy ARP was disabled, and a route lookup was always used to determine the egress interface. You could not configure these settings. In 8.4(2) and later, the default behavior for identity NAT was changed to match the behavior of other static NAT configurations: proxy ARP is enabled, and the NAT configuration determines the egress interface (if specified) by default. You can leave these settings as is, or you can enable or disable them discretely. Note that you can now also disable proxy ARP for regular static NAT. When upgrading to 8.4(2) from 8.3(1), 8.3(2), and 8.4(1), all identity NAT configurations will now include the **no-proxy-arp** and **route-lookup** keywords, to maintain existing functionality. We modified the following screen: Configuration > Firewall > NAT Rules > Add/Edit Network Object > Advanced NAT Settings.

Table 40-1 Feature History for Network Object NAT (continued)

Feature Name	Platform Releases	Feature Information
PAT pool and round robin address assignment	8.4(2)/8.5(1)	You can now specify a pool of PAT addresses instead of a single address. You can also optionally enable round-robin assignment of PAT addresses instead of first using all ports on a PAT address before using the next address in the pool. These features help prevent a large number of connections from a single PAT address from appearing to be part of a DoS attack and makes configuration of large numbers of PAT addresses easy. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit Network Object.
Round robin PAT pool allocation uses the same IP address for existing hosts	8.4(3)	When using a PAT pool with round robin allocation, if a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. We did not modify any screens. *This feature is not available in 8.5(1) or 8.6(1).*
Flat range of PAT ports for a PAT pool	8.4(3)	If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool. If you have a lot of traffic that uses the lower port ranges, when using a PAT pool, you can now specify a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit Network Object. *This feature is not available in 8.5(1) or 8.6(1).*
Extended PAT for a PAT pool	8.4(3)	Each PAT IP address allows up to 65535 ports. If 65535 ports do not provide enough translations, you can now enable extended PAT for a PAT pool. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit Network Object. *This feature is not available in 8.5(1) or 8.6(1).*

Table 40-1 Feature History for Network Object NAT (continued)

Feature Name	Platform Releases	Feature Information
Automatic NAT rules to translate a VPN peer's local IP address back to the peer's real IP address	8.4(3)	In rare situations, you might want to use a VPN peer's real IP address on the inside network instead of an assigned local IP address. Normally with VPN, the peer is given an assigned local IP address to access the inside network. However, you might want to translate the local IP address back to the peer's real public IP address if, for example, your inside servers and network security is based on the peer's real IP address. You can enable this feature on one interface per tunnel group. Object NAT rules are dynamically added and deleted when the VPN session is established or disconnected. You can view the rules using the **show nat** command. **Note** Because of routing issues, we do not recommend using this feature unless you know you need this feature; contact Cisco TAC to confirm feature compatibility with your network. See the following limitations: • Only supports Cisco IPsec and AnyConnect Client. • Return traffic to the public IP addresses must be routed back to the ASA so the NAT policy and VPN policy can be applied. • Does not support load-balancing (because of routing issues). • Does not support roaming (public IP changing). ASDM does not support this command; enter the command using the Command Line Tool.

Table 40-1 Feature History for Network Object NAT (continued)

Feature Name	Platform Releases	Feature Information
NAT support for IPv6	9.0(1)	NAT now supports IPv6 traffic, as well as translating between IPv4 and IPv6. Translating between IPv4 and IPv6 is not supported in transparent mode. We modified the following screen: Configuration > Firewall > Objects > Network Objects/Group.
Per-session PAT	9.0(1)	The per-session PAT feature improves the scalability of PAT and, for clustering, allows each member unit to own PAT connections; multi-session PAT connections have to be forwarded to and owned by the master unit. At the end of a per-session PAT session, the ASA sends a reset and immediately removes the xlate. This reset causes the end node to immediately release the connection, avoiding the TIME_WAIT state. Multi-session PAT, on the other hand, uses the PAT timeout, by default 30 seconds. For "hit-and-run" traffic, such as HTTP or HTTPS, the per-session feature can dramatically increase the connection rate supported by one address. Without the per-session feature, the maximum connection rate for one address for an IP protocol is approximately 2000 per second. With the per-session feature, the connection rate for one address for an IP protocol is 65535/*average-lifetime*. By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that requires multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT by creating a per-session deny rule. We introduced the following screen: Configuration > Firewall > Advanced > Per-Session NAT Rules.

Configuring Twice NAT (ASA 8.3 and Later)

Twice NAT lets you identify both the source and destination address in a single rule. This chapter shows you how to configure twice NAT and includes the following sections:

- Information About Twice NAT, page 41-1
- Licensing Requirements for Twice NAT, page 41-2
- Prerequisites for Twice NAT, page 41-2
- Guidelines and Limitations, page 41-2
- Default Settings, page 41-4
- Configuring Twice NAT, page 41-4
- Monitoring Twice NAT, page 41-30
- Configuration Examples for Twice NAT, page 41-30
- Feature History for Twice NAT, page 41-48

Note For detailed information about how NAT works, see Chapter 39, "Information About NAT (ASA 8.3 and Later)."

Information About Twice NAT

Twice NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y, for example.

Note For static NAT, the rule is bidirectional, so be aware that "source" and "destination" are used in commands and descriptions throughout this guide even though a given connection might originate at the "destination" address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then in the command, you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Twice NAT also lets you use service objects for static NAT-with-port-translation; network object NAT only accepts inline definition.

For detailed information about the differences between twice NAT and network object NAT, see the "How NAT is Implemented" section on page 39-15.

Twice NAT rules are added to section 1 of the NAT rules table, or if specified, section 3. For more information about NAT ordering, see the "NAT Rule Order" section on page 39-20.

Licensing Requirements for Twice NAT

Model	License Requirement
All models	Base License.

Prerequisites for Twice NAT

- For both the real and mapped addresses, configure network objects or network object groups. Network object groups are particularly useful for creating a mapped address pool with discontinuous IP address ranges or multiple hosts or subnets. To create a network object or group, see the "Configuring Network Objects and Groups" section on page 25-2.
- For static NAT-with-port-translation, configure TCP or UDP service objects. To create a service object, see the "Configuring Service Objects and Service Groups" section on page 25-4.

For specific guidelines for objects and groups, see the configuration section for the NAT type you want to configure. See also the "Guidelines and Limitations" section.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

- Supported in routed and transparent firewall mode.
- In transparent mode, you must specify the real and mapped interfaces; you cannot use --Any--.
- In transparent mode, you cannot configure interface PAT, because the transparent mode interfaces do not have IP addresses. You also cannot use the management IP address as a mapped address.
- In transparent mode, translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

IPv6 Guidelines

- Supports IPv6.

- For routed mode, you can also translate between IPv4 and IPv6.
- For transparent mode, translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.
- For transparent mode, a PAT pool is not supported for IPv6.
- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

Additional Guidelines

- You cannot configure FTP destination port translation when the source IP address is a subnet (or any other application that uses a secondary connection); the FTP data channel establishment does not succeed.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT information is used, you can clear the translation table using the **clear xlate** command. However, clearing the translation table disconnects all current connections that use translations.

Note If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** command. This safeguard ensures that the same address is not assigned to multiple hosts.

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- When using the **any** keyword in a NAT rule, the definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the ASA performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the ASA can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.
- Objects and object groups used in NAT cannot be undefined; they must include IP addresses.
- You can use the same objects in multiple rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify --Any-- interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the interface name instead of the IP address.
  - (Transparent mode) The management IP address.
  - (Dynamic NAT) The standby interface IP address when VPN is enabled.
  - Existing VPN pool addresses.

Default Settings

- By default, the rule is added to the end of section 1 of the NAT table.
- (Routed mode) The default real and mapped interface is Any, which applies the rule to all interfaces.
- (8.3(1), 8.3(2), and 8.4(1)) The default behavior for identity NAT has proxy ARP disabled. You cannot configure this setting. (8.4(2) and later) The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired.
- If you specify an optional interface, then the ASA uses the NAT configuration to determine the egress interface. (8.3(1) through 8.4(1)) The only exception is for identity NAT, which always uses a route lookup, regardless of the NAT configuration. (8.4(2) and later) For identity NAT, the default behavior is to use the NAT configuration, but you have the option to always use a route lookup instead.

Configuring Twice NAT

This section describes how to configure twice NAT. This section includes the following topics:

- Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool, page 41-4
- Configuring Dynamic PAT (Hide), page 41-12
- Configuring Static NAT or Static NAT-with-Port-Translation, page 41-18
- Configuring Identity NAT, page 41-24
- Configuring Per-Session PAT Rules, page 41-29

Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool

This section describes how to configure twice NAT for dynamic NAT or for dynamic PAT using a PAT pool. For more information, see the "Dynamic NAT" section on page 39-8 or the "Dynamic PAT" section on page 39-10.

Guidelines

For a PAT pool:

- If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used. (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you have a lot of traffic that uses the lower port ranges, you can now specify for a PAT pool a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535.
- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT and a flat range, then the other rule must also specify extended PAT and a flat range.

For extended PAT for a PAT pool (8.4(3) and later, not including 8.5(1) or 8.6(1)):

- Many application inspections do not support extended PAT. See the "Default Settings" section on page 57-4 in Chapter 57, "Getting Started with Application Layer Protocol Inspection," for a complete list of unsupported inspections.

- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.

For round robin for a PAT pool:

- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. **Note**: This "stickiness" does not survive a failover. If the ASA fails over, then subsequent connections from a host may not use the initial IP address.
- (8.4(2), 8.5(1), and 8.6(1)) If a host has an existing connection, then subsequent connections from that host will likely use *different* PAT addresses for each connection because of the round robin allocation. In this case, you may have problems when accessing two websites that exchange information about the host, for example an e-commerce site and a payment site. When these sites see two different IP addresses for what is supposed to be a single host, the transaction may fail.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

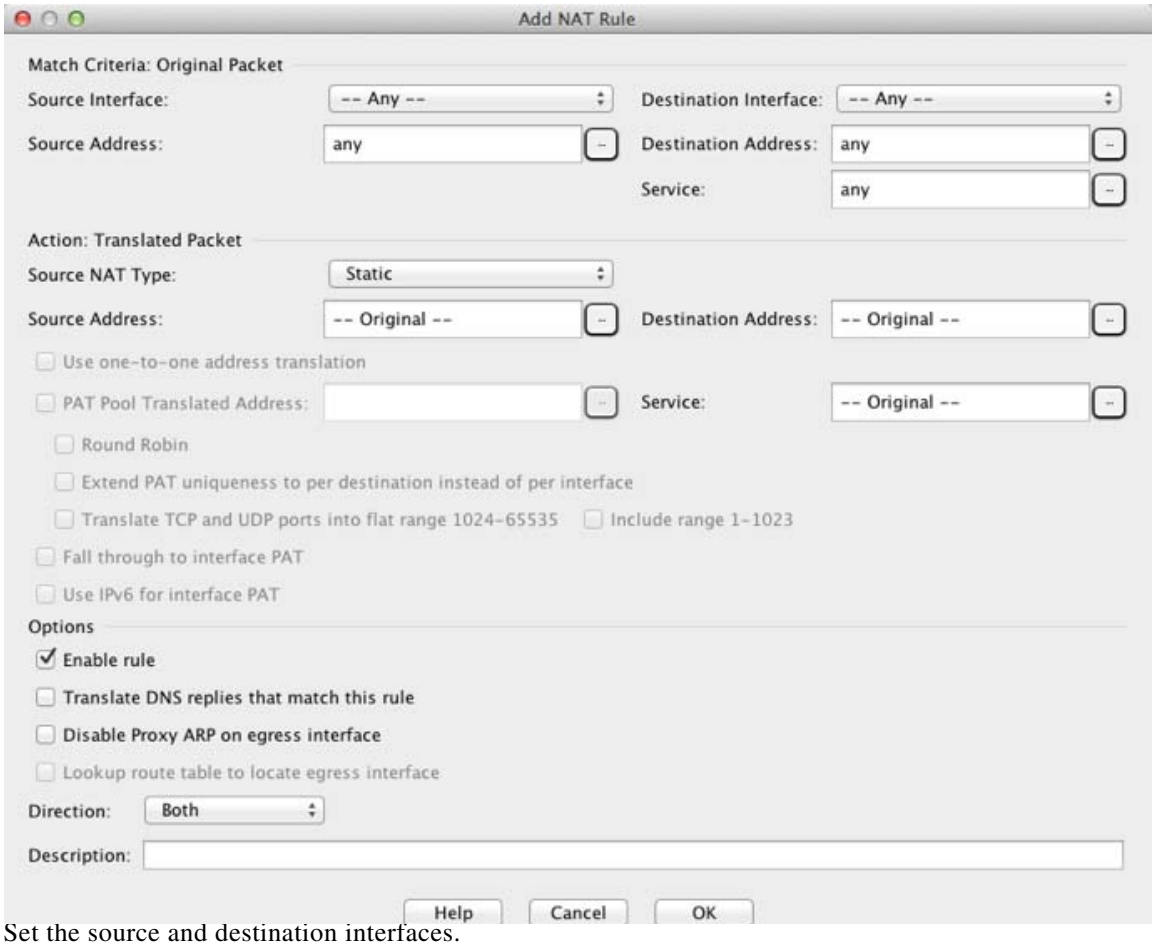
Detailed Steps

To configure dynamic NAT, perform the following steps:

Step 1 Choose **Configuration > Firewall > NAT Rules**, and then click **Add**.

If you want to add this rule to section 3 after the network object rules, then click the down arrow next to Add, and choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

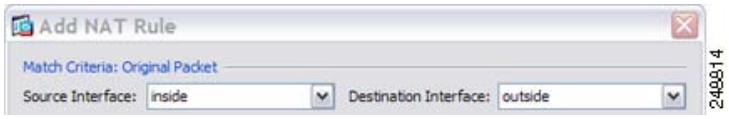


Step 2 Set the source and destination interfaces.

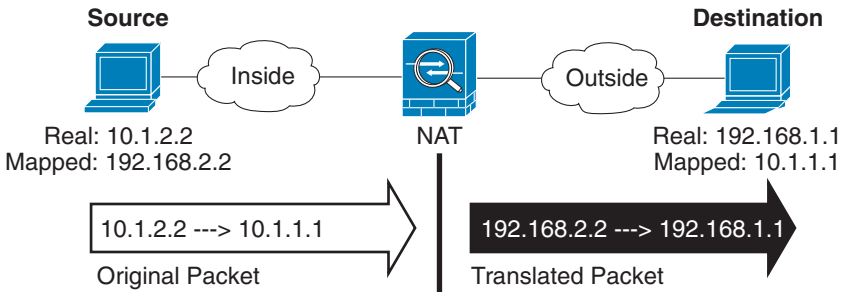
By default in routed mode, both interfaces are set to --Any--. In transparent firewall mode, you must set specific interfaces.

a. From the Match Criteria: Original Packet > Source Interface drop-down list, choose the source interface.

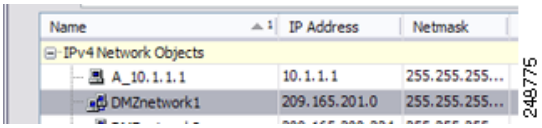
b. From the Match Criteria: Original Packet > Destination Interface drop-down list, choose the destination interface.



Step 3 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the source interface network (the *real source address* and the *mapped destination address*). See the following figure for an example of the original packet vs. the translated packet.



a. For the Match Criteria: Original Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Source Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. The default is **any**.

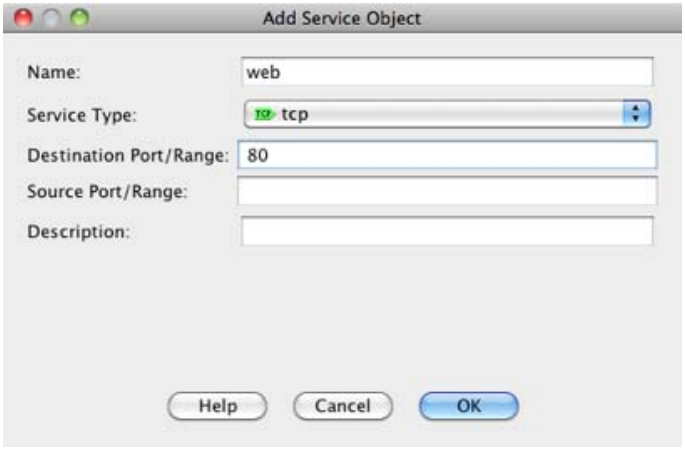


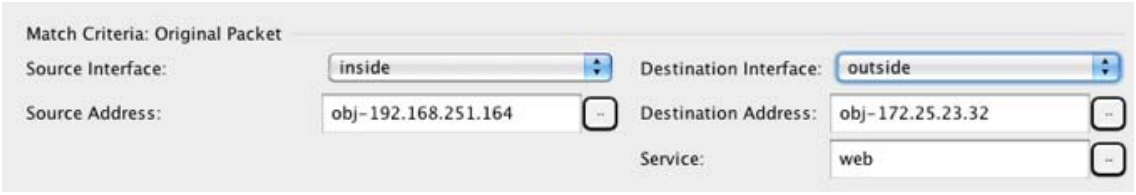
b. (Optional) For the Match Criteria: Original Packet > Destination Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Destination Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the "Main Differences Between Network Object NAT and Twice NAT" section on page 39-15.

Step 4 (Optional) Identify the original packet port (the *mapped destination port*). For the Match Criteria: Original Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Original Service dialog box.

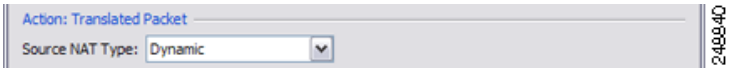
Dynamic NAT does not support port translation. However, because the destination translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



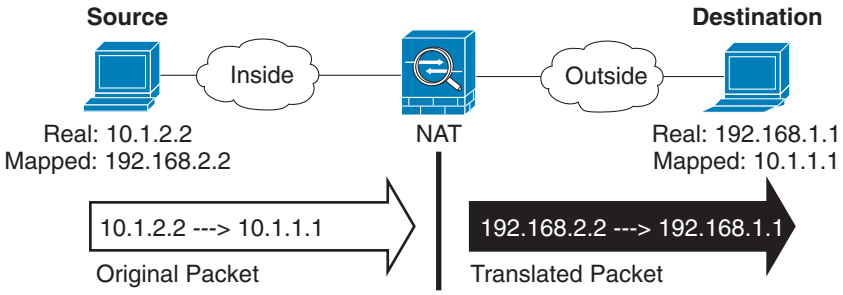


Step 5 Choose **Dynamic** from the Match Criteria: Translated Packet > Source NAT Type drop-down list.

This setting only applies to the source address; the destination translation is always static.



Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network (the *mapped source address* and the *real destination address*). You can translate between IPv4 and IPv6 if desired. See the following figure for an example of the original packet vs. the translated packet.



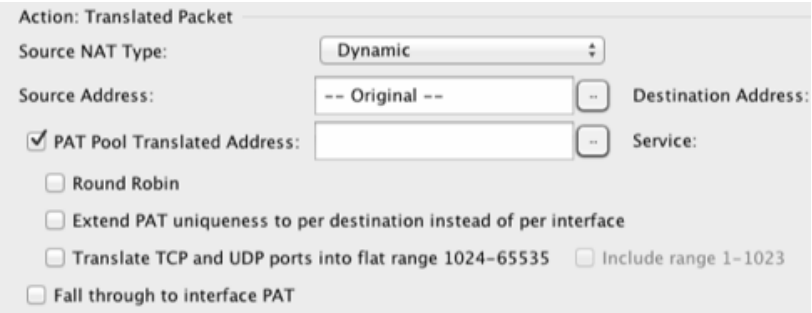
a. You can perform either dynamic NAT or Dynamic PAT using a PAT pool:

- Dynamic NAT—For the Match Criteria: Translated Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Translated Source Address dialog box.

  For dynamic NAT, you typically configure a larger group of source addresses to be mapped to a smaller group.

Note The object or group cannot contain a subnet.

- Dynamic PAT using a PAT pool—.To configure a PAT pool, check the **PAT Pool Translated Address** check box, then click the browse button and choose an existing network object or group or create a new object or group from the Browse Translated PAT Pool Address dialog box. **Note**: Leave the Source Address field empty.



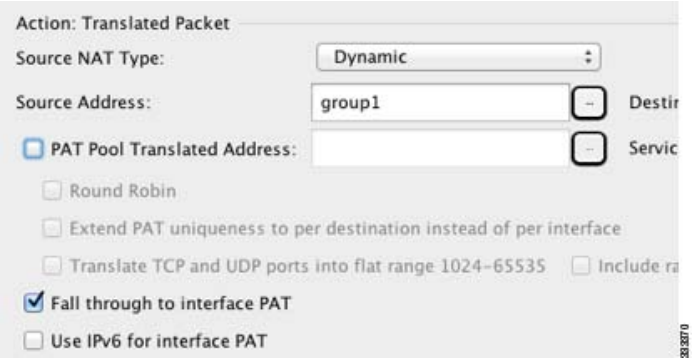
Note The object or group cannot contain a subnet.

(Optional) For a PAT pool, configure the following options:

  - To assign addresses/ports in a round-robin fashion, check the **Round Robin** check box. Without round-robin, by default, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns an address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
  - (8.4(3) and later, not including 8.5(1) or 8.6(1)) Check the **Extend PAT uniqueness to per destination instead of per interface** check box to use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80.
  - (8.4(3) and later, not including 8.5(1) or 8.6(1)) Check the **Translate TCP or UDP ports into flat range (1024-65535)** check box to use the 1024 to 65535 port range as a single flat range when allocating ports. When choosing the mapped port number for a translation, the ASA uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include range 1 to 1023** check box.

b. (Optional, Routed Mode Only) To use the interface IP address as a backup method if the other mapped source addresses are already allocated, check the **Fall through to interface PAT** check box. To use the IPv6 interface address, also check the **Use IPv6 for interface PAT** check box.

The destination interface IP address is used. This option is only available if you configure a specific Destination Interface.

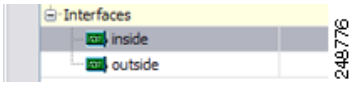


c. For the Match Criteria: Translated Packet > Destination Address, click the browse button and choose an existing network object, group, or interface or create a new object or group from the Browse Translated Destination Address dialog box.

For identity NAT for the destination address, simply use the same object or group for both the real and mapped addresses.

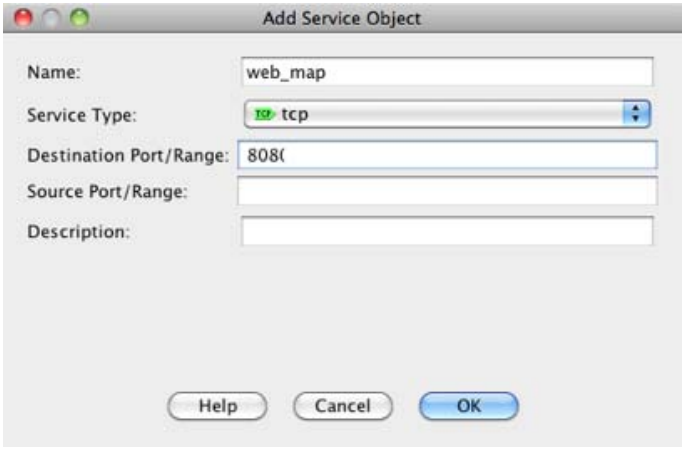
If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the "Static NAT" section on page 39-3. See the "Guidelines and Limitations" section on page 41-2 for information about disallowed mapped IP addresses.

For static interface NAT with port translation only, choose an interface from the Browse dialog box. Be sure to also configure a service translation (see Step 7). For this option, you must configure a specific interface for the Source Interface in Step 2. See the "Static Interface NAT with Port Translation" section on page 39-6 for more information.



Step 7 (Optional) Identify the translated packet port (the *real destination port*). For the Match Criteria: Translated Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Translated Service dialog box.

Dynamic NAT does not support port translation. However, because the destination translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



Step 8 (Optional) Configure NAT options in the Options area.

a. Enable rule —Enables this NAT rule. The rule is enabled by default.

b. (For a source-only rule) Translate DNS replies that match this rule—Rewrites the DNS A record in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure DNS modification if you configure a destination address. See the "DNS and NAT" section on page 39-30 for more information.

c. Description—Adds a description about the rule up to 200 characters in length.

Step 9 Click **OK**.

Configuring Dynamic PAT (Hide)

This section describes how to configure twice NAT for dynamic PAT (hide). For dynamic PAT using a PAT pool, see the "Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool" section on page 41-4 instead of using this section. For more information, see the "Dynamic PAT" section on page 39-10.

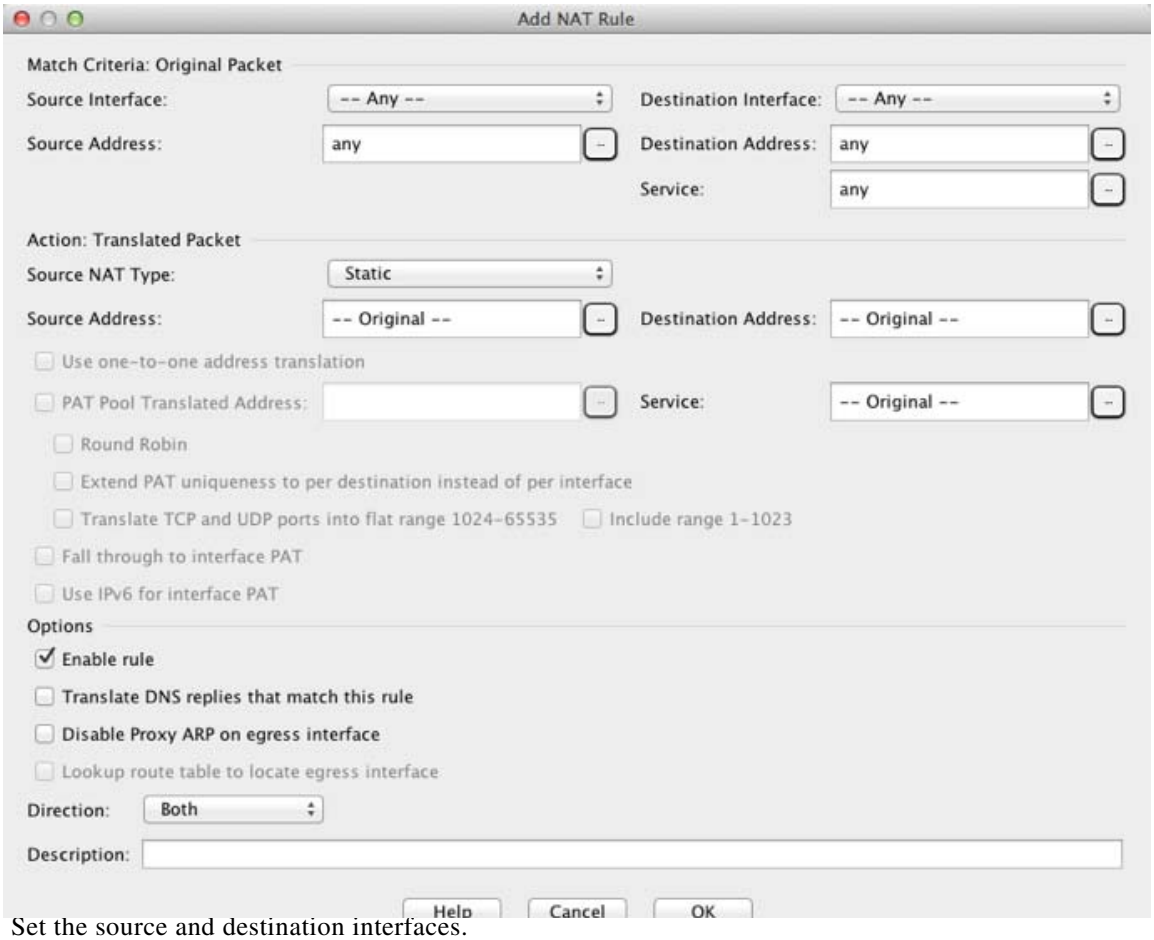
Detailed Steps

To configure dynamic PAT, perform the following steps:

Step 1 Choose **Configuration > Firewall > NAT Rules**, and then click **Add**.

If you want to add this rule to section 3 after the network object rules, then click the down arrow next to Add, and choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

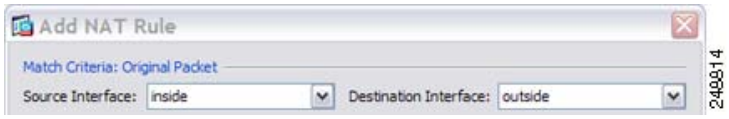


Step 2 Set the source and destination interfaces.

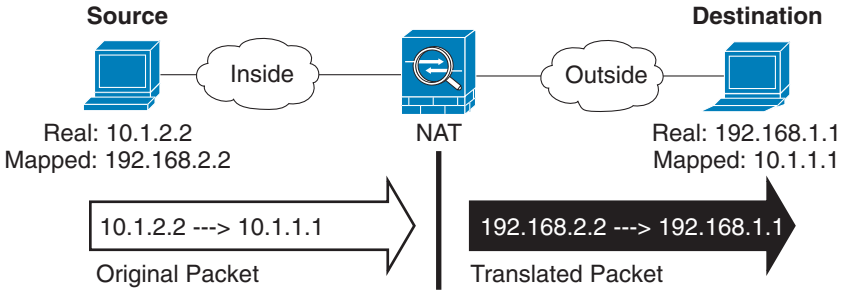
By default in routed mode, both interfaces are set to --Any--. In transparent firewall mode, you must set specific interfaces.

a. From the Match Criteria: Original Packet > Source Interface drop-down list, choose the source interface.

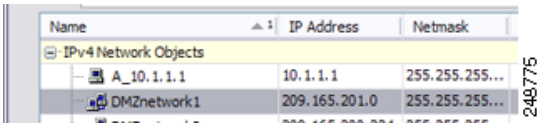
b. From the Match Criteria: Original Packet > Destination Interface drop-down list, choose the destination interface.



Step 3 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the source interface network (the *real source address* and the *mapped destination address*). See the following figure for an example of the original packet vs. the translated packet.



a. For the Match Criteria: Original Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Source Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. The default is **any**.

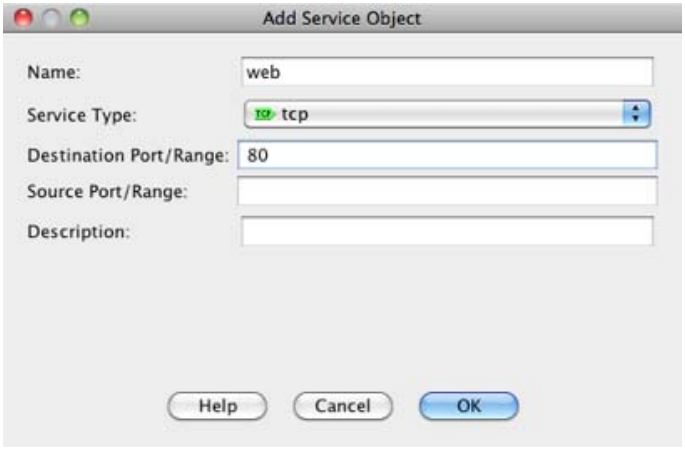


b. (Optional) For the Match Criteria: Original Packet > Destination Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Destination Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the "Main Differences Between Network Object NAT and Twice NAT" section on page 39-15.

Step 4 (Optional) Identify the original packet port (the *mapped destination port*). For the Match Criteria: Original Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Original Service dialog box.

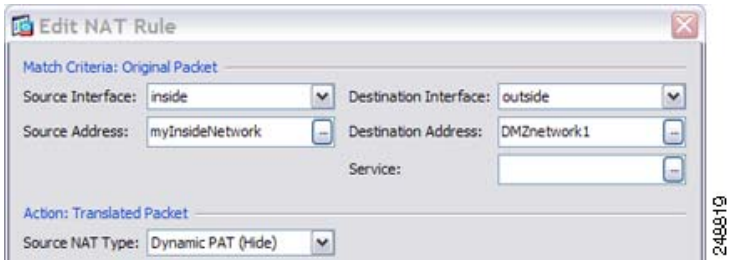
Dynamic PAT does not support additional port translation. However, because the destination translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



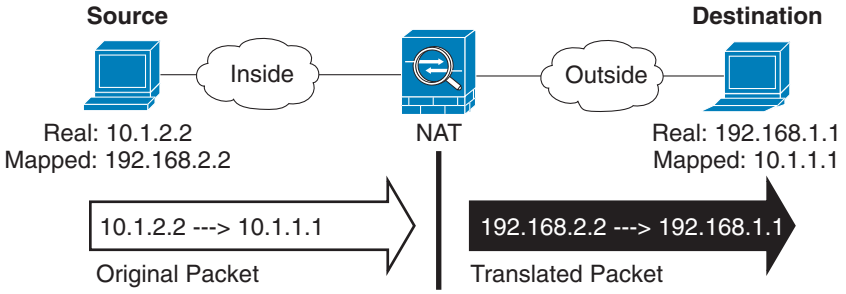
Step 5 Choose **Dynamic PAT (Hide)** from the Match Criteria: Translated Packet > Source NAT Type drop-down list.

This setting only applies to the source address; the destination translation is always static.

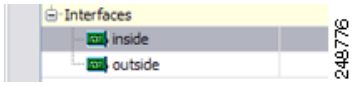
Note To configure dynamic PAT using a PAT pool, choose **Dynamic** instead of Dynamic PAT (Hide), see the "Configuring Dynamic NAT or Dynamic PAT Using a PAT Pool" section on page 41-4.



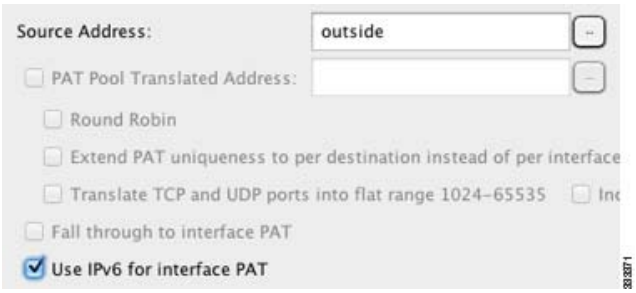
Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network (the *mapped source address* and the *real destination address*). You can translate between IPv4 and IPv6 if desired. See the following figure for an example of the original packet vs. the translated packet.



a. For the Match Criteria: Translated Packet > Source Address, click the browse button and choose an existing network object or interface or create a new object from the Browse Translated Source Address dialog box.



If you want to use the IPv6 address of the interface, check the **Use IPv6 for interface PAT** check box.



b. For the Match Criteria: Translated Packet > Destination Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Translated Destination Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

For identity NAT for the destination address, simply use the same object or group for both the real and mapped addresses.

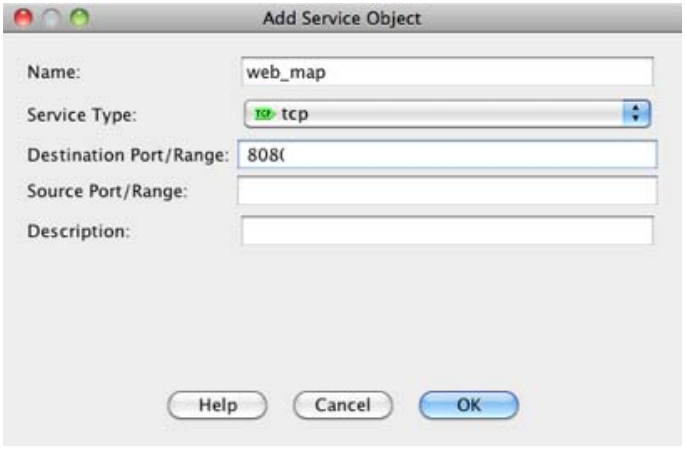
If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the "Static NAT" section on page 39-3. See the "Guidelines and Limitations" section on page 41-2 for information about disallowed mapped IP addresses.

For static interface NAT with port translation only, choose an interface from the Browse dialog box. Be sure to also configure a service translation (see Step 7). For this option, you must configure a specific interface for the Source Interface in Step 2. See the "Static Interface NAT with Port Translation" section on page 39-6 for more information.

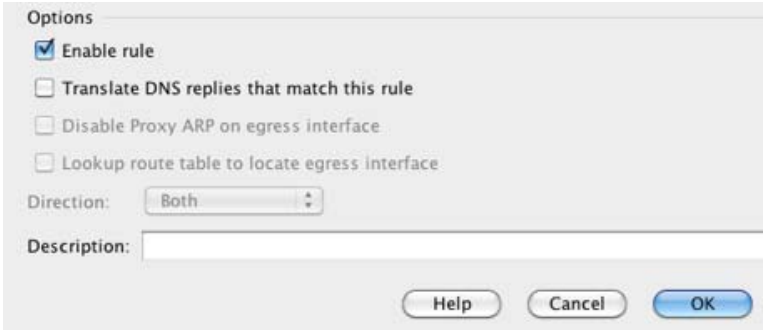
Step 7 (Optional) Identify the translated packet port (the *real destination port*). For the Match Criteria: Translated Packet > Service, click the browse button and choose an existing TCP or UDP service object from the Browse Translated Service dialog box.

You can also create a new service object from the Browse Translated Service dialog box and use this object as the mapped destination port.

Dynamic PAT does not support additional port translation. However, because the destination translation is always static, you can perform port translation for the destination port. A service object can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



Step 8 (Optional) Configure NAT options in the Options area.



a. Enable rule —Enables this NAT rule. The rule is enabled by default.

b. (For a source-only rule) Translate DNS replies that match this rule—Rewrites the DNS A record in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure DNS modification if you configure a destination address. See the "DNS and NAT" section on page 39-30 for more information.

c. Description—Adds a description about the rule up to 200 characters in length.

Step 9 Click **OK**.

Configuring Static NAT or Static NAT-with-Port-Translation

This section describes how to configure a static NAT rule using twice NAT. For more information about static NAT, see the "Static NAT" section on page 39-3.

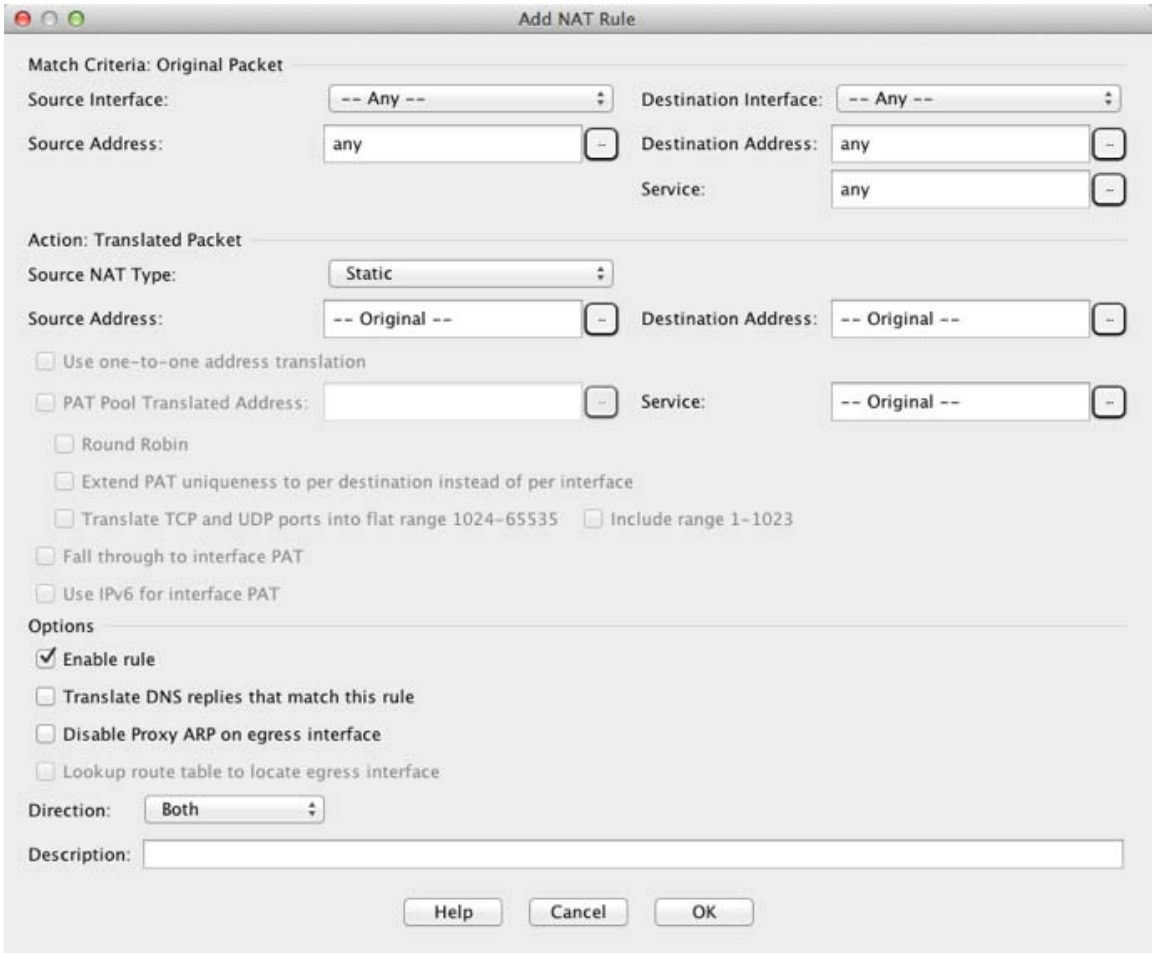
Detailed Steps

To configure static NAT, perform the following steps:

Step 1 Choose **Configuration > Firewall > NAT Rules**, and then click **Add**.

If you want to add this rule to section 3 after the network object rules, then click the down arrow next to Add, and choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

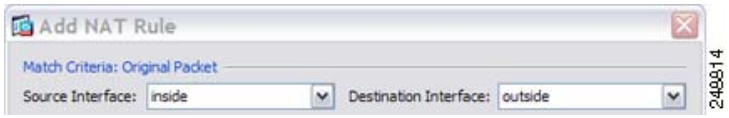


Step 2 Set the source and destination interfaces.

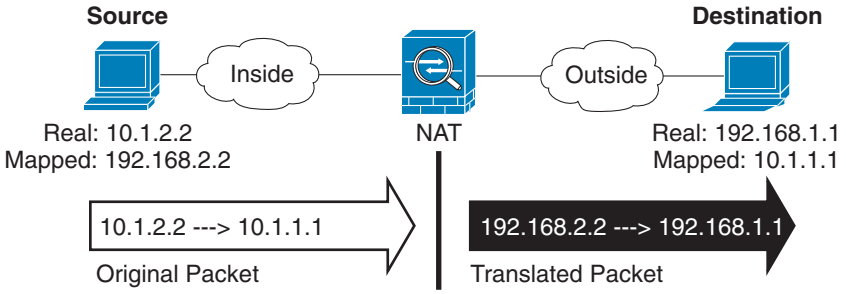
By default in routed mode, both interfaces are set to --Any--. In transparent firewall mode, you must set specific interfaces.

a. From the Match Criteria: Original Packet > Source Interface drop-down list, choose the source interface.

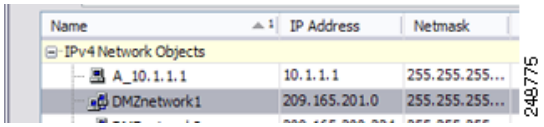
b. From the Match Criteria: Original Packet > Destination Interface drop-down list, choose the destination interface.



Step 3 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the source interface network (the *real source address* and the *mapped destination address*). See the following figure for an example of the original packet vs. the translated packet.



a. For the Match Criteria: Original Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Source Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. The default is **any**, but do not use this option except for identity NAT. See the "Configuring Identity NAT" section on page 41-24 for more information.

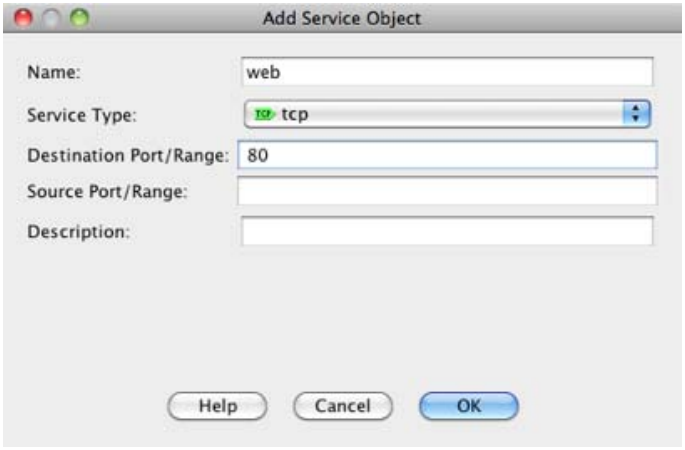


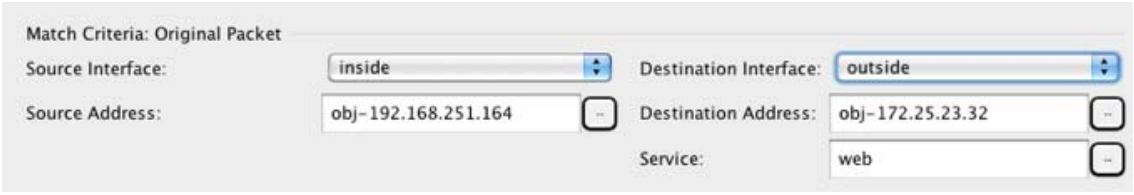
b. (Optional) For the Match Criteria: Original Packet > Destination Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Destination Address dialog box.

Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the "Main Differences Between Network Object NAT and Twice NAT" section on page 39-15.

Step 4 (Optional) Identify the original packet source or destination port (the *real source port* **or** the *mapped destination port*). For the Match Criteria: Original Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Original Service dialog box.

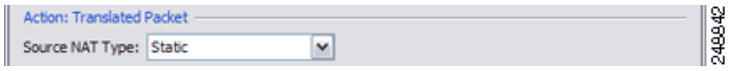
A service object can contain both a source and destination port. You should specify *either* the source *or* the destination port for both the real and mapped service objects. You should only specify *both* the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. In the rare case where you specify both the source and destination ports in the object, the original packet service object contains the real source port/mapped destination port; the translated packet service object contains the mapped source port/real destination port. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



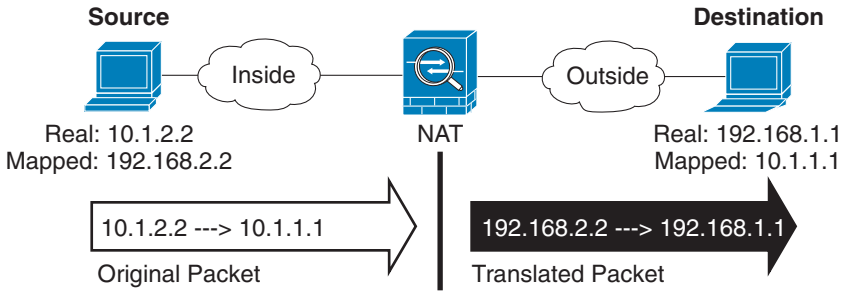


Step 5 Choose **Static** from the Match Criteria: Translated Packet > Source NAT Type drop-down list. Static is the default setting.

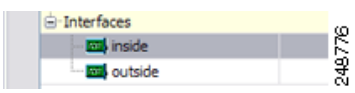
This setting only applies to the source address; the destination translation is always static.



Step 6 Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network (the *mapped source address* and the *real destination address*). You can translate between IPv4 and IPv6 if desired. See the following figure for an example of the original packet vs. the translated packet.

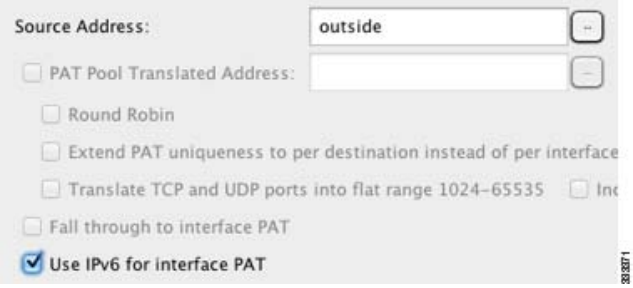


a. For the Match Criteria: Translated Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Translated Source Address dialog box.



For static NAT, the mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired.

For static interface NAT with port translation, you can specify the interface instead of a network object/group for the mapped address. If you want to use the IPv6 address of the interface, check the **Use IPv6 for interface PAT** check box.



For more information, see the "Static Interface NAT with Port Translation" section on page 39-6. See the "Guidelines and Limitations" section on page 41-2 for information about disallowed mapped IP addresses.

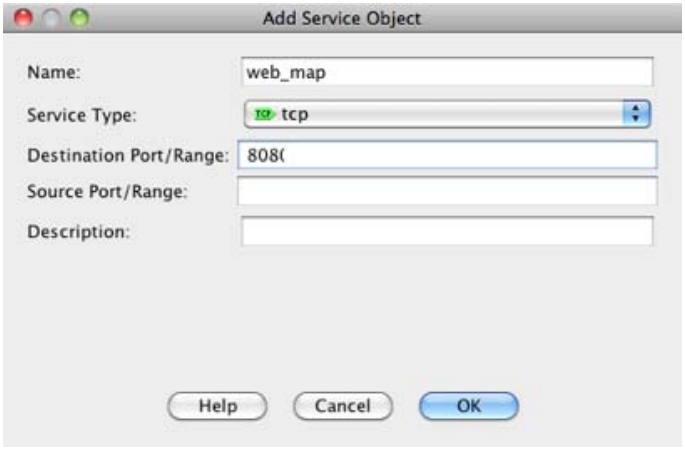
b. For the Match Criteria: Translated Packet > Destination Address, click the browse button and choose an existing network object, group, or interface or create a new object or group from the Browse Translated Destination Address dialog box.

For static NAT, the mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired.

For static interface NAT with port translation, you can specify the interface instead of a network object/group for the mapped address. For more information, see the "Static Interface NAT with Port Translation" section on page 39-6. See the "Guidelines and Limitations" section on page 41-2 for information about disallowed mapped IP addresses.

Step 7 (Optional) Identify the translated packet source or destination port (the *mapped source port* **or** the *real destination port*). For the Match Criteria: Translated Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Translated Service dialog box.

A service object can contain both a source and destination port. You should specify *either* the source *or* the destination port for both real and mapped service objects. You should only specify *both* the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. In the rare case where you specify both the source and destination ports in the object, the original packet service object contains the real source port/mapped destination port; the translated packet service object contains the mapped source port/real destination port. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



Step 8 (Optional) For NAT46, check the **Use one-to-one address translation** check box. For NAT46, specify one-to-one to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this keyword.

Step 9 (Optional) Configure NAT options in the Options area.

a. Enable rule —Enables this NAT rule. The rule is enabled by default.

b. (For a source-only rule) Translate DNS replies that match this rule—Rewrites the DNS A record in DNS replies. Be sure DNS inspection is enabled (it is enabled by default). You cannot configure DNS modification if you configure a destination address. See the "DNS and NAT" section on page 39-30 for more information.

c. Disable Proxy ARP on egress interface—Disables proxy ARP for incoming packets to the mapped IP addresses. See the "Mapped Addresses and Routing" section on page 39-22 for more information.

d. Direction—To make the rule unidirectional, choose **Unidirectional**. The default is Both. Making the rule unidirectional prevents traffic from initiating connections to the real addresses.

e. Description—Adds a description about the rule up to 200 characters in length.

Step 10 Click **OK**.

Configuring Identity NAT

This section describes how to configure an identity NAT rule using twice NAT. For more information about identity NAT, see the "Identity NAT" section on page 39-12.

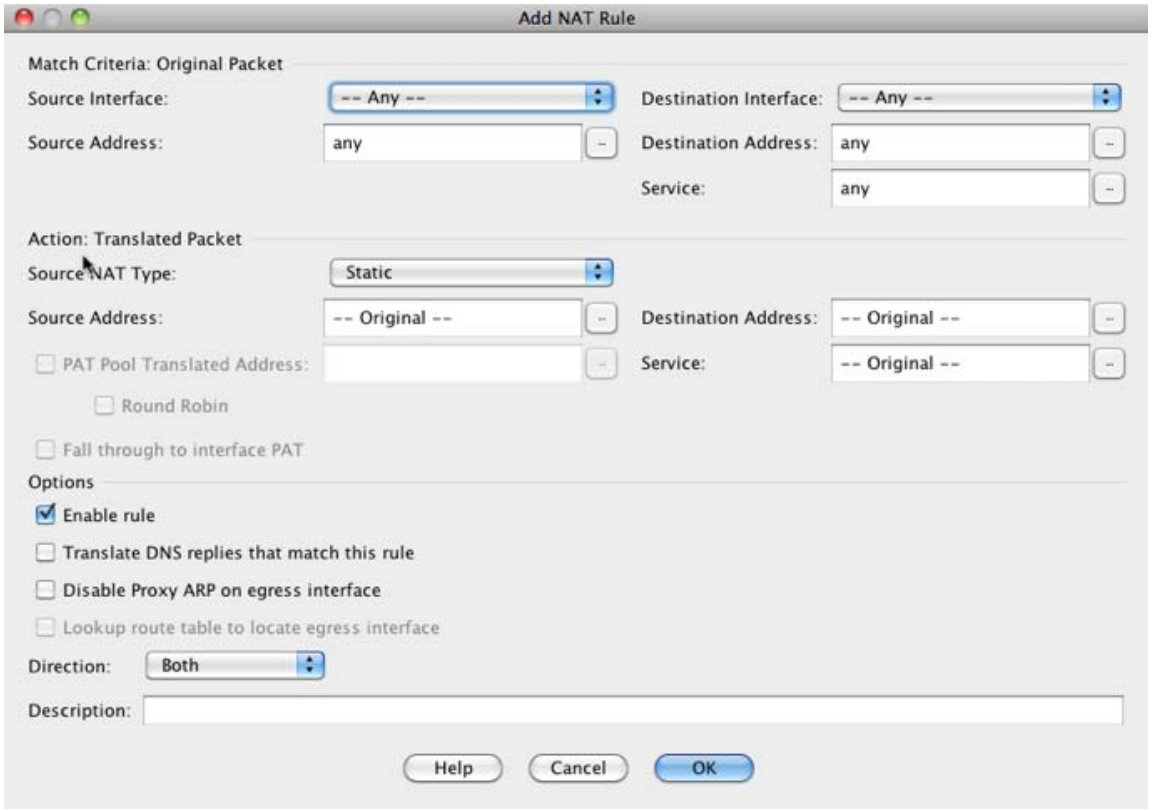
Detailed Steps

To configure identity NAT, perform the following steps:

Step 1 Choose **Configuration > Firewall > NAT Rules**, and then click **Add**.

If you want to add this rule to section 3 after the network object rules, then click the down arrow next to Add, and choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

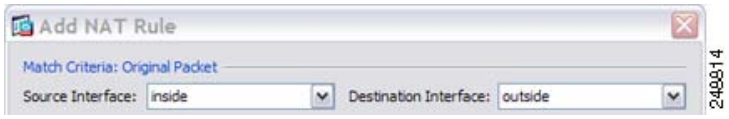


Step 2 Set the source and destination interfaces.

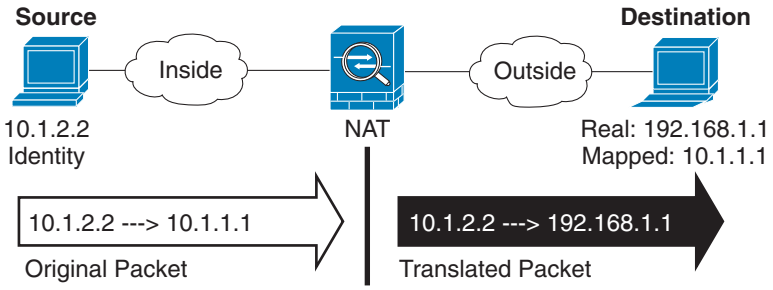
By default in routed mode, both interfaces are set to --Any--. In transparent firewall mode, you must set specific interfaces.

a. From the Match Criteria: Original Packet > Source Interface drop-down list, choose the source interface.

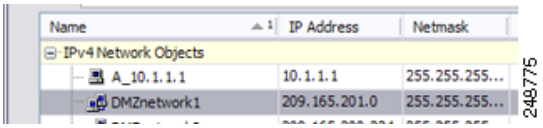
b. From the Match Criteria: Original Packet > Destination Interface drop-down list, choose the destination interface.



Step 3 Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the source interface network (the *real source address* and the *mapped destination address*). See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.



a. For the Match Criteria: Original Packet > Source Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Source Address dialog box. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. The default is **any**; only use this option when also setting the mapped address to **any**.

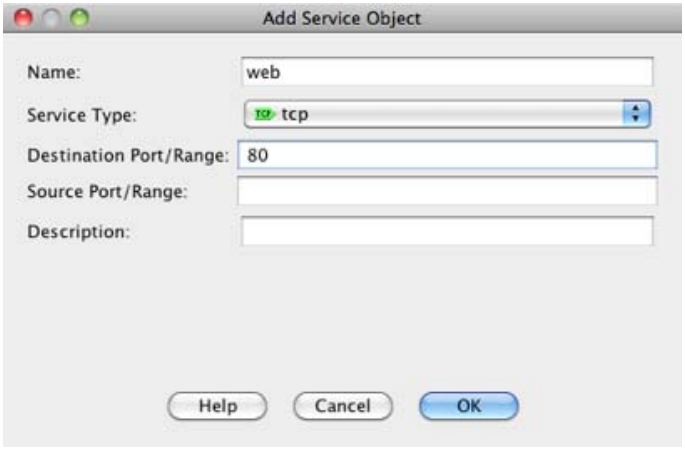


b. (Optional) For the Match Criteria: Original Packet > Destination Address, click the browse button and choose an existing network object or group or create a new object or group from the Browse Original Destination Address dialog box.

Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the "Main Differences Between Network Object NAT and Twice NAT" section on page 39-15.

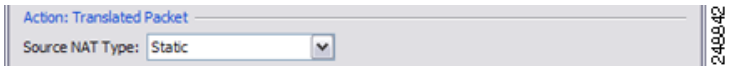
Step 4 (Optional) Identify the original packet source or destination port (the *real source port* **or** the *mapped destination port*). For the Match Criteria: Original Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Original Service dialog box.

A service object can contain both a source and destination port. You should specify *either* the source *or* the destination port for both service objects. You should only specify *both* the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. In the rare case where you specify both the source and destination ports in the object, the original packet service object contains the real source port/mapped destination port; the translated packet service object contains the mapped source port/real destination port. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.

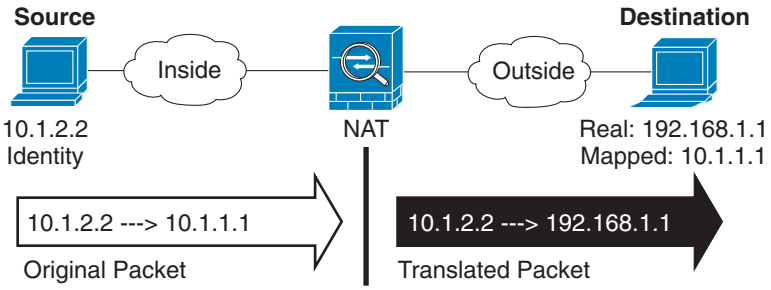


Step 5 Choose **Static** from the Match Criteria: Translated Packet > Source NAT Type drop-down list. Static is the default setting.

This setting only applies to the source address; the destination translation is always static.



Step 6 Identify the translated packet addresses; namely, the packet addresses as they appear on the destination interface network (the *mapped source address* and the *real destination address*). See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.



a. For the Match Criteria: Translated Packet > Source Address, click the browse button and choose the same network object or group from the Browse Translated Source Address dialog box that you chose for the real source address. Use **any** if you specified **any** for the real address.

b. For the Match Criteria: Translated Packet > Destination Address, click the browse button and choose an existing network object, group, or interface or create a new object or group from the Browse Translated Destination Address dialog box.

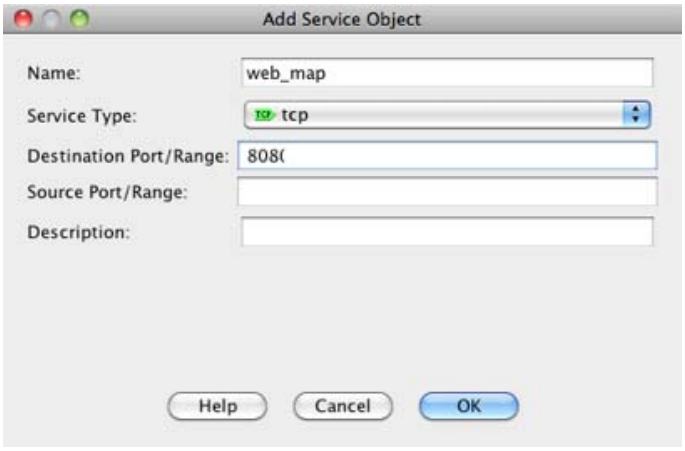
For identity NAT for the destination address, simply use the same object or group for both the real and mapped addresses.

If you want to translate the destination address, then the static mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the "Static NAT" section on page 39-3. See the "Guidelines and Limitations" section on page 41-2 for information about disallowed mapped IP addresses.

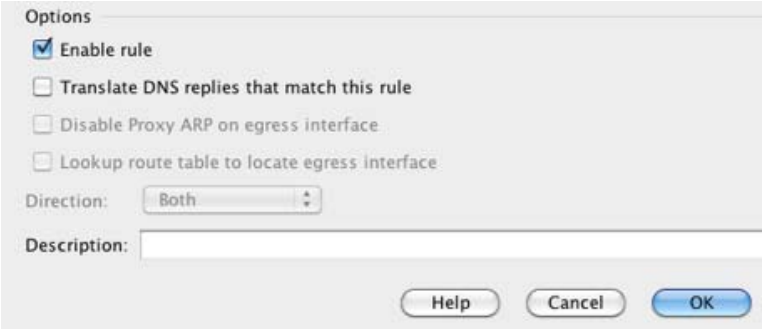
For static interface NAT with port translation only, choose an interface. If you specify an interface, be sure to also configure a a service translation. For more information, see the "Static Interface NAT with Port Translation" section on page 39-6.

Step 7 (Optional) Identify the translated packet source or destination port (the *mapped source port* **or** the *real destination port*). For the Match Criteria: Translated Packet > Service, click the browse button and choose an existing TCP or UDP service object or create a new object from the Browse Translated Service dialog box.

A service object can contain both a source and destination port. You should specify *either* the source *or* the destination port for both service objects. You should only specify *both* the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. In the rare case where you specify both the source and destination ports in the object, the original packet service object contains the real source port/mapped destination port; the translated packet service object contains the mapped source port/real destination port. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports. The "not equal" (**!=**) operator is not supported.



Step 8 (Optional) Configure NAT options in the Options area.



a. Enable rule —Enables this NAT rule. The rule is enabled by default.

b. Disable Proxy ARP on egress interface—Disables proxy ARP for incoming packets to the mapped IP addresses. See the "Mapped Addresses and Routing" section on page 39-22 for more information.

c. (Routed mode; interface(s) specified) Lookup route table to locate egress interface—Determines the egress interface using a route lookup instead of using the interface specified in the NAT command. See the "Determining the Egress Interface" section on page 39-24 for more information.

d. Direction—To make the rule unidirectional, choose **Unidirectional**. The default is Both. Making the rule unidirectional prevents traffic from initiating connections to the real addresses. You might want to use this setting for testing purposes.

e. Description—Adds a description about the rule up to 200 characters in length.

Note Although the "Translate DNS replies that match this rule" check box is available if you do not configure a destination address, this option is not applicable to identity NAT because you are translating the address to itself, so the DNS reply does not need modification. See the "DNS and NAT" section on page 39-30 for more information.

Step 9 Click **OK**.

Configuring Per-Session PAT Rules

By default, all TCP PAT traffic and all UDP DNS traffic uses per-session PAT. To use multi-session PAT for traffic, you can configure per-session PAT rules: a permit rule uses per-session PAT, and a deny rule uses multi-session PAT. For more information about per-session vs. multi-session PAT, see the "Per-Session PAT vs. Multi-Session PAT (Version 9.0(1) and Later)" section on page 39-11.

Detailed Steps

To configure a per-session PAT rule, see the "Configuring Per-Session PAT Rules" section on page 40-18.

Monitoring Twice NAT

The Monitoring > Properties > Connection Graphs > Xlates pane lets you view the active Network Address Translations in a graphical format. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Fields

- Available Graphs—Lists the components you can graph.
  - Xlate Utilization—Displays the ASA NAT utilization.
- Graph Window Title—Shows the graph window name to which you want to add a graph type. To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title.
- Add—Click to move the selected entries in the Available Graphs list to the Selected Graphs list.
- Remove—Click to remove the selected entry from the Selected Graphs list.
- Show Graphs—Click to display a new or updated graph window.

The Monitoring > Properties > Connection Graphs > Perfmon pane lets you view the performance information in a graphical format. You can choose up to four types of statistics to show in one graph window. You can open multiple graph windows at the same time.

Fields

- Available Graphs—Lists the components you can graph.
  - AAA Perfmon—Displays the ASA AAA performance information.
  - Inspection Perfmon—Displays the ASA inspection performance information.
  - Web Perfmon—Displays the ASA web performance information, including URL access and URL server requests.
  - Connections Perfmon—Displays the ASA connections performance information.
  - Xlate Perfmon—Displays the ASA NAT performance information.
- Graph Window Title—Shows the graph window name to which you want to add a graph type. To use an existing window title, select one from the drop-down list. To display graphs in a new window, enter a new window title.
- Add—Click to move the selected entries in the Available Graphs list to the Selected Graphs list.
- Remove—Click to remove the selected statistic type from the Selected Graphs list.
- Show Graphs—Click to display a new or updated graph window.

Configuration Examples for Twice NAT

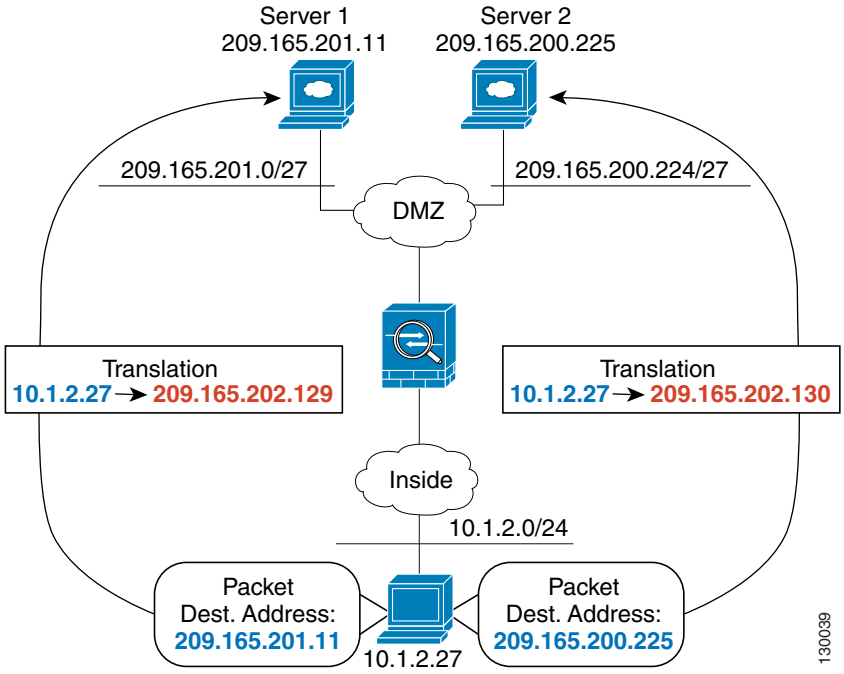
This section includes the following configuration examples:

- Different Translation Depending on the Destination (Dynamic PAT), page 41-31
- Different Translation Depending on the Destination Address and Port (Dynamic PAT), page 41-39

Different Translation Depending on the Destination (Dynamic PAT)

Figure 41-1 shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

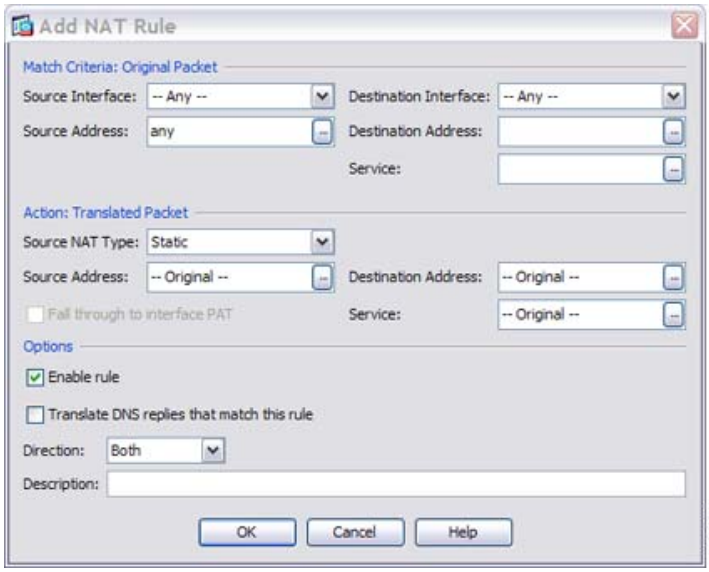
Figure 41-1 Twice NAT with Different Destination Addresses



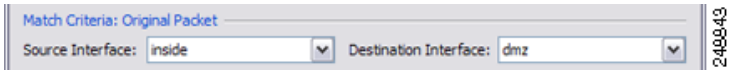
Step 1 Add a NAT rule for traffic from the inside network to DMZ network 1:

By default, the NAT rule is added to the end of section 1. If you want to add a NAT rule to section 3, after the network object NAT rules, choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

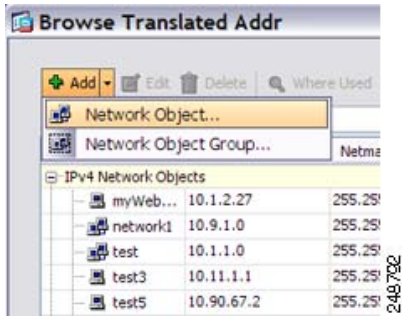


Step 2 Set the source and destination interfaces:



Step 3 For the Original Source Address, click the browse button to add a new network object for the inside network in the Browse Original Source Address dialog box.

a. Add the new network object.

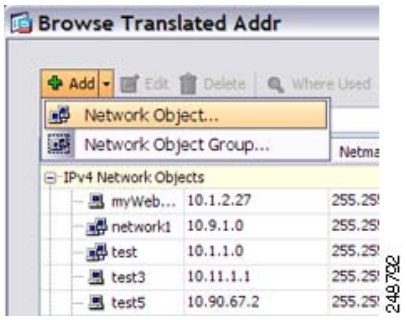


b. Define the inside network addresses, and click **OK**.

c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

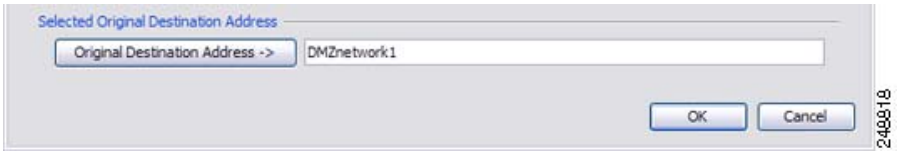
Step 4 For the Original Destination Address, click the browse button to add a new network object for DMZ network 1 in the Browse Original Destination Address dialog box.

a. Add the new network object.

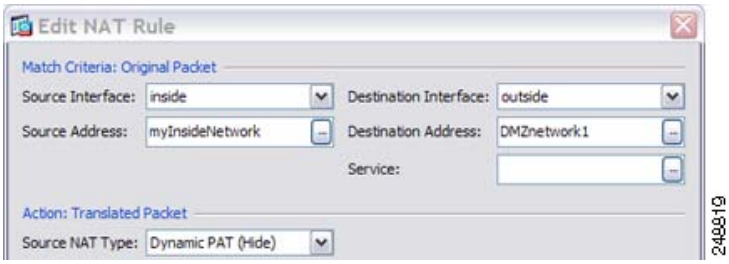


b. Define the DMZ network 1 addresses, and click **OK**.

c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

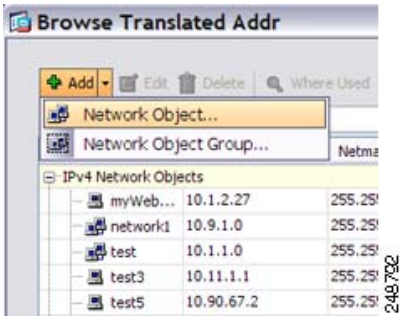


Step 5 Set the NAT Type to **Dynamic PAT (Hide)**:

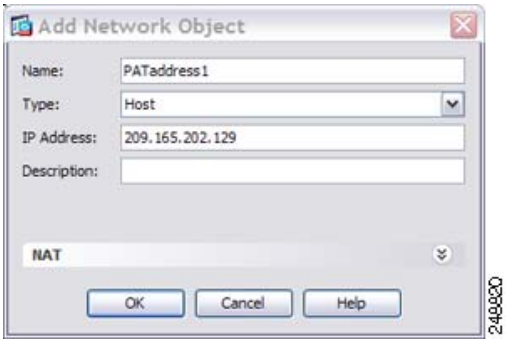


Step 6 For the Translated Source Address, click the browse button to add a new network object for the PAT address in the Browse Translated Source Address dialog box.

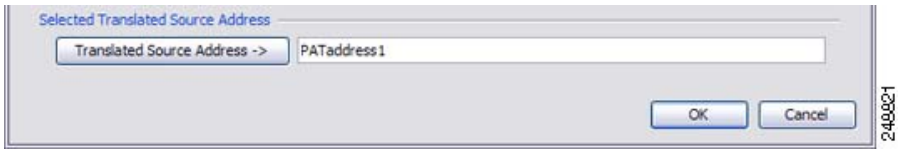
a. Add the new network object.



b. Define the PAT address, and click **OK**.

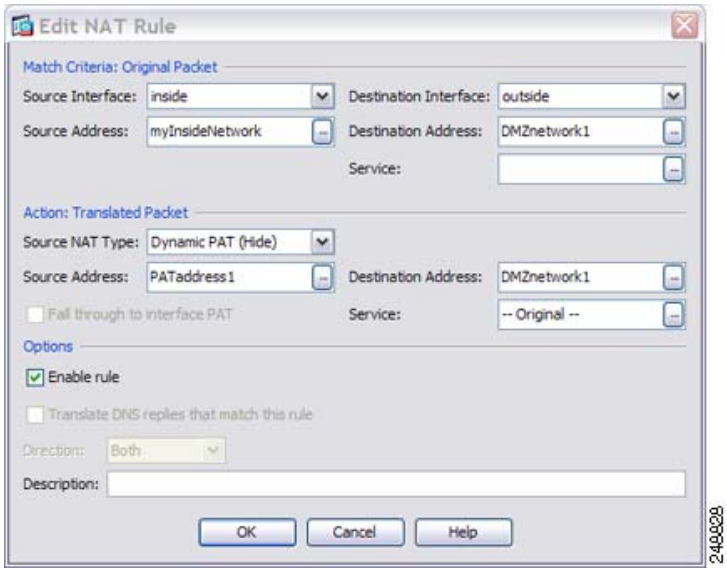


c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.



Step 7 For the Translated Destination Address, type the name of the Original Destination Address (DMZnetwork1) or click the browse button to choose it.

Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the Original and Translated destination addresses.

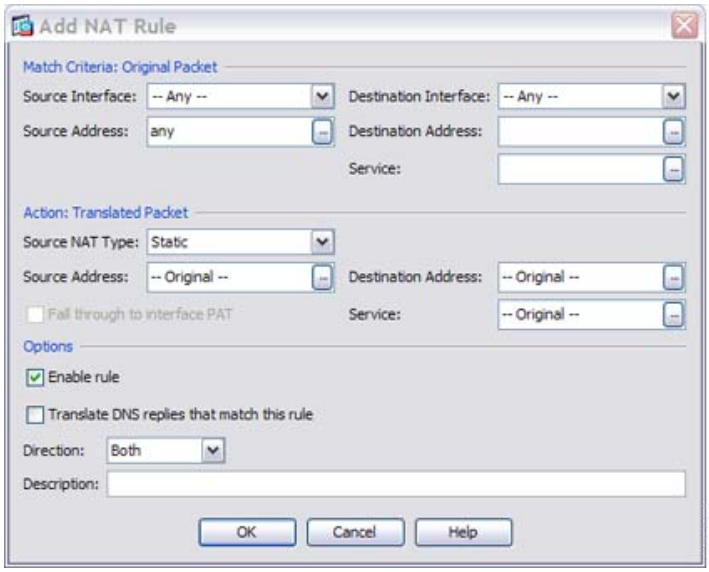


Step 8 Click **OK** to add the rule to the NAT table.

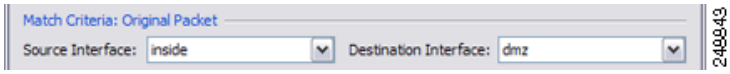
Step 9 Add a NAT rule for traffic from the inside network to DMZ network 2:

By default, the NAT rule is added to the end of section 1. If you want to add a NAT rule to section 3, after the network object NAT rules, choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.



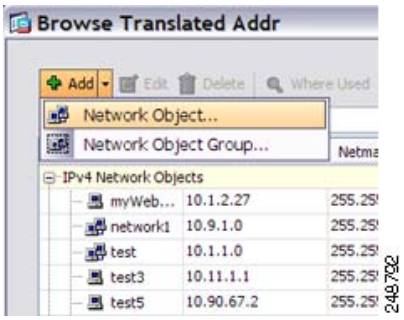
Step 10 Set the source and destination interfaces:



Step 11 For the Original Source Address, type the name of the inside network object (myInsideNetwork) or click the browse button to choose it.

Step 12 For the Original Destination Address, click the browse button to add a new network object for DMZ network 2 in the Browse Original Destination Address dialog box.

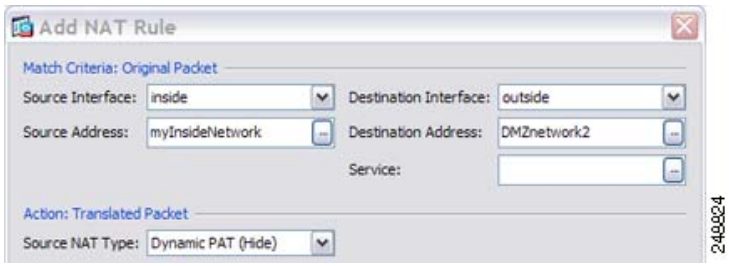
a. Add the new network object.



b. Define the DMZ network 2 addresses, and click **OK**.

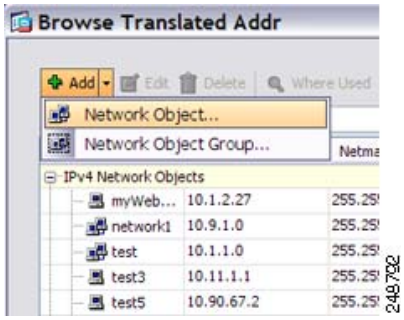
c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 13 Set the NAT Type to **Dynamic PAT (Hide)**:

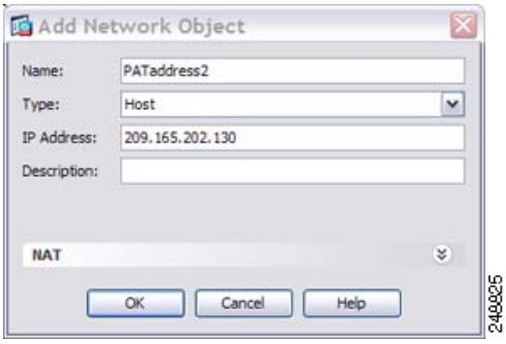


Step 14 For the Translated Source Address, click the browse button to add a new network object for the PAT address in the Browse Translated Source Address dialog box.

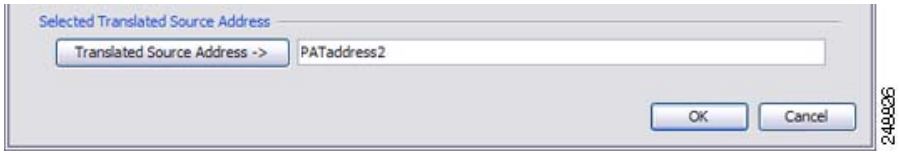
a. Add the new network object.



b. Define the PAT address, and click **OK**.

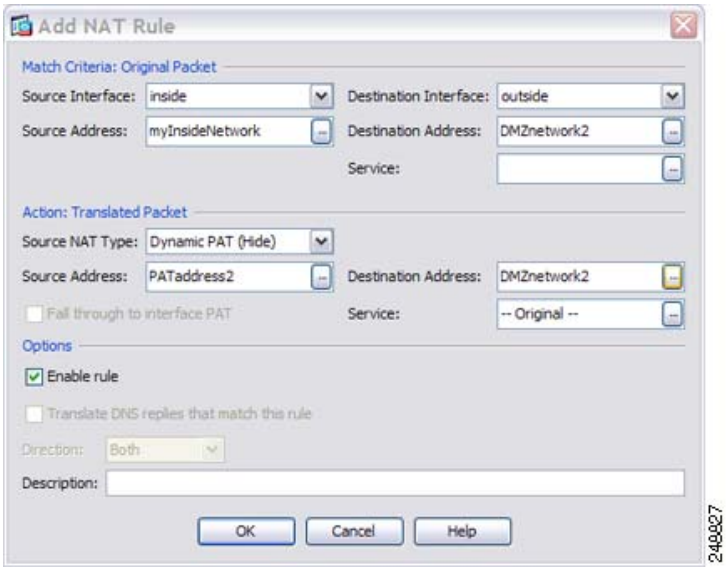


c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.



Step 15 For the Translated Destination Address, type the name of the Original Destination Address (DMZnetwork2) or click the browse button to choose it.

Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the Original and Translated destination addresses.



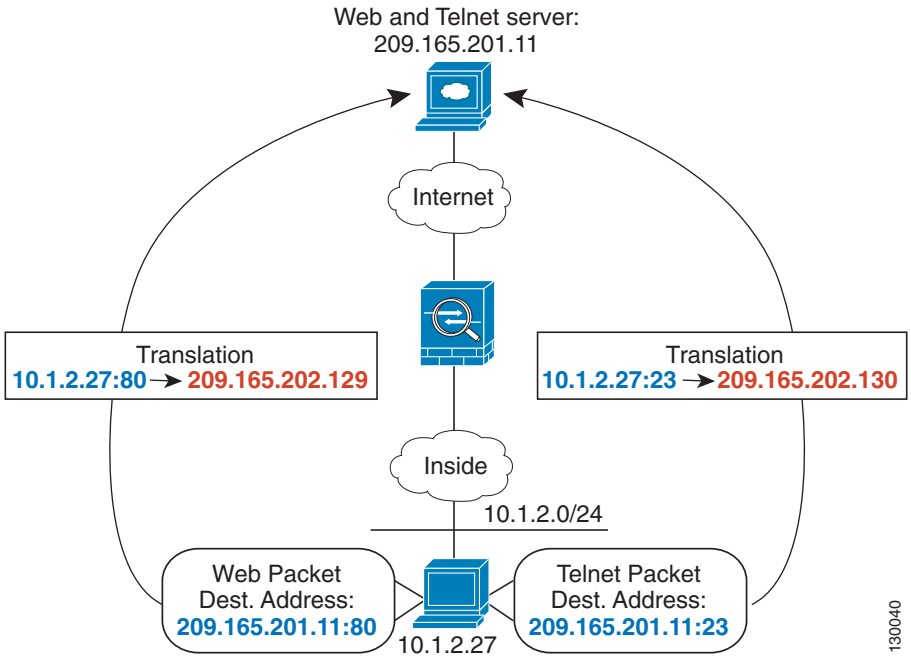
Step 16 Click **OK** to add the rule to the NAT table.

Step 17 Click **Apply**.

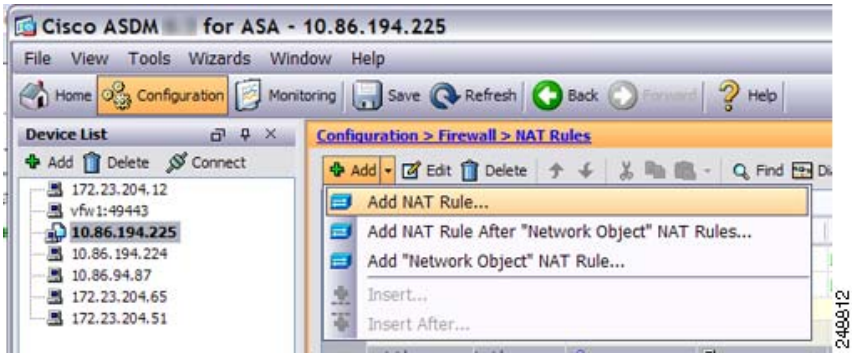
Different Translation Depending on the Destination Address and Port (Dynamic PAT)

Figure 41-2 shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:*port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:*port*.

Figure 41-2 Twice NAT with Different Destination Ports

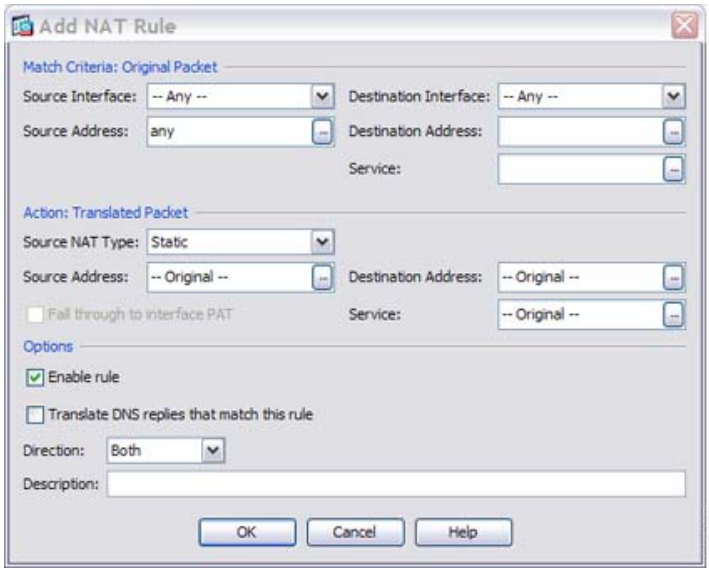


Step 1 Add a NAT rule for traffic from the inside network to the Telnet server:

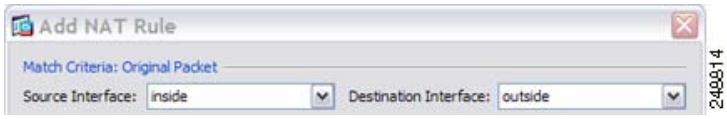


By default, the NAT rule is added to the end of section 1. If you want to add a NAT rule to section 3, after the network object NAT rules, choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.

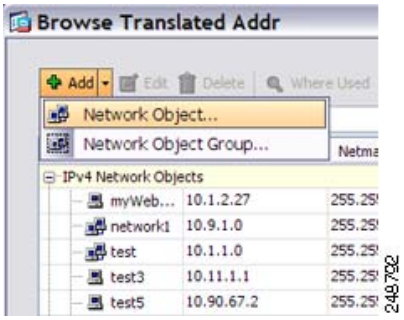


Step 2 Set the source and destination interfaces:

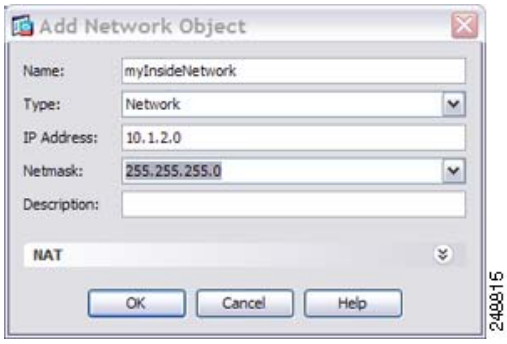


Step 3 For the Original Source Address, click the browse button to add a new network object for the inside network in the Browse Original Source Address dialog box.

a. Add the new network object.



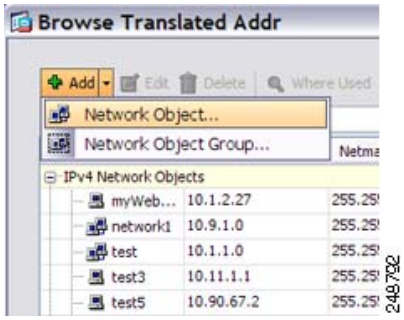
b. Define the inside network addresses, and click **OK**.



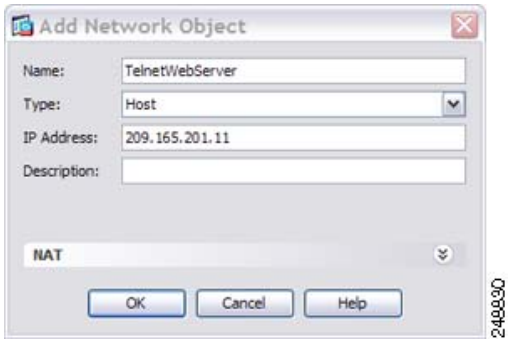
c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 4 For the Original Destination Address, click the browse button to add a new network object for the Telnet/Web server in the Browse Original Destination Address dialog box.

a. Add the new network object.



b. Define the server address, and click **OK**.

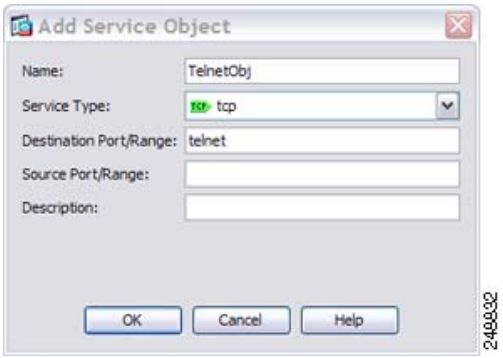


c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 5 For the Original Service, click the browse button to add a new service object for Telnet in the Browse Original Service dialog box.

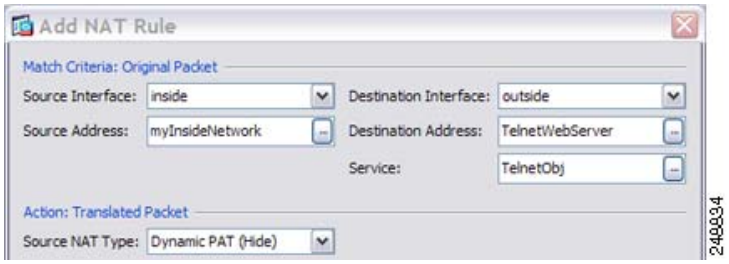
a. Add the new service object.

b. Define the protocol and port, and click **OK**.



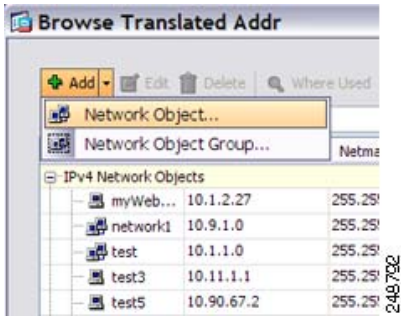
c. Choose the new service object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 6 Set the NAT Type to **Dynamic PAT (Hide)**:

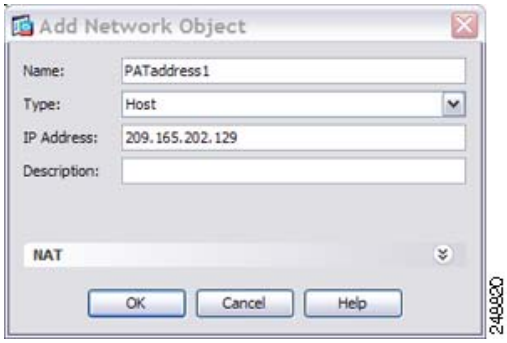


Step 7 For the Translated Source Address, click the browse button to add a new network object for the PAT address in the Browse Translated Source Address dialog box.

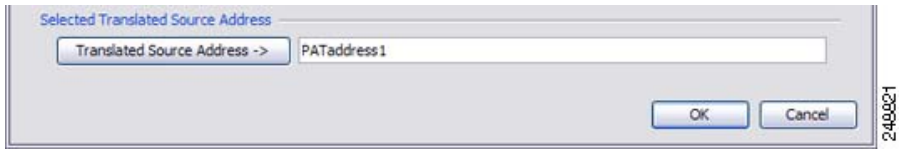
a. Add the new network object.



b. Define the PAT address, and click **OK**.

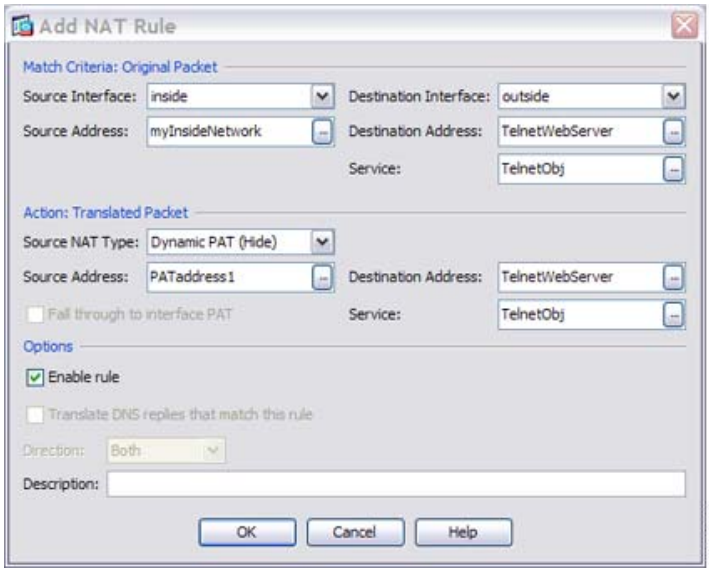


c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.



Step 8 For the Translated Destination Address, type the name of the Original Destination Address (TelnetWebServer) or click the browse button to choose it.

Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the Original and Translated destination addresses.

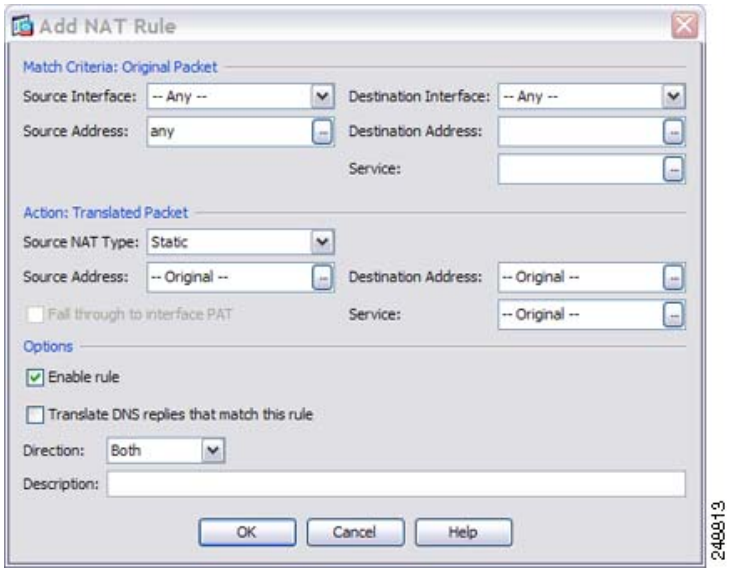


Step 9 Click **OK** to add the rule to the NAT table.

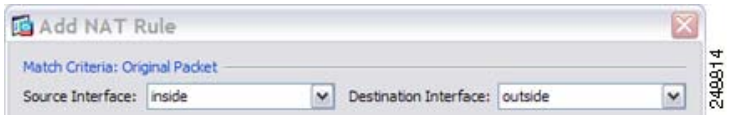
Step 10 Add a NAT rule for traffic from the inside network to the web server:

By default, the NAT rule is added to the end of section 1. If you want to add a NAT rule to section 3, after the network object NAT rules, choose **Add NAT Rule After Network Object NAT Rules**.

The Add NAT Rule dialog box appears.



Step 11 Set the real and mapped interfaces:



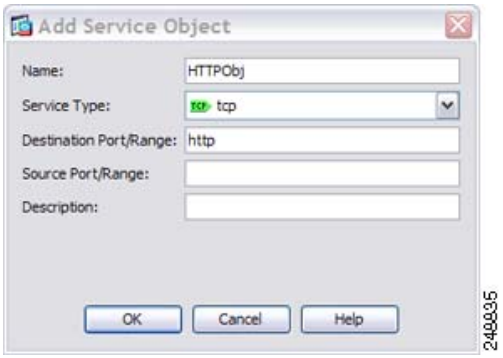
Step 12 For the Original Source Address, type the name of the inside network object (myInsideNetwork) or click the browse button to choose it.

Step 13 For the Original Destination Address, type the name of the Telnet/web server network object (TelnetWebServer) or click the browse button to choose it.

Step 14 For the Original Service, click the browse button to add a new service object for HTTP in the Browse Original Service dialog box.

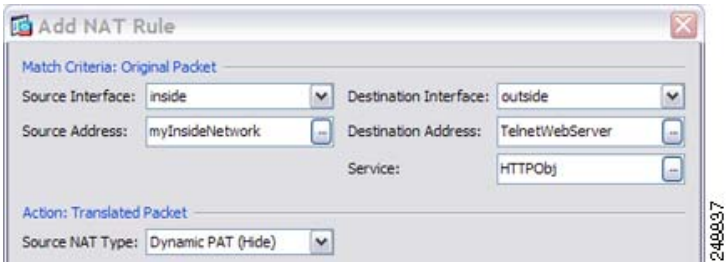
a. Add the new service object.

b. Define the protocol and port, and click **OK**.



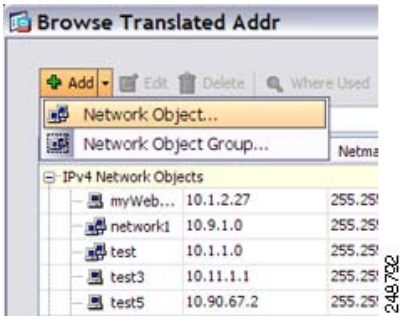
c. Choose the new service object by double-clicking it. Click **OK** to return to the NAT configuration.

Step 15 Set the NAT Type to **Dynamic PAT (Hide)**:

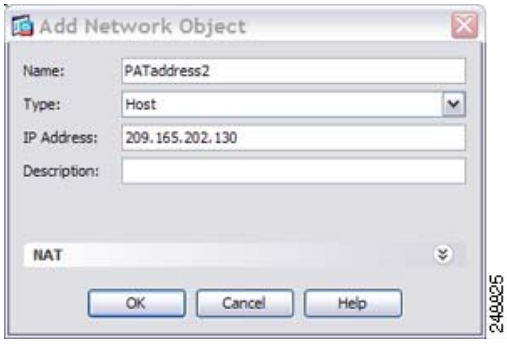


Step 16 For the Translated Source Address, click the browse button to add a new network object for the PAT address in the Browse Translated Source Address dialog box.

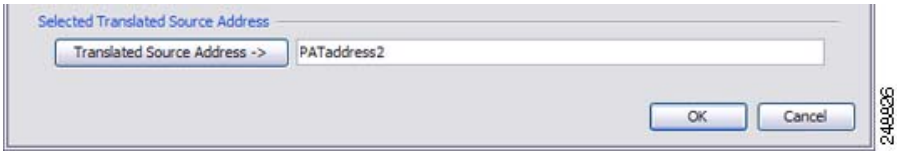
a. Add the new network object.



b. Define the PAT address, and click **OK**.

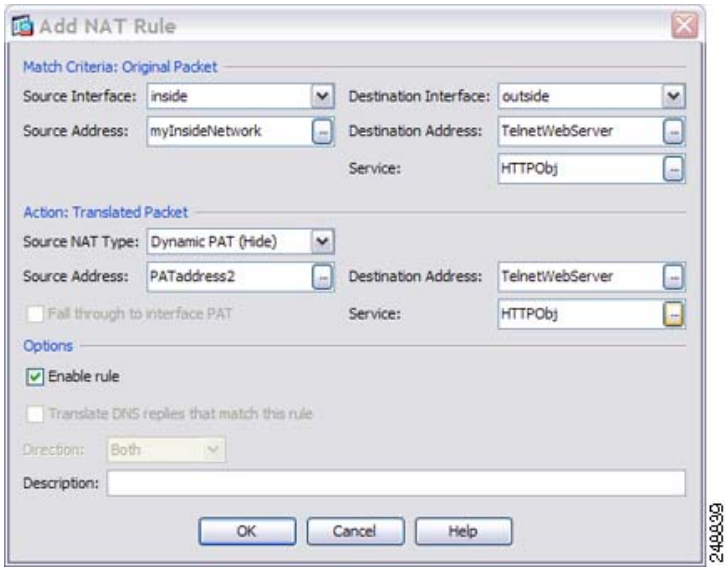


c. Choose the new network object by double-clicking it. Click **OK** to return to the NAT configuration.



Step 17 For the Translated Destination Address, type the name of the Original Destination Address (TelnetWebServer) or click the browse button to choose it.

Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the Original and Translated destination addresses.



Step 18 Click **OK** to add the rule to the NAT table.

Step 19 Click **Apply**.

Feature History for Twice NAT

Table 41-1 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 41-1 Feature History for Twice NAT

Feature Name	Platform Releases	Feature Information
Twice NAT	8.3(1)	Twice NAT lets you identify both the source and destination address in a single rule. We modified the following screen: Configuration > Firewall > NAT Rules.
Identity NAT configurable proxy ARP and route lookup	8.4(2)/8.5(1)	In earlier releases for identity NAT, proxy ARP was disabled, and a route lookup was always used to determine the egress interface. You could not configure these settings. In 8.4(2) and later, the default behavior for identity NAT was changed to match the behavior of other static NAT configurations: proxy ARP is enabled, and the NAT configuration determines the egress interface (if specified) by default. You can leave these settings as is, or you can enable or disable them discretely. Note that you can now also disable proxy ARP for regular static NAT. For pre-8.3 configurations, the migration of NAT exempt rules (the **nat 0 access-list** command) to 8.4(2) and later now includes the following keywords to disable proxy ARP and to use a route lookup: **no-proxy-arp** and **route-lookup**. The **unidirectional** keyword that was used for migrating to 8.3(2) and 8.4(1) is no longer used for migration. When upgrading to 8.4(2) from 8.3(1), 8.3(2), and 8.4(1), all identity NAT configurations will now include the **no-proxy-arp** and **route-lookup** keywords, to maintain existing functionality. The **unidirectional** keyword is removed. We modified the following screen: Configuration > Firewall > NAT Rules > Add/Edit NAT Rule
PAT pool and round robin address assignment	8.4(2)/8.5(1)	You can now specify a pool of PAT addresses instead of a single address. You can also optionally enable round-robin assignment of PAT addresses instead of first using all ports on a PAT address before using the next address in the pool. These features help prevent a large number of connections from a single PAT address from appearing to be part of a DoS attack and makes configuration of large numbers of PAT addresses easy. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit NAT Rule.

Table 41-1 Feature History for Twice NAT (continued)

Feature Name	Platform Releases	Feature Information
Round robin PAT pool allocation uses the same IP address for existing hosts	8.4(3)	When using a PAT pool with round robin allocation, if a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. We did not modify any screens. *This feature is not available in 8.5(1) or 8.6(1).*
Flat range of PAT ports for a PAT pool	8.4(3)	If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool. If you have a lot of traffic that uses the lower port ranges, when using a PAT pool, you can now specify a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit NAT Rule. *This feature is not available in 8.5(1) or 8.6(1).*
Extended PAT for a PAT pool	8.4(3)	Each PAT IP address allows up to 65535 ports. If 65535 ports do not provide enough translations, you can now enable extended PAT for a PAT pool. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. We modified the following screens: Configuration > Firewall > NAT Rules > Add/Edit NAT Rule. *This feature is not available in 8.5(1) or 8.6(1).*

Table 41-1 Feature History for Twice NAT (continued)

Feature Name	Platform Releases	Feature Information
Automatic NAT rules to translate a VPN peer's local IP address back to the peer's real IP address	8.4(3)	In rare situations, you might want to use a VPN peer's real IP address on the inside network instead of an assigned local IP address. Normally with VPN, the peer is given an assigned local IP address to access the inside network. However, you might want to translate the local IP address back to the peer's real public IP address if, for example, your inside servers and network security is based on the peer's real IP address. You can enable this feature on one interface per tunnel group. Object NAT rules are dynamically added and deleted when the VPN session is established or disconnected. You can view the rules using the **show nat** command. **Note** Because of routing issues, we do not recommend using this feature unless you know you need this feature; contact Cisco TAC to confirm feature compatibility with your network. See the following limitations: • Only supports Cisco IPsec and AnyConnect Client. • Return traffic to the public IP addresses must be routed back to the ASA so the NAT policy and VPN policy can be applied. • Does not support load-balancing (because of routing issues). • Does not support roaming (public IP changing). ASDM does not support this command; enter the command using the Command Line Tool.

Table 41-1 Feature History for Twice NAT (continued)

Feature Name	Platform Releases	Feature Information
NAT support for IPv6	9.0(1)	NAT now supports IPv6 traffic, as well as translating between IPv4 and IPv6. Translating between IPv4 and IPv6 is not supported in transparent mode. We modified the following screen: Configuration > Firewall > NAT Rules.
Per-session PAT	9.0(1)	The per-session PAT feature improves the scalability of PAT and, for clustering, allows each member unit to own PAT connections; multi-session PAT connections have to be forwarded to and owned by the master unit. At the end of a per-session PAT session, the ASA sends a reset and immediately removes the xlate. This reset causes the end node to immediately release the connection, avoiding the TIME_WAIT state. Multi-session PAT, on the other hand, uses the PAT timeout, by default 30 seconds. For "hit-and-run" traffic, such as HTTP or HTTPS, the per-session feature can dramatically increase the connection rate supported by one address. Without the per-session feature, the maximum connection rate for one address for an IP protocol is approximately 2000 per second. With the per-session feature, the connection rate for one address for an IP protocol is 65535/*average-lifetime*. By default, all TCP traffic and UDP DNS traffic use a per-session PAT xlate. For traffic that requires multi-session PAT, such as H.323, SIP, or Skinny, you can disable per-session PAT by creating a per-session deny rule. We introduced the following screen: Configuration > Firewall > Advanced > Per-Session NAT Rules.

Configuring NAT (ASA 8.2 and Earlier)

This chapter describes Network Address Translation, and includes the following sections:

- NAT Overview, page 42-1
- Configuring NAT Control, page 42-15
- Using Dynamic NAT, page 42-16
- Using Static NAT, page 42-26
- Using NAT Exemption, page 42-32

NAT Overview

This section describes how NAT works on the ASA, and includes the following topics:

- Introduction to NAT, page 42-1
- NAT in Routed Mode, page 42-2
- NAT in Transparent Mode, page 42-3
- NAT Control, page 42-4
- NAT Types, page 42-6
- Policy NAT, page 42-10
- NAT and Same Security Level Interfaces, page 42-12

Introduction to NAT

Address translation substitutes the real address in a packet with a mapped address that is routable on the destination network. NAT is composed of two steps: the process by which a real address is translated into a mapped address, and the process to undo translation for returning traffic.

The ASA translates an address when a NAT rule matches the traffic. If no NAT rule matches, processing for the packet continues. The exception is when you enable NAT control. NAT control requires that packets traversing from a higher security interface (inside) to a lower security interface (outside) match

a NAT rule, or processing for the packet stops. See the "Security Levels" section on page 17-1 for more information about security levels. See the "NAT Control" section on page 42-4 for more information about NAT control.

Note In this document, all types of translation are referred to as NAT. When describing NAT, the terms *inside* and *outside* represent the security relationship between any two interfaces. The higher security level is inside and the lower security level is outside. For example, interface 1 is at 60 and interface 2 is at 50; therefore, interface 1 is "inside" and interface 2 is "outside."

Some of the benefits of NAT are as follows:

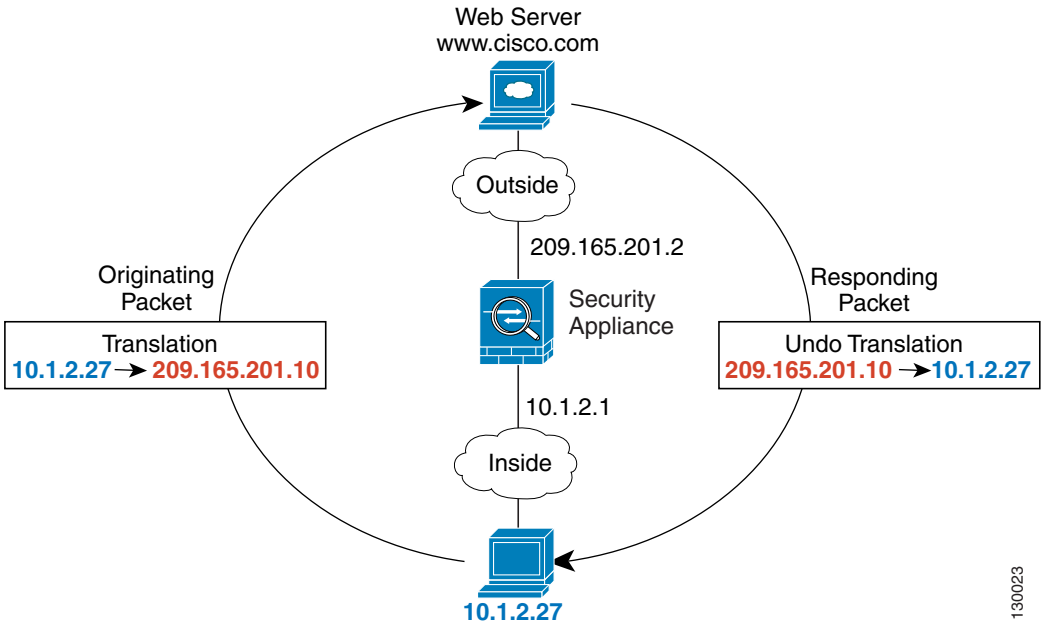
- You can use private addresses on your inside networks. Private addresses are not routable on the Internet.
- NAT hides the real addresses from other networks, so attackers cannot learn the real address of a host.
- You can resolve IP routing problems such as overlapping addresses.

See Table 57-1 on page 57-4 for information about protocols that do not support NAT.

NAT in Routed Mode

Figure 42-1 shows a typical NAT example in routed mode, with a private network on the inside. When the inside host at 10.1.1.27 sends a packet to a web server, the real source address, 10.1.1.27, of the packet is changed to a mapped address, 209.165.201.10. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the security appliance receives the packet. The security appliance then changes the translation of the mapped address, 209.165.201.10 back to the real address, 10.1.1.1.27 before sending it to the host.

Figure 42-1 NAT Example: Routed Mode



NAT in Transparent Mode

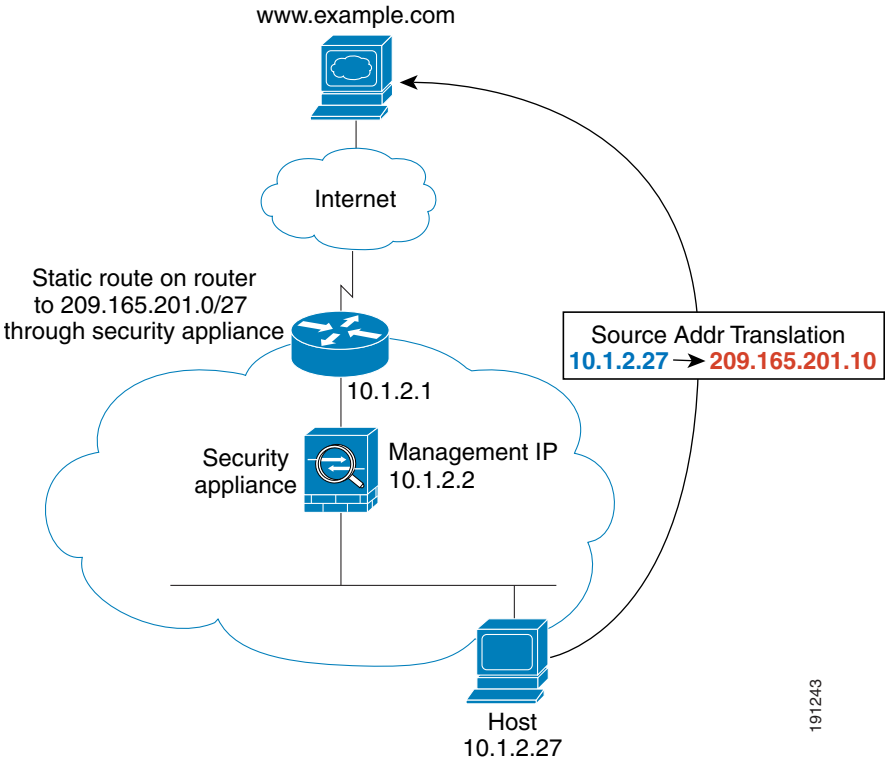
Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. For example, a transparent firewall ASA is useful between two VRFs so you can establish BGP neighbor relations between the VRFs and the global table. However, NAT per VRF might not be supported. In this case, using NAT in transparent mode is essential.

NAT in transparent mode has the following requirements and limitations:

- When the mapped addresses are not on the same network as the transparent firewall, then on the upstream router, you need to add a static route for the mapped addresses that points to the downstream router (through the ASA).
- When you have VoIP or DNS traffic with NAT and inspection enabled, to successfully translate the IP address inside VoIP and DNS packets, the ASA needs to perform a route lookup. Unless the host is on a directly-connected network, then you need to add a static route on the ASA for the real host address that is embedded in the packet.
- The **alias** command is not supported.
- Because the transparent firewall does not have any interface IP addresses, you cannot use interface PAT.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the firewall sends an ARP request to a host on the other side of the firewall, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.

Figure 42-2 shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT. When the inside host at 10.1.1.27 sends a packet to a web server, the real source address of the packet, 10.1.1.27, is changed to a mapped address, 209.165.201.10. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the ASA receives the packet because the upstream router includes this mapped network in a static route directed through the ASA. The ASA then undoes the translation of the mapped address, 209.165.201.10 back to the real address, 10.1.1.1.27. Because the real address is directly-connected, the ASA sends it directly to the host.

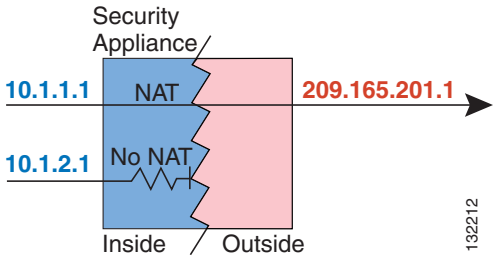
Figure 42-2 NAT Example: Transparent Mode



NAT Control

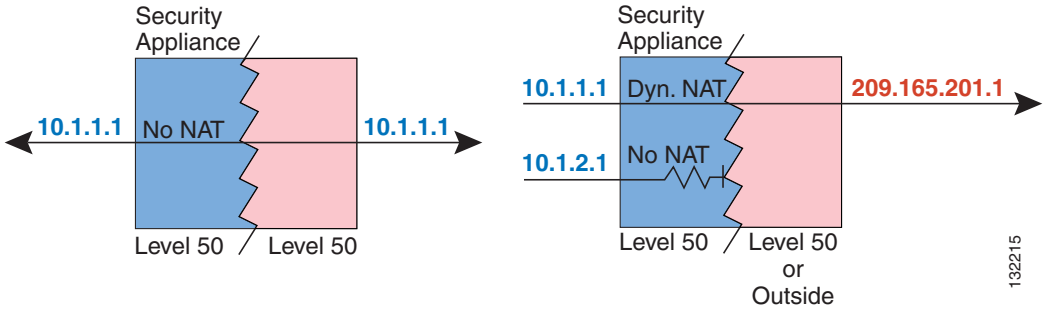
NAT control requires that packets traversing from an inside interface to an outside interface match a NAT rule; for any host on the inside network to access a host on the outside network, you must configure NAT to translate the inside host address, as shown in Figure 42-3.

Figure 42-3 NAT Control and Outbound Traffic



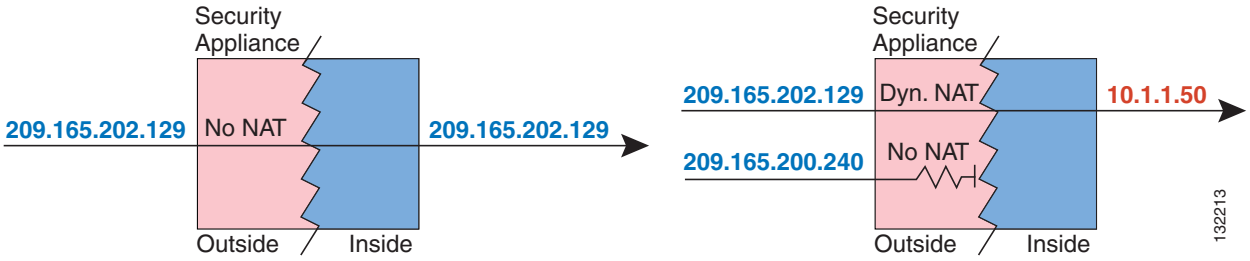
Interfaces at the same security level are not required to use NAT to communicate. However, if you configure dynamic NAT or PAT on a same security interface, then all traffic from the interface to a same security interface or an outside interface must match a NAT rule, as shown in Figure 42-4.

Figure 42-4 NAT Control and Same Security Traffic



Similarly, if you enable outside dynamic NAT or PAT, then all outside traffic must match a NAT rule when it accesses an inside interface (see Figure 42-5).

Figure 42-5 NAT Control and Inbound Traffic



Static NAT does not cause these restrictions.

By default, NAT control is disabled; therefore, you do not need to perform NAT on any networks unless you want to do so. If you upgraded from an earlier version of software, however, NAT control might be enabled on your system. Even with NAT control disabled, you need to perform NAT on any addresses for which you configure dynamic NAT. See the "Dynamic NAT Implementation" section on page 42-16 for more information about how dynamic NAT is applied.

If you want the added security of NAT control but do not want to translate inside addresses in some cases, you can apply a NAT exemption or identity NAT rule on those addresses. (See the "Using NAT Exemption" section on page 42-32 for more information).

To configure NAT control, see the "Configuring NAT Control" section on page 42-15.

Note In multiple context mode, the packet classifier might rely on the NAT configuration to assign packets to contexts if you do not enable unique MAC addresses for shared interfaces. See the "How the ASA Classifies Packets" section on page 9-3 for more information about the relationship between the classifier and NAT.

NAT Types

This section describes the available NAT types, and includes the following topics:

- Dynamic NAT, page 42-6
- PAT, page 42-8
- Static NAT, page 42-8
- Static PAT, page 42-9
- Bypassing NAT When NAT Control is Enabled, page 42-10

You can implement address translation as dynamic NAT, Port Address Translation, static NAT, static PAT, or as a mix of these types. You can also configure rules to bypass NAT; for example, to enable NAT control when you do not want to perform NAT.

Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool may include fewer addresses than the real group. When a host you want to translate accesses the destination network, the ASA assigns the host an IP address from the mapped pool. The translation is added only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, although the connection is allowed by an access list, and the ASA rejects any attempt to connect to a real host address directly. See the "Static NAT" or "Static PAT" section for information on how to obtain reliable access to hosts.

Note In some cases, a translation is added for a connection, although the session is denied by the ASA. This condition occurs with an outbound access list, a management-only interface, or a backup interface in which the translation times out normally.

Figure 42-6 shows a remote host attempting to connect to the real address. The connection is denied, because the ASA only allows returning connections to the mapped address.

Figure 42-6 Remote Host Attempts to Connect to the Real Address

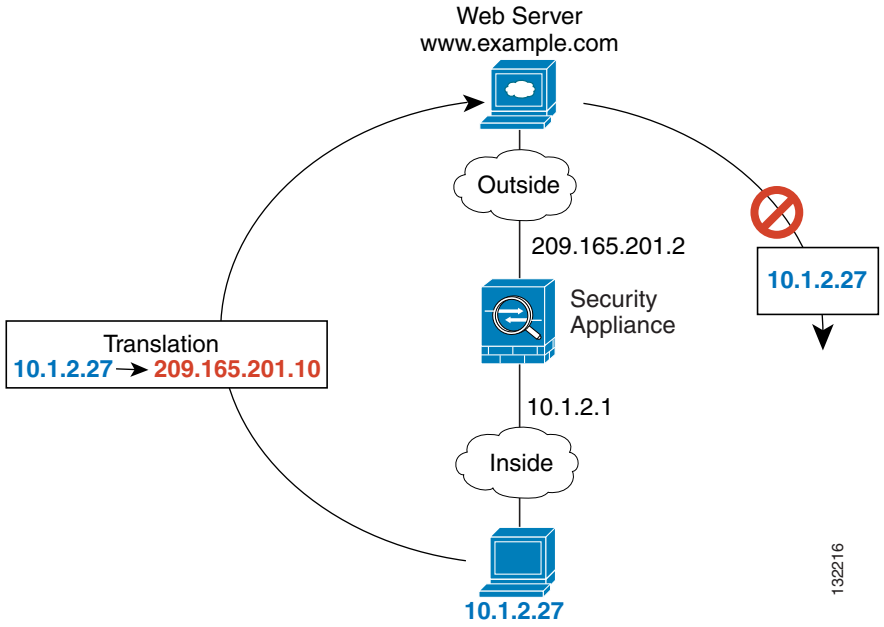


Figure 42-7 shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the ASA drops the packet.

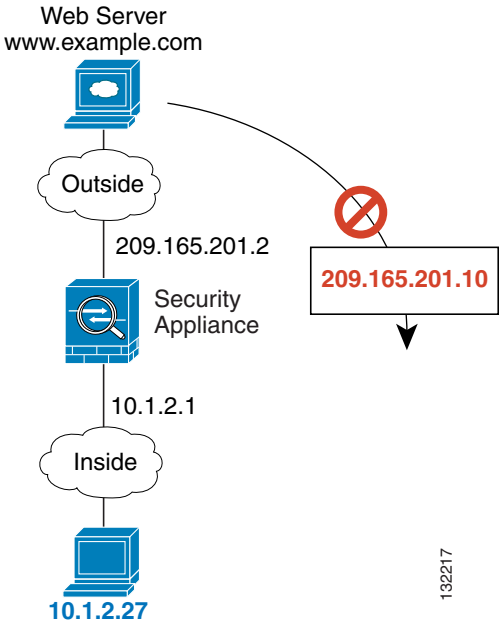
Figure 42-7 Remote Host Attempts to Initiate a Connection to a Mapped Address



Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access list allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case, you can rely on the security of the access list.

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

  Use PAT if this event occurs often, because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool; if the destination network requires registered addresses, such as the Internet, you might encounter a shortage of usable addresses.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

See the "When to Use Application Protocol Inspection" section on page 57-2 for more information about NAT and PAT support.

PAT

PAT translates multiple real addresses to a single mapped IP address. Specifically, the security appliance translates the real address and source port (real socket) to the mapped address and a unique port above 1024 (mapped socket). Each connection requires a separate translation, because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

After the connection expires, the port translation also expires after 30 seconds of inactivity. The timeout is not configurable. Users on the destination network cannot reliably initiate a connection to a host that uses PAT (even if the connection is allowed by an access list). Not only can you not predict the real or mapped port number of the host, but the ASA does not create a translation at all unless the translated host is the initiator. See the following "Static NAT" or "Static PAT" sections for reliable access to hosts.

PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the ASA interface IP address as the PAT address. PAT does not work with some multimedia applications that have a data stream that is different from the control path. See the "When to Use Application Protocol Inspection" section on page 57-2 for more information about NAT and PAT support.

Note For the duration of the translation, a remote host can initiate a connection to the translated host if an access list allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case, you can rely on the security of the access list. However, policy PAT does not support time-based ACLs.

Static NAT

Static NAT creates a fixed translation of real address(es) to mapped address(es).With dynamic NAT and PAT, each host uses a different address or port for each subsequent translation. Because the mapped address is the same for each consecutive connection with static NAT, and a persistent translation rule exists, static NAT allows hosts on the destination network to initiate traffic to a translated host (if an access list exists that allows it).

The main difference between dynamic NAT and a range of addresses for static NAT is that static NAT allows a remote host to initiate a connection to a translated host (if an access list exists that allows it), while dynamic NAT does not. You also need an equal number of mapped addresses as real addresses with static NAT.

Static PAT

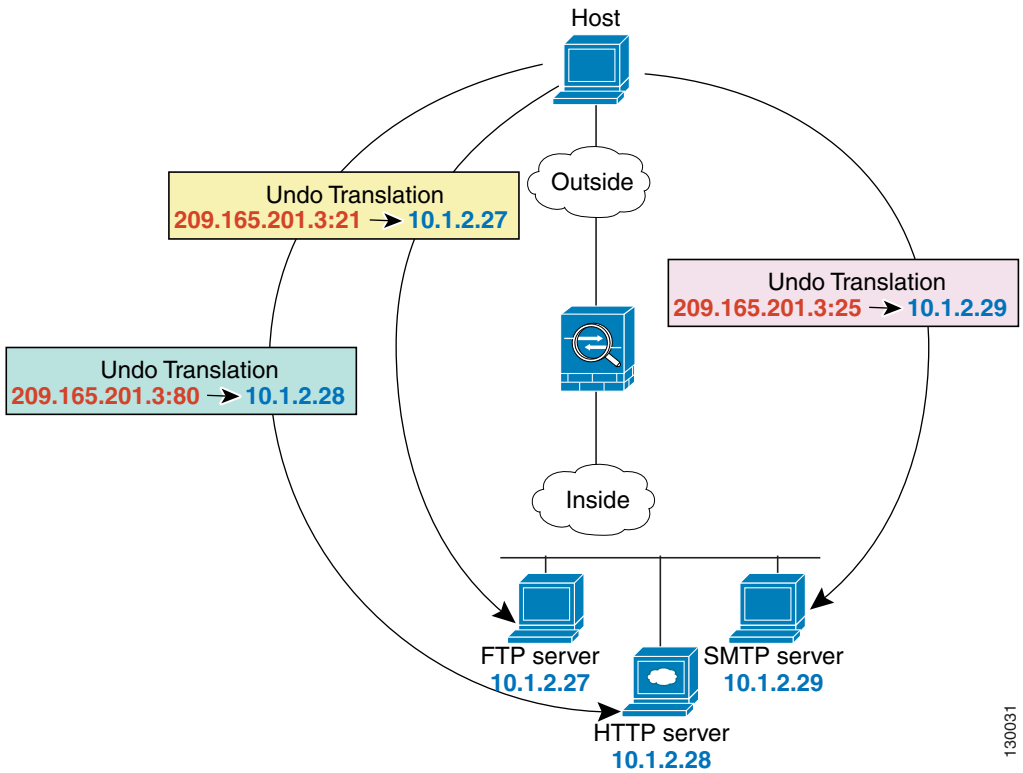
Static PAT is the same as static NAT, except that it lets you specify the protocol (TCP or UDP) and port for the real and mapped addresses.

This feature lets you identify the same mapped address across many different static statements, provided the port is different for each statement. You cannot use the same mapped address for multiple static NAT statements.

For applications that require inspection for secondary channels (for example, FTP and VoIP), the ASA automatically translates the secondary ports.

For example, if you want to provide a single address for remote users to access FTP, HTTP, and SMTP, but these are all actually different servers on the real network, you can specify static PAT statements for each server that uses the same mapped IP address, but different ports (see Figure 42-8).

Figure 42-8 Static PAT



You can also use static PAT to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

Bypassing NAT When NAT Control is Enabled

If you enable NAT control, then inside hosts must match a NAT rule when accessing outside hosts. If you do not want to perform NAT for some hosts, then you can bypass NAT for those hosts or you can disable NAT control. You might want to bypass NAT, for example, if you are using an application that does not support NAT. See the "When to Use Application Protocol Inspection" section on page 57-2 for information about inspection engines that do not support NAT.

You can configure traffic to bypass NAT using one of three methods. All methods achieve compatibility with inspection engines. However, each method offers slightly different capabilities, as follows:

- Identity NAT—When you configure identity NAT (which is similar to dynamic NAT), you do not limit translation for a host on specific interfaces; you must use identity NAT for connections through all interfaces. Therefore, you cannot choose to perform normal translation on real addresses when you access interface A, but use identity NAT when accessing interface B. Regular dynamic NAT, on the other hand, lets you specify a particular interface on which to translate the addresses. Make sure that the real addresses for which you use identity NAT are routable on all networks that are available according to your access lists.

  For identity NAT, even though the mapped address is the same as the real address, you cannot initiate a connection from the outside to the inside (even if the interface access list allows it). Use static identity NAT or NAT exemption for this functionality.

- Static identity NAT—Static identity NAT lets you specify the interface on which you want to allow the real addresses to appear, so you can use identity NAT when you access interface A, and use regular translation when you access interface B. Static identity NAT also lets you use policy NAT, which identifies the real and destination addresses when determining the real addresses to translate (see the "Policy NAT" section on page 42-10 for more information about policy NAT). For example, you can use static identity NAT for an inside address when it accesses the outside interface and the destination is server A, but use a normal translation when accessing the outside server B.

- NAT exemption—NAT exemption allows both translated and remote hosts to initiate connections. Like identity NAT, you do not limit translation for a host on specific interfaces; you must use NAT exemption for connections through all interfaces. However, NAT exemption does let you specify the real and destination addresses when determining the real addresses to translate (similar to policy NAT), so you have greater control using NAT exemption. However unlike policy NAT, NAT exemption does not consider the ports in the access list. NAT exemption also does not let you configure connection limits such as maximum TCP connections.

Policy NAT

Policy NAT lets you identify real addresses for address translation by specifying the source and destination addresses. You can also optionally specify the source and destination ports. Regular NAT can only consider the source addresses, and not the destination. For example, with policy NAT, you can translate the real address to mapped address A when it accesses server A, but translate the real address to mapped address B when it accesses server B.

For applications that require application inspection for secondary channels (for example, FTP and VoIP), the policy specified in the policy NAT rule should include the secondary ports. When the ports cannot be predicted, the policy should specify only the IP addresses for the secondary channel. With this configuration, the security appliance translates the secondary ports.

Figure 42-9 shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130. Consequently, the host appears to be on the same network as the servers, which can help with routing.

Figure 42-9 Policy NAT with Different Destination Addresses

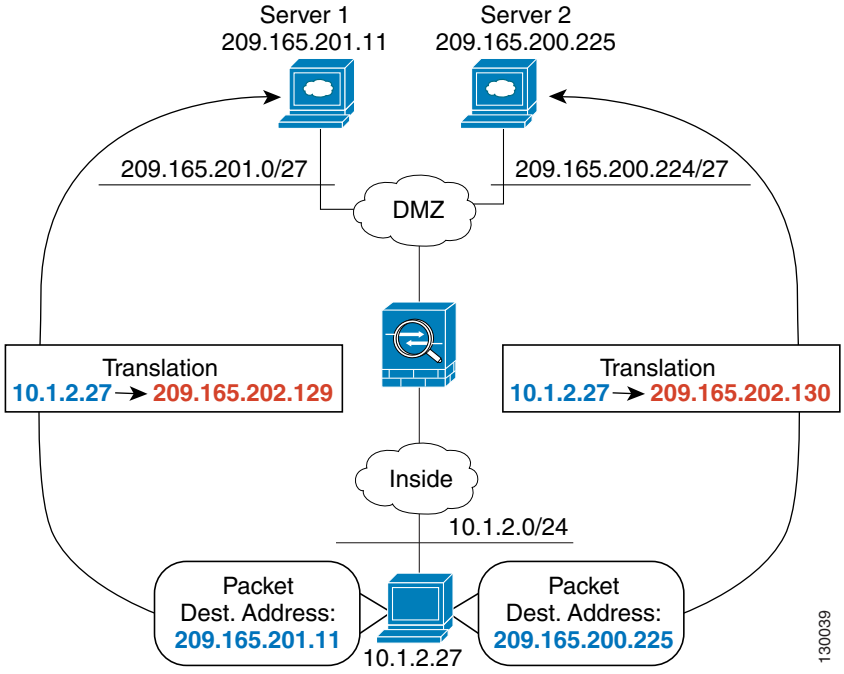


Figure 42-10 shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for web services, the real address is translated to 209.165.202.129. When the host accesses the same server for Telnet services, the real address is translated to 209.165.202.130.

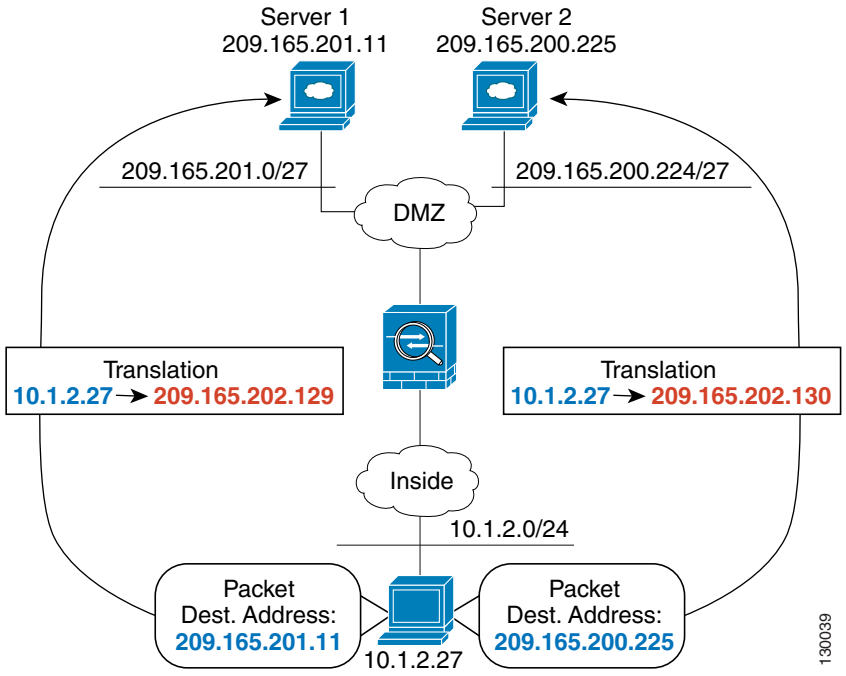
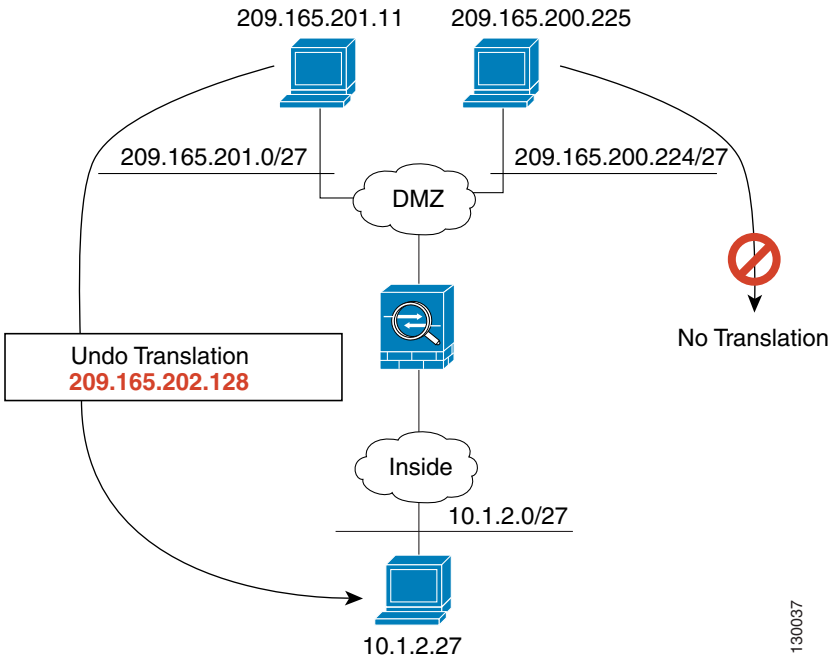
Figure 42-10 Policy NAT with Different Destination Ports



For policy static NAT, both translated and remote hosts can originate traffic. For traffic originated on the translated network, the NAT rule specifies the real addresses and the *destination* addresses, but for traffic originated on the remote network, the rule identifies the real addresses and the *source* addresses of remote hosts who are allowed to connect to the host using this translation.

Figure 42-11 shows a remote host connecting to a translated host. The translated host has a policy static NAT translation that translates the real address only for traffic to and from the 209.165.201.0/27 network. A translation does not exist for the 209.165.200.224/27 network, so the translated host cannot connect to that network, nor can a host on that network connect to the translated host.

Figure 42-11 Policy Static NAT with Destination Address Translation



Note Policy NAT does not support SQL*Net, but it is supported by regular NAT. See the "When to Use Application Protocol Inspection" section on page 57-2 for information about NAT support for other protocols.

NAT and Same Security Level Interfaces

NAT is not required between same security level interfaces even if you enable NAT control. You can optionally configure NAT if desired. However, if you configure dynamic NAT when NAT control is enabled, then NAT is required. See the "NAT Control" section on page 42-4 for more information. Also, when you specify a group of IP address(es) for dynamic NAT or PAT on a same security interface, then you must perform NAT on that group of addresses when they access any lower or same security level interface (even when NAT control is not enabled). Traffic identified for static NAT is not affected.

Note The ASA does not support VoIP inspection engines when you configure NAT on same security interfaces. These inspection engines include Skinny, SIP, and H.323. See the "When to Use Application Protocol Inspection" section on page 57-2 for supported inspection engines.

Order of NAT Rules Used to Match Real Addresses

The ASA matches real addresses to NAT rules in the following order:

1. NAT exemption—In order, until the first match.
2. Static NAT and Static PAT (regular and policy)—In order, until the first match. Static identity NAT is included in this category.
3. Policy dynamic NAT—In order, until the first match. Overlapping addresses are allowed.
4. Regular dynamic NAT—Best match. Regular identity NAT is included in this category. The order of the NAT rules does not matter; the NAT rule that best matches the real address is used. For example, you can create a general rule to translate all addresses (0.0.0.0) on an interface. If you want to translate a subset of your network (10.1.1.1) to a different address, then you can create a rule to translate only 10.1.1.1. When 10.1.1.1 makes a connection, the specific rule for 10.1.1.1 is used because it matches the real address best. We do not recommend using overlapping rules; they use more memory and can slow the performance of the ASA.

Mapped Address Guidelines

When you translate the real address to a mapped address, you can use the following mapped addresses:

- Addresses on the same network as the mapped interface.

  If you use addresses on the same network as the mapped interface (through which traffic exits the ASA), the ASA uses proxy ARP to answer any requests for mapped addresses, and thus intercepts traffic destined for a real address. This solution simplifies routing, because the ASA does not have to be the gateway for any additional networks. However, this approach does put a limit on the number of available addresses used for translations.

  For PAT, you can even use the IP address of the mapped interface.

- Addresses on a unique network.

  If you need more addresses than are available on the mapped interface network, you can identify addresses on a different subnet. The ASA uses proxy ARP to answer any requests for mapped addresses, and thus intercepts traffic destined for a real address. If you use OSPF, and you advertise routes on the mapped interface, then the ASA advertises the mapped addresses. If the mapped interface is passive (not advertising routes) or you are using static routing, then you need to add a static route on the upstream router that sends traffic destined for the mapped addresses to the ASA.

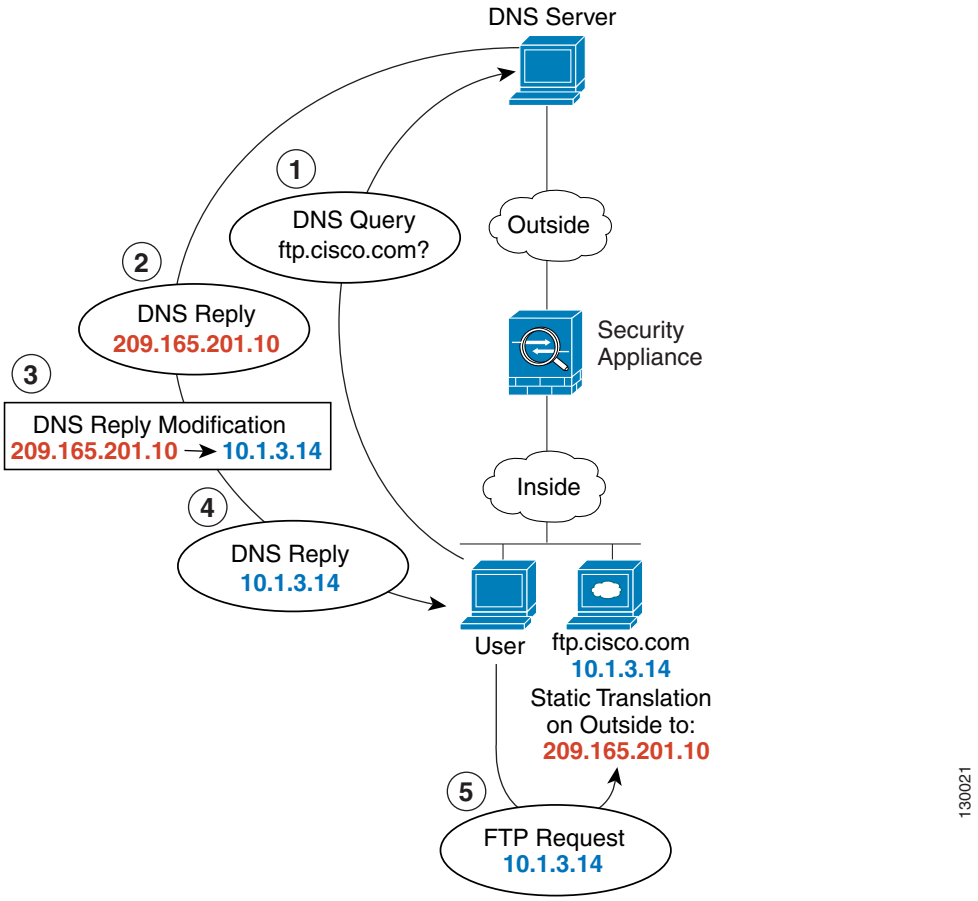
DNS and NAT

You might need to configure the ASA to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation.

For example, a DNS server is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure the ASA to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network (see Figure 42-12). In this case, you want to enable DNS reply modification on this static statement so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The ASA refers to the static statement for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

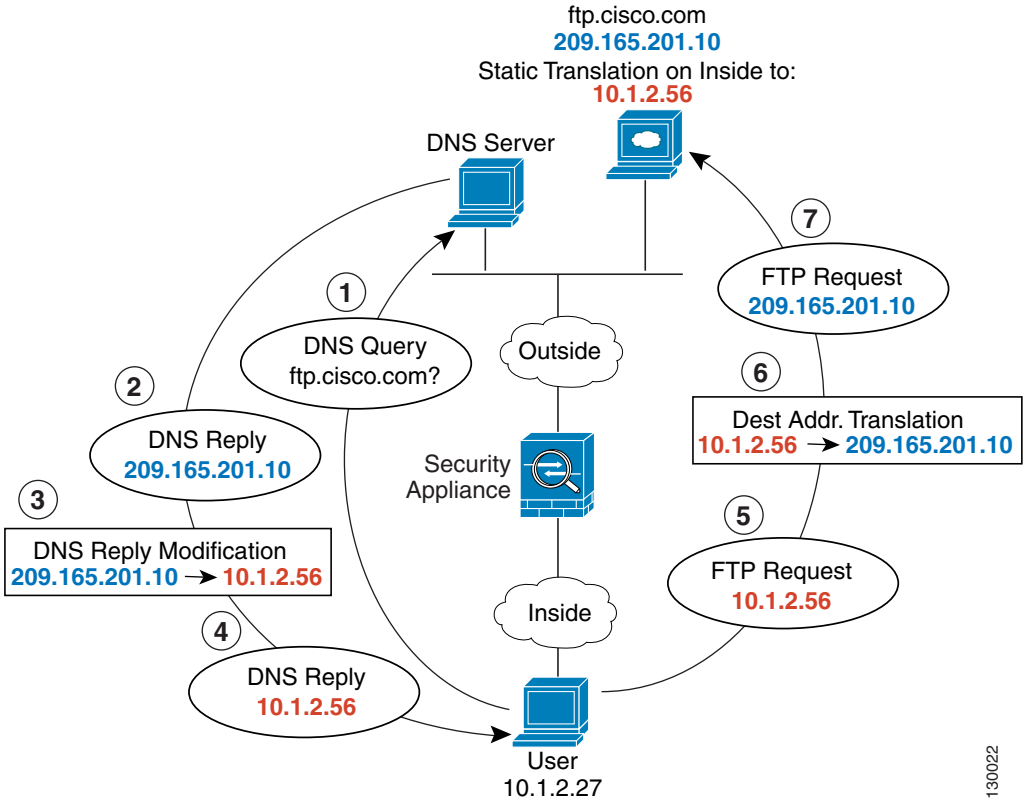
Figure 42-12 DNS Reply Modification



Note If a user on a different network (for example, DMZ) also requests the IP address for ftp.cisco.com from the outside DNS server, then the IP address in the DNS reply is also modified for this user, even though the user is not on the Inside interface referenced by the static rule.

Figure 42-13 shows a web server and DNS server on the outside. The ASA has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

Figure 42-13 DNS Reply Modification Using Outside NAT



Configuring NAT Control

NAT control requires that packets traversing from an inside interface to an outside interface match a NAT rule. See the "NAT Control" section on page 42-4 for more information.

To enable NAT control, in the Configuration > Firewall > NAT Rules pane, check the **Enable traffic through the firewall without address translation** check box.

Using Dynamic NAT

This section describes how to configure dynamic NAT, including dynamic NAT and PAT, dynamic policy NAT and PAT, and identity NAT.

Policy NAT lets you identify real addresses for address translation by specifying the source and destination addresses. You can also optionally specify the source and destination ports. Regular NAT can only consider the source addresses, and not the destination. See the "Policy NAT" section on page 42-10 for more information.

This section includes the following topics:

- Dynamic NAT Implementation, page 42-16
- Managing Global Pools, page 42-21
- Configuring Dynamic NAT, PAT, or Identity NAT, page 42-22
- Configuring Dynamic Policy NAT or PAT, page 42-24

Dynamic NAT Implementation

This section describes how dynamic NAT is implemented, and includes the following topics:

- Real Addresses and Global Pools Paired Using a Pool ID, page 42-17
- NAT Rules on Different Interfaces with the Same Global Pools, page 42-17
- Global Pools on Different Interfaces with the Same Pool ID, page 42-18
- Multiple NAT Rules with Different Global Pools on the Same Interface, page 42-18
- Multiple Addresses in the Same Global Pool, page 42-19
- Outside NAT, page 42-20
- Real Addresses in a NAT Rule Must be Translated on All Lower or Same Security Interfaces, page 42-21

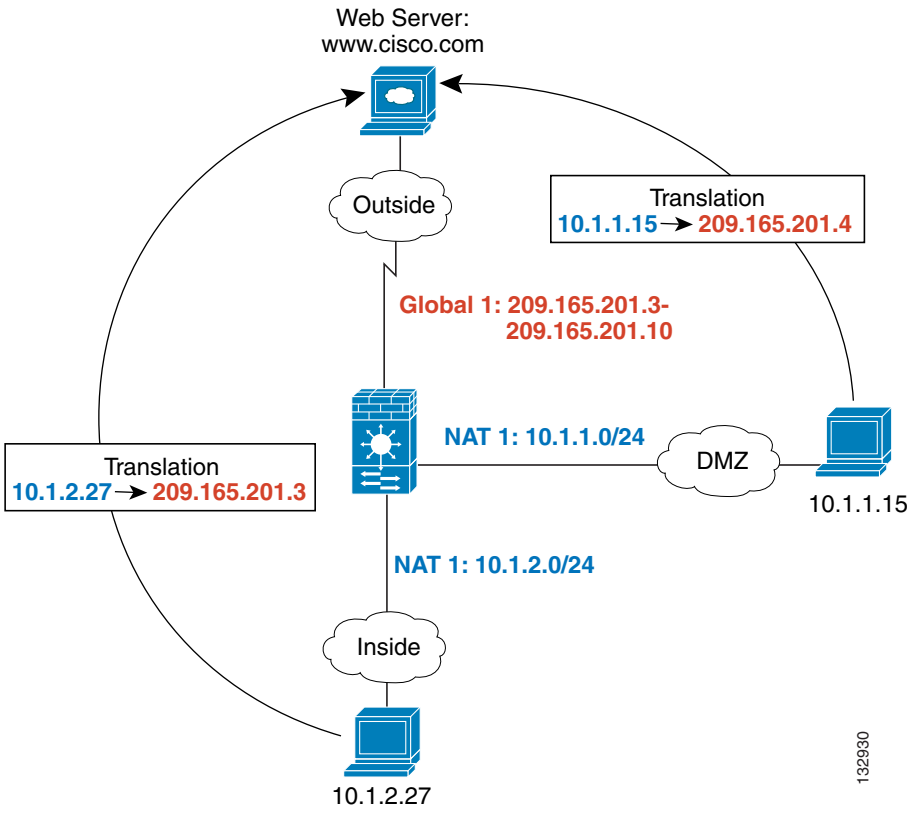
Real Addresses and Global Pools Paired Using a Pool ID

In a dynamic NAT rule, you specify real addresses and then pair them with a global pool of addresses to which the real addresses are mapped when they exit another interface (in the case of PAT, this is one address, and in the case of identity NAT, this is the same as the real address). Each global pool is assigned a pool ID.

NAT Rules on Different Interfaces with the Same Global Pools

You can create a NAT rule for each interface using the same global address pool. For example, you can configure NAT rules for Inside and DMZ interfaces, both using global pool 1 on the outside interface. Traffic from the Inside interface and the DMZ interface share a mapped pool or a PAT address when exiting the Outside interface (see Figure 42-14).

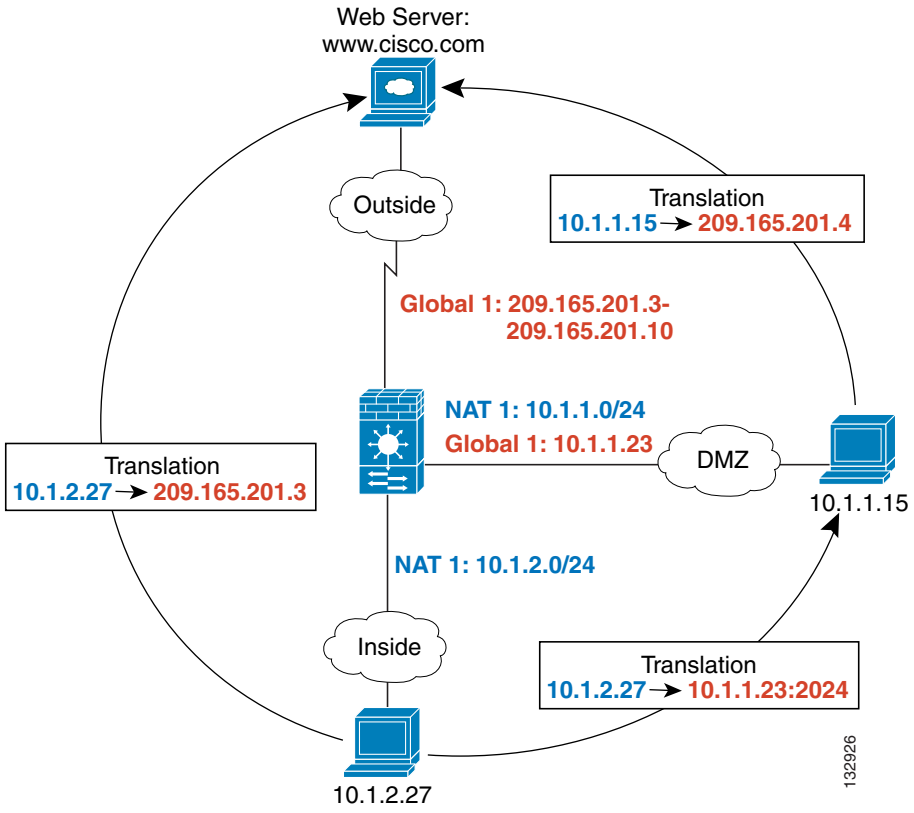
Figure 42-14 NAT Rules on Multiple Interfaces Using the Same Global Pool



Global Pools on Different Interfaces with the Same Pool ID

You can create a global pool for each interface using the same pool ID. If you create a global pool for the Outside and DMZ interfaces on ID 1, then a single NAT rule associated with ID 1 identifies traffic to be translated when going to both the Outside and the DMZ interfaces. Similarly, if you create a NAT rule for the DMZ interface on ID 1, then all global pools on ID 1 are also used for DMZ traffic. (See Figure 42-15).

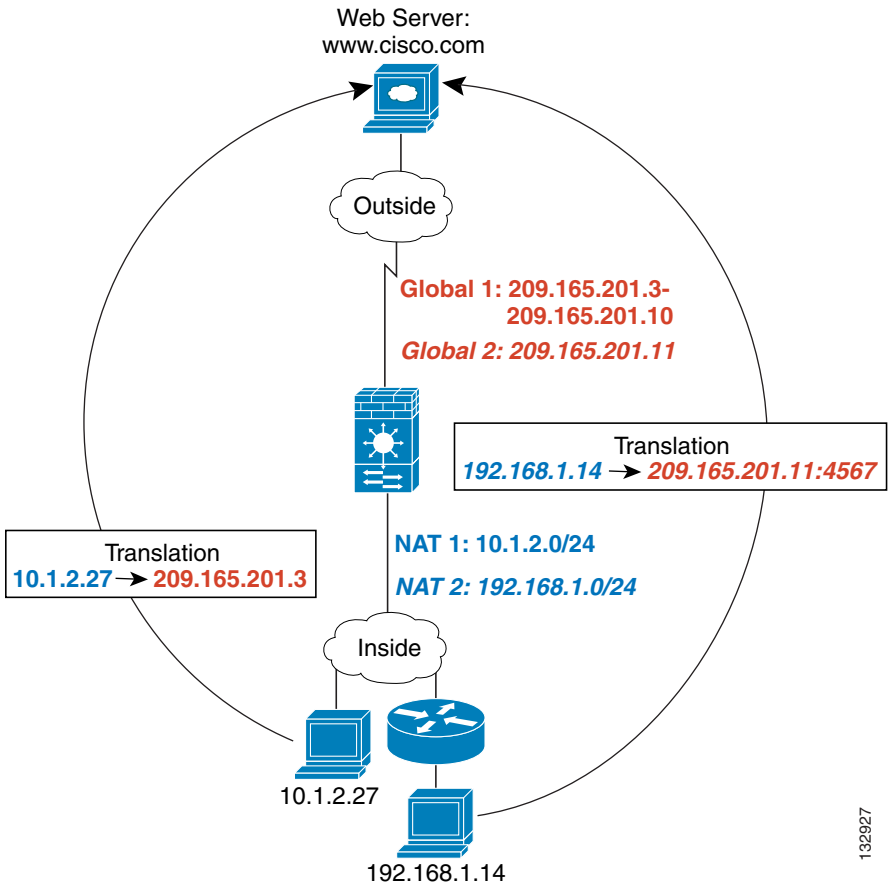
Figure 42-15 NAT Rules and Global Pools using the Same ID on Multiple Interfaces



Multiple NAT Rules with Different Global Pools on the Same Interface

You can identify different sets of real addresses to have different mapped addresses. For example, on the Inside interface, you can have two NAT rules on two different pool IDs. On the Outside interface, you configure two global pools for these two IDs. Then, when traffic from Inside network A exits the Outside interface, the IP addresses are translated to pool 1 addresses; while traffic from Inside network B are translated to pool 2 addresses (see Figure 42-16). If you use policy NAT, you can specify the same real addresses for multiple NAT rules, as long as the destination addresses and ports are unique in each access list.

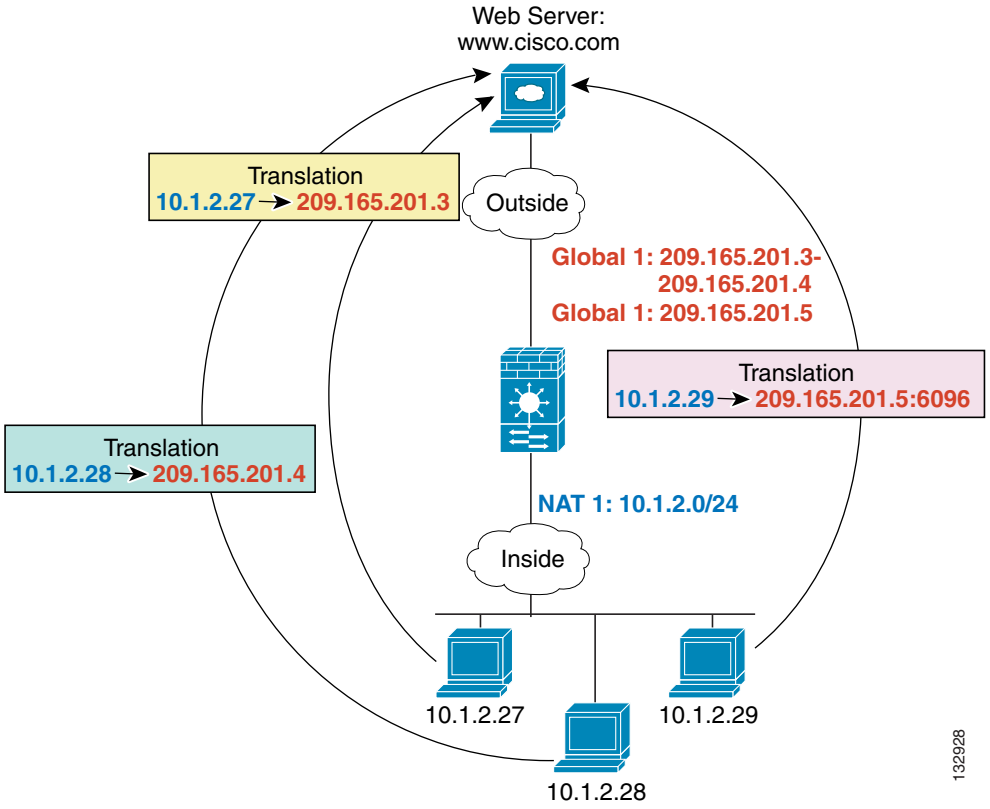
Figure 42-16 Different NAT IDs



Multiple Addresses in the Same Global Pool

You can have multiple addresses in the same global pool; the ASA uses the dynamic NAT ranges of addresses first, in the order they are in the configuration, and then uses the PAT single addresses in order. You might want to add both a range of addresses and a PAT address if you need to use dynamic NAT for a particular application, but want to have a backup PAT rule in case all the dynamic NAT addresses are depleted. Similarly, you might want two PAT addresses in the pool if you need more than the approximately 64,000 PAT sessions that a single PAT mapped address supports (see Figure 42-17).

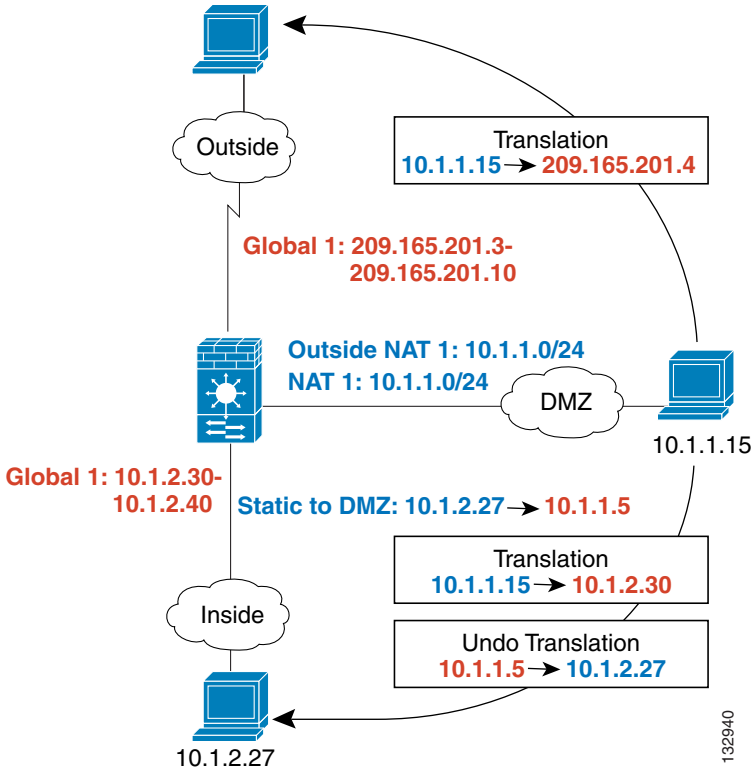
Figure 42-17 NAT and PAT Together



Outside NAT

If a NAT rule translates addresses from an outside interface to an inside interface, then the rule is an outside NAT rule, and you need to specify that it translates inbound traffic. If you also want to translate the same traffic when it accesses a lower security interface (for example, traffic on a DMZ is translated when accessing the Inside and the Outside interfaces), then you can create a second NAT rule using the same NAT ID (see Figure 42-18), but specifying outbound. Note that for outside NAT (DMZ interface to Inside interface), the inside host uses a static rule to allow outside access, so both the source and destination addresses are translated.

Figure 42-18 Outside NAT and Inside NAT Combined



Real Addresses in a NAT Rule Must be Translated on All Lower or Same Security Interfaces

When you create a NAT rule for a group of IP addresses, then you must perform NAT on that group of addresses when they access any lower or same security level interface; you must create a global pool with the same pool ID on each interface, or use a static rule. NAT is not required for that group when it accesses a higher security interface. If you create an outside NAT rule, then the NAT requirements preceding come into effect for that group of addresses when they access all higher security interfaces. Traffic identified by a static rule is not affected.

Managing Global Pools

Dynamic NAT uses global pools for translation. For information about how global pools work, see the "Dynamic NAT Implementation" section on page 42-16.

To manage a global pool, perform the following steps:

Step 1 In the Configuration > Firewall > Objects > Global Pools pane, click **Add** to add a new pool, or select a pool, and click **Edit**.

You can also manage global pools from the Add/Edit Dynamic NAT Rule dialog box by clicking **Manage**.

The Add/Edit Global Address Pool dialog box appears.

Step 2 For a new pool, from the Interface drop-down list, choose the interface where you want to use the mapped IP addresses.

Step 3 For a new pool, in the Pool ID field, enter a number between 1 and 2147483647. Do not enter a pool ID that is already in use, or your configuration will be rejected.

Step 4 In the IP Addresses to Add area, click **Range**, **Port Address Translation (PAT)**, or **PAT Address Translation (PAT) Using IP Address of the interface**.

If you specify a range of addresses, the ASA performs dynamic NAT. If you specify a subnet mask in the Netmask field, the value specifies the subnet mask assigned to the mapped address when it is assigned to a host. If you do not specify a mask, then the default mask for the address class is used.

Step 5 Click **Add** to add the addresses to the Addresses Pool pane.

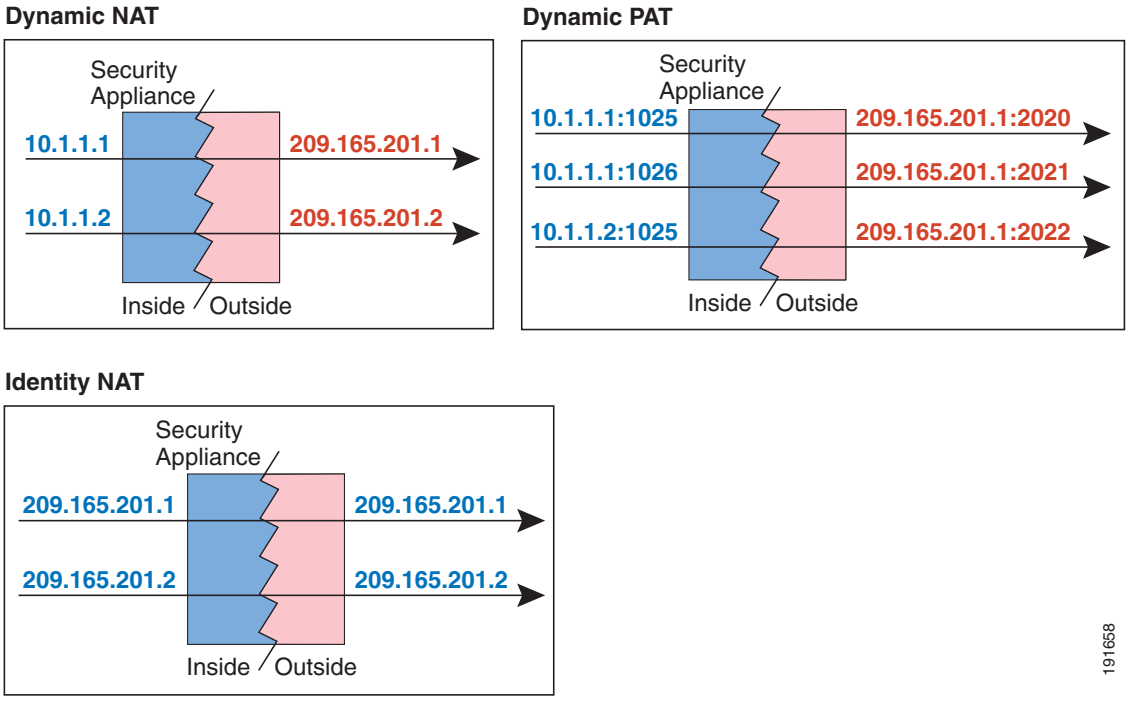
Step 6 (Optional) You can add multiple addresses to the global pool. If you want to add a PAT address after you configure a dynamic range, for example, then complete the value for PAT and click **Add** again. See the "Multiple Addresses in the Same Global Pool" section on page 42-19 for information about using multiple addresses on the same pool ID for an interface.

Step 7 Click **OK**.

Configuring Dynamic NAT, PAT, or Identity NAT

Figure 42-19 shows typical dynamic NAT, dynamic PAT, and identity NAT scenarios. Only real hosts can initiate connections.

Figure 42-19 Dynamic NAT Scenarios



To configure a dynamic NAT, PAT, or identity NAT rule, perform the following steps.

Step 1 In the Configuration > Firewall > NAT Rules pane, choose **Add > Add Dynamic NAT Rule**.

The Add Dynamic NAT Rule dialog box appears.

Step 2 In the Original area, from the Interface drop-down list, choose the interface that is connected to the hosts with real addresses that you want to translate.

Step 3 Enter the real addresses in the Source field, or click the **...** button to select an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Step 4 To choose a global pool, use one of the following options:

- Select an already-defined global pool.

  If the pool includes a range of addresses, then the ASA performs dynamic NAT. If the pool includes a single address, then the ASA performs dynamic PAT. If a pool includes both ranges and single addresses, then the ranges are used in order, and then the PAT addresses are used in order. See the "Multiple Addresses in the Same Global Pool" section on page 42-19 for more information.

  Pools are identified by a pool ID. If multiple global pools on different interfaces share the same pool ID, then they are grouped. If you choose a multi-interface pool ID, then traffic is translated as specified when it accesses any of the interfaces in the pool. For more information about pool IDs, see the "Dynamic NAT Implementation" section on page 42-16.

- Create a new global pool or edit an existing pool by clicking **Manage**. See the "Managing Global Pools" section on page 42-21.

- Choose identity NAT by selecting **global pool 0**.

Step 5 (Optional) To enable translation of addresses inside DNS replies, expand the **Connection Settings** area, and check the **Translate the DNS replies that match the translation rule** check box.

If your NAT rule includes the real address of a host that has an entry in a DNS server, and the DNS server is on a different interface from a client, then the client and the DNS server need different addresses for the host; one needs the mapped address and one needs the real address. This option rewrites the address in the DNS reply to the client. The mapped host needs to be on the same interface as either the client or the DNS server. Typically, hosts that need to allow access from other interfaces use a static translation, so this option is more likely to be used with a static rule. See the "DNS and NAT" section on page 42-13 for more information.

Step 6 (Optional) To enable connection settings, expand the **Connection Settings** area, and set one or more of the following options:

Note You can also set these values using a security policy rule (see Chapter 71, "Configuring Connection Settings"). If you set them in both places, then the ASA uses the lower limit. For TCP sequence randomization, if it is disabled using either method, then the ASA disables TCP sequence randomization.

- **Randomize sequence number**—With this check box checked (the default), the ASA randomizes the sequence number of TCP packets. Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

  Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

TCP initial sequence number randomization can be disabled if required. For example:

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.

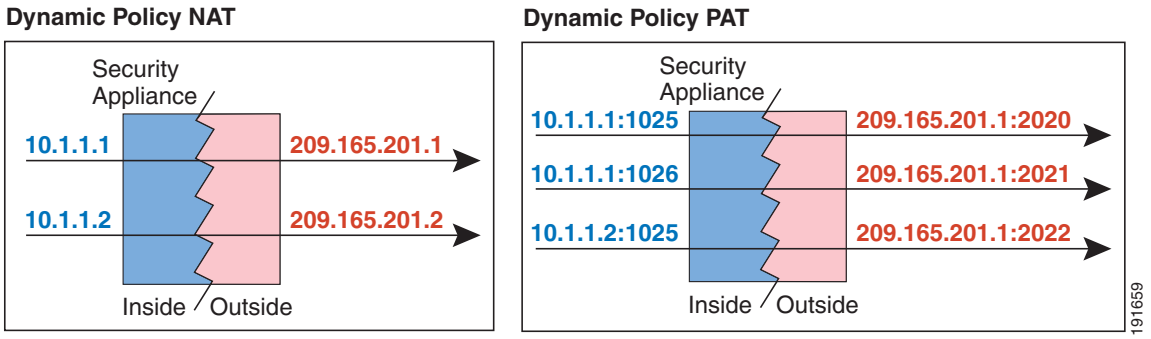
- **Maximum TCP Connections**—Specifies the maximum number of TCP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum UDP Connections**—Specifies the maximum number of UDP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum Embryonic Connections**—Specifies the maximum number of embryonic connections per host up to 65,536. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is **0**, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.

Step 7 Click **OK**.

Configuring Dynamic Policy NAT or PAT

Figure 42-20 shows typical dynamic policy NAT and PAT scenarios. Only real hosts can initiate connections.

Figure 42-20 Dynamic Policy NAT Scenarios



To configure dynamic policy NAT or PAT, perform the following steps:

Step 1 In the Configuration > Firewall > NAT Rules pane, choose **Add > Advanced > Add Dynamic Policy NAT Rule**.

The Add Dynamic Policy NAT Rule dialog box appears.

Step 2 In the Original area, from the Interface drop-down list, choose the interface that is connected to the hosts with real addresses that you want to translate.

Step 3 Enter the real addresses in the Source field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Separate multiple real addresses by a comma.

Step 4 Enter the destination addresses in the Destination field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Separate multiple destination addresses by a comma.

By default, the field shows **any**, which allows any destination address.

Step 5 To choose a global pool, use one of the following options:

- Choose an already-defined global pool.

  If the pool includes a range of addresses, then the ASA performs dynamic NAT. If the pool includes a single address, then the ASA performs dynamic PAT. If a pool includes both ranges and single addresses, then the ranges are used in order, and then the PAT addresses are used in order. See the "Multiple Addresses in the Same Global Pool" section on page 42-19 for more information.

  Pools are identified by a pool ID. If multiple global pools on different interfaces share the same pool ID, then they are grouped. If you choose a multi-interface pool ID, then traffic is translated as specified when it accesses any of the interfaces in the pool. For more information about pool IDs, see the "Dynamic NAT Implementation" section on page 42-16.

- Create a new global pool or edit an existing pool by clicking **Manage**. See the "Managing Global Pools" section on page 42-21.

- Choose identity NAT by choosing global pool 0.

Step 6 (Optional) Enter a description in the Description field.

Step 7 (Optional) To enable translation of addresses inside DNS replies, expand the **Connection Settings** area, and check the **Translate the DNS replies that match the translation rule** check box.

If your NAT rule includes the real address of a host that has an entry in a DNS server, and the DNS server is on a different interface from a client, then the client and the DNS server need different addresses for the host; one needs the mapped address and one needs the real address. This option rewrites the address in the DNS reply to the client. The mapped host needs to be on the same interface as either the client or the DNS server. Typically, hosts that need to allow access from other interfaces use a static translation, so this option is more likely to be used with a static rule. See the "DNS and NAT" section on page 42-13 for more information.

Step 8 (Optional) To enable connection settings, expand the **Connection Settings** area, and set one or more of the following options:

Note You can also set these values using a security policy rule. To set the number of rate intervals maintained for host statistics, on the Configuration > Firewall > Threat Detection > Scanning Threat Statistics area, choose **1**, **2**, or **3** from the User can specify the number of rate for Threat Detection Host drop-down list. Because host statistics use a lot of memory, reducing the number of rate intervals from the default of 3 reduces the memory usage. By default, the Firewall Dashboard Tab shows information for three rate intervals, for example, for the last 1 hour, 8 hours, and 24 hours. If you set this keyword to **1**, then only the shortest rate interval statistics are maintained. If you set the value to **2**, then the two shortest intervals are maintained. If you set them in both places, then the ASA uses the lower limit. For TCP sequence randomization, if it is disabled using either method, then the ASA disables TCP sequence randomization.

- **Randomize sequence number**—With this check box checked (the default), the ASA randomizes the sequence number of TCP packets. Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

  Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

  TCP initial sequence number randomization can be disabled if required. For example:

  - If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
  - If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
  - You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.

- **Maximum TCP Connections**—Specifies the maximum number of TCP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum UDP Connections**—Specifies the maximum number of UDP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum Embryonic Connections**—Specifies the maximum number of embryonic connections per host up to 65,536. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is **0**, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.

Step 9 Click **OK**.

Using Static NAT

This section describes how to configure a static translation, using regular or policy static NAT, PAT, or identity NAT.

For more information about static NAT, see the "Static NAT" section on page 42-8.

Policy NAT lets you identify real addresses for address translation by specifying the source and destination addresses. You can also optionally specify the source and destination ports. Regular NAT can only consider the source addresses, and not the destination. See the "Policy NAT" section on page 42-10 for more information.

Static PAT lets you translate the real IP address to a mapped IP address, as well as the real port to a mapped port. You can choose to translate the real port to the same port, which lets you translate only specific types of traffic, or you can take it further by translating to a different port. For applications that require application inspection for secondary channels (for example, FTP and VoIP), the ASA automatically translates the secondary ports. For more information about static PAT, see the "Static PAT" section on page 42-9.

You cannot use the same real or mapped address in multiple static rules between the same two interfaces unless you use static PAT. Do not use a mapped address in the static rule that is also defined in a global pool for the same mapped interface.

Static identity NAT translates the real IP address to the same IP address.

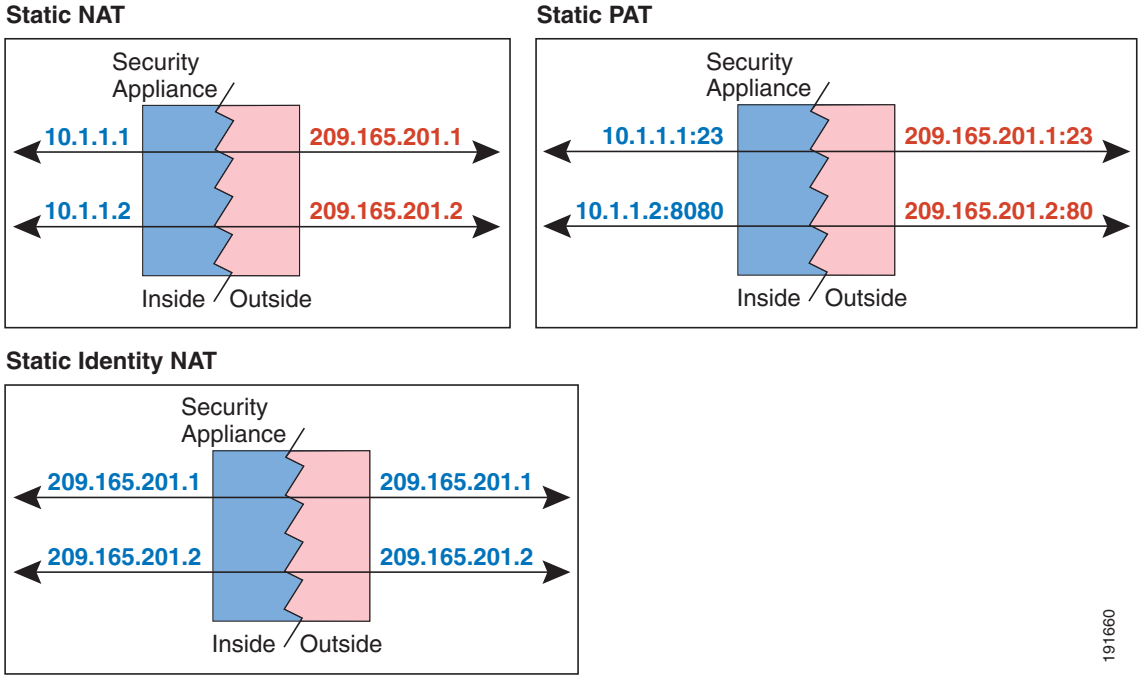
This section includes the following topics:

- Configuring Static NAT, PAT, or Identity NAT, page 42-27
- Configuring Static Policy NAT, PAT, or Identity NAT, page 42-30

Configuring Static NAT, PAT, or Identity NAT

Figure 42-21 shows typical static NAT, static PAT, and static identity NAT scenarios. The translation is always active so both translated and remote hosts can originate connections.

Figure 42-21 Static NAT Scenarios



To configure static NAT, PAT, or identity NAT, perform the following steps:

Step 1 In the Configuration > Firewall > NAT Rules pane, choose **Add > Add Static NAT Rule**.

The Add Static NAT Rule dialog box appears.

Step 2 In the Original area, from the Interface drop-down list, choose the interface that is connected to the hosts with real addresses that you want to translate.

Step 3 Enter the real addresses in the Source field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Step 4 In the Translated area, from the Interface drop-down list, choose the interface where you want to use the mapped addresses.

Step 5 Specify the mapped IP address by clicking one of the following:

- **Use IP Address**

  Enter the IP address or click the **...** button to choose an IP address that you already defined in ASDM.

  Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

- **Use Interface IP Address**

The real and mapped addresses must have the same subnet mask.

Note For identity NAT, enter the same IP address in the Original and Translated fields.

Step 6 (Optional) To use static PAT, check **Enable Port Address Translation (PAT)**.

a. For the Protocol, click **TCP** or **UDP**.

b. In the Original Port field, enter the real port number.

c. In the Translated Port field, enter the mapped port number.

Step 7 (Optional) To enable translation of addresses inside DNS replies, expand the **Connection Settings** area, and check the **Translate the DNS replies that match the translation rule** check box.

If your NAT rule includes the real address of a host that has an entry in a DNS server, and the DNS server is on a different interface from a client, then the client and the DNS server need different addresses for the host; one needs the mapped address and one needs the real address. This option rewrites the address in the DNS reply to the client. The mapped host needs to be on the same interface as either the client or the DNS server. See the "DNS and NAT" section on page 42-13 for more information.

Step 8 (Optional) To enable connection settings, expand the **Connection Settings** area, and set one or more of the following options:

Note You can also set these values using a security policy rule. To set the number of rate intervals maintained for host statistics, on the Configuration > Firewall > Threat Detection > Scanning Threat Statistics area, choose **1**, **2**, or **3** from the User can specify the number of rate for Threat Detection Host drop-down list. Because host statistics use a lot of memory, reducing the number of rate intervals from the default of 3 reduces the memory usage. By default, the Firewall Dashboard Tab shows information for three rate intervals, for example, for the last 1 hour, 8 hours, and 24 hours. If you set this keyword to **1**, then only the shortest rate interval statistics are maintained. If you set the value to **2**, then the two shortest intervals are maintained. If you set them in both places, then the ASA uses the lower limit. For TCP sequence randomization, if it is disabled using either method, then the ASA disables TCP sequence randomization.

- **Randomize sequence number**—With this check box checked (the default), the ASA randomizes the sequence number of TCP packets. Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

  Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

  TCP initial sequence number randomization can be disabled if required. For example:

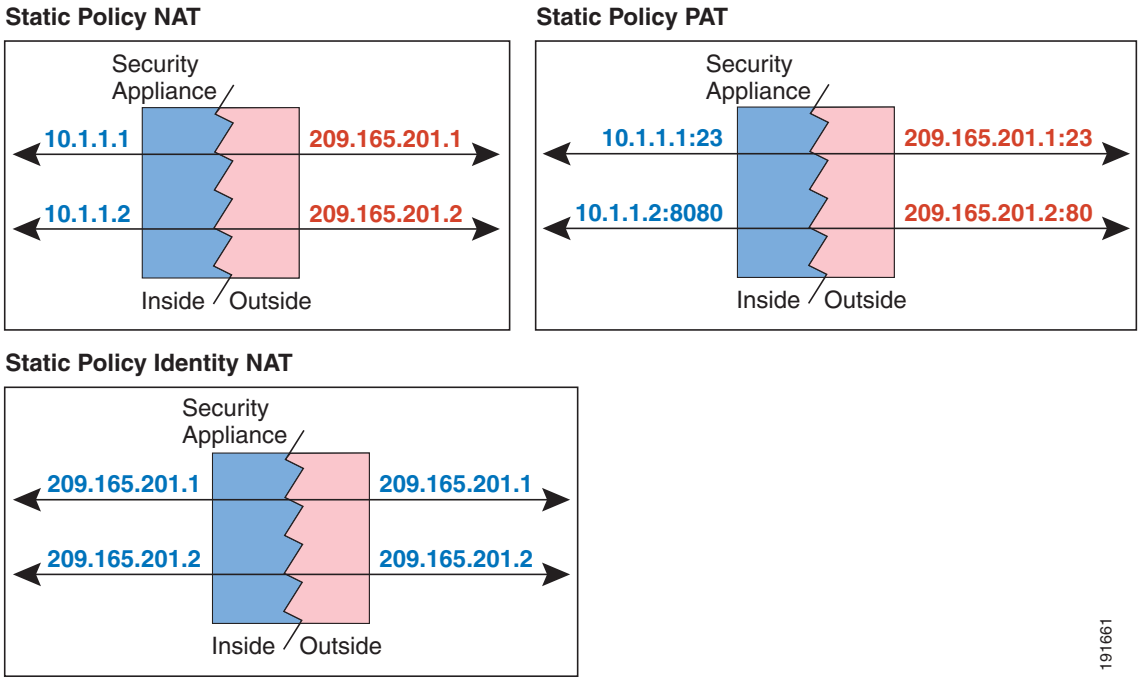
  - If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
  - If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
  - You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.
- **Maximum TCP Connections**—Specifies the maximum number of TCP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum UDP Connections**—Specifies the maximum number of UDP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum Embryonic Connections**—Specifies the maximum number of embryonic connections per host up to 65,536. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is **0**, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.

Step 9 Click **OK**.

Configuring Static Policy NAT, PAT, or Identity NAT

Figure 42-22 shows typical static policy NAT, static policy PAT, and static policy identity NAT scenarios. The translation is always active so both translated and remote hosts can originate connections.

Figure 42-22 Static Policy NAT Scenarios



To configure static policy NAT, PAT, or identity NAT, perform the following steps:

Step 1 In the Configuration > Firewall > NAT Rules pane, choose **Add > Advanced > Add Static Policy NAT Rule**.

The Add Static Policy NAT Rule dialog box appears.

Step 2 In the Original area, from the Interface drop-down list, choose the interface that is connected to the hosts with real addresses that you want to translate.

Step 3 Enter the real addresses in the Source field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Step 4 Enter the destination addresses in the Destination field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Separate multiple destination addresses by a comma.

By default, the field shows **any**, which allows any destination address.

Step 5 In the Translated area, from the Interface drop-down list, choose the interface where you want to use the mapped addresses.

Step 6 Specify the mapped IP address by clicking one of the following:

- **Use IP Address**

  Enter the IP address or click the **...** button to choose an IP address that you already defined in ASDM.

  Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

- **Use Interface IP Address**

The real and mapped addresses must have the same subnet mask.

Step 7 (Optional) To use static PAT, check **Enable Port Address Translation (PAT)**.

a. For the Protocol, click **TCP** or **UDP**.

b. In the Original Port field, enter the real port number.

c. In the Translated Port field, enter the mapped port number.

Step 8 (Optional) Enter a description in the Description field.

Step 9 (Optional) To enable translation of addresses inside DNS replies, expand the **Connection Settings** area, and check the **Translate the DNS replies that match the translation rule** check box.

If your NAT rule includes the real address of a host that has an entry in a DNS server, and the DNS server is on a different interface from a client, then the client and the DNS server need different addresses for the host; one needs the mapped address and one needs the real address. This option rewrites the address in the DNS reply to the client. The mapped host needs to be on the same interface as either the client or the DNS server. See the "DNS and NAT" section on page 42-13 for more information.

Step 10 (Optional) To enable connection settings, expand the **Connection Settings** area, and set one or more of the following options:

Note You can also set these values using a security policy rule. To set the number of rate intervals maintained for host statistics, on the Configuration > Firewall > Threat Detection > Scanning Threat Statistics area, choose **1**, **2**, or **3** from the User can specify the number of rate for Threat Detection Host drop-down list. Because host statistics use a lot of memory, reducing the number of rate intervals from the default of 3 reduces the memory usage. By default, the the Firewall Dashboard Tab shows information for three rate intervals, for example, for the last 1 hour, 8 hours, and 24 hours. If you set this keyword to **1**, then only the shortest rate interval statistics are maintained. If you set the value to **2**, then the two shortest intervals are maintained. If you set them in both places, then the ASA uses the lower limit. For TCP sequence randomization, if it is disabled using either method, then the ASA disables TCP sequence randomization.

- **Randomize sequence number**—With this check box checked (the default), the ASA randomizes the sequence number of TCP packets. Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

  Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session.

  TCP initial sequence number randomization can be disabled if required. For example:

  – If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.

  – If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.

  - You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.

- **Maximum TCP Connections**—Specifies the maximum number of TCP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum UDP Connections**—Specifies the maximum number of UDP connections, between 0 and 65,535. If this value is set to 0, the number of connections is unlimited.
- **Maximum Embryonic Connections**—Specifies the maximum number of embryonic connections per host up to 65,536. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. This limit enables the TCP Intercept feature. The default is **0**, which means the maximum embryonic connections. TCP Intercept protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. When the embryonic limit has been surpassed, the TCP intercept feature intercepts TCP SYN packets from clients to servers on a higher security level. SYN cookies are used during the validation process and help to minimize the amount of valid traffic being dropped. Thus, connection attempts from unreachable hosts will never reach the server.

Step 11 Click **OK**.

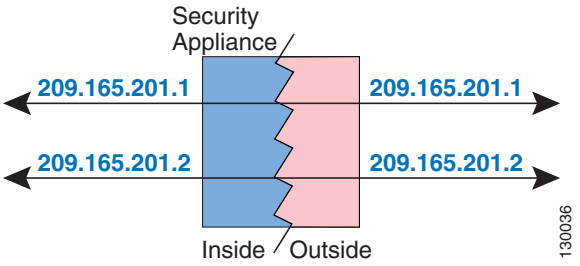
Using NAT Exemption

NAT exemption exempts addresses from translation and allows both real and remote hosts to originate connections. NAT exemption lets you specify the real and destination addresses when determining the real traffic to exempt (similar to policy NAT), so you have greater control using NAT exemption than dynamic identity NAT. However unlike policy NAT, NAT exemption does not consider the ports. Use static policy identity NAT to consider ports.

For more information about NAT exemption, see the "Bypassing NAT When NAT Control is Enabled" section on page 42-10.

Figure 42-23 shows a typical NAT exemption scenario.

Figure 42-23 NAT Exemption



To configure NAT exemption, perform the following steps:

Step 1 In the Configuration > Firewall > NAT Rules pane, choose **Add > Add NAT Exempt Rule**.

The Add NAT Exempt Rule dialog box appears.

Step 2 Click **Action: Exempt**.

Step 3 In the Original area, from the Interface drop-down list, choose the interface that is connected to the hosts with real addresses that you want to exempt.

Step 4 Enter the real addresses in the Source field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Note You can later specify addresses that you do not want to exempt. For example, you can specify a subnet to exempt such as 10.1.1.0/24, but if you want to translate 10.1.1.50, then you can create a separate rule for that address that removes the exemption.

Separate multiple real addresses by a comma.

Step 5 Enter the destination addresses in the Destination field, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Separate multiple destination addresses by a comma.

By default, the field shows **any**, which allows any destination address.

Step 6 In the NAT Exempt Direction area, choose whether you want to exempt traffic going to lower security interfaces (the default) or to higher security interfaces by clicking the appropriate radio button.

Step 7 (Optional) Enter a description in the Description field.

Step 8 Click **OK**.

Step 9 (Optional) If you do not want to exempt some addresses that were included in your NAT exempt rule, then create another rule to remove the exemption. Right-click the existing NAT Exempt rule, and choose **Insert**.

The Add NAT Exempt Rule dialog box appears.

a. Click **Action: Do not exempt**.

b. Complete Steps 3 through 8 to complete the rule.

The No Exempt rule is added before the Exempt rule. The order of Exempt and No Exempt rules is important. When the ASA decides whether to exempt a packet, the ASA tests the packet against each NAT exempt and No Exempt rule in the order in which the rules are listed. After a match is found, no more rules are checked.

PART 7

Configuring Service Policies

Configuring a Service Policy

Service policies provide a consistent and flexible way to configure ASA features. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple service policy rules applied to an interface or applied globally.

This chapter includes the following sections:

- Information About Service Policies, page 44-1
- Licensing Requirements for Service Policies, page 44-5
- Guidelines and Limitations, page 44-6
- Default Settings, page 44-7
- Task Flows for Configuring Service Policies, page 44-8
- Adding a Service Policy Rule for Through Traffic, page 44-8
- Adding a Service Policy Rule for Management Traffic, page 44-13
- Managing the Order of Service Policy Rules, page 44-16
- Feature History for Service Policies, page 44-17

Information About Service Policies

This section describes how service policies work and includes the following topics:

- Supported Features, page 44-1
- Feature Directionality, page 44-2
- Feature Matching Within a Service Policy, page 44-3
- Order in Which Multiple Feature Actions are Applied, page 44-4
- Incompatibility of Certain Feature Actions, page 44-4
- Feature Matching for Multiple Service Policies, page 44-5

Supported Features

Table 44-1 lists the features supported by service policy rules.

Table 44-1 Service Policy Rule Features

Feature	For Through Traffic?	For Management Traffic?	See:
Application inspection (multiple types)	**All** except RADIUS accounting	**RADIUS accounting** only	• Chapter 57, "Getting Started with Application Layer Protocol Inspection." • Chapter 58, "Configuring Inspection of Basic Internet Protocols." • Chapter 59, "Configuring Inspection for Voice and Video Protocols." • Chapter 60, "Configuring Inspection of Database and Directory Protocols." • Chapter 61, "Configuring Inspection for Management Application Protocols." • Chapter 75, "Configuring the ASA for Cisco Cloud Web Security."
ASA CSC	**Yes**	No	Chapter 83, "Configuring the ASA CSC Module."
ASA IPS	**Yes**	No	Chapter 81, "Configuring the ASA IPS Module."
ASA CX	**Yes**	No	Chapter 82, "Configuring the ASA CX Module."
NetFlow Secure Event Logging filtering	**Yes**	**Yes**	Chapter 97, "Configuring NetFlow Secure Event Logging (NSEL)."
QoS input and output policing	**Yes**	No	Chapter 72, "Configuring QoS."
QoS standard priority queue	**Yes**	No	Chapter 72, "Configuring QoS."
QoS traffic shaping, hierarchical priority queue	**Yes**	**Yes**	Chapter 72, "Configuring QoS."
TCP and UDP connection limits and timeouts, and TCP sequence number randomization	**Yes**	**Yes**	Chapter 71, "Configuring Connection Settings."
TCP normalization	**Yes**	No	Chapter 71, "Configuring Connection Settings."
TCP state bypass	**Yes**	No	Chapter 71, "Configuring Connection Settings."
User statistics for Identity Firewall	**Yes**	**Yes**	See the **user-statistics** command in the command reference.

Feature Directionality

Actions are applied to traffic bidirectionally or unidirectionally depending on the feature. For features that are applied bidirectionally, all traffic that enters or exits the interface to which you apply the policy map is affected if the traffic matches the class map for both directions.

Note When you use a global policy, all features are unidirectional; features that are normally bidirectional when applied to a single interface only apply to the ingress of each interface when applied globally. Because the policy is applied to all interfaces, the policy will be applied in both directions so bidirectionality in this case is redundant.

For features that are applied unidirectionally, for example QoS priority queue, only traffic that enters (or exits, depending on the feature) the interface to which you apply the policy map is affected. See Table 44-2 for the directionality of each feature.

Table 44-2 Feature Directionality

Feature	Single Interface Direction	Global Direction
Application inspection (multiple types)	Bidirectional	Ingress
ASA CSC	Bidirectional	Ingress
ASA CX	Bidirectional	Ingress
ASA CX authentication proxy	Ingress	Ingress
ASA IPS	Bidirectional	Ingress
NetFlow Secure Event Logging filtering	N/A	Ingress
QoS input policing	Ingress	Ingress
QoS output policing	Egress	Egress
QoS standard priority queue	Egress	Egress
QoS traffic shaping, hierarchical priority queue	Egress	Egress
TCP and UDP connection limits and timeouts, and TCP sequence number randomization	Bidirectional	Ingress
TCP normalization	Bidirectional	Ingress
TCP state bypass	Bidirectional	Ingress
User statistics for Identity Firewall	Bidirectional	Ingress

Feature Matching Within a Service Policy

See the following information for how a packet matches rules in a policy for a given interface:

1. A packet can match only one rule for an interface for each feature type.
2. When the packet matches a rule for a feature type, the ASA does not attempt to match it to any subsequent rules for that feature type.
3. If the packet matches a subsequent rule for a different feature type, however, then the ASA also applies the actions for the subsequent rule, if supported. See the "Incompatibility of Certain Feature Actions" section on page 44-4 for more information about unsupported combinations.

Note Application inspection includes multiple inspection types, and most are mutually exclusive. For inspections that can be combined, each inspection is considered to be a separate feature.

For example, if a packet matches a rulefor connection limits, and also matches a rule for an application inspection, then both actions are applied.

If a packet matches a rulefor HTTP inspection, but also matches another rule that includes HTTP inspection, then the second rule actions are not applied.

If a packet matches a rulefor HTTP inspection, but also matches another rule that includes FTP inspection, then the second rule actions are not applied because HTTP and FTP inspections cannpt be combined.

If a packet matches a rulefor HTTP inspection, but also matches another rule that includes IPv6 inspection, then both actions are applied because the IPv6 inspection can be combined with any other type of inspection.

Order in Which Multiple Feature Actions are Applied

The order in which different types of actions in a service policy are performed is independent of the order in which the actions appear in the table.

Note NetFlow Secure Event Logging filtering and User statistics for Identity Firewall are order-independent.

Actions are performed in the following order:

1. QoS input policing
2. TCP normalization, TCP and UDP connection limits and timeouts, TCP sequence number randomization, and TCP state bypass.

Note When a the ASA performs a proxy service (such as AAA or CSC) or it modifies the TCP payload (such as FTP inspection), the TCP normalizer acts in dual mode, where it is applied before and after the proxy or payload modifying service.

3. ASA CSC
4. Application inspections that can be combined with other inspections:
   a. IPv6
   b. IP options
   c. WAAS
5. Application inspections that cannot be combined with other inspections. See the "Incompatibility of Certain Feature Actions" section on page 44-4 for more information.
6. ASA IPS
7. ASA CX
8. QoS output policing
9. QoS standard priority queue
10. QoS traffic shaping, hierarchical priority queue

Incompatibility of Certain Feature Actions

Some features are not compatible with each other for the same traffic. The following list may not include all incompatibilities; for information about compatibility of each feature, see the chapter or section for your feature:

- You cannot configure QoS priority queueing and QoS policing for the same set of traffic.

- Most inspections should not be combined with another inspection, so the ASA only applies one inspection if you configure multiple inspections for the same traffic. HTTP inspection can be combined with the Cloud Web Security inspection. Other exceptions are listed in the "Order in Which Multiple Feature Actions are Applied" section on page 44-4.
- You cannot configure traffic to be sent to multiple modules, such as the ASA CX and ASA IPS.
- HTTP inspection is not compatible with the ASA CX.
- The ASA CX is not compatible with Cloud Web Security.

Note The Default Inspection Traffic traffic class, which is used in the default global policy, is a special CLI shortcut to match the default ports for all inspections. When used in a policy map, this class map ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the ASA, then the ASA applies the TFTP inspection; when TCP traffic for port 21 arrives, then the ASA applies the FTP inspection. So in this case only, you can configure multiple inspections for the same class map. Normally, the ASA does not use the port number to determine which inspection to apply, thus giving you the flexibility to apply inspections to non-standard ports, for example.

This traffic class does not include the default ports for Cloud Web Security inspection (80 and 443).

Feature Matching for Multiple Service Policies

For TCP and UDP traffic (and ICMP when you enable stateful ICMP inspection), service policies operate on traffic flows, and not just individual packets. If traffic is part of an existing connection that matches a feature in a policy on one interface, that traffic flow cannot also match the same feature in a policy on another interface; only the first policy is used.

For example, if HTTP traffic matches a policy on the inside interface to inspect HTTP traffic, and you have a separate policy on the outside interface for HTTP inspection, then that traffic is not also inspected on the egress of the outside interface. Similarly, the return traffic for that connection will not be inspected by the ingress policy of the outside interface, nor by the egress policy of the inside interface.

For traffic that is not treated as a flow, for example ICMP when you do not enable stateful ICMP inspection, returning traffic can match a different policy map on the returning interface. For example, if you configure IPS on the inside and outside interfaces, but the inside policy uses virtual sensor 1 while the outside policy uses virtual sensor 2, then a non-stateful Ping will match virtual sensor 1 outbound, but will match virtual sensor 2 inbound.

Licensing Requirements for Service Policies

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6 for the following features:

- Application inspection for DNS, FTP, HTTP, ICMP, ScanSafe, SIP, SMTP, IPsec-pass-thru, and IPv6.
- ASA IPS
- ASA CX
- NetFlow Secure Event Logging filtering
- TCP and UDP connection limits and timeouts, TCP sequence number randomization
- TCP normalization
- TCP state bypass
- User statistics for Identity Firewall

Traffic Class Guidelines

The maximum number of traffic classes of all types is 255 in single mode or per context in multiple mode. Class maps include the following types:

- Layer 3/4 class maps (for through traffic and management traffic).
- Inspection class maps
- Regular expression class maps
- **match** commands used directly underneath an inspection policy map

This limit also includes default traffic classes of all types, limiting user-configured traffic classes to approximately 235. See the "Default Traffic Classes" section on page 44-8.

Service Policy Guidelines

- Interface service policies take precedence over the global service policy for a given feature. For example, if you have a global policy with FTP inspection, and an interface policy with TCP normalization, then both FTP inspection and TCP normalization are applied to the interface. However, if you have a global policy with FTP inspection, and an interface policy with FTP inspection, then only the interface policy FTP inspection is applied to that interface.
- You can only apply one global policy. For example, you cannot create a global policy that includes feature set 1, and a separate global policy that includes feature set 2. All features must be included in a single policy.
- When you make service policy changes to the configuration, all *new* connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. **show** command output will not include data about the old connections.

For example, if you remove a QoS service policy from an interface, then re-add a modified version, then the **show service-policy** command only displays QoS counters associated with new connections that match the new service policy; existing connections on the old policy no longer show in the command output.

To ensure that all connections use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. See the **clear conn** or **clear local-host** commands.

Default Settings

The following topics describe the default settings for Modular Policy Framework:

- Default Configuration, page 44-7
- Default Traffic Classes, page 44-8

Default Configuration

By default, the configuration includes a policy that matches all default application inspection traffic and applies certain inspections to the traffic on all interfaces (a global policy). Not all inspections are enabled by default. You can only apply one global policy, so if you want to alter the global policy, you need to either edit the default policy or disable it and apply a new one. (An interface policy overrides the global policy for a particular feature.)

The default policy includes the following application inspections:

- DNS inspection for the maximum message length of 512 bytes
- FTP
- H323 (H225)
- H323 (RAS)
- RSH
- RTSP
- ESMTP
- SQLnet
- Skinny (SCCP)
- SunRPC
- XDMCP
- SIP
- NetBios
- TFTP
- IP Options

Default Traffic Classes

The configuration includes a default traffic class that the ASA uses in the default global policy called Default Inspection Traffic; it matches the default inspection traffic. This class, which is used in the default global policy, is a special shortcut to match the default ports for all inspections. When used in a policy, this class ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the ASA, then the ASA applies the TFTP inspection; when TCP traffic for port 21 arrives, then the ASA applies the FTP inspection. So in this case only, you can configure multiple inspections for the same class map. Normally, the ASA does not use the port number to determine which inspection to apply, thus giving you the flexibility to apply inspections to non-standard ports, for example.

Another class map that exists in the default configuration is called class-default, and it matches all traffic. You can use the class-default class if desired, rather than using the Any traffic class. In fact, some features are only available for class-default, such as QoS traffic shaping.

Task Flows for Configuring Service Policies

This section includes the following topics:

- Task Flow for Configuring a Service Policy Rule, page 44-8

Task Flow for Configuring a Service Policy Rule

Configuring a service policy consists of adding one or more service policy rules per interface or for the global policy. For each rule, you identify the following elements:

Step 1 Identify the interface to which you want to apply the rule, or identify the global policy.

Step 2 Identify the traffic to which you want to apply actions. You can identify Layer 3 and 4 through traffic.

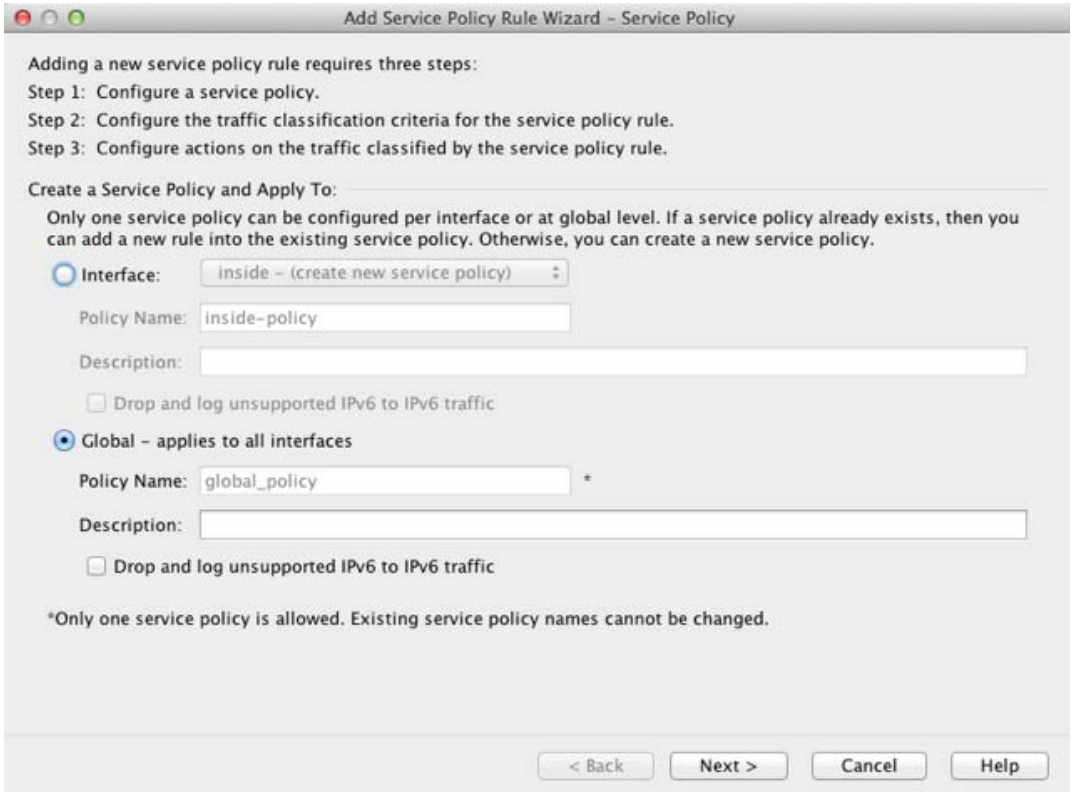
Step 3 Apply actions to the traffic class. You can apply multiple actions for each traffic class.

Adding a Service Policy Rule for Through Traffic

See the "Supported Features" section on page 44-1 for more information. To add a service policy rule for through traffic, perform the following steps:

Step 1 Choose **Configuration > Firewall > Service Policy Rules** pane, and click **Add**.

The Add Service Policy Rule Wizard - Service Policy dialog box appears.



Note When you click the Add button, and not the small arrow on the right of the Add button, you add a through traffic rule by default. If you click the arrow on the Add button, you can choose between a through traffic rule and a management traffic rule.

Step 2 In the Create a Service Policy and Apply To area, click one of the following options:

- **Interface**. This option applies the service policy to a single interface. Interface service policies take precedence over the global service policy for a given feature. For example, if you have a global policy with FTP inspection, and an interface policy with TCP connection limits, then both FTP inspection and TCP connection limits are applied to the interface. However, if you have a global policy with FTP inspection, and an interface policy with FTP inspection, then only the interface policy FTP inspection is applied to that interface.
  a. Choose an interface from the drop-down list.

     If you choose an interface that already has a policy, then the wizard lets you add a new service policy rule to the interface.
  b. If it is a new service policy, enter a name in the Policy Name field.
  c. (Optional) Enter a description in the Description field.
  d. (Optional) Check the **Drop and log unsupported IPv6 to IPv6 traffic** check box to generate a syslog (767001) for IPv6 traffic that is dropped by application inspections that do not support IPv6 traffic. By default, syslogs are not generated. For a list of inspections that support IPv6, see the "IPv6 Guidelines" section on page 44-6.

- **Global - applies to all interfaces**. This option applies the service policy globally to all interfaces. By default, a global policy exists that includes a service policy rule for default application inspection. See the "Default Settings" section on page 44-7 for more information. You can add a rule to the global policy using the wizard.

  a. If it is a new service policy, enter a name in the Policy Name field.

  b. (Optional) Enter a description in the Description field.

  c. (Optional) Check the **Drop and log unsupported IPv6 to IPv6 traffic** check box to generate a syslog (767001) for IPv6 traffic that is dropped by application inspections that do not support IPv6 traffic. By default, syslogs are not generated. For a list of inspections that support IPv6, see the "IPv6 Guidelines" section on page 44-6.

Step 3 Click **Next**.

The Add Service Policy Rule Wizard - Traffic Classification Criteria dialog box appears.

Step 4 Click one of the following options to specify the traffic to which to apply the policy actions:

- **Create a new traffic class**. Enter a traffic class name in the Create a new traffic class field, and enter an optional description.

  Identify the traffic using one of several criteria:

  – **Default Inspection Traffic**—The class matches the default TCP and UDP ports used by all applications that the ASA can inspect.

    This option, which is used in the default global policy, is a special shortcut that when used in a rule, ensures that the correct inspection is applied to each packet, based on the destination port of the traffic. For example, when UDP traffic for port 69 reaches the ASA, then the ASA applies the TFTP inspection; when TCP traffic for port 21 arrives, then the ASA applies the FTP inspection. So in this case only, you can configure multiple inspections for the same rule (See the "Incompatibility of Certain Feature Actions" section on page 44-4 for more information about combining actions). Normally, the ASA does not use the port number to determine the inspection applied, thus giving you the flexibility to apply inspections to non-standard ports, for example.

    See the "Default Settings" section on page 57-4 for a list of default ports. The ASA includes a default global policy that matches the default inspection traffic, and applies common inspections to the traffic on all interfaces. Not all applications whose ports are included in the Default Inspection Traffic class are enabled by default in the policy map.

    You can specify a Source and Destination IP Address (uses ACL) class along with the Default Inspection Traffic class to narrow the matched traffic. Because the Default Inspection Traffic class specifies the ports and protocols to match, any ports and protocols in the access list are ignored.

  – **Source and Destination IP Address (uses ACL)**—The class matches traffic specified by an extended access list. If the ASA is operating in transparent firewall mode, you can use an EtherType access list.

Note When you create a new traffic class of this type, you can only specify one access control entry (ACE) initially. After you finish adding the rule, you can add additional ACEs by adding a new rule to the same interface or global policy, and then specifying **Add rule to existing traffic class** on the Traffic Classification dialog box (see below).

- **Tunnel Group**—The class matches traffic for a tunnel group to which you want to apply QoS. You can also specify one other traffic match option to refine the traffic match, excluding Any Traffic, Source and Destination IP Address (uses ACL), or Default Inspection Traffic.
- **TCP or UDP Destination Port**—The class matches a single port or a contiguous range of ports.

Tip For applications that use multiple, non-contiguous ports, use the Source and Destination IP Address (uses ACL) to match each port.

- **RTP Range**—The class map matches RTP traffic.
- **IP DiffServ CodePoints (DSCP)**—The class matches up to eight DSCP values in the IP header.
- **IP Precedence**—The class map matches up to four precedence values, represented by the TOS byte in the IP header.
- **Any Traffic**—Matches all traffic.

- **Add rule to existing traffic class**. If you already have a service policy rule on the same interface, or you are adding to the global service policy, this option lets you add an ACE to an existing access list. You can add an ACE to any access list that you previously created when you chose the Source and Destination IP Address (uses ACL) option for a service policy rule on this interface. For this traffic class, you can have only one set of rule actions even if you add multiple ACEs. You can add multiple ACEs to the same traffic class by repeating this entire procedure. See the "Managing the Order of Service Policy Rules" section on page 44-16 for information about changing the order of ACEs.
- **Use an existing traffic class.** If you created a traffic class used by a rule on a different interface, you can reuse the traffic class definition for this rule. Note that if you alter the traffic class for one rule, the change is inherited by all rules that use that traffic class. If your configuration includes any **class-map** commands that you entered at the CLI, those traffic class names are also available (although to view the definition of the traffic class, you need to create the rule).
- **Use class default as the traffic class**. This option uses the class-default class, which matches all traffic. The class-default class is created automatically by the ASA and placed at the end of the policy. If you do not apply any actions to it, it is still created by the ASA, but for internal purposes only. You can apply actions to this class, if desired, which might be more convenient than creating a new traffic class that matches all traffic. You can only create one rule for this service policy using the class-default class, because each traffic class can only be associated with a single rule per service policy.

Step 5 Click **Next**.

Step 6 The next dialog box depends on the traffic match criteria you chose.

Note The Any Traffic option does not have a special dialog box for additional configuration.

- Default Inspections—This dialog box is informational only, and shows the applications and the ports that are included in the traffic class.
- Source and Destination Address—This dialog box lets you set the source and destination addresses:

  a. Click **Match** or **Do Not Match**.

  The Match option creates a rule where traffic matching the addresses have actions applied. The Do Not Match option exempts the traffic from having the specified actions applied. For example, you want to match all traffic in 10.1.1.0/24 and apply connection limits to it, except

for 10.1.1.25. In this case, create two rules, one for 10.1.1.0/24 using the Match option and one for 10.1.1.25 using the Do Not Match option. Be sure to arrange the rules so that the Do Not Match rule is above the Match rule, or else 10.1.1.25 will match the Match rule first.

b. In the Source field, enter the source IP address, or click the **...** button to choose an IP address that you already defined in ASDM.

   Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

   Enter **any** to specify any source address.

   Separate multiple addresses by a comma.

c. In the Destination field, enter the destination IP address, or click the **...** button to choose an IP address that you already defined in ASDM.

   Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

   Enter **any** to specify any destination address.

   Separate multiple addresses by a comma.

d. In the Service field, enter an IP service name or number for the destination service, or click the **...** button to choose a service.

   If you want to specify a TCP or UDP port number, or an ICMP service number, enter *protocol*/*port*. For example, enter TCP/8080.

   By default, the service is IP.

   Separate multiple services by a comma.

e. (Optional) Enter a description in the Description field.

f. (Optional) To specify a source service for TCP or UDP, click the **More Options** area open, and enter a TCP or UDP service in the Source Service field.

   The destination service and source service must be the same. Copy and paste the destination Service field to the Source Service field.

g. (Optional) To make the rule inactive, click the **More Options** area open, and uncheck **Enable Rule**.

   This setting might be useful if you do not want to remove the rule, but want to turn it off.

h. (Optional) To set a time range for the rule, click the **More Options** area open, and from the Time Range drop-down list, choose a time range.

   To add a new time range, click the **...** button. See the "Configuring Time Ranges" section on page 25-15 for more information.

   This setting might be useful if you only want the rule to be active at predefined times.

- Tunnel Group—Choose a tunnel group from the Tunnel Group drop-down list, or click **New** to add a new tunnel group. See the "Add or Edit an IPsec Remote Access Connection Profile" section on page 87-74 for more information.

  To police each flow, check **Match flow destination IP address**. All traffic going to a unique IP destination address is considered a flow.

- Destination Port—Click **TCP** or **UDP**.

  In the Service field, enter a port number or name, or click **...** to choose one already defined in ASDM.

- RTP Range—Enter an RTP port range, between 2000 and 65534. The maximum number of port sin the range is 16383.

- IP DiffServ CodePoints (DSCP)—In the DSCP Value to Add area, choose a value from the **Select Named DSCP Values** or enter a value in the **Enter DSCP Value (0-63) field**, and click **Add**.

  Add additional values as desired, or remove them using the **Remove** button.

- IP Precedence—From the Available IP Precedence area, choose a value and click **Add**.

  Add additional values as desired, or remove them using the **Remove** button.

Step 7 Click **Next**.

The Add Service Policy Rule - Rule Actions dialog box appears.

Step 8 Configure one or more rule actions. See the "Supported Features" section on page 44-1 for a list of features.

Step 9 Click **Finish**.

Adding a Service Policy Rule for Management Traffic

You can create a service policy for traffic directed to the ASA for management purposes. See the "Supported Features" section on page 44-1 for more information. This section includes the following topics:

Configuring a Service Policy Rule for Management Traffic

To add a service policy rule for management traffic, perform the following steps:

Step 1 From the Configuration > Firewall > Service Policy Rules pane, click the down arrow next to Add.

Step 2 Choose **Add Management Service Policy Rule**.

The Add Management Service Policy Rule Wizard - Service Policy dialog box appears.

Step 3 In the Create a Service Policy and Apply To area, click one of the following options:

- **Interface**. This option applies the service policy to a single interface. Interface service policies take precedence over the global service policy for a given feature. For example, if you have a global policy with RADIUS accounting inspection, and an interface policy with connection limits, then both RADIUS accounting and connection limits are applied to the interface. However, if you have a global policy with RADIUS accounting, and an interface policy with RADIUS accounting, then only the interface policy RADIUS accounting is applied to that interface.

  a. Choose an interface from the drop-down list.

     If you choose an interface that already has a policy, then the wizard lets you add a new service policy rule to the interface.

  b. If it is a new service policy, enter a name in the Policy Name field.

  c. (Optional) Enter a description in the Description field.

- **Global - applies to all interfaces**. This option applies the service policy globally to all interfaces. By default, a global policy exists that includes a service policy rule for default application inspection. See the "Default Settings" section on page 44-7 for more information. You can add a rule to the global policy using the wizard.

Step 4 Click **Next**.

The Add Management Service Policy Rule Wizard - Traffic Classification Criteria dialog box appears.

Step 5 Click one of the following options to specify the traffic to which to apply the policy actions:

- **Create a new traffic class**. Enter a traffic class name in the Create a new traffic class field, and enter an optional description.

  Identify the traffic using one of several criteria:

  – **Source and Destination IP Address (uses ACL)**—The class matches traffic specified by an extended access list. If the ASA is operating in transparent firewall mode, you can use an EtherType access list.

  Note When you create a new traffic class of this type, you can only specify one access control entry (ACE) initially. After you finish adding the rule, you can add additional ACEs by adding a new rule to the same interface or global policy, and then specifying **Add rule to existing traffic class** on the Traffic Classification dialog box (see below).

  – **TCP or UDP Destination Port**—The class matches a single port or a contiguous range of ports.

  Tip For applications that use multiple, non-contiguous ports, use the Source and Destination IP Address (uses ACL) to match each port.

- **Add rule to existing traffic class**. If you already have a service policy rule on the same interface, or you are adding to the global service policy, this option lets you add an ACE to an existing access list. You can add an ACE to any access list that you previously created when you chose the Source and Destination IP Address (uses ACL) option for a service policy rule on this interface. For this traffic class, you can have only one set of rule actions even if you add multiple ACEs. You can add multiple ACEs to the same traffic class by repeating this entire procedure. See the "Managing the Order of Service Policy Rules" section on page 44-16 for information about changing the order of ACEs.
- **Use an existing traffic class.** If you created a traffic class used by a rule on a different interface, you can reuse the traffic class definition for this rule. Note that if you alter the traffic class for one rule, the change is inherited by all rules that use that traffic class. If your configuration includes any **class-map** commands that you entered at the CLI, those traffic class names are also available (although to view the definition of the traffic class, you need to create the rule).

Step 6 Click **Next**.

Step 7 The next dialog box depends on the traffic match criteria you chose.

- Source and Destination Address—This dialog box lets you set the source and destination addresses:

  a. Click **Match** or **Do Not Match**.

  The Match option creates a rule where traffic matching the addresses have actions applied. The Do Not Match option exempts the traffic from having the specified actions applied. For example, you want to match all traffic in 10.1.1.0/24 and apply connection limits to it, except for 10.1.1.25. In this case, create two rules, one for 10.1.1.0/24 using the Match option and one for 10.1.1.25 using the Do Not Match option. Be sure to arrange the rules so that the Do Not Match rule is above the Match rule, or else 10.1.1.25 will match the Match rule first.

  b. In the Source field, enter the source IP address, or click the **...** button to choose an IP address that you already defined in ASDM.

  Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Enter **any** to specify any source address.

Separate multiple addresses by a comma.

c. In the Destination field, enter the destination IP address, or click the **...** button to choose an IP address that you already defined in ASDM.

Specify the address and subnet mask using prefix/length notation, such as 10.1.1.0/24. If you enter an IP address without a mask, it is considered to be a host address, even if it ends with a 0.

Enter **any** to specify any destination address.

Separate multiple addresses by a comma.

d. In the Service field, enter an IP service name or number for the destination service, or click the **...** button to choose a service.

If you want to specify a TCP or UDP port number, or an ICMP service number, enter *protocol/port*. For example, enter TCP/8080.

By default, the service is IP.

Separate multiple services by a comma.

e. (Optional) Enter a description in the Description field.

f. (Optional) To specify a source service for TCP or UDP, click the **More Options** area open, and enter a TCP or UDP service in the Source Service field.

The destination service and source service must be the same. Copy and paste the destination Service field to the Source Service field.

g. (Optional) To make the rule inactive, click the **More Options** area open, and uncheck **Enable Rule**.

This setting might be useful if you do not want to remove the rule, but want to turn it off.

h. (Optional) To set a time range for the rule, click the **More Options** area open, and from the Time Range drop-down list, choose a time range.

To add a new time range, click the **...** button. See the "Configuring Time Ranges" section on page 25-15 for more information.

This setting might be useful if you only want the rule to be active at predefined times.

- Destination Port—Click **TCP** or **UDP**.

  In the Service field, enter a port number or name, or click **...** to choose one already defined in ASDM.

Step 8 Click **Next**.

The Add Management Service Policy Rule - Rule Actions dialog box appears.

Step 9 To configure RADIUS accounting inspection, choose an inspect map from the RADIUS Accounting Map drop-down list, or click **Configure** to add a map.

See the "Feature Directionality" section on page 44-2 for more information.

Step 10 To configure connection settings, see the "Configuring Connection Settings" section on page 71-8.

Step 11 Click **Finish**.

Managing the Order of Service Policy Rules

The order of service policy rules on an interface or in the global policy affects how actions are applied to traffic. See the following guidelines for how a packet matches rules in a service policy:

- A packet can match only one rule in a service policy for each feature type.
- When the packet matches a rule that includes actions for a feature type, the ASA does not attempt to match it to any subsequent rules including that feature type.
- If the packet matches a subsequent rule for a different feature type, however, then the ASA also applies the actions for the subsequent rule.

For example, if a packet matches a rule for connection limits, and also matches a rule for application inspection, then both rule actions are applied.

If a packet matches a rule for application inspection, but also matches another rule that includes application inspection, then the second rule actions are not applied.

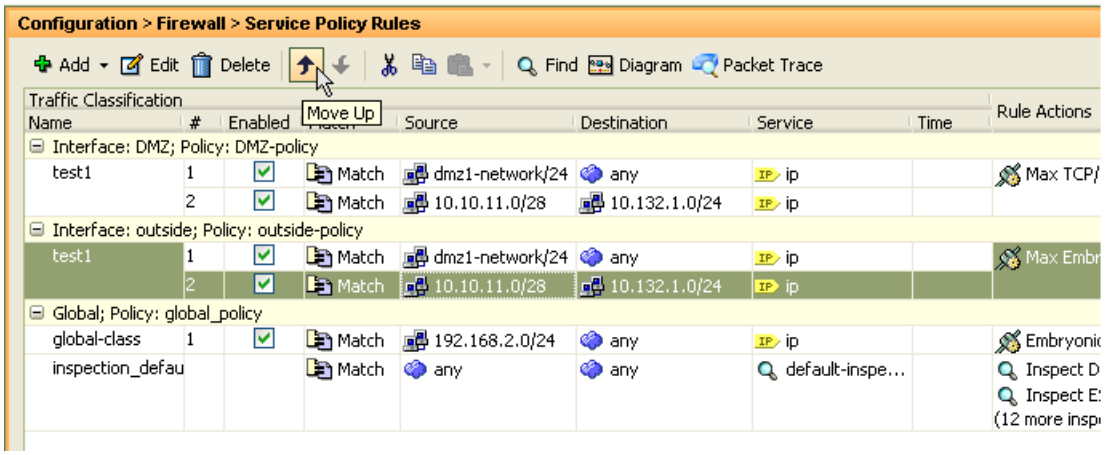
If your rule includes an access list with multiple ACEs, then the order of ACEs also affects the packet flow. The ASA tests the packet against each ACE in the order in which the entries are listed. After a match is found, no more ACEs are checked. For example, if you create an ACE at the beginning of an access list that explicitly permits all traffic, no further statements are ever checked.

To change the order of rules or ACEs within a rule, perform the following steps:

Step 1 From the Configuration > Firewall > Service Policy Rules pane, choose the rule or ACE that you want to move up or down.

Step 2 Click the Move Up or Move Down cursor (see Figure 44-1).

Figure 44-1 Moving an ACE



Note If you rearrange ACEs in an access list that is used in multiple service policies, then the change is inherited in all service policies.

Step 3 When you are done rearranging your rules or ACEs, click **Apply**.

Feature History for Service Policies

Table 44-3 lists the release history for this feature.

Table 44-3 Feature History for Service Policies

Feature Name	Releases	Feature Information
Modular Policy Framework	7.0(1)	Modular Policy Framework was introduced.
Management class map for use with RADIUS accounting traffic	7.2(1)	The management class map was introduced for use with RADIUS accounting traffic. The following commands were introduced: **class-map type management**, and **inspect radius-accounting**.
Inspection policy maps	7.2(1)	The inspection policy map was introduced. The following command was introduced: **class-map type inspect**.
Regular expressions and policy maps	7.2(1)	Regular expressions and policy maps were introduced to be used under inspection policy maps. The following commands were introduced: **class-map type regex**, **regex**, **match regex**.
Match any for inspection policy maps	8.0(2)	The **match any** keyword was introduced for use with inspection policy maps: traffic can match one or more criteria to match the class map. Formerly, only **match all** was available.

PART 8

Configuring AAA Servers and the Local Database

Configuring AAA Servers and the Local Database

This chapter describes support for authentication, authorization, and accounting (AAA, pronounced "triple A"), and how to configure AAA servers and the local database.

The chapter includes the following sections:

- Information About AAA, page 46-1
- Licensing Requirements for AAA Servers, page 46-9
- Guidelines and Limitations, page 46-10
- Configuring AAA, page 46-10
- Testing Server Authentication and Authorization, page 46-27
- Monitoring AAA Servers, page 46-27
- Additional References, page 46-28
- Feature History for AAA Servers, page 46-28

Information About AAA

AAA enables the ASA to determine who the user is (authentication), what the user can do (authorization), and what the user did (accounting).

AAA provides an extra level of protection and control for user access than using access lists alone. For example, you can create an access list allowing all outside users to access Telnet on a server on the DMZ network. If you want only some users to access the server and you might not always know IP addresses of these users, you can enable AAA to allow only authenticated and/or authorized users to connect through the ASA. (The Telnet server enforces authentication, too; the ASA prevents unauthorized users from attempting to access the server.)

You can use authentication alone or with authorization and accounting. Authorization always requires a user to be authenticated first. You can use accounting alone, or with authentication and authorization.

This section includes the following topics:

- Information About Authentication, page 46-2
- Information About Authorization, page 46-2
- Information About Accounting, page 46-3
- Summary of Server Support, page 46-3
- RADIUS Server Support, page 46-4

- TACACS+ Server Support, page 46-5
- RSA/SDI Server Support, page 46-5
- NT Server Support, page 46-6
- Kerberos Server Support, page 46-6
- LDAP Server Support, page 46-6
- Local Database Support, Including as a Fallback Method, page 46-7
- How Fallback Works with Multiple Servers in a Group, page 46-8
- Using Certificates and User Login Credentials, page 46-8
- Task Flow for Configuring AAA, page 46-10

Information About Authentication

Authentication controls access by requiring valid user credentials, which are usually a username and password. You can configure the ASA to authenticate the following items:

- All administrative connections to the ASA, including the following sessions:
  - Telnet
  - SSH
  - Serial console
  - ASDM using HTTPS
  - VPN management access
- The **enable** command
- Network access
- VPN access

Information About Authorization

Authorization controls access *per user* after users are authenticated. You can configure the ASA to authorize the following items:

- Management commands
- Network access
- VPN access

Authorization controls the services and commands that are available to each authenticated user. If you did not enable authorization, authentication alone would provide the same access to services for all authenticated users.

If you need the control that authorization provides, you can configure a broad authentication rule, and then have a detailed authorization configuration. For example, you can authenticate inside users who try to access any server on the outside network and then limit the outside servers that a particular user can access using authorization.

The ASA caches the first 16 authorization requests per user, so if the user accesses the same services during the current authentication session, the ASA does not resend the request to the authorization server.

Information About Accounting

Accounting tracks traffic that passes through the ASA, enabling you to have a record of user activity. If you enable authentication for that traffic, you can account for traffic per user. If you do not authenticate the traffic, you can account for traffic per IP address. Accounting information includes session start and stop times, username, the number of bytes that pass through the ASA for the session, the service used, and the duration of each session.

Summary of Server Support

Table 46-1 summarizes the support for each AAA service by each AAA server type, including the local database. For more information about support for a specific AAA server type, see the topics following the table.

Table 46-1 Summary of AAA Support

	Database Type							
AAA Service	**Local**	**RADIUS**	**TACACS+**	**SDI (RSA)**	**NT**	**Kerberos**	**LDAP**	**HTTP Form**
Authentication of...								
VPN users[1]	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes[2]
Firewall sessions	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
Administrators	Yes	Yes	Yes	Yes[3]	Yes	Yes	Yes	No
Authorization of...								
VPN users	Yes	Yes	No	No	No	No	Yes	No
Firewall sessions	No	Yes[4]	Yes	No	No	No	No	No
Administrators	Yes[5]	No	Yes	No	No	No	No	No
Accounting of...								
VPN connections	No	Yes	Yes	No	No	No	No	No
Firewall sessions	No	Yes	Yes	No	No	No	No	No
Administrators	No	Yes[6]	Yes	No	No	No	No	No

1. For SSL VPN connections, either PAP or MS-CHAPv2 can be used.
2. HTTP Form protocol supports both authentication and SSO operations for clientless SSL VPN users sessions only.
3. RSA/SDI is supported for ASDM HTTP administrative access with ASA 5500 software version 8.2(1) or later.
4. For firewall sessions, RADIUS authorization is supported with user-specific access lists only, which are received or specified in a RADIUS authentication response.
5. Local command authorization is supported by privilege level only.
6. Command accounting is available for TACACS+ only.

Note In addition to the native protocol authentication listed in Table 46-1, the ASA supports proxying authentication. For example, the ASA can proxy to an RSA/SDI and/or LDAP server via a RADIUS server. Authentication via digital certificates and/or digital certificates with the AAA combinations listed in the table are also supported.

RADIUS Server Support

The ASA supports the following RFC-compliant RADIUS servers for AAA:

- Cisco Secure ACS 3.2, 4.0, 4.1, 4.2, and 5.x
- Cisco Identity Services Engine (ISE)
- RSA RADIUS in RSA Authentication Manager 5.2, 6.1, and 7.x
- Microsoft

Authentication Methods

The ASA supports the following authentication methods with RADIUS:

- PAP—For all connection types.
- CHAP and MS-CHAPv1—For L2TP-over-IPsec connections.
- MS-CHAPv2—For L2TP-over-IPsec connections, and for regular IPsec remote access connections when the password management feature is enabled. You can also use MS-CHAPv2 with clientless connections.
- Authentication Proxy modes—Including RADIUS to Active Directory, RADIUS to RSA/SDI, RADIUS to Token-server, and RSA/SDI to RADIUS connections,

Note To enable MS-CHAPv2 as the protocol used between the ASA and the RADIUS server for a VPN connection, password management must be enabled in the tunnel group general attributes. Enabling password management generates an MS-CHAPv2 authentication request from the ASA to the RADIUS server. See the description of the **password-management** command for details.

If you use double authentication and enable password management in the tunnel group, then the primary and secondary authentication requests include MS-CHAPv2 request attributes. If a RADIUS server does not support MS-CHAPv2, then you can configure that server to send a non-MS-CHAPv2 authentication request by using the **no mschapv2-capable** command.

Attribute Support

The ASA supports the following sets of RADIUS attributes:

- Authentication attributes defined in RFC 2138.
- Accounting attributes defined in RFC 2139.
- RADIUS attributes for tunneled protocol support, defined in RFC 2868.
- Cisco IOS Vendor-Specific Attributes (VSAs), identified by RADIUS vendor ID 9.
- Cisco VPN-related VSAs, identified by RADIUS vendor ID 3076.
- Microsoft VSAs, defined in RFC 2548.
- Cisco VSA (Cisco-Priv-Level), which provides a standard 0-15 numeric ranking of privileges, with 1 being the lowest level and 15 being the highest level. A zero level indicates no privileges. The first level (login) allows privileged EXEC access for the commands available at this level. The second level (enable) allows CLI configuration privileges.

- A list of attributes is available at the following URL: http://www.cisco.com/en/US/docs/security/asa/asa84/configuration/guide/ref_extserver.html#wp1605508

RADIUS Authorization Functions

The ASA can use RADIUS servers for user authorization of VPN remote access and firewall cut-through-proxy sessions using dynamic access lists or access list names per user. To implement dynamic access lists, you must configure the RADIUS server to support it. When the user authenticates, the RADIUS server sends a downloadable access list or access list name to the ASA. Access to a given service is either permitted or denied by the access list. The ASA deletes the access list when the authentication session expires.

In addition to access lists, the ASA supports many other attributes for authorization and setting of permissions for VPN remote access and firewall cut-through proxy sessions. For a complete list of authorization attributes, see the following URL: http://www.cisco.com/en/US/docs/security/asa/asa84/configuration/guide/ref_extserver.html#wp1605508

TACACS+ Server Support

The ASA supports TACACS+ authentication with ASCII, PAP, CHAP, and MS-CHAPv1.

RSA/SDI Server Support

The RSA SecureID servers are also known as SDI servers.

This section includes the following topics:

- RSA/SDI Version Support, page 46-5
- Two-step Authentication Process, page 46-5
- RSA/SDI Primary and Replica Servers, page 46-6

RSA/SDI Version Support

The ASA supports SDI Versions 5.x, 6.x, and 7.x. SDI uses the concepts of an SDI primary and SDI replica servers. Each primary and its replicas share a single node secret file. The node secret file has its name based on the hexadecimal value of the ACE or Server IP address, with .sdi appended.

A version 5.x, 6.x, or 7.x SDI server that you configure on the ASA can be either the primary or any one of the replicas. See the "RSA/SDI Primary and Replica Servers" section on page 46-6 for information about how the SDI agent selects servers to authenticate users.

Two-step Authentication Process

SDI Versions 5.x, 6.x, or 7.x use a two-step process to prevent an intruder from capturing information from an RSA SecurID authentication request and using it to authenticate to another server. The agent first sends a lock request to the SecurID server before sending the user authentication request. The server

locks the username, preventing another (replica) server from accepting it. This actions means that the same user cannot authenticate to two ASAs using the same authentication servers simultaneously. After a successful username lock, the ASA sends the passcode.

RSA/SDI Primary and Replica Servers

The ASA obtains the server list when the first user authenticates to the configured server, which can be either a primary or a replica. The ASA then assigns priorities to each of the servers on the list, and subsequent server selection is derived at random from those assigned priorities. The highest priority servers have a higher likelihood of being selected.

NT Server Support

The ASA supports Microsoft Windows server operating systems that support NTLM Version 1, collectively referred to as NT servers.

Note NT servers have a maximum length of 14 characters for user passwords. Longer passwords are truncated, which is a limitation of NTLM Version 1.

Kerberos Server Support

The ASA supports 3DES, DES, and RC4 encryption types.

Note The ASA does not support changing user passwords during tunnel negotiation. To avoid this situation happening inadvertently, disable password expiration on the Kerberos/Active Directory server for users connecting to the ASA.

LDAP Server Support

The ASA supports LDAP. This section includes the following topics:

- Authentication with LDAP, page 46-6
- LDAP Server Types, page 46-7

Authentication with LDAP

During authentication, the ASA acts as a client proxy to the LDAP server for the user, and authenticates to the LDAP server in either plain text or by using the SASL protocol. By default, the ASA passes authentication parameters, usually a username and password, to the LDAP server in plain text.

The ASA supports the following SASL mechanisms, listed in order of increasing strength:

- Digest-MD5—The ASA responds to the LDAP server with an MD5 value computed from the username and password.
- Kerberos—The ASA responds to the LDAP server by sending the username and realm using the GSSAPI Kerberos mechanism.

You can configure the ASA and LDAP server to support any combination of these SASL mechanisms. If you configure multiple mechanisms, the ASA retrieves the list of SASL mechanisms that are configured on the server and sets the authentication mechanism to the strongest mechanism configured on both the ASA and the server. For example, if both the LDAP server and the ASA support both mechanisms, the ASA selects Kerberos, the stronger of the mechanisms.

When user LDAP authentication has succeeded, the LDAP server returns the attributes for the authenticated user. For VPN authentication, these attributes generally include authorization data that is applied to the VPN session. Thus, using LDAP accomplishes authentication and authorization in a single step.

LDAP Server Types

The ASA supports LDAP version 3 and is compatible with the Sun Microsystems JAVA System Directory Server (formerly named the Sun ONE Directory Server), the Microsoft Active Directory, Novell, OpenLDAP, and other LDAPv3 directory servers.

By default, the ASA auto-detects whether it is connected to Microsoft Active Directory, Sun LDAP, Novell, OpenLDAP, or a generic LDAPv3 directory server. However, if auto-detection fails to determine the LDAP server type, and you know the server is either a Microsoft, Sun or generic LDAP server, you can manually configure the server type.

When configuring the server type, note the following guidelines:

- The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACL on the default password policy.
- You must configure LDAP over SSL to enable password management with Microsoft Active Directory and Sun servers.
- The ASA does not support password management with Novell, OpenLDAP, and other LDAPv3 directory servers.
- The ASA uses the Login Distinguished Name (DN) and Login Password to establish a trust relationship (bind) with an LDAP server. For more information, see the "Binding the ASA to the LDAP Server" section on page B-4.

HTTP Forms Authentication for Clientless SSL VPN

The ASA can use the HTTP Form protocol for both authentication and SSO operations of Clientless SSL VPN user sessions only.

Local Database Support, Including as a Fallback Method

The ASA maintains a local database that you can populate with user profiles.

The local database can act as a fallback method for several functions. This behavior is designed to help you prevent accidental lockout from the ASA.

For users who need fallback support, we recommend that their usernames and passwords in the local database match their usernames and passwords on the AAA servers. This practice provides transparent fallback support. Because the user cannot determine whether a AAA server or the local database is

providing the service, using usernames and passwords on AAA servers that are different than the usernames and passwords in the local database means that the user cannot be certain which username and password should be given.

The local database supports the following fallback functions:

- Console and enable password authentication—If the servers in the group are all unavailable, the ASA uses the local database to authenticate administrative access, which can also include enable password authentication.
- Command authorization—If the TACACS+ servers in the group are all unavailable, the local database is used to authorize commands based on privilege levels.
- VPN authentication and authorization—VPN authentication and authorization are supported to enable remote access to the ASA if AAA servers that normally support these VPN services are unavailable. When a VPN client of an administrator specifies a tunnel group configured to fallback to the local database, the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured with the necessary attributes.

How Fallback Works with Multiple Servers in a Group

If you configure multiple servers in a server group and you enable fallback to the local database for the server group, fallback occurs when no server in the group responds to the authentication request from the ASA. To illustrate, consider this scenario:

You configure an LDAP server group with two Active Directory servers, server 1 and server 2, in that order. When the remote user logs in, the ASA attempts to authenticate to server 1.

If server 1 responds with an authentication failure (such as *user not found*), the ASA does not attempt to authenticate to server 2.

If server 1 does not respond within the timeout period (or the number of authentication attempts exceeds the configured maximum), the ASA tries server 2.

If both servers in the group do not respond, and the ASA is configured to fall back to the local database, the ASA tries to authenticate to the local database.

Using Certificates and User Login Credentials

The following section describes the different methods of using certificates and user login credentials (username and password) for authentication and authorization. These methods apply to IPsec, AnyConnect, and Clientless SSL VPN.

In all cases, LDAP authorization does not use the password as a credential. RADIUS authorization uses either a common password for all users or the username as a password.

This section includes the following topics:

- Using User Login Credentials, page 46-8
- Using Certificates, page 46-9

Using User Login Credentials

The default method for authentication and authorization uses the user login credentials.

- Authentication

  - Enabled by the authentication server group setting in the tunnel group (also called ASDM Connection Profile)
  - Uses the username and password as credentials
- Authorization
  - Enabled by the authorization server group setting in the tunnel group (also called ASDM Connection Profile)
  - Uses the username as a credential

Using Certificates

If user digital certificates are configured, the ASA first validates the certificate. It does not, however, use any of the DNs from certificates as a username for the authentication.

If both authentication and authorization are enabled, the ASA uses the user login credentials for both user authentication and authorization.

- Authentication
  - Enabled by the authentication server group setting
  - Uses the username and password as credentials
- Authorization
  - Enabled by the authorization server group setting
  - Uses the username as a credential

If authentication is disabled and authorization is enabled, the ASA uses the primary DN field for authorization.

- Authentication
  - DISABLED (set to None) by the authentication server group setting
  - No credentials used
- Authorization
  - Enabled by the authorization server group setting
  - Uses the username value of the certificate primary DN field as a credential

Note If the primary DN field is not present in the certificate, the ASA uses the secondary DN field value as the username for the authorization request.

For example, consider a user certificate that includes the following Subject DN fields and values:

```
Cn=anyuser,OU=sales;O=XYZCorporation;L=boston;S=mass;C=us;ea=anyuser@example.com
```

If the Primary DN = EA (E-mail Address) and the Secondary DN = CN (Common Name), then the username used in the authorization request would be anyuser@example.com.

Licensing Requirements for AAA Servers

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6.

Configuring AAA

This section includes the following topics:

- Configuring AAA Server Groups, page 46-11
- Adding a Server to a Group, page 46-12
- Configuring AAA Server Parameters, page 46-13
- Configuring LDAP Attribute Maps, page 46-19
- Adding a User Account to the Local Database, page 46-20
- Authenticating Users with a Public Key for SSH, page 46-25
- Adding an Authentication Prompt, page 46-26

Task Flow for Configuring AAA

Step 1 Do one or both of the following:

- Add a AAA server group. See the "Configuring AAA Server Groups" section on page 46-11.
- Add a user to the local database. See the "Adding a User Account to the Local Database" section on page 46-20.

Step 2 For a server group, add a server to the group. See the "Adding a Server to a Group" section on page 46-12.

Step 3 For a server group, configure server parameters. See the "Configuring AAA Server Parameters" section on page 46-13.

Step 4 For an LDAP server, configure LDAP attribute maps. See the "Configuring LDAP Attribute Maps" section on page 46-19.

Step 5 (Optional) Specify text to display to the user during the AAA authentication challenge process. See the "Adding an Authentication Prompt" section on page 46-26.

Configuring AAA Server Groups

If you want to use an external AAA server for authentication, authorization, or accounting, you must first create at least one AAA server group per AAA protocol and add one or more servers to each group. You identify AAA server groups by name. Each server group is specific to one type of server: Kerberos, LDAP, NT, RADIUS, SDI, or TACACS+.

Guidelines

- You can have up to 100 server groups in single mode or 4 server groups per context in multiple mode.
- Each group can have up to 16 servers in single mode or 4 servers in multiple mode.
- When a user logs in, the servers are accessed one at a time, starting with the first server you specify in the configuration, until a server responds. If all servers in the group are unavailable, the ASA tries the local database if you configured it as a fallback method (management authentication and authorization only). If you do not have a fallback method, the ASA continues to try the AAA servers.

Detailed Steps

To add a server group, perform the following steps:

Step 1 Choose **Configuration > Device Management > Users/AAA > AAA Server Groups**.

Step 2 In the AAA Server Groups area, click **Add**.

The Add AAA Server Group dialog box appears.

Step 3 In the Server Group field, enter a name for the group.

Step 4 From the Protocol drop-down list, choose the server type:

- RADIUS
- TACACS+
- SDI
- NT Domain
- Kerberos
- LDAP
- HTTP Form

Step 5 In the Accounting Mode field, click the radio button for the mode you want to use (**Simultaneous** or **Single**).

In Single mode, the ASA sends accounting data to only one server.

In Simultaneous mode, the ASA sends accounting data to all servers in the group.

Note This option is not available for the following protocols: HTTP Form, SDI, NT, Kerberos, and LDAP.

Step 6 In the Reactivation Mode field, click the radio button for the mode you want to use (**Depletion** or **Timed**).

In Depletion mode, failed servers are reactivated only after all of the servers in the group are inactive.

In Timed mode, failed servers are reactivated after 30 seconds of down time.

Step 7 If you chose the Depletion reactivation mode, enter a time interval in the Dead Time field.

The Dead Time is the duration of time, in minutes, that elapses between the disabling of the last server in a group and the subsequent re-enabling of all servers.

Step 8 In the Max Failed Attempts field, add the number of failed attempts allowed.

This option sets the number of failed connection attempts allowed before declaring a nonresponsive server to be inactive.

Step 9 (Optional) If you are adding a RADIUS server type, perform the following steps:

a. Check the **Enable interim accounting update** check box if you want to enable multi-session accounting for clientless SSL and AnyConnect sessions.

b. Check the **Enable Active Directory Agent Mode** check box to specify the shared secret between the ASA and the AD agent and indicate that a RADIUS server group includes AD agents that are not full-function RADIUS servers. Only a RADIUS server group that has been configured using this option can be associated with user identity.

c. Click the **VPN3K Compatibility Option** down arrow to expand the list, and click one of the following radio buttons to specify whether or not a downloadable ACL received from a RADIUS packet should be merged with a Cisco AV pair ACL:

   – **Do not merge**

   – **Place the downloadable ACL after Cisco AV-pair ACL**

   – **Place the downloadable ACL before Cisco AV-pair ACL**

Step 10 Click **OK**.

The Add AAA Server Group dialog box closes, and the new server group is added to the AAA Server Groups table.

Step 11 In the AAA Server Groups dialog box, click **Apply** to save the changes.

The changes are saved to the running configuration.

Adding a Server to a Group

To add a AAA server to a group, perform the following steps.

Detailed Steps

Step 1 Choose **Configuration > Device Management > Users/AAA > AAA Server Groups**, and in the AAA Server Groups area, click the server group to which you want to add a server.

The row is highlighted in the table.

Step 2 In the Servers in the Selected Group area (lower pane), click **Add**.

The Add AAA Server Group dialog box appears for the server group.

Step 3 From the Interface Name drop-down list, choose the interface name on which the authentication server resides.

Step 4 In the Server Name or IP Address field, add either a server name or IP address for the server that you are adding to the group.

Step 5 In the Timeout field, either add a timeout value or keep the default. The timeout is the duration of time, in seconds, that the ASA waits for a response from the primary server before sending the request to the backup server.

Step 6 The other parameters available depend on the server type. See the following sections for parameters that are unique to each server type:

- RADIUS Server Fields, page 46-14
- TACACS+ Server Fields, page 46-15
- SDI Server Fields, page 46-15
- Windows NT Domain Server Fields, page 46-15
- Kerberos Server Fields, page 46-16
- LDAP Server Fields, page 46-16
- HTTP Form Server Fields, page 46-18

Step 7 Click **OK**.

The Add AAA Server Group dialog box closes, and the AAA server is added to the AAA server group.

Step 8 In the AAA Server Groups pane, click **Apply** to save the changes.

The changes are saved to the running configuration.

Configuring AAA Server Parameters

This section lists the unique fields for each server type when you add a server to a server group and includes the following topics:

- RADIUS Server Fields, page 46-14
- TACACS+ Server Fields, page 46-15
- SDI Server Fields, page 46-15
- Windows NT Domain Server Fields, page 46-15
- Kerberos Server Fields, page 46-16
- LDAP Server Fields, page 46-16
- HTTP Form Server Fields, page 46-18

For more information, see the "Adding a Server to a Group" section on page 46-12.

RADIUS Server Fields

The following table describes the unique fields for configuring RADIUS servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
ACL Netmask Convert	How you want the ASA to handle netmasks received in downloadable access lists. • Detect automatically: The ASA attempts to determine the type of netmask expression used. If the ASA detects a wildcard netmask expression, the ASA converts it to a standard netmask expression. **Note** Because some wildcard expressions are difficult to detect clearly, this setting may misinterpret a wildcard netmask expression as a standard netmask expression. • Standard: The ASA assumes downloadable access lists received from the RADIUS server contain only standard netmask expressions. No translation from wildcard netmask expressions is performed. • Wildcard: The ASA assumes downloadable access lists received from the RADIUS server contain only wildcard netmask expressions, and it converts them all to standard netmask expressions when the access lists are downloaded.
Common Password	A case-sensitive password that is common among users who access this RADIUS authorization server through this ASA. Be sure to provide this information to your RADIUS server administrator. **Note** For an authentication RADIUS server (rather than authorization), do not configure a common password. If you leave this field blank, the user username is the password for accessing this RADIUS authorization server. Never use a RADIUS authorization server for authentication. Common passwords or usernames as passwords are less secure than assigning unique user passwords. **Note** Although the password is required by the RADIUS protocol and the RADIUS server, users do not need to know it.
Microsoft CHAPv2 Capable	If you use double authentication and enable password management in the tunnel group, then the primary and secondary authentication requests include MS-CHAPv2 request attributes. If a RADIUS server does not support MS-CHAPv2, then you can configure that server to send a non-MS-CHAPv2 authentication request by unchecking this check box.
Retry Interval	The duration of time, 1 to 10 seconds, that the ASA waits between attempts to contact the server.
Server Accounting Port	The server port to be used for accounting of users. The default port is 1646.

Field	Description
Server Authentication Port	The server port to be used for authentication of users. The default port is 1645.
Server Secret Key	The shared secret key used to authenticate the RADIUS server to the ASA. The server secret that you configure here should match the one configured on the RADIUS server. If you do not know the server secret, ask the RADIUS server administrator. The maximum field length is 64 characters.

TACACS+ Server Fields

The following table describes the unique fields for configuring TACACS+ servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Server Port	The port to be used for this server.
Server Secret Key	The shared secret key used to authenticate the TACACS+ server to the ASA. The server secret that you configure here should match the one that is configured on the TACACS+ server. If you do not know the server secret, ask the RADIUS server administrator. The maximum field length is 64 characters.

SDI Server Fields

The following table describes the unique fields for configuring SDI servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Server Port	The TCP port number by which this server is accessed.
Retry Interval	The duration of time, 1 to 10 seconds, that the ASA waits between attempts to contact the server.

Windows NT Domain Server Fields

The following table describes the unique fields for configuring Windows NT Domain servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Server Port	Port number 139, or the TCP port number used by the ASA to communicate with the Windows NT server.
Domain Controller	The host name (no more than 15 characters) of the NT Primary Domain Controller for this server (for example, PDC01). You must enter a name, and it must be the correct host name for the server whose IP address you added in the field, Authentication Server Address. If the name is incorrect, authentication fails.

Kerberos Server Fields

The following table describes the unique fields for configuring Kerberos servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Server Port	Server port number 88, or the UDP port number over which the ASA communicates with the Kerberos server.
Retry Interval	The duration of time, 1 to 10 seconds, that the ASA waits between attempts to contact the server.
Realm	The name of the Kerberos realm. For example: • EXAMPLE.COM • EXAMPLE.NET • EXAMPLE.ORG **Note** Most Kerberos servers require the realm to be all uppercase for authentication to succeed. The maximum length is 64 characters. The following types of servers require that you enter the realm name in all uppercase letters: • Windows 2000 • Windows XP • Windows.NET You must enter the correct realm name for the server whose IP address you entered in the Server IP Address field.

LDAP Server Fields

The following table describes the unique fields for configuring LDAP servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Enable LDAP over SSL check box	When checked, SSL secures communications between the ASA and the LDAP server. Also called secure LDAP (LDAP-S). **Note** If you do not configure the SASL protocol, we strongly recommend that you secure LDAP communications with SSL.
Server Port	TCP port number 389, the port which the ASA uses to access the LDAP server for simple (non-secure) authentication, or TCP port 636 for secure authentication (LDAP-S). All LDAP servers support authentication and authorization. Only Microsoft AD and Sun LDAP servers additionally provide a VPN remote access password management capability, which requires LDAP-S.

Field	Description
Server Type	A drop-down list for choosing one of the following LDAP server types: • Detect Automatically/Use Generic Type • Microsoft • Novell • OpenLDAP • Sun
Base DN	The Base Distinguished Name, or location in the LDAP hierarchy where the server should begin searching when it receives an LDAP request (for example, OU=people, dc=cisco, dc=com).
Scope	The extent of the search the server should make in the LDAP hierarchy when it receives an authorization request. The available options are: • One Level—Searches only one level beneath the Base DN. This option is quicker. • All Levels—Searches all levels beneath the Base DN (that is, searches the entire subtree hierarchy). This option takes more time.
Naming Attribute(s)	The Relative Distinguished Name attribute (or attributes) that uniquely identifies an entry on the LDAP server. Common naming attributes are Common Name (CN), sAMAccountName, userPrincipalName, and User ID (uid).
Login DN	The ASA uses the Login Distinguished Name (DN) and Login Password to establish trust (bind) with an LDAP server. The Login DN represents a user record in the LDAP server that the administrator uses for binding. When binding, the ASA authenticates to the server using the Login DN and the Login password. When performing a Microsoft Active Directory read-only operation (such as authentication, authorization, or group-search), the ASA can bind with a Login DN with fewer privileges. For example, the Login DN can be a user whose AD “Member Of” designation is part of Domain Users. For VPN password management operations, the Login DN needs elevated privileges and must be part of the Account Operators AD group. The following is an example of a Login DN: `cn=Binduser1,ou=Admins,ou=Users,dc=company_A,dc=com` The ASA supports: • Simple LDAP authentication with an unencrypted password on port 389 • Secure LDAP (LDAP-S) on port 636 • Simple Authentication and Security Layer (SASL) MD5 • SASL Kerberos The ASA does not support anonymous authentication.
Login Password	The password for the Login DN user account. The characters you type are replaced with asterisks.

Field	Description
LDAP Attribute Map	The LDAP attribute maps that you can apply to LDAP server. Used to map Cisco attribute names to user-defined attribute names and values. For more information, see the "Adding an Authentication Prompt" section on page 46-26.
SASL MD5 authentication check box	When checked, the MD5 mechanism of the SASL authenticates communications between the ASA and the LDAP server.
SASL Kerberos authentication	When checked, the Kerberos mechanism of the SASL secures authentication communications between the ASA and the LDAP server.
Kerberos Server Group	The Kerberos server or server group used for authentication. The Kerberos Server group option is disabled by default and is enabled only when SASL Kerberos authentication is chosen.
Group Base DN	Used only for Active Directory servers using LDAP protocol. This DN specifies the location in the LDAP hierarchy to begin searching for the AD groups (that is, the list of memberOf enumerations). If this field is not configured, the ASA uses the Base DN for AD group retrieval. ASDM uses the list of retrieved AD groups to define AAA selection criteria for dynamic access policies. For more information, see the **show ad-groups** command.
Group Search Timeout	Specifies the maximum time to wait for a response from an AD server that was queried for available groups.

HTTP Form Server Fields

This area appears only when the selected server group uses HTTP Form, and only the server group name and the protocol are visible. Other fields are not available when using HTTP Form.

If you do not know what the following parameters are, use an HTTP header analyzer to extract the data from the HTTP GET and POST exchanges when logging into the authenticating web server directly, not through the ASA.

The following table describes the unique fields for configuring HTTP Form servers, for use with the "Adding a Server to a Group" section on page 46-12.

Field	Description
Start URL	The complete URL of the authenticating web server location where a pre-login cookie can be retrieved. This parameter must be configured only when the authenticating web server loads a pre-login cookie with the login page. A drop-down list offers both HTTP and HTTPS. The maximum number of characters is 1024, and there is no minimum.
Action URI	The complete Uniform Resource Identifier for the authentication program on the authorizing web server. The maximum number of characters for the complete URI is 2048 characters.
Username	The name of a username parameter—not a specific username—that must be submitted as part of the HTTP form used for SSO authentication. The maximum number of characters is 128, and there is no minimum.

Field	Description
Password	The name of a user password parameter—not a specific password value—that must be submitted as part of the HTTP form used for SSO authentication. The maximum number of characters is 128, and there is no minimum.
Hidden Values	The hidden parameters for the HTTP POST request submitted to the authenticating web server for SSO authentication. This parameter is necessary only when it is expected by the authenticating web server as indicated by its presence in the HTTP POST request. The maximum number of characters is 2048.
Authentication Cookie Name	(Optional) The name of the cookie that is set by the server on successful login and that contains the authentication information. It is used to assign a meaningful name to the authentication cookie to help distinguish it from other cookies that the web server may pass back. The maximum number of characters is 128, and there is no minimum.

Configuring LDAP Attribute Maps

The ASA can use an LDAP directory for authenticating VPN remote access users or firewall network access/cut-through-proxy sessions and/or for setting policy permissions (also called authorization attributes), such as ACLs, bookmark lists, DNS or WINS settings, session timers, and so on. That is, you can set the key attributes that exist in a local group policy externally through an LDAP server.

The authorization process is accomplished by means of LDAP attribute maps (similar to a RADIUS dictionary that defines vendor-specific attributes), which translate the native LDAP user attributes to Cisco ASA attribute names. You can then bind these attribute maps to LDAP servers or remove them, as needed. You can also show or clear attribute maps.

Guidelines

The ldap-attribute-map has a limitation with multi-valued attributes. For example, if a user is a memberOf of several AD groups and the ldap attribute map matches on more than one of them, the mapped value is chosen based on the alphabetization of the matched entries.

To use the attribute mapping features correctly, you need to understand Cisco LDAP attribute names and values, as well as the user-defined attribute names and values. For more information about LDAP attribute maps, see the "Active Directory/LDAP VPN Remote Access Authorization Examples" section on page B-15.

The names of frequently mapped Cisco LDAP attributes and the type of user-defined attributes that they would commonly be mapped to include the following:

- IETF-Radius-Class (Group_Policy in ASA version 8.2 and later)—Sets the group policy based on the directory's department or user group (for example, Microsoft Active Directory memberOf) attribute value. The group-policy attribute replaced the IETF-Radius-Class attribute with ASDM version 6.2/ASA version 8.2 or later.
- IETF-Radius-Filter-Id—An access control list or ACL applied to VPN clients, IPsec, and SSL.
- IETF-Radius-Framed-IP-Address—Assigns a static IP address assigned to a VPN remote access client, IPsec, and SSL.
- Banner1—Displays a text banner when the VPN remote access user logs in.
- Tunneling-Protocols—Allows or denies the VPN remote access session based on the access type.

Note A single ldap attribute map may contain one or many attributes. You can only assign one ldap attribute to a specific LDAP server.

To map LDAP features correctly, perform the following steps:

Detailed Steps

Step 1 Choose **Configuration > Remote Access VPN > AAA Local Users > LDAP Attribute Map**, and then click **Add**.

The Add LDAP Attribute Map dialog box appears with the Map Name tab active.

Step 2 In the Name field, add a name for the map.

Step 3 In the Customer Name field, add the name of the corresponding attribute of your organization.

Step 4 From the Cisco Name drop-down list, choose an attribute.

Step 5 Click **Add**.

Step 6 To add more names, repeat Steps 1 through 5.

Step 7 To map the customer names, click the **Map Value** tab.

Step 8 Click **Add**.

The Add LDAP Attributes Map Value dialog box appears.

Step 9 Choose the attribute from the Customer Name drop-down list.

Step 10 In the Customer Value field, add the value for this attribute.

Step 11 In the Cisco Value field, add the Cisco value to which the value specified in the previous step maps.

Step 12 Click **Add**.

The values are mapped.

Step 13 To map more names, repeat Steps 8 through 12.

Step 14 Click **OK** to return to the Map Value tab, and then click **OK** again to close the dialog box.

Step 15 In the LDAP Attribute Map pane, click **Apply**.

The value mappings are saved to the running configuration.

Adding a User Account to the Local Database

This section describes how to manage users in the local database.

This section includes the following topics:

- Adding a User, page 46-21
- Configuring VPN Policy Attributes for a User, page 46-23

Adding a User

To add a user to the local database, perform the following steps:

To add a user to the local database, perform the following steps:

Guidelines

The local database is used for the following features:

- ASDM per-user access

  By default, you can log into ASDM with a blank username and the enable password (see the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1). However, if you enter a username and password at the login screen (instead of leaving the username blank), ASDM checks the local database for a match.
- Console authentication
- Telnet and SSH authentication.
- **enable** command authentication

  This setting is for CLI-access only and does not affect the ASDM login.
- Command authorization

  If you turn on command authorization using the local database, then the ASA refers to the user privilege level to determine which commands are available. Otherwise, the privilege level is not generally used. By default, all commands are either privilege level 0 or level 15. ASDM allows you to enable three predefined privilege levels, with commands assigned to level 15 (Admin), level 5 (Read Only), and level 3 (Monitor Only). If you use the predefined levels, then assign users to one of these three privilege levels.
- Network access authentication
- VPN client authentication

For multiple context mode, you can configure usernames in the system execution space to provide individual logins at the CLI using the **login** command; however, you cannot configure any AAA rules that use the local database in the system execution space.

Limitations

You cannot use the local database for network access authorization.

Detailed Steps

Step 1 Choose **Configuration > Device Management > Users/AAA > User Accounts**, and then click **Add**.

The Add User Account-Identity dialog box appears.

Step 2 In the Username field, enter a username from 4 to 64 characters long.

Step 3 In the Password field, enter a password between 3 and 32 characters. Passwords are case-sensitive. The field displays only asterisks. To protect security, we recommend a password length of at least 8 characters.

Note To configure the enable password from the User Accounts pane (see the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1), change the password for the enable_15 user. The enable_15 user is always present in the User Accounts pane, and represents the default username. This method of configuring the enable password is the only method available in ASDM for the system configuration. If you configured other enable level passwords at the CLI (**enable password 10**, for example), then those users are listed as enable_10, and so on.

Step 4 In the Confirm Password field, reenter the password.

For security purposes, only asterisks appear in the password fields.

Step 5 To enable MS-CHAP authentication, check the **User authenticated using MSCHAP** check box.

This option specifies that the password is converted to Unicode and hashed using MD4 after you enter it. Use this feature if users are authenticated using MS-CHAPv1 or MS-CHAPv2.

Step 6 To specify the VPN groups that the user belongs to, enter a group name in the Member of field, and click **Add**.

To delete a VPN group, choose the group in the window, and click **Delete**.

Step 7 In the Access Restriction area, set the management access level for a user. You must first enable management authorization by clicking the **Perform authorization for exec shell access** option on the Configuration > Device Management > Users/AAA > AAA Access > Authorization tab.

Choose one of the following options:

- **Full Access (ASDM, Telnet, SSH and console)**—If you configure authentication for management access using the local database (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20), then this option lets the user use ASDM, SSH, Telnet, and the console port. If you also enable authentication, then the user can access global configuration mode.
  - **Privilege Level**—Selects the privilege level for this user to use with local command authorization. The range is 0 (lowest) to 15 (highest). See the "Configuring Command Authorization" section on page 52-23 for more information.
- **CLI login prompt for SSH, Telnet and console (no ASDM access)**—If you configure authentication for management access using the local database (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20), then this option lets the user use SSH, Telnet, and the console port. The user cannot use ASDM for configuration (if you configure HTTP authentication). ASDM monitoring is allowed. If you also configure enable authentication, then the user cannot access global configuration mode.
- **No ASDM, SSH, Telnet, or console access**—If you configure authentication for management access using the local database (see the "Configuring Authentication for CLI, ASDM, and enable command Access" section on page 52-20), then this option disallows the user from accessing any management access method for which you configured authentication (excluding the Serial option; serial access is allowed).

Step 8 If you want to configure VPN policy attributes for this user, see the "Configuring VPN Policy Attributes for a User" section on page 46-23.

Step 9 Click **Apply**.

The user is added to the local ASA database, and the changes are saved to the running configuration.

Tip You can search for specific text in each column of the Configuration > Device Management > Users/AAA > User Accounts pane. Enter the specific text that you want to locate in the Find box, then click the **Up** or **Down** arrow. You can also use the asterisk ("*") and question mark ("?") as wild card characters in the text search.

Configuring VPN Policy Attributes for a User

Prerequisites

This procedure describes how to edit an existing user. To add a user select **Configuration > Remote Access VPN > AAA/Local Users > Local Users** and click **Add**. For more information see "Adding a User Account to the Local Database" section on page 46-20.

Guidelines

By default, the **Inherit** check box is checked for each setting on the Edit User Account screen, which means that the user account inherits the value of that setting from the default group policy, DfltGrpPolicy.

To override each setting, uncheck the **Inherit** check box, and enter a new value. The detailed steps that follow describe each of the settings on the Edit User Account screen.

Detailed Steps

Step 1 Start ASDM and select **Configuration > Remote Access VPN > AAA/Local Users > Local Users**.

Step 2 Select the user you want configure and click **Edit**.

The Edit User Account screen opens.

Step 3 In the left-hand pane, click **VPN Policy**.

Step 4 Specify a group policy for the user. The user policy will inherit the attributes of this group policy. If there are other fields on this screen that are set to **Inherit** the configuration from the Default Group Policy, the attributes specified in this group policy will take precedence over those set in the Default Group Policy.

Step 5 Specify which tunneling protocols are available for the user, or whether the value is inherited from the group policy. Check the desired **Tunneling Protocols** check boxes to choose the VPN tunneling protocols that are available for use. Only the selected protocols are available for use. The choices are as follows:

- Clientless SSL VPN (VPN via SSL/TLS) uses a web browser to establish a secure remote-access tunnel to a VPN Concentrator; requires neither a software nor hardware client. Clientless SSL VPN can provide easy access to a broad range of enterprise resources, including corporate websites, web-enabled applications, NT/AD file shares (web-enabled), e-mail, and other TCP-based applications from almost any computer that can reach HTTPS Internet sites.
- The SSL VPN Client lets users connect after downloading the Cisco AnyConnect Client application. Users use a clientless SSL VPN connection to download this application the first time. Client updates then occur automatically as needed whenever the user connects.

- IPsec IKEv1—IP Security Protocol. Regarded as the most secure protocol, IPsec provides the most complete architecture for VPN tunnels. Both Site-to-Site (peer-to-peer) connections and Cisco VPN client-to-LAN connections can use IPsec IKEv1.
- IPsec IKEv2—Supported by the AnyConnect Secure Mobility Client. AnyConnect connections using IPsec with IKEv2 provide advanced features such as software updates, client profiles, GUI localization (translation) and customization, Cisco Secure Desktop, and SCEP proxy.
- L2TP over IPsec allows remote users with VPN clients provided with several common PC and mobile PC operating systems to establish secure connections over the public IP network to the ASA and private corporate networks.

Note If no protocol is selected, an error message appears.

Step 6 Specify which filter (IPv4 or IPv6) to use, or whether to inherit the value from the group policy. Filters consist of rules that determine whether to allow or reject tunneled data packets coming through the ASA, based on criteria such as source address, destination address, and protocol. To configure filters and rules, choose **Configuration > Remote Access VPN > Network (Client) Access > Group Policies > Add/Edit > General > More Options > Filter.**

Click **Manage** to display the ACL Manager pane, on which you can add, edit, and delete ACLs and ACEs.

Step 7 Specify whether to inherit the Connection Profile (tunnel group) lock or to use the selected tunnel group lock, if any. Selecting a specific lock restricts users to remote access through this group only. Tunnel Group Lock restricts users by checking if the group configured in the VPN client is the same as the users assigned group. If it is not, the ASA prevents the user from connecting. If the Inherit check box is not checked, the default value is None.

Step 8 Specify whether to inherit the Store Password on Client System setting from the group. Uncheck the **Inherit** check box to activate the Yes and No radio buttons. Click **Yes** to store the login password on the client system (potentially a less-secure option). Click **No** (the default) to require the user to enter the password with each connection. For maximum security, we recommend that you *not allow* password storage. This parameter has no effect on interactive hardware client authentication or individual user authentication for a VPN 3002.

Step 9 Specify an Access Hours policy to apply to this user, create a new access hours policy for the user, or leave the Inherit box checked. The default value is Inherit, or, if the Inherit check box is not checked, the default value is Unrestricted.

Click **Manage** to open the Add Time Range dialog box, in which you can specify a new set of access hours.

Step 10 Specify the number of simultaneous logins by the user. The Simultaneous Logins parameter specifies the maximum number of simultaneous logins allowed for this user. The default value is 3. The minimum value is 0, which disables login and prevents user access.

Note While there is no maximum limit, allowing several simultaneous connections could compromise security and affect performance.

Step 11 Specify the **maximum connection time** for the user connection time in minutes. At the end of this time, the system terminates the connection. The minimum is 1 minute, and the maximum is 2147483647 minutes (over 4000 years, should we all be so lucky). To allow unlimited connection time, check the **Unlimited** check box (the default).

Step 12 Specify the Idle Timeout for the user in minutes. If there is no communication activity on the connection by this user in this period, the system terminates the connection. The minimum time is 1 minute, and the maximum time is 10080 minutes. This value does not apply to users of clientless SSL VPN connections.

Step 13 Configure the Session Alert Interval. If you uncheck the Inherit check box, the Default check box is checked automatically. This sets the session alert interval to 30 minutes. If you want to specify a new value, uncheck the Default check box and specify a session alert interval from 1 to 30 minutes in the minutes box.

Step 14 Configure the Idle Alert Interval. If you uncheck the Inherit check box, the Default check box is checked automatically. This sets the idle alert interval to 30 minutes. If you want to specify a new value, uncheck the Default check box and specify a session alert interval from 1 to 30 minutes in the minutes box.

Step 15 To set a dedicated IPv4 address for this user, enter an IPv4 address and subnet mask in the Dedicated IPv4 Address (Optional) area.

Step 16 To set a dedicated IPv6 address for this user, enter an IPv6 address with an IPv6 prefix in the Dedicated IPv6 Address (Optional) field. The IPv6 prefix indicates the subnet on which the IPv6 address resides.

Step 17 To configure clientless SSL settings, in the left-hand pane, click **Clientless SSL VPN**. To override each setting, uncheck the **Inherit** check box, and enter a new value.

Step 18 Click **Apply**.

The changes are saved to the running configuration.

Authenticating Users with a Public Key for SSH

Users can authenticate with a public key for SSH. The public key can be hashed or not hashed.

To authenticate with a public key for SSH, perform the following steps:

Step 1 In the ASDM main application window, choose **Configuration > Device Management > Users/AAA > User Accounts**.

Step 2 Select a user from the list, then click **Edit**.

The Edit User Account dialog box appears.

Step 3 Click **Public Key Authentication** in the navigation pane.

Step 4 If you want to hash the public key, check the **Key is hashed** check box. To not have the public key hashed, leave this check box unchecked.

If the public key is hashed, the value of the public key must have been previously hashed with SHA-256 and be 32 bytes long, with each byte separated by a colon (for parsing purposes).

If the public key is not hashed, the value of the key must be a Base 64 encoded public key that is generated by SSH key generation software that can generate SSH-RSA raw keys (that is, with no certificates). After you submit the Base 64 encoded public key, that key is then hashed via SHA-256 and the corresponding 32-byte hash is used for all further comparisons.

Step 5 Enter the public key.

Step 6 Click **OK**.

Step 7 Click **Apply** to save the configuration changes.

Adding an Authentication Prompt

You can specify text to display to the user during the AAA authentication challenge process. You can specify the AAA challenge text for HTTP, FTP, and Telnet access through the ASA when requiring user authentication from TACACS+ or RADIUS servers. This text is primarily for cosmetic purposes and appears above the username and password prompts that users see when they log in.

If you do not specify an authentication prompt, users see the following when authenticating with a RADIUS or TACACS+ server:

Connection Type	Default Prompt
FTP	FTP authentication
HTTP	HTTP Authentication
Telnet	None

To add an authentication prompt, perform the following steps:

Step 1 From the Configuration > Device Management > Users/AAA > Authentication Prompt pane, enter text in the Prompt field to add as a message to appear above the username and password prompts that users see when they log in.

The following table shows the allowed character limits for authentication prompts:

Application	Character Limit for Authentication Prompt
Microsoft Internet Explorer	37
Telnet	235
FTP	235

Step 2 In the Messages area, add messages in the User accepted message and User rejected message fields.

If the user authentication occurs from Telnet, you can use the User accepted message and User rejected message options to display different status prompts to indicate that the authentication attempt is accepted or rejected by the AAA server.

If the AAA server authenticates the user, the ASA displays the User accepted message text, if specified, to the user; otherwise, the ASA displays the User rejected message text, if specified. Authentication of HTTP and FTP sessions displays only the challenge text at the prompt. The User accepted message and User rejected message text are not displayed.

Step 3 Click **Apply**.

The changes are saved to the running configuration.

Testing Server Authentication and Authorization

To determine whether the ASA can contact an AAA server and authenticate or authorize a user, perform the following steps:

Step 1 From the Configuration > Device Management > Users/AAA > AAA Server Groups > AAA Server Groups table, click the server group in which the server resides.

The row is highlighted in the table.

Step 2 From the Servers in the Selected Group table, click the server that you want to test.

The row is highlighted in the table.

Step 3 Click **Test**.

The Test AAA Server dialog box appears for the selected server.

Step 4 Click the type of test that you want to perform—**Authentication** or **Authorization**.

Step 5 In the Username field, enter a username.

Step 6 If you are testing authentication, in the Password field, enter the password for the username.

Step 7 Click **OK**.

The ASA sends an authentication or authorization test message to the server. If the test fails, ASDM displays an error message.

Monitoring AAA Servers

To monitor AAA servers, see the following panes:

Path	Purpose
Monitoring > Properties > AAA Servers	Shows the configured AAA server statistics.
Monitoring > Properties > AAA Servers	Shows the AAA server running configuration.
Choose **Tools > Command Line Interface**, enter the **show running-config all ldap attribute-map** command, then press **Send**.	Shows all LDAP attribute maps in the running configuration.
Choose **Tools > Command Line Interface**, enter the **show running-config zonelabs-integrity** command, then press **Send**.	Shows the Zone Labs Integrity server configuration.
Choose **Tools > Command Line Interface**, enter the **show ad-groups** *name* [**filter** *string*] command, then press **Send**.	Applies only to AD servers using LDAP, and shows groups that are listed on an AD server.

Additional References

For additional information related to implementing LDAP mapping, see the "RFCs" section on page 46-28.

RFCs

RFC	Title
2138	*Remote Authentication Dial In User Service (RADIUS)*
2139	*RADIUS Accounting*
2548	*Microsoft Vendor-specific RADIUS Attributes*
2868	*RADIUS Attributes for Tunnel Protocol Support*

Feature History for AAA Servers

Table 46-2 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 46-2 Feature History for AAA Servers

Feature Name	Platform Releases	Feature Information
AAA Servers	7.0(1)	AAA Servers describe support for AAA and how to configure AAA servers and the local database. We introduced the following screens: Configuration > Device Management > Users/AAA > AAA Server Groups Configuration > Remote Access VPN > AAA Local Users > LDAP Attribute Map Configuration > Device Management > Users/AAA > User Accounts Configuration > Device Management > Users/AAA > Authentication Prompt
Key vendor-specific attributes (VSAs) sent in RADIUS access request and accounting request packets from the ASA	8.4(3)	Four New VSAs—Tunnel Group Name (146) and Client Type (150) are sent in RADIUS access request packets from the ASA. Session Type (151) and Session Subtype (152) are sent in RADIUS accounting request packets from the ASA. All four attributes are sent for all accounting request packet types: Start, Interim-Update, and Stop. The RADIUS server (for example, ACS and ISE) can then enforce authorization and policy attributes or use them for accounting and billing purposes.

Configuring the Identity Firewall

This chapter describes how to configure the ASA for the Identity Firewall. The chapter includes the following sections:

- Information About the Identity Firewall, page 47-1
- Licensing for the Identity Firewall, page 47-7
- Guidelines and Limitations, page 47-7
- Prerequisites, page 47-8
- Configuring the Identity Firewall, page 47-9
- Monitoring the Identity Firewall, page 47-16
- Feature History for the Identity Firewall, page 47-18

Information About the Identity Firewall

This section includes the following topics:

- Overview of the Identity Firewall, page 47-1
- Architecture for Identity Firewall Deployments, page 47-2
- Features of the Identity Firewall, page 47-3
- Deployment Scenarios, page 47-4

Overview of the Identity Firewall

In an enterprise, users often need access to one or more server resources. Typically, a firewall is not aware of the users' identities and, therefore, cannot apply security policies based on identity. To configure per-user access policies, you must configure a user authentication proxy, which requires user interaction (a user name/password query).

The Identity Firewall in the ASA provides more granular access control based on users' identities. You can configure access rules and security policies based on user names and user groups name rather than through source IP addresses. The ASA applies the security policies based on an association of IP addresses to Windows Active Directory login information and reports events based on the mapped user names instead of network IP addresses.

The Identity Firewall integrates with Microsoft Active Directory in conjunction with an external Active Directory (AD) Agent that provides the actual identity mapping. The ASA uses Windows Active Directory as the source to retrieve the current user identity information for specific IP addresses and allows transparent authentication for Active Directory users.

Identity-based firewall services enhance the existing access control and security policy mechanisms by allowing users or groups to be specified in place of source IP addresses. Identity-based security policies can be interleaved without restriction between traditional IP address based rules.

The key benefits of the Identity Firewall include:

- Decoupling network topology from security policies
- Simplifying the creation of security policies
- Providing the ability to easily identify user activities on network resources
- Simplify user activity monitoring

Architecture for Identity Firewall Deployments

The Identity Firewall integrates with Window Active Directory in conjunction with an external Active Directory (AD) Agent that provides the actual identity mapping.

The identity firewall consists of three components:

- **ASA**
- **Microsoft Active Directory**

  Though Active Directory is part of the Identity Firewall on the ASA, they are managed by Active Directory administrators. The reliability and accuracy of the data depends on data in Active Directory.

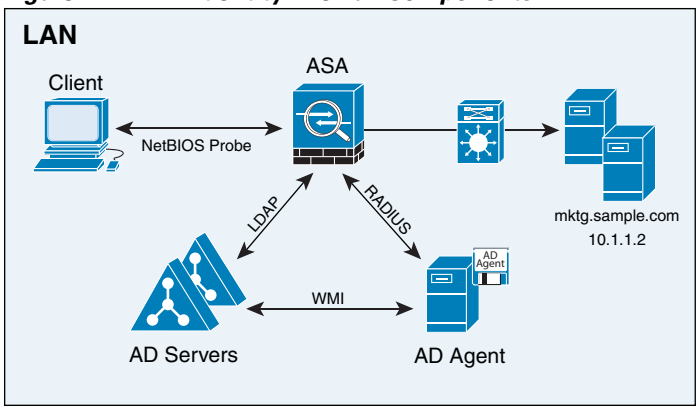
  Supported versions include Windows Server 2003, Windows Server 2008, and Windows Server 2008 R2 servers.

- **Active Directory (AD) Agent**

  The AD Agent runs on a Windows server. Supported Windows servers include Windows 2003, Windows 2008, and Windows 2008 R2.

Note Windows 2003 R2 is not supported for the AD Agent server.

Figure 47-1 Identity Firewall Components



1	**On the ASA**: Configure local user groups and Identity Firewall policies.	**4**	**Client <-> ASA**: The client logs onto the network through Microsoft Active Directory. The AD Server authenticates users and generates user logon security logs. Alternatively, the client can log onto the network through a cut-through proxy or by using VPN.
2	**ASA <-> AD Server**: The ASA sends an LDAP query for the Active Directory groups configured on the AD Server. The ASA consolidates local and Active Directory groups and applies access rules and MPF security policies based on user identity.	**5**	**ASA <-> Client**: Based on the policies configured on the ASA, it grants or denies access to the client. If configured, the ASA probes the NetBIOS of the client to pass inactive and no-response users.
3	**ASA <-> AD Agent**: Depending on the Identity Firewall configuration, the ASA downloads the IP-user database or sends a RADIUS request to the AD Agent querying the user's IP address. The ASA forwards the new mappings learned from web authentication and VPN sessions to the AD Agent.	**6**	**AD Agent <-> AD Server**: Periodically or on-demand, the AD Agent monitors the AD Server security event log file via WMI for client login and logoff events. The AD Agent maintains a cache of user ID and IP address mappings. and notifies the ASA of changes. The AD Agent sends logs to a syslog server.

Features of the Identity Firewall

The Identity Firewall has the following key features.

Flexibility

- The ASA can retrieve user identity and IP address mappings from the AD Agent by querying the AD Agent for each new IP address or by maintaining a local copy of the entire user identity and IP address database.
- Supports host group, subnet, or IP address for the destination of a user identity policy.
- Supports a fully qualified domain name (FQDN) for the source and destination of a user identity policy.

- Supports the combination of 5-tuple policies with ID-based policies. The identity-based feature works in tandem with existing 5-tuple solution.
- Supports usage with IPS and Application Inspection policies.
- Retrieves user identity information from remote access VPN, AnyConnect VPN, L2TP VPN and cut-through proxy. All retrieved users are populated to all ASA devices connected to the AD Agent.

Scalability

- Each AD Agent supports 100 ASA devices. Multiple ASA devices are able to communicate with a single AD Agent to provide scalability in larger network deployments.
- Supports 30 Active Directory servers provided the IP address is unique among all domains.
- Each user identity in a domain can have up to 8 IP addresses.
- Supports up to 64,000 user identity-IP address mappings in active ASA policies for ASA 5500 Series models. This limit controls the maximum users who have policies applied. The total users are the aggregated users configured on all different contexts.
- Supports up to 1024 user identity-IP address mappings in active ASA policies for the ASA 5505.
- Supports up to 256 user groups in active ASA policies.
- A single rule can contain one or more user groups or users.
- Supports multiple domains.

Availability

- The ASA retrieves group information from Active Directory and falls back to web authentication for IP addresses that the AD Agent cannot map a source IP address to a user identity.
- The AD Agent continues to function when any of the Active Directory servers or the ASA are not responding.
- Supports configuring a primary AD Agent and a secondary AD Agent on the ASA. If the primary AD Agent stops responding, the ASA can switch to the secondary AD Agent.
- If the AD Agent is unavailable, the ASA can fall back to existing identity sources such as cut through proxy and VPN authentication.
- The AD Agent runs a watchdog process that automatically restarts its services when they are down.
- Allows a distributed IP address/user mapping database among ASA devices.

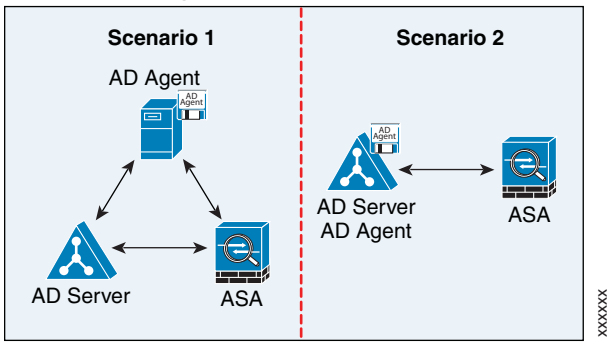
Deployment Scenarios

You can deploy the components of the Identity Firewall in the following ways depending on your environmental requirement.

As shown in Figure 47-2, you can deploy the components of the Identity Firewall to allow for redundancy. Scenario 1 shows a simple installation without component redundancy.

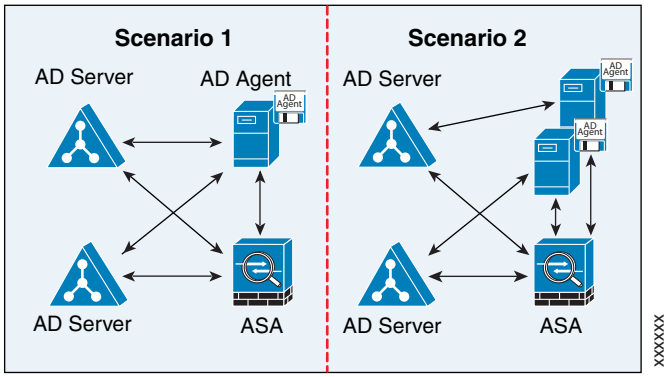
Scenario 2 also shows a simple installation without redundancy. However, in that deployment scenario, the Active Directory server and AD Agent are co-located on one Windows server.

Figure 47-2 Deployment Scenario without Redundancy



As shown in Figure 47-3, you can deploy the Identity Firewall components to support redundancy. Scenario 1 shows a deployment with multiple Active Directory servers and a single AD Agent installed on a separate Windows server. Scenario 2 shows a deployment with multiple Active Directory servers and multiple AD Agents installed on separate Windows servers.

Figure 47-3 Deployment Scenario with Redundant Components



As shown in Figure 47-4, all Identity Firewall components—Active Directory server, the AD Agent, and the clients—are installed and communicate on the LAN.

Figure 47-4 LAN -based Deployment

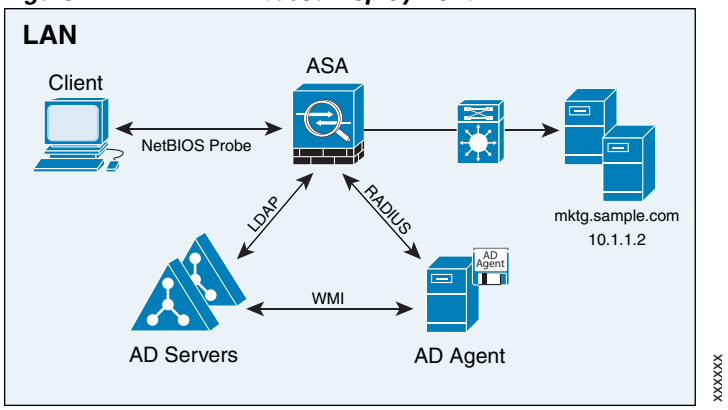


Figure 47-5 shows a WAN-based deployment to support a remote site. The Active Directory server and the AD Agent are installed on the main site LAN. The clients are located at a remote site and connect to the Identity Firewall components over a WAN.

Figure 47-5 WAN-based Deployment

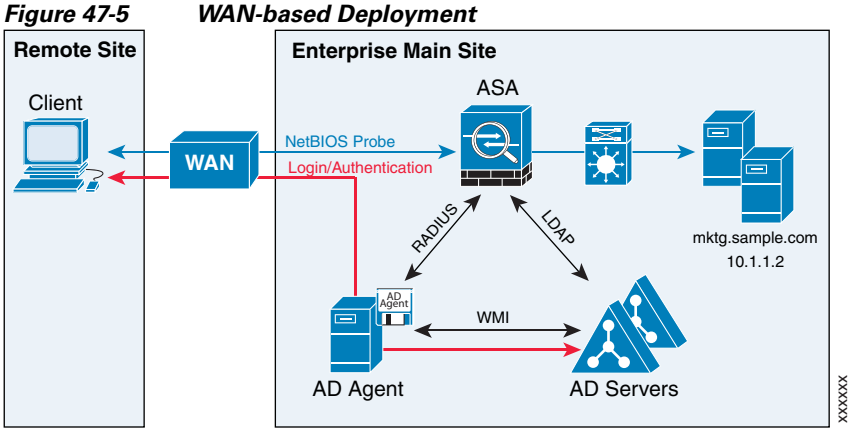

Figure 47-6 also shows a WAN-based deployment to support a remote site. The Active Directory server is installed on the main site LAN. However, the AD Agent is installed and access by the clients at the remote site. The remote clients connect to the Active Directory servers at the main site over a WAN.

Figure 47-6 WAN-based Deployment with Remote AD Agent

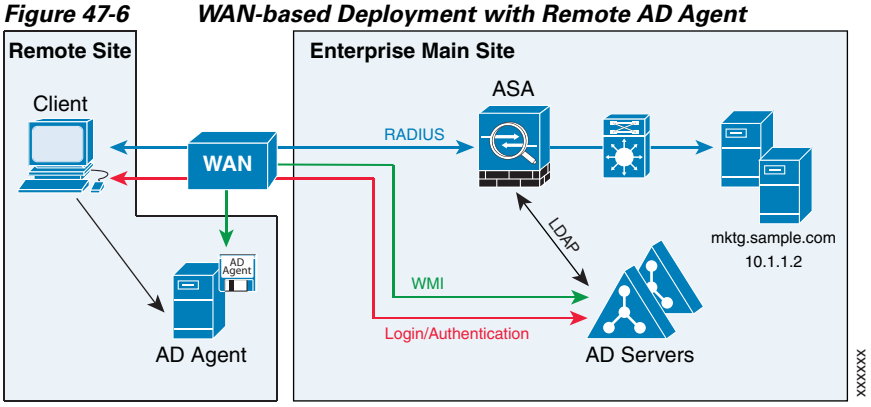

Figure 47-7 shows an expanded remote site installation. An AD Agent and Active Directory servers are installed at the remote site. The clients access these components locally when logging into network resources located at the main site. The remote Active Directory server must synchronize its data with the central Active Directory servers located at the main site.

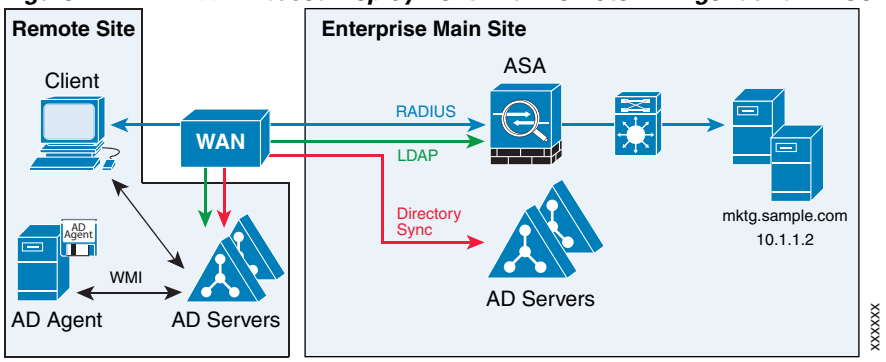
Figure 47-7 WAN-based Deployment with Remote AD Agent and AD Servers



Licensing for the Identity Firewall

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall modes.

Failover Guidelines

The Identity Firewall supports user identity-IP address mappings and AD Agent status replication from active to standby when stateful failover is enabled. However, only user identity-IP address mappings, AD Agent status, and domain status are replicated. User and user group records are not replicated to the standby ASA.

When failover is configured, the standby ASA must also be configured to connect to the AD Agent directly to retrieve user groups. The standby ASA does not send NetBIOS packets to clients even when the NetBIOS probing options are configured for the Identity Firewall.

When a client is determined as inactive by the active ASA, the information is propagated to the standby ASA. User statistics are not propagated to the standby ASA.

When you have failover configured, you must configure the AD Agent to communicate with both the active and standby ASA devices. See the *Installation and Setup Guide for the Active Directory Agent* for the steps to configure the ASA on the AD Agent server.

IPv6 Guidelines

- Supports IPv6.

  The AD Agent supports endpoints with IPv6 addresses. It can receive IPv6 addresses in log events, maintain them in its cache, and send them through RADIUS messages.

- NetBIOS over IPv6 is not supported

Additional Guidelines and Limitations

- A full URL as a destination address is not supported.
- For NetBIOS probing to function, the network between the ASA, AD Agent, and clients must support UDP-encapsulated NetBIOS traffic.
- MAC address checking by the Identity Firewall does not work when intervening routers are present. Users logged onto clients that are behind the same router have the same MAC addresses. With this implementation, all the packets from the same router are able to pass the check, because the ASA is unable to ascertain to the actual MAC addresses behind the router.
- The following ASA features do not support using the identity-based object and FQDN in an extended ACL:
  - route-map
  - Crypto map
  - WCCP
  - NAT
  - group-policy (except VPN filter)
  - DAP

Prerequisites

Before configuring the Identity Firewall in the ASA, you must meet the prerequisites for the AD Agent and Microsoft Active Directory.

AD Agent

The AD Agent must be installed on a Windows server that is accessible to the ASA. Additionally, you must configure the AD Agent to obtain information from the Active Directory servers. Configure the AD Agent to communicate with the ASA.

Supported Windows servers include Windows 2003, Windows 2008, and Windows 2008 R2.

Note Windows 2003 R2 is not supported for the AD Agent server.

For the steps to install and configure the AD Agent, see the *Installation and Setup Guide for the Active Directory Agent*.

Before configuring the AD Agent in the ASA, obtain the secret key value that the AD Agent and the ASA use to communicate. This value must match on both the AD Agent and the ASA.

Microsoft Active Directory

Microsoft Active Directory must be installed on a Windows server and accessible by the ASA. Supported versions include Windows 2003, 2008, and 2008 R2 servers.

Before configuring the Active Directory server on the ASA, create a user account in Active Directory for the ASA.

Additionally, the ASA sends encrypted log in information to the Active Directory server by using SSL enabled over LDAP. SSL must be enabled on the Active Directory server. See the documentation for Microsft Active Diretory for the steps to enable SSL for Active Directory.

Note Before running the AD Agent Installer, you must install the following patches on every Microsoft Active Directory server that the AD Agent monitors. These patches are required even when the AD Agent is installed directly on the domain controller server. See the *README First for the Cisco Active Directory Agent*.

Configuring the Identity Firewall

This section contains the following topic:

- Task Flow for Configuring the Identity Firewall, page 47-9
- Configuring the Active Directory Domain, page 47-10
- Configuring Active Directory Server Groups, page 47-10
- Configuring Active Directory Server Groups, page 47-10
- Configuring Active Directory Agent Groups, page 47-12
- Configuring Identity Options, page 47-12
- Configuring Identity-Based Security Policy, page 47-15

Task Flow for Configuring the Identity Firewall

To configure the Identity Firewall, perform the following tasks:

Step 1 Configure the Active Directory domain in the ASA.

See Configuring the Active Directory Domain, page 47-10 and Configuring Active Directory Server Groups, page 47-10.

See also Deployment Scenarios, page 47-4 for the ways in which you can deploy the Active Directory servers to meet your environment requirements.

Step 2 Configure the AD Agent in ASA.

See Configuring Active Directory Server Groups, page 47-10 and Configuring Active Directory Agent Groups, page 47-12.

See also Deployment Scenarios, page 47-4 for the ways in which you can deploy the AD Agents to meet your environment requirements.

Step 3 Configure Identity Options.

See Configuring Identity Options, page 47-12.

Step 4 Configure Identity-based Security Policy.

After AD domain and AD-Agent are configured, you can create identity-based object groups and ACLs for use in many features. See Configuring Identity-Based Security Policy, page 47-15.

Configuring the Active Directory Domain

Active Directory domain configuration on the ASA is required for the ASA to download Active Directory groups and accept user identities from specific domains when receiving IP-user mapping from the AD Agent.

Prerequisites

- Active Directory server IP address
- Distinguished Name for LDAP base dn
- Distinguished Name and password for the Active Directory user that the Identity Firewall uses to connect to the Active Directory domain controller

To configure the Active Directory domain, perform the following steps:

Step 1 Choose **Configuration > Firewall > Identity Options**. The Identity Options pane appears.

Step 2 If necessary, check the Enable User Identity check box to enable the feature.

Step 3 In the Domains section, click **Add** or select a domain from the list and click **Edit**. The Domain dialog box appears.

Step 4 In the Domain NETBIOS Name field, enter a name up to 32 characters consisting of [a-z], [A-Z], [0-9], [!@#$%^&()-_=+[]{};,.] except '.' and ' ' at the first character. If the domain name contains a space, you must enclose that space character in quotation marks. The domain name is not case sensitive.

When you edit the name of an existing domain, the domain name associated with existing users and user groups is not changed.

Step 5 From the AD Server Group list, select the Active Directory servers to associate with this domain or click **Manage** to add a new server group to the list. See Configuring Active Directory Server Groups, page 47-10.

Step 6 Click **OK** to save the domain settings.

What to Do Next

Configure Active Directory server groups. See Configuring Active Directory Server Groups, page 47-10.

Configure AD Agents. See Configuring Active Directory Server Groups, page 47-10 and Configuring Active Directory Agent Groups, page 47-12.

Configuring Active Directory Server Groups

To configure the Active Directory server group, perform the following steps:

Step 1 Choose **Configuration > Firewall > Identity Options > Add > Manage**. The Configure Active Directory Server Groups dialog appears.

Step 2 To add an Active Directory server group for the Identify Firewall, click **Add** for the Active Directory Server Groups table. The Add Active Directory Server Group dialog box appears. See the "Configuring AAA Server Groups" section on page 46-11.

Step 3 To add servers to an Active Directory server group, select the group from the Active Directory Server Groups list and click **Add** for the Servers in the Selected Group table. The Add Active Directory Server dialog box appears. See the "Adding a Server to a Group" section on page 46-12.

Step 4 Click **OK** to save the settings.

What to Do Next

Configure AD Agents. See Configuring Active Directory Agents, page 47-11 and Configuring Active Directory Agent Groups, page 47-12.

Configuring Active Directory Agents

Periodically or on-demand, the AD Agent monitors the Active Directory server security event log file via WMI for user login and logoff events. The AD Agent maintains a cache of user ID and IP address mappings. and notifies the ASA of changes.

Requirement

- AD agent IP address
- Shared secret between ASA and AD agent

To configure the AD Agents, perform the following steps:

Step 1 Open the **Configuration > Firewall > Identity Options** pane.

Step 2 If necessary, check the Enable User Identity check box to enable the feature.

Step 3 In the Active Directory Agent section, click **Manage**.

The Configure Active Directory Agents dialog box appears.

Step 4 To add an AD Agent, click the **Add** button.

OR

Select an agent group from the list and click **Edit**.

See Configuring Active Directory Agent Groups, page 47-12.

Step 5 Click **OK** to save your changes.

What to Do Next

Configure AD Agent groups. See Configuring Active Directory Agent Groups, page 47-12.

Configure access rules for the Identity Firewall. See Configuring Identity-Based Security Policy, page 47-15.

Configuring Active Directory Agent Groups

Configure the primary and secondary AD Agents for the AD Agent Server Group. When the ASA detects that the primary AD Agent is not responding and a secondary agent is specified, the ASA switches to secondary AD Agent. The Active Directory server for the AD agent uses RADIUS as the communication protocol; therefore, you should specify a key attribute for the shared secret between ASA and AD Agent.

To configure the AD Agent Groups, perform the following steps:

Step 1 From the Configure Active Directory Agents dialog, click **Add**. The Add Active Directory Agent Group dialog box appears.

Step 2 Enter a name for the AD Agent group.

Step 3 From the Primary Active Directory Agent section, specify the interface on which the ASA listens for traffic from the AD Agent server, and enter the FQDN of the server or IP address.

Step 4 In the Primary Active Directory Agent section, enter a timeout interval and the retry interval for the attempts that the ASA will continue to contact the AD Agent when it is not responding.

Step 5 Enter the shared secret key that is used between primary AD Agent and the ASA.

Step 6 From the Secondary Active Directory Agent section, specify the interface on which the ASA listens for traffic from the AD Agent server, and enter the FQDN of the server or IP address.

Step 7 In the Secondary Active Directory Agent section, enter a timeout interval and the retry interval for the the attempts that the ASA will continue to contact the AD Agent when it is not responding.

Step 8 Enter the shared secret key that is used between secondary AD Agent and the ASA.

Step 9 Click **OK** to save your changes.

What to Do Next

Configure access rules for the Identity Firewall. See Configuring Identity-Based Security Policy, page 47-15.

Configuring Identity Options

Use this pane to add or edit the Identity Firewall feature; select the Enable check box to enable the feature. By default, the Identity Firewall feature is disabled.

Prerequisites

Before configuring the identify options for the Identity Firewall, you must you must meet the prerequisites for the AD Agent and Microsoft Active Directory. See Prerequisites, page 47-8 the requirements for the AD Agent and Microsoft Active Directory installation.

To configure the Identity Options for the Identity Firewall, perform the following steps:

Step 1 Choose **Configuration > Firewall > Identity Options**. The Identity Option pane appears.

Step 2 If necessary, check the Enable User Identity check box to enable the feature.

Step 3 To add a domain for the Identity Firewall, click **Add** by the Domains table. The Add Domain dialog box appears. See Configuring the Active Directory Domain, page 47-10.

Step 4 For domains already been added to the Domains list, check whether to disable rules when the domain is down because the Active Directory domain controller is not responding.

When a domain is down and this option is checked for that domain, the ASA disables the user identity rules associated with the users in that domain. Additionally, the status of all user IP addresses in that domain are marked as disabled in the **Monitoring > Properties > Identity > Users** pane.

Step 5 From the Default Domain drop-down list, select the default domain for the Identity Firewall.

The default domain is used for all users and user groups when a domain has not been explicitly configured for those users or groups. When a default domain is not specified, the default domain for users and groups is LOCAL.

Additionally, the Identity Firewall uses the LOCAL domain for all locally defined user groups or locally defined users (users who log in and authenticate by using a VPN or web portal).

Note The default domain name you select must match the NetBIOS domain name configured on the Active Directory domain controller. If the domain name does not match, the AD Agent will incorrectly associate the user-IP mappings with the domain name you enter when configuring the ASA.
To view the NetBIOS domain name, open the Active Directory user event security log in any text editor.

For multiple context modes, you can set a default domain name for each context, as well as within the system execution space.

Step 6 In the Active Directory Agent section, select the AD Agent group from the drop-down list. To add AD Agent groups, click **Manage**. See Configuring Active Directory Agents, page 47-11.

Step 7 In the Hello Timer field, enter a number between 10 to 65535 seconds.

The hello timer between the ASA and the AD Agent defines how frequently the ASA exchanges hello packets. The ASA uses the hello packet to obtain ASA replication status (in-sync or out-of-sync) and domain status (up or down). If the ASA does not receive a response from the AD Agent, it resends a hello packet after the specified interval.

Specify the number of times that the ASA will continue to send hello packets to the AD Agent. By default, the number of seconds is set to 30 and the retry times is set to 5.

Step 8 In the Poll Group Timer field, enter the number of hours that the ASA uses to query the DNS server to resolve fully-qualified domain names (FQDN). By default, the poll timer is set to 4 hours.

Step 9 In the Retrieve User Information, select an option from the list:

- On Demand—specifies that the ASA retrieve the user mapping information of an IP address from the AD Agent when the ASA receives a packet that requires a new connection and the user of its source IP address is not in the user-identity database.
- Full Download—specifies that the ASA send a request to the AD Agent to download the entire IP-user mapping table when the ASA starts and then to receive incremental IP-user mapping when users log in and log out.

Note Selecting On Demand has the benefit of using less memory as only users of received packets are queried and stored.

Step 10 In the Error Conditions section, select whether to disable rules in the AD Agent is not responding.

When the AD Agent is down and this option is selected, the ASA disables the user identity rules associated with the users in that domain. Additionally, the status of all user IP addresses in that domain are marked as disabled in **Monitoring > Properties > Identity > Users** pane.

Step 11 In the Error Conditions section, select whether to remove a user's IP address when the NetBIOS probe fails.

Selecting this option specifies the action when NetBIOS probing to a user is blocked (for example, the user client does not respond to a NetBIOS probe). The network connection might be blocked to that client or the client is not active. When this option is selected, the ASA disables the identity rules associated with that user's IP address.

Step 12 In the Error Conditions section, select whether to remove a user's MAC address when it is inconsistent with the IP address that the ASA has currently mapped to that MAC address. When this option is selected, the ASA disables the user identity rules associated with the specific user.

Step 13 In the Error Conditions section, select whether to track users that are not found.

Step 14 In the Users section, select the Idle Timeout option and enter a time in minutes from 1 minute to 65535. By default, the idle timeout is set to 60 minutes.

Enabling this option configures a timer when an active user is considered idle, meaning the ASA does not receive traffic from the user's IP address for more than the specified time. Once the timer expires, the user's IP address is marked inactive and removed from the local cached IP-user database and the ASA no longer notifies the AD Agent about that IP address. Existing traffic is still allowed to pass. When the Idle Timeout option is enabled, the ASA runs an inactive timer even when the NetBIOS Logout Probe is configured.

Note The Idle Timeout option does not apply to VPN or cut through proxy users.

Step 15 In the NetBIOS Logout Probe section, enable NetBIOS probing and set the probe timer (from1 to 65535 minutes) before a user's IP addresses is probed and the retry interval (from 1 to 256 retries) between retry probes.

Enabling this option configures how often the ASA probes the user host to determine whether the user client is still active. To minimize the NetBIOS packets, ASA only sends a NetBIOS probe to the client when the user has been idle for more than the specified number of minutes in the Idle Timeout minutes field.

Step 16 In the NetBIOS Logout Probe section, select an option from the User Name list:

- Match Any—As long as the NetBIOS response from the host contains the user name of the user assigned to the IP address, the user identity is be considered valid. Specifying this option requires that the host enabled the Messenger service and configured a WINS server.
- Exact Match—The user name of the user assigned to the IP address must be the only one in the NetBIOS response. Otherwise, the user identity of that IP address is considered invalid. Specifying this option requires that the host enabled the Messenger service and configured a WINS server.
- User Not Needed—As long as the ASA received a NetBIOS response from the host the user identity is considered valid.

Step 17 Click **Apply** to save the Identity Firewall Configuration.

What to Do Next

Configure the Active Directory domain and server groups. See Configuring the Active Directory Domain, page 47-10 and Configuring Active Directory Server Groups, page 47-10.

Configure AD Agents. See Configuring Active Directory Server Groups, page 47-10.

Configuring Identity-Based Security Policy

You can incorporate identity-based policy in many ASA features. Any feature that uses extended ACLs (other than those listed as unsupported in the "Guidelines and Limitations" section on page 47-7) can take advantage of identity firewall. You can now add user identity arguments to extended ACLs, as well as network-based parameters.

- To configure an extended ACL, see Chapter 19, "Adding an Extended Access Control List."
- To configure local user groups, which can be used in the ACL, see the "Configuring Local User Groups" section on page 25-7.

Features that can use identity include the following:

- Access rules—An access rule permits or denies traffic on an interface using network information. With identity firewall, you can now control access based on user identity. See Chapter 51, "Configuring Access Rules."
- AAA rules—An authentication rule (also known as "cut-through proxy") controls network access based on user. Because this function is very similar to an access rule + identity firewall, AAA rules can now be used as a backup method of authentication if a user's AD login expires. For example, for any user without a valid login, you can trigger a AAA rule. To ensure that the AAA rule is only triggered for users that do not have valid logins, you can specify special usernames in the extended ACL used for the access rule and for the AAA rule: None (users without a valid login) and Any (users with a valid login). In the access rule, configure your policy as usual for users and groups, but then include a rule that permits all None users; you must permit these users so they can later trigger a AAA rule. Then, configure a AAA rule that denies Any users (these users are not subject to the AAA rule, and were handled already by the access rule), but permits all None users:

```
access-list 100 ex permit ip user CISCO\xyz any any
access-list 100 ex deny ip user CISCO\abc any any
access-list 100 ex permit ip user NONE any any   ----> these users will match AAA rule
access-list 100 ex deny any any
access-group 100 in interface inside

access-list 200 ex deny ip user ANY any any -----> skips users who already logged in
access-list 200 ex permit user NONE any any
aaa authenticate match 200 inside user-identity
```

  See Chapter 53, "Configuring AAA Rules for Network Access."
- Cloud Web Security—You can control which users are sent to the Cloud Web Security proxy server. In addition, you can configure policy on the Cloud Web Security ScanCenter that is based on user groups that are included in ASA traffic headers sent to Cloud Web Security. See Chapter 75, "Configuring the ASA for Cisco Cloud Web Security."
- VPN filter—Although VPN does not support identity firewall ACLs in general, you can use configure the ASA to enforce identity-based access rules on VPN traffic. By default, VPN traffic is not subject to access rules. You can force VPN clients to abide by access rules that use an identity firewall ACL (**no sysopt connection permit-vpn** command). You can also use an identity firewall ACL with the VPN filter feature; VPN filter accomplishes a similar effect as allowing access rules in general.

- And many more...

Monitoring the Identity Firewall

This section contains the following topic:

- Monitoring AD Agents, page 47-16
- Monitoring Groups, page 47-16
- Monitoring Memory Usage for the Identity Firewall, page 47-17
- Monitoring Users for the Identity Firewall, page 47-17

Monitoring AD Agents

You can monitor the AD Agent component of the Identity Firewall.

Step 1 Open the **Monitoring > Properties > Identity > AD Agent**.

The Active Directory Agent Information pane appears.

Step 2 Click Refresh to update the data in the pane.

This pane displays the following information about the primary and secondary AD Agents:

- Status of the AD Agents
- Status of the domains
- Statistics for the AD Agents

Monitoring Groups

You can monitor the user groups configured for the Identity Firewall.

Step 1 Open the **Monitoring > Properties > Identity > Group**.

The Activated Groups pane appears.

Step 2 To display a list of the access rules using the selected group, click **Where used**.

Step 3 Click Refresh to update the data in the pane.

This pane displays displays the list of user groups in the following format:

domain\group_name

Monitoring Memory Usage for the Identity Firewall

You can monitor the memory usage that the Identity Firewall consumes on the ASA.

Step 1 Open the **Monitoring > Properties > Identity > Memory Usage**.

The Memory Usage of Identity Modules pane appears.

Step 2 Click Refresh to update the data in the pane.

This pane displays the memory usage in bytes of various modules in the Identity Firewall:

- Users
- Groups
- User Stats
- LDAP

  The ASA sends an LDAP query for the Active Directory groups configured on the Active Directory server. The Active Directory server authenticates users and generates user logon security logs.
- AD Agent
- Miscellaneous
- Total Memory Usage

Note How you configure the Identity Firewall to retrieve user information from the AD Agent impacts the amount of memory used by the feature. You specify whether the ASA uses **on demand** retrieval or **full download** retrieval. Selecting **On Demand** has the benefit of using less memory as only users of received packets are queried and stored. See Configuring Identity Options, page 47-12 for a description of these options.

Monitoring Users for the Identity Firewall

You can display information about all users contained in the IP-user mapping database used by the Identity Firewall.

Step 1 Open the **Monitoring > Properties > Identity > User**.

The Users in the User Database pane appears.

Note Active users are highlighted in green.

Step 2 To display additional information about an active user, select the user in the list and click **Details**. The Details button is enabled for active users only.

Step 3 To display a list of the access rules using the selected user, click **Where used**.

Step 4 Click Refresh to update the data in the pane.

This pane displays the following information for users:

domain\user_name	Status (active or inactive)	Connections	Minutes Idle

The default domain name can be the real domain name, a special reserved word, or LOCAL. The Identity Firewall uses the LOCAL domain name for all locally defined user groups or locally defined users (users who log in and authenticate by using a VPN or web portal). When default domain is not specified, the default domain is LOCAL.

The idle time is stored on a per user basis instead of per the IP address of a user.

If the option to disable rules when the Active Directory server is down and the domain is down, or the option to disable rules in the AD Agent is down and the AD Agent is down, all the logged on users have the status disabled. You configure these options in the Identity Options pane.

Alternatively, you can view statistics for users by accessing the Firewall Dashboard pane. The Firewall Dashboard pane lets you view important information about the traffic passing through your ASA. Choose **Home > Firewall Dashboard > Top 10 Users** tab in the Top Usage Status area.

The Top 10 Users tab displays data only when you have configured the Identity Firewall feature in the ASA, which includes configuring these additional components—Microsoft Active Directory and Cisco Active Directory (AD) Agent. See Configuring the Identity Firewall, page 47-9 for information.

Depending on which option you choose, the Top 10 Users tab shows statistics for received EPS packets, sent EPS packets, and sent attacks for the top 10 users. For each user (displayed as *domain\user_name*), the tab displays the average EPS packet, the current EPS packet, the trigger, and total events for that user.

Note The first three tabs in the Top Usage Status area display threat detection data and are unrelated to the Identity Firewall feature.

Feature History for the Identity Firewall

Table 47-1 lists the release history for this feature.

Table 47-1 Feature History for the Identity Firewall

Feature Name	Releases	Feature Information
Identity Firewall	8.4(2)	The Identity Firewall feature was introduced. We introduced or modified the following screens: Configuration > Firewall > Identity Options Configuration > Firewall > Objects > Local User Groups Monitoring > Properties > Identity

Configuring the ASA to Integrate with Cisco TrustSec

This chapter includes the following sections:

- Information About the ASA Integrated with Cisco TrustSec, page 48-1
- Licensing Requirements when Integrating the ASA with Cisco TrustSec, page 48-8
- Prerequisites for Integrating the ASA with Cisco TrustSec, page 48-8
- Guidelines and Limitations, page 48-9
- Configuring the ASA for Cisco TrustSec Integration, page 48-11
- Monitoring the ASA Integrated with Cisco TrustSec, page 48-17
- Feature History for the ASA-Cisco TrustSec Integration, page 48-21

Information About the ASA Integrated with Cisco TrustSec

This section includes the following topics:

- Information about Cisco TrustSec, page 48-1
- About SGT and SXP Support in Cisco TrustSec, page 48-2
- Roles in the Cisco TrustSec Solution, page 48-3
- Security Group Policy Enforcement, page 48-3
- How the ASA Enforces Security Group Based Policies, page 48-4
- About Speaker and Listener Roles on the ASA, page 48-6
- Features of the ASA-Cisco TrustSec Integration, page 48-6

Information about Cisco TrustSec

Traditionally, security features such as firewalls performed access control based on predefined IP addresses, subnets and protocols. However, with enterprises transitioning to borderless networks, both the technology used to connect people and organizations and the security requirements for protecting data and networks have evolved significantly. End points are becoming increasingly nomadic and users often utilize a variety of end points (for example, laptop versus desktop, smart phone, or tablet), which

means that a combination of user attributes plus end-point attributes provide the key characteristics, in addition to existing 5-tuple based rules, that enforcement devices, such as switches and routers with firewall features or dedicated firewalls, can reliably use for making access control decisions.

As a result, the availability and propagation of end point attributes or client identity attributes have become increasingly important requirements to enable security solutions across the customers' networks, at the access, distribution, and core layers of the network and in the data center to name but a few examples.

Cisco TrustSec provides an access-control solution that builds upon an existing identity-aware infrastructure to ensure data confidentiality between network devices and integrate security access services on one platform. In the Cisco TrustSec solution, enforcement devices utilize a combination of user attributes and end-point attributes to make role-based and identity-based access control decisions. The availability and propagation of this information enables security solutions across networks at the access, distribution, and core layers of the network.

Implementing Cisco TrustSec into your environment has the following advantages:

- Provides a growing mobile and complex workforce with appropriate and more secure access from any device
- Lowers security risks by providing comprehensive visibility of who and what is connecting to the wired or wireless network
- Offers exceptional control over activity of network users accessing physical or cloud-based IT resources
- Reduces total cost of ownership through centralized, highly secure access policy management and scalable enforcement mechanisms

For information about Cisco TrustSec, see http://www.cisco.com/go/trustsec.

About SGT and SXP Support in Cisco TrustSec

In the Cisco TrustSec solution, security group access transforms a topology-aware network into a role-based network, thus enabling end-to-end policies enforced on the basis of role-based access-control (RBACL). Device and user credentials acquired during authentication are used to classify packets by security groups. Every packet entering the Cisco TrustSec cloud is tagged with an security group tag (SGT). The tagging helps trusted intermediaries identify the source identity of the packet and enforce security policies along the data path. An SGT can indicate a privilege level across the domain when the SGT is used to define a security group access list.

An SGT is assigned to a device through IEEE 802.1X authentication, web authentication, or MAC authentication bypass (MAB), which happens with a RADIUS vendor-specific attribute. An SGT can be assigned statically to a particular IP address or to a switch interface. An SGT is passed along dynamically to a switch or access point after successful authentication.

The Security-group eXchange Protocol (SXP) is a protocol developed for Cisco TrustSec to propagate the IP-to-SGT mapping database across network devices that do not have SGT-capable hardware support to hardware that supports SGTs and security group access lists. SXP, a control plane protocol, passes IP-SGT mappings from authentication points (such as legacy access layer switches) to upstream devices in the network.

The SXP connections are point-to-point and use TCP as the underlying transport protocol. SXP uses the well known TCP port number 64999 when initiating a connection. Additionally, an SXP connection is uniquely identified by the source and destination IP addresses.

Roles in the Cisco TrustSec Solution

To provide identity and policy-based access enforcement, the Cisco TrustSec solution includes the functionality:

- **Access Requestor (AR)**: Access requestors are end-point devices that request access to protected resources in the network. They are primary subjects of the architecture and their access privilege depends on their Identity credentials.

  Access requestors include end-point devices such PCs, laptops, mobile phones, printers, cameras, and MACsec-capable IP phones.

- **Policy Decision Point (PDP)**: A policy decision point is responsible for making access control decisions. The PDP provides features such as 802.1x, MAB, and Web authentication. The PDP supports authorization and enforcement through VLAN, DACL, and security group access (SGACL/SXP/SGT).

  In the Cisco TrustSec solution, the Cisco Identity Services Engine (ISE) acts as the PDP. The Cisco ISE provides identity and access control policy functionality.

- **Policy Information Point (PIP)**: A policy information point is a source that provides external information (for example, reputation, location, and LDAP attributes) to policy decision points.

  Policy information points include devices such as Session Directory, Sensors IPS, and Communication Manager.

- **Policy Administration Point (PAP)**: A policy administration point defines and inserts policies into authorization system. The PAP acts as an identity repository, by providing Cisco TrustSec tag to user identity mapping and Cisco Trustsec tag to server resource mapping.

  In the Cisco TrustSec solution, the Cisco Secure Access Control System (a policy server with integrated 802.1x and SGT support) acts as the PAP.

- **Policy Enforcement Point (PEP)**: A policy enforcement point is the entity that carries out the decisions (policy rules and actions) made by the PDP for each AR. PEP devices learn identity information through the primary communication path that exists across networks. PEP devices learn the identity attributes of each AR from many sources, such as end-point agents, authorization servers, peer-enforcement devices, and network flows. In turn, PEP devices use SXP to propagate IP-SGT mappings to mutually-trusted peer devices across the network.

  Policy enforcement points include network devices such as Catalyst switches, routers, firewalls (specifically the ASA), servers, VPN devices, and SAN devices.

The ASA serves the role of the PEP in the identity architecture. Using SXP, the ASA learns identity information directly from authentication points and uses that to enforce identity-based policies.

Security Group Policy Enforcement

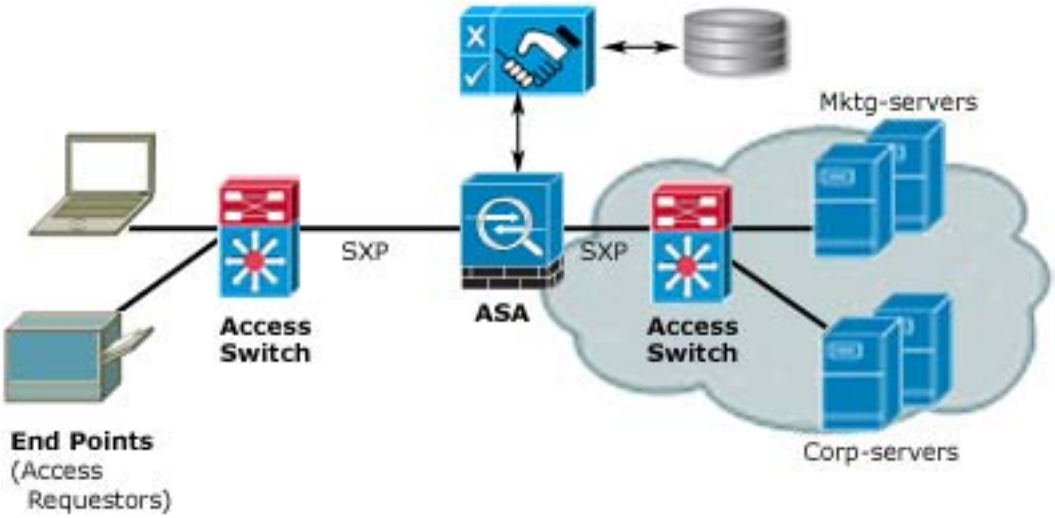
Security policy enforcement is based on security group name. An end-point device attempts to access a resource in the data center. Compared to traditional IP-based policies configured on firewalls, identity-based policies are configured based on user and device identities. For example, mktg-contractor is allowed to access mktg-servers; mktg-corp-users are allowed to access mktg-server and corp-servers.

The benefits of this type of deployment include:

- User group and Resource is defined and enforced using single object (SGT) – simplified policy management.

- User identity and resource identity are retained throughout the Cisco Trustsec capable switch infrastructure.

Figure 48-1 Security Group Name Based Policy Enforcement Deployment



Implementing Cisco TrustSec allows for configuration of security policies supporting server segmentation.

- A pool of servers can be assigned an SGT for simplified policy management.
- The SGT information is retained within the infrastructure of Cisco Trustsec capable switches.
- The ASA can leverage the IP-SGT mapping for policy enforcement across the Cisco TrustSec domain.
- Deployment simplification is possible because 802.1x authorization for servers is mandatory.

How the ASA Enforces Security Group Based Policies

Note User-based security policies and security-group based policies, can coexist on the ASA. Any combination of network, user-based and security-group based attributes can be configured in an security policy. See Chapter 47, "Configuring the Identity Firewall" for information about configuring user-based security policies.

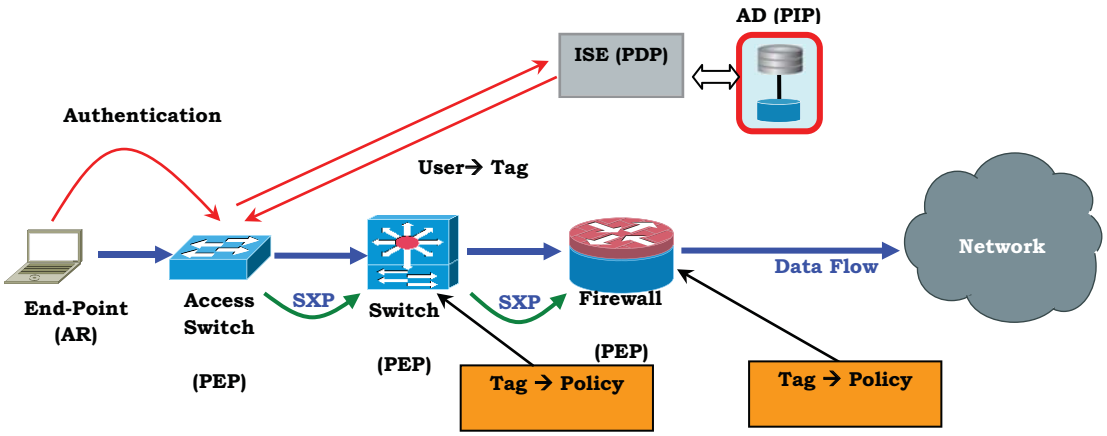
As part of configuring the ASA to function with Cisco TrustSec, you must import a Protected Access Credential (PAC) file from the ISE. Importing a Protected Access Credential (PAC) File, page 48-13.

Importing the PAC file to the ASA establishes a secure communication channel with the ISE. After the channel is established, the ASA initiates a PAC secure RADIUS transaction with the ISE and downloads Cisco TrustSec environment data; specifically, the ASA downloads the security group table. The security group table maps SGTs to security group names. Security group names are created on the ISE and provide user-friendly names for security groups.

The first time the ASA downloads the security group table, it walks through all entries in the table and resolves all the security group names contained in security policies configured on the ASA; then, the ASA activates those security policies locally. If the ASA is unable to resolve a security group name, it generates a system log message for the unknown security group name.

The following figure shows how a security policy is enforced in Cisco TrustSec.

Figure 48-2 Security Policy Enforcement



1. An end-point device connects to an access layer device directly or via remote access and authenticates with Cisco TrustSec.
2. The access layer device authenticates the end-point device with the ISE by using authentication methods such as 802.1X or web authentication. The end-point device passes role and group membership to classify the device into the appropriate security group.
3. The access layer device uses SXP to propagate the IP-SGT mapping to the upstream devices.
4. The ASA receives the packet. Using the IP-SGT mapping passed by SXP, the ASA looks up the SGTs for the source and destination IP addresses.

   If the mapping is new, the ASA records it in its local IP-SGT Manager database. The IP-SGT Manager database, which runs in the control plan, tracks IP-SGT mappings for each IPv4 or IPv6 address. The database records the source from which the mapping was learned. The peer IP address of the SXP connection is used as the source of the mapping. Multiple sources can exist for each IP-SGT mapping.

   If the ASA is configured as a Speaker, the ASA transmits all IP-SGT mappings to its SXP peers. See About Speaker and Listener Roles on the ASA, page 48-6.
5. If a security policy is configured on the ASA with that SGT or security group name, the ASA enforces the policy. (You can create security policies on the ASAthat contain SGTs or security group names. To enforce policies based on security group names, the ASA needs the security group table to map security group names to SGTs.)

   If the ASA cannot find a security group name in the security group table and it is included in a security policy, the ASA considers the security group name unknown and generates a system log message. When it becomes know after the ASA refreshes the security group table from the ISE, the ASA generates a system log message indicating that the security group name is known.

About Speaker and Listener Roles on the ASA

The ASA supports SXP to send and receive IP-SGT mappings to and from other network devices. Employing SXP allows security devices and firewalls to learn identity information from access switches without the need for hardware upgrades or changes. SXP can also be used to pass IP-SGT mappings from upstream devices (such as datacenter devices) back to the downstream devices. The ASA can receive information from both upstream and downstream directions.

When configuring an SXP connection on the ASA to an SXP peer, you must designate the ASA as a Speaker or a Listener for that connection so that it can exchange identity information:

- **Speaker mode**—configures the ASA so that it can forward all active IP-SGT mappings collected on the ASA to upstream devices for policy enforcement.
- **Listener mode**—configures the ASA so that it can receive IP-SGT mappings from downstream devices (SGT-capable switches) and use that information in creating policy definitions.

If one end of an SXP connection is configured as Speaker, then the other end must be configured as a Listener, and vice versa. If both devices on each end of an SXP connection are configured with the same role (either both as Speakers or both as Listeners), the SXP connection will fail and the ASA will generate a system log message.

Configuring the ASA to be both a Speaker and a Listener for an SXP connection can cause SXP looping, meanings that SXP data can be received by an SXP peer that originally transmitted it.

As part of configuring SXP on the ASA, you configure an SXP reconcile timer. After an SXP peer terminates its SXP connection, the ASA starts a hold down timer. Only SXP peers designated as Listener devices can terminate a connection. If an SXP peer connects while the hold down timer is running, the ASA starts the reconcile timer; then, the ASA updates the IP-SGT mapping database to learn the latest mappings.

Features of the ASA-Cisco TrustSec Integration

The ASA leverages Cisco TrustSec as part of its identity-based firewall feature. The integrating the ASA with Cisco TrustSec provides the following key features.

Flexibility

- The ASA can be configured as an SXP Speaker or Listener, or both.

  See About Speaker and Listener Roles on the ASA, page 48-6.
- The ASA supports SXP for IPv6 and IPv6 capable network devices.
- The ASA negotiates SXP versions with different SXP-capable network devices. SXP version negotiation eliminates the need for static configuration of versions.
- You can configure the ASA to refresh the security group table when the SXP reconcile timer expires and you can download the security group table on demand. When the security group table on the ASA is updated from the ISE, changes are reflected in the appropriate security policies.
- The ASA supports security policies based on security group names in the source or destination fields, or both. You can configure security policies on the ASA based on combinations of security groups, IP address, Active Directory group/user name, and FQDN.

Availability

- You can configure security group based policies on the ASA in Active/Active and Active/Standby configuration.

- The ASA can communicate with the ISE configured for high availability (HA).
- If the PAC file downloaded from the ISE expires on the ASA and the ASA cannot download an updated security group table, the ASA continues to enforce security policies based on the last downloaded security group table until the ASA downloads an updated table.

Scalability

The ASA supports the following number of IP-SGT mapped entries:

Table 48-1 Capacity Numbers for IP-SGT Mappings

ASA Platform	Number of IP-SGT Mapped Entries
5505	250
5510	1000
5520	2500
5540	5000
5550	7500
5580-20	10,000
5580-40	20,000
5585-X with SSP-10	18,750
5585-X with SSP-20	25,000
5585-X with SSP-40	50,000
5585-X with SSP-60	100,000

The ASA supports the following number of SXP connections:

Table 48-2 SXP Connections

ASA Platform	Number of SXP TCP Connections
5505	10
5510	25
5520	50
5540	100
5550	150
5580-20	250
5580-40	500
5585-X with SSP-10	150
5585-X with SSP-20	250
5585-X with SSP-40	500
5585-X with SSP-60	1000

Licensing Requirements when Integrating the ASA with Cisco TrustSec

Model	License Requirement
All models	Base License.

Prerequisites for Integrating the ASA with Cisco TrustSec

Before configuring the ASA to integrate with Cisco TrustSec, you must perform the following prerequisites:

- Register the ASA with the ISE.
- Create a security group for the ASA on the ISE.
- Generate the PAC file on the ISE to import into the ASA.

Registering the ASA with the ISE

The ASA must be configured as a recognized Cisco TrustSec network device in the ISE before the ASA can successfully import a PAC file.

1. Log into the ISE.
2. Choose **Administration > Network Devices > Network Devices**.
3. Click **Add**.
4. Enter the IP address of the ASA.
5. When the ISE is being used for user authentication in the Cisco TrustSec solution, enter a shared secret in the Authentication Settings area.

   When you configure the AAA sever on the ASA, provide the shared secret you create here on the ISE. The AAA server on the ASA uses this shared secret to communicate with the ISE.
6. Specify a device name, device ID, password, and a download interval for the ASA. See the ISE documentation for the details to perform these tasks.

Creating a Security Group on the ISE

When configuring the ASA to communicate with the ISE, you specify a AAA server. When configuring the AAA server on the ASA, you must specify a server group.

The security group must be configured to use the RADIUS protocol.

1. Log into the ISE.
2. Choose **Policy > Policy Elements > Results > Security Group Access > Security Group**.
3. Add a security group for the ASA. (Security groups are global and not ASA specific.)

   The ISE creates an entry under Security Groups with a tag.
4. Under the Security Group Access section, configure a device ID credentials and password for the ASA.

Generating the PAC File

For information about the PAC file, see Importing a Protected Access Credential (PAC) File, page 48-13.

Before generating the PAC file, you must have registered the ASA with the ISE.

1. Log into the ISE.
2. Choose **Administration > Network Resources > Network Devices**.
3. From the list of devices, select the ASA device.
4. Under the Security Group Access (SGA), click **Generate PAC**.
5. To encrypt the PAC file, enter a password.

   The password (or encryption key) you enter to encrypt the PAC file is independent of the password that was configured on the ISE as part of the device credentials.

The ISE generates the PAC file. The ASA can import the PAC from flash or from a remote server via TFTP, FTP, HTTP, HTTPS, or SMB. (The PAC does not have to reside on the ASA flash before you can import it.)

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

IPv6 Guidelines

Supports IPv6

Clustering Guideline

Supported only on the master device in a clustering setting.

High Availability Guideline

Supports a list of servers via configuration. If the first server is unreachable, the ASA will try to contact the second server in the list, and so on. However, the server list downloaded as part of the Cisco TrustSec environment data is ignored.

Limitations

- The ASA can only be configured to interoperate in a single Cisco TrustSec domain.
- The ASA does not support static configuration of SGT-name mappings on the device.
- NAT is not supported in SXP messages.
- SXP conveys IP-SGT mappings to enforcement points in the network. If an access layer switch belongs to a different NAT domain than the enforcing point, the IP-SGT map it uploads is invalid and an IP-SGT mappings database lookup on the enforcement device will not yield valid results; therefore, the ASA cannot apply security group aware security policy on the enforcement device.

- When configuring the ASA to integrate with Cisco TrustSec, you configure a default password for the ASA to use for SXP connections, or you can elect to not use a password; however, connection specific passwords are not supported for SXP peers. The configured default SXP password should be consistent cross the deployment network.
- SXP connection loops can form when a device has bidirectional connections to a peer, or is part of a unidirectionally connected chain of devices. (The ASA can learn IP-DGT mappings for resources from the access layer in the data center. The ASA might need to propagate these tags to downstream devices.) SXP connection loops can cause unexpected behavior of SXP message transport. In cases where the ASA is configured to be a Speaker and Listener, an SXP connection loop can occur causing SXP data to be received by the peer that originally transmitted it.
- When changing the ASA local IP address, you must ensure that all SXP peers have updated their peer list. Likewise, if an SXP peers changes its IP addresses, you must ensure those changes are reflected on the ASA.
- Automatic PAC file provisioning is not supported. The ASA administrator must request the PAC file from the ISE administrative interface and import it to the ASA. For information about the PAC file, see Generating the PAC File, page 48-9 and Importing a Protected Access Credential (PAC) File, page 48-13.
- PAC files have expiration dates. You must import the updated PAC file before the current PAC file expires; otherwise, the ASA will not be able to retrieve environment data updates.
- When a security group changes on the ISE (for example, it is renamed or deleted), the ASA does not change the status of any ASA security policies that contain an SGT or security group name associated with the changed security group; however, the ASA generates a system log message to indicate that those security policies changed.

  See Refreshing Environment Data, page 48-16 for information about manually updating the security group table on the ASA to pick up changes from the ISE.
- The multicast types are not supported in ISE 1.0.
- An SXP connection stays in the initializing state among two SXP peers interconnected by the ASA; as shown in the following example:

  (SXP peer A) - - - - (ASA) - - - (SXP peer B)

  Therefore, when configuring the ASA to integrate with Cisco TrustSec, you must enable the no-NAT, no-SEQ-RAND, and MD5-AUTHENTICATION TCP options on the ASA. Create a TCP-state-bypass policy for traffic destined to SXP port TCP 64999 among the SXP peers. Apply the policy on the appropriate interfaces.

  For example, configure the ASA as shown in this sample configuration for a TCP-state-bypass policy:

```
access-list SXP-MD5-ACL extended permit tcp host <peerA> host <peerB> eq 64999
access-list SXP-MD5-ACL extended permit tcp host <peerB> host <peerA> eq 64999

tcp-map SXP-MD5-OPTION-ALLOW
 tcp-options range 19 19 allow

class-map SXP-MD5-CLASSMAP
 match access-list SXP-MD5-ACL

policy-map type inspect dns preset_dns_map
 parameters
  message-length maximum 512
policy-map global_policy
class SXP-MD5-CLASSMAP
  set connection random-sequence-number disable
  set connection advanced-options SXP-MD5-OPTION-ALLOW
```

```
  set connection advanced-options tcp-state-bypass
service-policy global_policy global
```

Configuring the ASA for Cisco TrustSec Integration

This section contains the following topics:

- Task Flow for Configuring the ASA to Integrate with Cisco TrustSec, page 48-11
- Configuring the AAA Server for Cisco TrustSec Integration, page 48-12
- Importing a Protected Access Credential (PAC) File, page 48-13
- Configuring the Security Exchange Protocol (SXP), page 48-14
- Adding an SXP Connection Peer, page 48-15
- Refreshing Environment Data, page 48-16
- Configuring the Security Policy, page 48-17

Task Flow for Configuring the ASA to Integrate with Cisco TrustSec

Prerequisite

Before configuring the ASA to integrate with Cisco TrustSec, you must meet the following prerequisites:

- Register the ASA with the ISE.
- Generate the PAC file on the ISE to import into the ASA.

See the "Prerequisites for Integrating the ASA with Cisco TrustSec" section on page 48-8 for information.

Task Flow in the ASA

To configure the ASA to integrate with Cisco TrustSec, perform the following tasks:

Step 1 Configure the AAA server.

See Configuring the AAA Server for Cisco TrustSec Integration, page 48-12.

Step 2 Import the PAC file from the ISE.

See Importing a Protected Access Credential (PAC) File, page 48-13.

Step 3 Enable and set the default values for SXP.

See Configuring the Security Exchange Protocol (SXP), page 48-14.

Step 4 Add SXP connection peers for the Cisco TrustSec architecture.

See Adding an SXP Connection Peer, page 48-15.

Step 5 As necessary, refresh environment data for the ASA integrated with Cisco TrustSec.

See Refreshing Environment Data, page 48-16.

Step 6 Configure the Security Policy.

See Configuring the Security Policy, page 48-17.

Configuring the AAA Server for Cisco TrustSec Integration

As part of configuring the ASA to integrate with Cisco TrustSec, you must configure the ASA so that it can communicate with the ISE.

See also the "Configuring AAA Server Groups" section on page 46-11 and the "Adding a Server to a Group" section on page 46-12 for more information.

Prerequisites

- The referenced server group must be configured to use the RADIUS protocol. If you add a non-RADIUS server group to the ASA, the feature configuration will fail.
- If the ISE is also used for user authentication, obtain the shared secret that was entered on the ISE when you registered the ASA with the ISE. Contact your ISE administrator if you do not have this information.

To configure the ASA to communicate with the ISE for Cisco TrustSec integration, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Firewall > Identity By TrustSec**. The Identity By TrustSec pane appears.

Step 2 To add a server group to the ASA, click **Manage** in the Server Group Setup area, The Configure AAA Server Group dialog box appears.

Step 3 In the AAA Server Group field, enter the name of the security group created on the ISE for the ASA.

The server group name you specify here must match the name of the security group created on the ISE for the ASA. If these two group names do not match, the ASA will not be able to communicate with the ISE. Contact your ISE administrator if you do not have this information.

Step 4 In the Protocol drop-down list, select RADIUS.

For information about completing the remaining fields in the AAA Server Group dialog box, see Configuring AAA Server Groups, page 46-11

Step 5 Click **OK**. The ASA adds the group to the list of AAA Server Groups.

Step 6 To add a server to a group, select the AAA sever group you just created and click **Add** in the Servers in the Selected Group area (lower pane). The Add AAA Server dialog box appears.

Step 7 In the Interface Name field, select the network interface where the ISE server resides.

Step 8 In the Server Name or IP Address field, enter the IP address of the ISE server.

For information about completing the remaining fields in the AAA Server dialog box, see See Adding a Server to a Group, page 46-12.

Step 9 Click **OK**. The ASA adds the ISE server to the list of AAA servers.

Step 10 Click **OK** to save the addition of the ISE server and server group for the integration with Cisco TrustSec.

The changes are saved to the running configuration.

Importing a Protected Access Credential (PAC) File

Importing the PAC file to the ASA establishes the connection with the ISE. After the channel is established, the ASA initiates a secure RADIUS transaction with the ISE and downloads Cisco TrustSec environment data; specifically, the ASA downloads the security group table. The security group table maps SGTs to security group names. Security group names are created on the ISE and provide user-friendly names for security groups.

More specifically, no channel is established prior to the radius transaction. The ASA simply initiates a radius transaction with the ISE using the PAC for authentication

Tip The PAC file contains a shared key that allows the ASA and ISE to secure the RADIUS transactions that occur between them. Given the sensitive nature of this key, it must be stored securely on the ASA.

When you import the PAC file, the file is converted to ASCII HEX format and sent to the ASA in non-interactive mode. After successfully importing the file, the ASA download Cisco TrustSec environment data from the ISE without requiring the device password configured in the ISE.

Prerequisites

- The ASA must be configured as a recognized Cisco TrustSec network device in the ISE before the ASA can generate a PAC file. The ASA can import any PAC file but it will only work on the ASA when the file was generated by a properly configured ISE. See Registering the ASA with the ISE, page 48-8.
- Obtain the password used to encrypt the PAC file when generating it on the ISE.

  The ASA requires this password to import and decrypt the PAC file.
- Access to the PAC file generated by the ISE. The ASA can import the PAC from flash or from a remote server via TFTP, FTP, HTTP, HTTPS, or SMB. (The PAC does not have to reside on the ASA flash before you can import it.)
- The server group has been configured for the ASA.

Restrictions

- When the ASA is part of an HA configuration, you must import the PAC file to the primary ASA device.
- When the ASA is part of a clustering configuration, you must import the PAC to the master device.

To import a PAC file, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Firewall > Identity By TrustSec**. The Identity By TrustSec pane appears.

Step 2 Check the Enable Security Exchange Protocol checkbox to enable SXP.

Step 3 In the Server Group Setup area, click Import PAC. The Import PAC dialog box appears.

Step 4 In the Filename field, enter the path and filename for the PAC file by using one of the following formats:

- disk0: Path and filename on disk0
- disk1: Path and filename on disk1
- flash: Path and filename on flash

Step 5 In the Password field, enter the password used to encrypt the PAC file. The password is independent of the password that was configured on the ISE as part of the device credentials.

Step 6 In the Confirm Password field, re-enter the password to confirm it.

Step 7 Click **Import**. The Identity By TrustSec pane reappears.

Step 8 Click **Apply** to save the changes.

The changes are saved to the running configuration.

Configuring the Security Exchange Protocol (SXP)

Configuring the Security Exchange Protocol (SXP) involves enabling the protocol in the ASA and setting the following default values for SXP:

- The source IP address of SXP connections
- The authentication password between SXP peers
- The retry interval for SXP connections
- The Cisco TrustSec SXP reconcile period

To configure the default settings for the ASA integration with Cisco TrustSec, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Firewall > Identity By TrustSec**. The Identity By TrustSec pane appears.

Step 2 Check the Enable Security Exchange Protocol checkbox to enable SXP. By default, SXP is disabled.

In multi-context mode, enabling SXP is done in the user context.

Step 3 In the Default Source field, enter the default local IP address for SXP connections. The IP address can be an IPv4 or IPv6 address.

Note The ASA determines the local IP address for an SXP connection as the outgoing interface IP address that is reachable by the peer IP address. If the configured local address is different from the outgoing interface IP address, the ASA cannot connect to the SXP peer and generates a system log message.

Step 4 In the Default Password field, enter the default password for TCP MD5 authentication with SXP peers. By default, SXP connections do not have a password set.

You can specify the password as an encrypted string up to 162 characters or an ASCII key string up to 80 characters. Configuring an encryption level for the password is optional. If you configure an encryption level, you can only set one level:

- Level 0—unencrypted cleartext
- Level 8—encrypted text

Step 5 In the Retry Timer field, enter the default time interval between ASA attempts to set up new SXP connections between SXP peers.

The ASA will continue to attempt to connect to new SXP peers until a successful connection is made. The retry timer is triggered as long as there is one SXP connection on the ASA that is not up.

Enter the retry timer value as a number of seconds in the range of 0 to 64000 seconds. If you specify 0 seconds, the timer never expires and the ASA will not attempt to connect to SXP peers. By default, the *timervalue* is 120 seconds.

When the retry timer expires, the ASA goes through the connection database and if the database contains any connections that are off or in a "pending on" state, the ASA restarts the retry timer.

Step 6 In the Reconcile Timer field, enter the default reconcile timer.

After an SXP peer terminates its SXP connection, the ASA starts a hold down timer. If an SXP peer connects while the hold down timer is running, the ASA starts the reconcile timer; then, the ASA updates the SXP mapping database to learn the latest mappings.

When the reconcile timer expires, the ASA scans the SXP mapping database to identify stale mapping entries (entries that were learned in a previous connection session). The ASA marks these connections as obsolete. When the reconcile timer expires, the ASA removes the obsolete entries from the SXP mapping database.

Enter the reconcile timer value as a number of seconds in the range of 1 to 64000 seconds. By default, the *timervalue* is 120 seconds.

Note You cannot specify 0 for the timer because specifying 0 would prevent the reconcile timer from starting. Not allowing the reconcile timer to run would keep stale entries for an undefined time and cause unexpected results from the policy enforcement.

Step 7 Click **Apply** to save the default settings.

The changes are saved to the running configuration.

Adding an SXP Connection Peer

SXP connections between peers are point-to-point and use TCP as the underlying transport protocol.

To add an SXP connection peer, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Firewall > Identity By TrustSec**. The Identity By TrustSec pane appears.

Step 2 If necessary, check the Enable Security Exchange Protocol checkbox to enable SXP.

Step 3 Click **Add**. The Add Connection dialog box appears.

Step 4 In the Peer IP Address field, enter the IPv4 or IPv6 address of the SXP peer. The peer IP address must be reachable from the ASA outgoing interface.

Step 5 **(Optional)** In the Source IP Address field, enter the local IPv4 or IPv6 address of the SXP connection. Specifying the source IP address is optional, however, specifying it safeguards misconfiguration.

Step 6 From the Password drop-down list, specify whether to use the authentication key for the SXP connection by selecting the following values:

- Default—Use the default password configured for SXP connections.

  See Configuring the Security Exchange Protocol (SXP), page 48-14.
- None—Do not use a password for the SXP connection.

Step 7 **(Optional)** From the Mode drop-down list, specify the mode of the SXP connection by selecting one of the following values:

- Local—Use the local SXP device.
- Peer—Use the peer SXP device.

Step 8 From the Role drop-down list, specify whether the ASA functions as a Speaker or Listener for the SXP connection:

- Speaker—The ASA can forward IP-SGT mappings to upstream devices.
- Listener—The ASA can receive IP-SGT mappings from downstream devices.

See About Speaker and Listener Roles on the ASA, page 48-6.

Step 9 Click **OK**. The peer appears in the Connection Peers list.

Step 10 Click **Apply** to save SXP peer settings.

The changes are saved to the running configuration.

Refreshing Environment Data

The ASA downloads environment data from the ISE, which includes the Security Group Tag (SGT) name table. The ASA automatically refreshes its environment data obtained from the ISE when you complete the following tasks on the ASA:

- Configure a AAA server to communicate with the ISE.
- Import a PAC file from the ISE.
- Identify the AAA server group that the ASA will use for retrieval of Cisco TrustSec environment data.

Normally, you will not need to manually refresh the environment data from the ISE; however, security groups can change on the ISE. These changes are not reflected on the ASA until you refresh the data in the ASA security group table. Refresh the data on the ASA to make sure any security group made on the ISE are reflected on the ASA.

Tip We recommend that you schedule policy configuration changes on the ISE and the manual data refresh on the ASA during a maintenance window. Handling policy configuration changes in this way maximizes the chances of security group names getting resolved and security policies becoming active immediately on the ASA.

Prerequisites

The ASA must be configured as a recognized Cisco TrustSec network device in the ISE and the ASA must have successfully imported a PAC file, so that the changes made for Cisco TrustSec are applied to the ASA.

Restrictions

- When the ASA is part of an HA configuration, you must refresh the environment data on the primary ASA device.
- When the ASA is part of a clustering configuration, you must refresh the environment data on the master device.

To Refresh Environment Data

In the main ASDM application window, choose **Configuration > Firewall > Identity By TrustSec**. The Identity By TrustSec pane appears. In the Server Group Setup area, click **Refresh Environment Data**.

The ASA refreshes the Cisco TrustSec environment data from the ISE and resets the reconcile timer to the configured default value.

Configuring the Security Policy

You can incorporate TrustSec policy in many ASA features. Any feature that uses extended ACLs (unless listed in this chapter as unsupported) can take advantage of TrustSec. You can now add security group arguments to extended ACLs, as well as traditional network-based parameters.

- To configure an extended ACL, see Chapter 19, "Adding an Extended Access Control List."
- To configure security group object groups, which can be used in the ACL, see the "Configuring Local User Groups" section on page 25-7.

For example, an access rule permits or denies traffic on an interface using network information. With TrustSec, you can now control access based on security group. See Chapter 51, "Configuring Access Rules." For example, you could create an access rule for sample_securitygroup1 10.0.0.0 255.0.0.0, meaning the security group could have any IP address on subnet 10.0.0.0/8.

You can configure security policies based on combinations of security group names (servers, users, unmanaged devices, etc.), user-based attributes, and traditional IP-address-based objects (IP address, Active Directory object, and FQDN). Security-group membership can extend beyond roles to include device and location attributes and is independent of user-group membership.

Monitoring the ASA Integrated with Cisco TrustSec

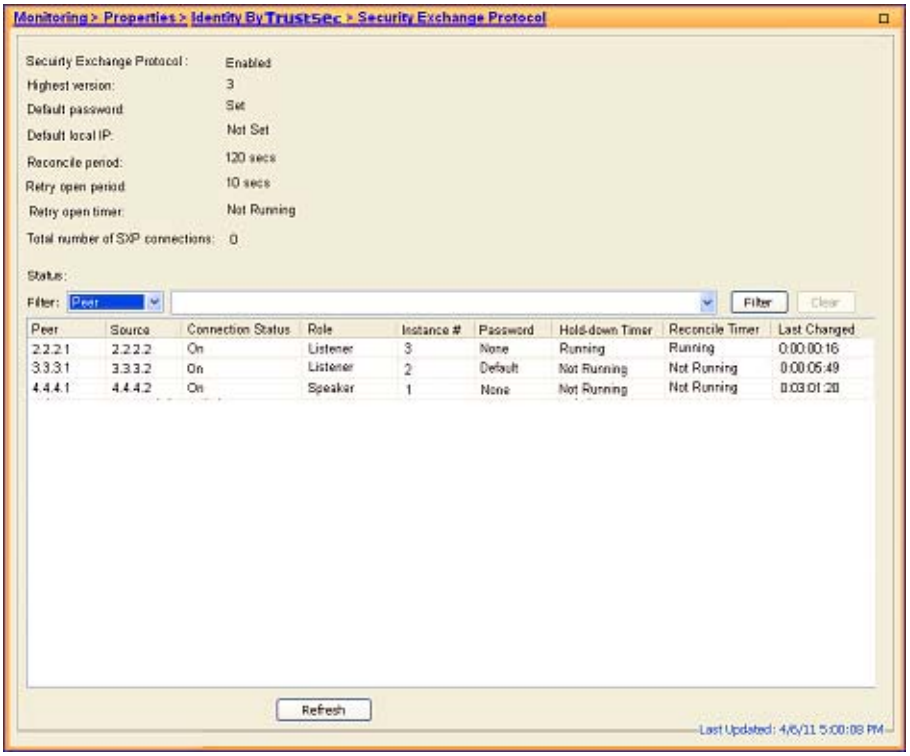
This section contains the following topics:

- Monitoring SXP Connections, page 48-17
- Monitoring Environment Data, page 48-18
- Monitoring Cisco TrustSec IP-SGT Mappings, page 48-19
- Monitoring the PAC File, page 48-20

Monitoring SXP Connections

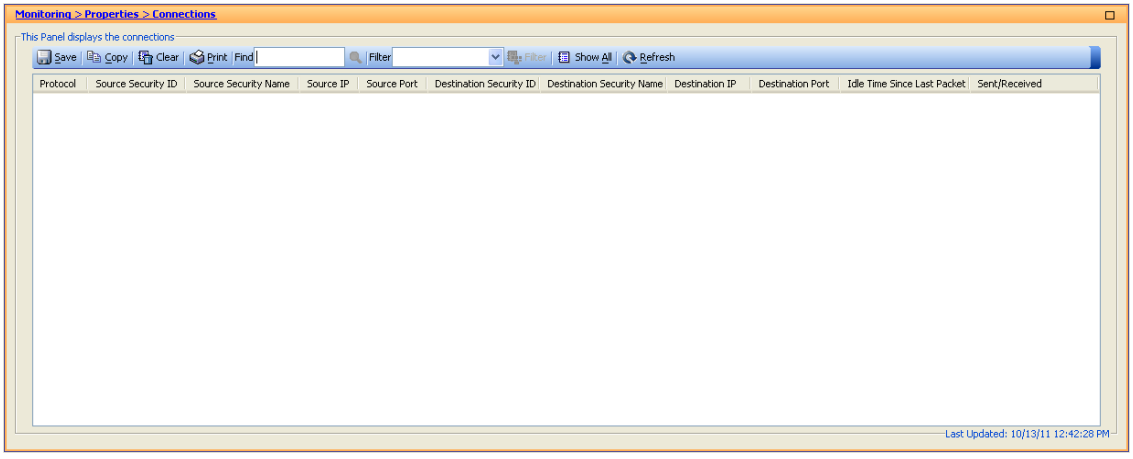
To verify which SXP connections are up and running, you can view the Security Exchange Protocol monitoring panel in ASDM. This panel displays the SXP connections on the ASA for a particular user context when multi-context mode is used.

In the main ASDM application window, choose **Monitoring > Properties > Identity By TrustSec > Security Exchange Protocol**. The following monitoring panel appears.



Alternatively, you can view the Connection monitoring panel in ASDM to display all connections configured for the ASA including the SXP connections. In the main ASDM application window, choose **Monitoring > Properties > Connections**. The following monitoring panel appears.

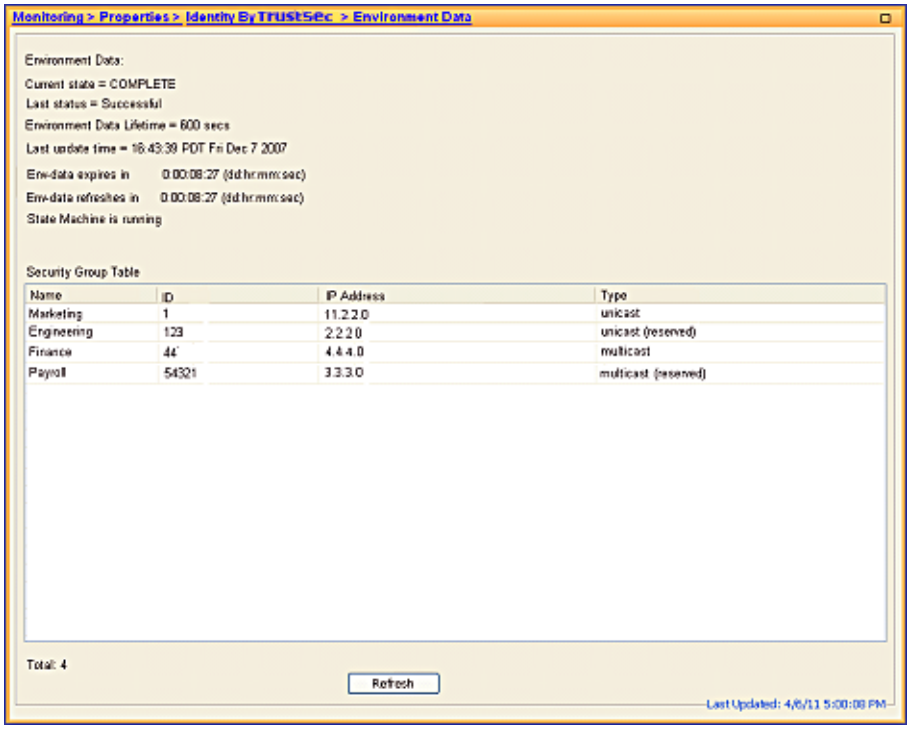
You can filter the IP-SGT mappings so that you view the data by SGT value, security group name, or IP address.



Monitoring Environment Data

To display the Cisco TrustSec environment information contained in security group table on the ASA, you can view the Environment Data monitoring panel in ASDM. The information in this panel includes the expiry timeout and security group name table. The security group table is populated with data from the ISE when you import the PAC file.

In the main ASDM application window, choose **Monitoring > Properties > Identity By TrustSec > Environment Data**. The following monitoring panel appears.

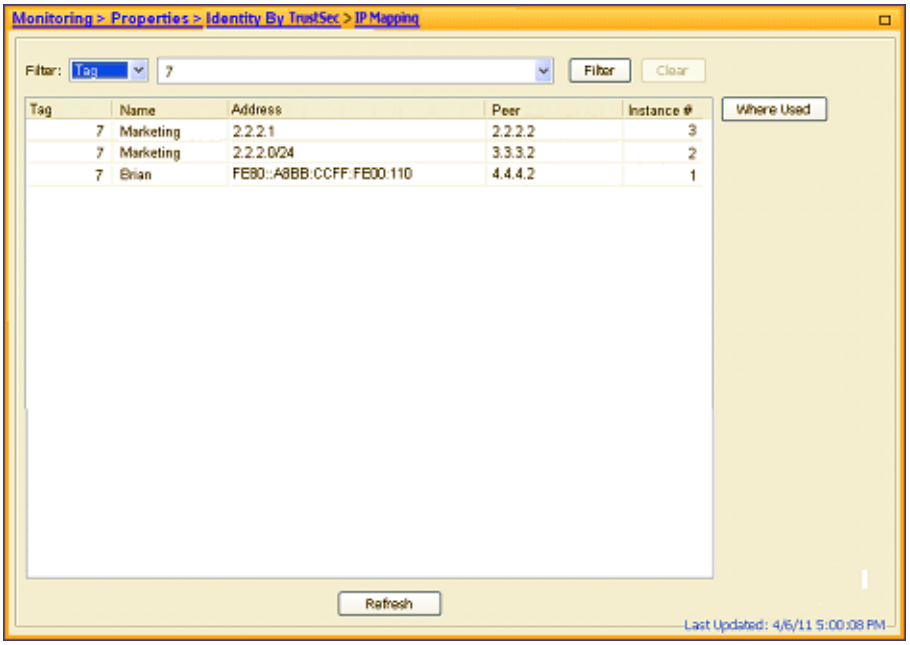


Monitoring Cisco TrustSec IP-SGT Mappings

To display the active IP-SGT mappings on the ASA consolidated from SXP, you can view the IP Mappings monitoring panel in ASDM.

In the main ASDM application window, choose **Monitoring > Properties > Identity By TrustSec > IP Mapping**. The following monitoring panel appears. You can filter the IP-SGT mappings so that you view the data by SGT value, security group name, or IP address.

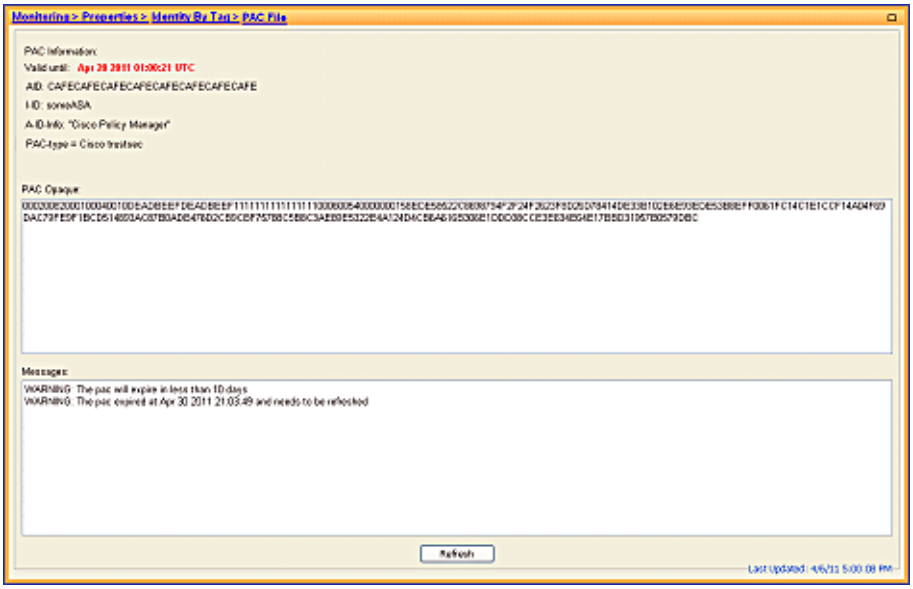
Tip: Click **Where Used** to display where the selected security group object is used in an access list or nested in another security group object.



Monitoring the PAC File

To display the active PAC file imported into the ASA, you can view the PAC File monitoring panel in ASDM.

In the main ASDM application window, choose **Monitoring > Properties > Identity By TrustSec > PAC File**. The following monitoring panel appears.



Feature History for the ASA-Cisco TrustSec Integration

Table 48-3 lists each feature change and the platform release in which it was implemented. ASDM is backwards-compatible with multiple platform releases, so the specific ASDM release in which support was added is not listed.

Table 48-3 Feature History for the ASA-Cisco TrustSec Integration

Feature Name	Platform Releases	Feature Information
Cisco TrustSec Integration	9.0(1)	Cisco TrustSec provides an access-control solution that builds upon an existing identity-aware infrastructure to ensure data confidentiality between network devices and integrate security access services on one platform. In the Cisco TrustSec solution, enforcement devices utilize a combination of user attributes and end-point attributes to make role-based and identity-based access control decisions. In this release, the ASA integrates with Cisco TrustSec to provide security group based policy enforcement. Access policies within the Cisco TrustSec domain are topology-independent, based on the roles of source and destination devices rather than on network IP addresses. The ASA can utilize the Cisco TrustSec solution for other types of security group based policies, such as application inspection; for example, you can configure a class map containing an access policy based on a security group. We introduced or modified the following screens: Configuration > Firewall > Identity By TrustSec Configuration > Firewall > Objects > Security Groups Object Groups Configuration > Firewall > Access Rules > Add Access Rules Monitoring > Properties > Identity By Tag

Configuring Digital Certificates

This chapter describes how to configure digital certificates and includes the following sections:

- Information About Digital Certificates, page 49-1
- Licensing Requirements for Digital Certificates, page 49-8
- Prerequisites for Local Certificates, page 49-8
- Guidelines and Limitations, page 49-9
- Configuring Digital Certificates, page 49-10
- Configuring CA Certificate Authentication, page 49-11
- Monitoring CRLs, page 49-18
- Configuring Identity Certificates Authentication, page 49-22
- Configuring Code Signer Certificates, page 49-27
- Authenticating Using the Local CA, page 49-29
- Managing the User Database, page 49-33
- Managing User Certificates, page 49-35
- Monitoring CRLs, page 49-36
- Feature History for Certificate Management, page 49-37

Information About Digital Certificates

Digital certificates provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that "sign" certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security.

For authentication using digital certificates, at least one identity certificate and its issuing CA certificate must exist on an ASA. This configuration allows multiple identities, roots, and certificate hierarchies. The ASA evaluates third-party certificates against CRLs, also called authority revocation lists, all the way from the identity certificate up the chain of subordinate certificate authorities.

Descriptions of several different types of available digital certificates follow:

- A *CA certificate* is used to sign other certificates. It is self-signed and called a *root certificate*. A certificate that is issued by another CA certificate is called a *subordinate certificate*. For more information, see the "Configuring CA Certificate Authentication" section on page 49-11.
- CAs also issue *identity certificates*, which are certificates for specific systems or hosts. For more information, see the "Configuring Identity Certificates Authentication" section on page 49-22.
- *Code-signer certificates* are special certificates that are used to create digital signatures to sign code, with the signed code itself revealing the certificate origin. For more information, see the "Configuring Code Signer Certificates" section on page 49-27.

The local CA integrates an independent certificate authority feature on the ASA, deploys certificates, and provides secure revocation checking of issued certificates. The local CA provides a secure, configurable, in-house authority for certificate authentication with user enrollment through a website login page.

For more information, see the "Authenticating Using the Local CA" section on page 49-29, the "Managing the User Database" section on page 49-33, and the "Managing User Certificates" section on page 49-35.

Note CA certificates and identity certificates apply to both site-to-site VPN connections and remote access VPN connections. Procedures in this document refer to remote access VPN use in the ASDM GUI.

Digital certificates provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that "sign" certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security.

For authentication using digital certificates, at least one identity certificate and its issuing CA certificate must exist on an ASA. This configuration allows multiple identities, roots, and certificate hierarchies. Descriptions of several different types of available digital certificates follow:

- A *CA certificate* is used to sign other certificates. It is self-signed and called a *root certificate*.
- A certificate that is issued by another CA certificate is called a *subordinate certificate*. For more information, see the "Configuring CA Certificate Authentication" section on page 49-13.

CAs are responsible for managing certificate requests and issuing digital certificates. A digital certificate includes information that identifies a user or device, such as a name, serial number, company, department, or IP address. A digital certificate also includes a copy of the public key for the user or device. A CA can be a trusted third party, such as VeriSign, or a private (in-house) CA that you establish within your organization.

Tip For an example of a scenario that includes certificate configuration and load balancing, see the following URL: https://supportforums.cisco.com/docs/DOC-5964.

This section includes the following topics:

- Public Key Cryptography, page 49-3
- Certificate Scalability, page 49-3
- Key Pairs, page 49-4
- Trustpoints, page 49-4
- Revocation Checking, page 49-5

- The Local CA, page 49-7

Public Key Cryptography

Digital signatures, enabled by public key cryptography, provide a way to authenticate devices and users. In public key cryptography, such as the RSA encryption system, each user has a key pair containing both a public and a private key. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other.

In simple terms, a signature is formed when data is encrypted with a private key. The signature is attached to the data and sent to the receiver. The receiver applies the public key of the sender to the data. If the signature sent with the data matches the result of applying the public key to the data, the validity of the message is established.

This process relies on the receiver having a copy of the public key of the sender and a high degree of certainty that this key belongs to the sender, not to someone pretending to be the sender.

Obtaining the public key of a sender is normally handled externally or through an operation performed at installation. For example, most web browsers are configured with the root certificates of several CAs by default. For VPN, the IKE protocol, a component of IPsec, can use digital signatures to authenticate peer devices before setting up security associations.

Certificate Scalability

Without digital certificates, you must manually configure each IPsec peer for each peer with which it communicates; as a result, each new peer that you add to a network would require a configuration change on each peer with which it needs to communicate securely.

When you use digital certificates, each peer is enrolled with a CA. When two peers try to communicate, they exchange certificates and digitally sign data to authenticate each other. When a new peer is added to the network, you enroll that peer with a CA and none of the other peers need modification. When the new peer attempts an IPsec connection, certificates are automatically exchanged and the peer can be authenticated.

With a CA, a peer authenticates itself to the remote peer by sending a certificate to the remote peer and performing some public key cryptography. Each peer sends its unique certificate, which was issued by the CA. This process works because each certificate encapsulates the public key for the associated peer, each certificate is authenticated by the CA, and all participating peers recognize the CA as an authenticating authority. The process is called IKE with an RSA signature.

The peer can continue sending its certificate for multiple IPsec sessions, and to multiple IPsec peers, until the certificate expires. When its certificate expires, the peer administrator must obtain a new one from the CA.

CAs can also revoke certificates for peers that no longer participate in IPsec. Revoked certificates are not recognized as valid by other peers. Revoked certificates are listed in a CRL, which each peer may check before accepting a certificate from another peer.

Some CAs have an RA as part of their implementation. An RA is a server that acts as a proxy for the CA, so that CA functions can continue when the CA is unavailable.

Key Pairs

Key pairs are RSA keys, which have the following characteristics:

- RSA keys can be used for SSH or SSL.
- SCEP enrollment supports the certification of RSA keys.
- For the purposes of generating keys, the maximum key modulus for RSA keys is 2048 bits. The default size is 1024. Many SSL connections using identity certificates with RSA key pairs that exceed 1024 bits can cause a high CPU usage on the ASA and rejected clientless logins.
- For signature operations, the supported maximum key size is 4096 bits.
- You can generate a general purpose RSA key pair, used for both signing and encryption, or you can generate separate RSA key pairs for each purpose. Separate signing and encryption keys help to reduce exposure of the keys, because SSL uses a key for encryption but not signing. However, IKE uses a key for signing but not encryption. By using separate keys for each, exposure of the keys is minimized.

Trustpoints

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

After you have defined a trustpoint, you can reference it by name in commands requiring that you specify a CA. You can configure many trustpoints.

Note If an ASA has multiple trustpoints that share the same CA, only one of these trustpoints sharing the CA can be used to validate user certificates. To control which trustpoint sharing a CA is used for validation of user certificates issued by that CA, use the **support-user-cert-validation** command.

For automatic enrollment, a trustpoint must be configured with an enrollment URL, and the CA that the trustpoint represents must be available on the network and must support SCEP.

You can export and import the keypair and issued certificates associated with a trustpoint in PKCS12 format. This format is useful to manually duplicate a trustpoint configuration on a different ASA.

Certificate Enrollment

The ASA needs a CA certificate for each trustpoint and one or two certificates for itself, depending upon the configuration of the keys used by the trustpoint. If the trustpoint uses separate RSA keys for signing and encryption, the ASA needs two certificates, one for each purpose. In other key configurations, only one certificate is needed.

The ASA supports automatic enrollment with SCEP and with manual enrollment, which lets you paste a base-64-encoded certificate directly into the terminal. For site-to-site VPNs, you must enroll each ASA. For remote access VPNs, you must enroll each ASA and each remote access VPN client.

Proxy for SCEP Requests

The ASA can proxy SCEP requests between AnyConnect and a third-party CA. The CA only needs to be accessible to the ASA if it is acting as the proxy. For the ASA to provide this service, the user must authenticate using any of the methods supported by AAA before the ASA sends an enrollment request. You can also use host scan and dynamic access policies to enforce rules of eligibility to enroll.

The ASA supports this feature only with an AnyConnect SSL or IKEv2 VPN session. It supports all SCEP-compliant CAs, including IOS CS, Windows Server 2003 CA, and Windows Server 2008 CA.

Clientless (browser-based) access does not support SCEP proxy, although WebLaunch—clientless-initiated AnyConnect—does support it.

The ASA does not support polling for certificates.

The ASA supports load balancing for this feature.

Revocation Checking

When a certificate is issued, it is valid for a fixed period of time. Sometimes a CA revokes a certificate before this time period expires; for example, because of security concerns or a change of name or association. CAs periodically issue a signed list of revoked certificates. Enabling revocation checking forces the ASA to check that the CA has not revoked a certificate each time that it uses the certificate for authentication.

When you enable revocation checking, the ASA checks certificate revocation status during the PKI certificate validation process, which can use either CRL checking, OCSP, or both. OCSP is only used when the first method returns an error (for example, indicating that the server is unavailable).

With CRL checking, the ASA retrieves, parses, and caches CRLs, which provide a complete list of revoked (and unrevoked) certificates with their certificate serial numbers. The ASA evaluates certificates according to CRLs, also called authority revocation lists, from the identity certificate up the chain of subordinate certificate authorities.

OCSP offers a more scalable method of checking revocation status in that it localizes certificate status through a validation authority, which it queries for status of a specific certificate.

Supported CA Servers

The ASA supports the following CA servers:

Cisco IOS CS, ASA Local CA, and third-party X.509 compliant CA vendors including, but not limited to:

- Baltimore Technologies
- Entrust
- Digicert
- Geotrust
- GoDaddy
- iPlanet/Netscape
- Microsoft Certificate Services
- RSA Keon
- Thawte

- VeriSign

CRLs

CRLs provide the ASA with one way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. CRL configuration is part of configuration of a trustpoint.

You can configure the ASA to make CRL checks mandatory when authenticating a certificate by using the **revocation-check crl** command. You can also make the CRL check optional by using the **revocation-check crl none** command, which allows the certificate authentication to succeed when the CA is unavailable to provide updated CRL data.

The ASA can retrieve CRLs from CAs using HTTP, SCEP, or LDAP. CRLs retrieved for each trustpoint are cached for a configurable amount of time for each trustpoint.

When the ASA has cached a CRL for longer than the amount of time it is configured to cache CRLs, the ASA considers the CRL too old to be reliable, or "stale." The ASA tries to retrieve a newer version of the CRL the next time that a certificate authentication requires a check of the stale CRL.

The ASA caches CRLs for an amount of time determined by the following two factors:

- The number of minutes specified with the **cache-time** command. The default value is 60 minutes.
- The NextUpdate field in the CRLs retrieved, which may be absent from CRLs. You control whether the ASA requires and uses the NextUpdate field with the **enforcenextupdate** command.

The ASA uses these two factors in the following ways:

- If the NextUpdate field is not required, the ASA marks CRLs as stale after the length of time defined by the **cache-time** command.
- If the NextUpdate field is required, the ASA marks CRLs as stale at the sooner of the two times specified by the **cache-time** command and the NextUpdate field. For example, if the **cache-time** command is set to 100 minutes and the NextUpdate field specifies that the next update is 70 minutes away, the ASA marks CRLs as stale in 70 minutes.

If the ASA has insufficient memory to store all CRLs cached for a given trustpoint, it deletes the least recently used CRL to make room for a newly retrieved CRL.

OCSP

OCSP provides the ASA with a way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. OCSP configuration is part of trustpoint configuration.

OCSP localizes certificate status on a validation authority (an OCSP server, also called the *responder*) which the ASA queries for the status of a specific certificate. This method provides better scalability and more up-to-date revocation status than does CRL checking, and helps organizations with large PKI installations deploy and expand secure networks.

Note The ASA allows a five-second time skew for OCSP responses.

You can configure the ASA to make OCSP checks mandatory when authenticating a certificate by using the **revocation-check ocsp** command. You can also make the OCSP check optional by using the **revocation-check ocsp none** command, which allows the certificate authentication to succeed when the validation authority is unavailable to provide updated OCSP data.

OCSP provides three ways to define the OCSP server URL. The ASA uses these servers in the following order:

1. The OCSP URL defined in a match certificate override rule by using the **match certificate** command).
2. The OCSP URL configured by using the **ocsp url** command.
3. The AIA field of the client certificate.

Note To configure a trustpoint to validate a self-signed OCSP responder certificate, you import the self-signed responder certificate into its own trustpoint as a trusted CA certificate. Then you configure the **match certificate** command in the client certificate validating trustpoint to use the trustpoint that includes the self-signed OCSP responder certificate to validate the responder certificate. Use the same procedure for configuring validating responder certificates external to the validation path of the client certificate.

The OCSP server (responder) certificate usually signs the OCSP response. After receiving the response, the ASA tries to verify the responder certificate. The CA normally sets the lifetime of the OCSP responder certificate to a relatively short period to minimize the chance of being compromised. The CA usually also includes an ocsp-no-check extension in the responder certificate, which indicates that this certificate does not need revocation status checking. However, if this extension is not present, the ASA tries to check revocation status using the same method specified in the trustpoint. If the responder certificate is not verifiable, revocation checks fail. To avoid this possibility, use the **revocation-check none** command to configure the responder certificate validating trustpoint, and use the r**evocation-check ocsp** command to configure the client certificate.

The Local CA

The local CA performs the following tasks:

- Integrates basic certificate authority operation on the ASA.
- Deploys certificates.
- Provides secure revocation checking of issued certificates.
- Provides a certificate authority on the ASA for use with browser-based and client-based SSL VPN connections.
- Provides trusted digital certificates to users, without the need to rely on external certificate authorization.
- Provides a secure, in-house authority for certificate authentication and offers straightforward user enrollment by means of a website login.

Storage for Local CA Files

The ASA accesses and implements user information, issued certificates, and revocation lists using a local CA database. This database resides in local flash memory by default, or can be configured to reside on an external file system that is mounted and accessible to the ASA.

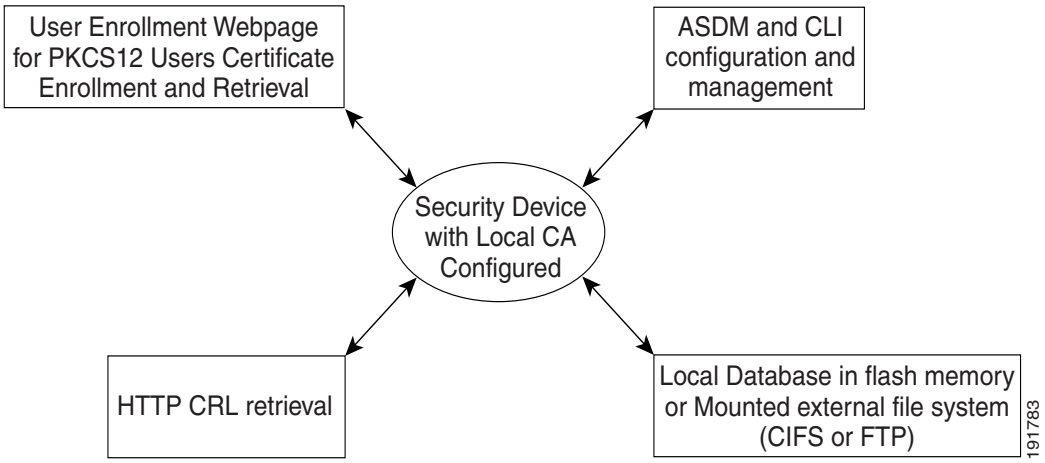
No limits exist on the number of users that can be stored in the local CA user database; however, if flash memory storage issues arise, syslogs are generated to alert the administrator to take action, and the local CA could be disabled until the storage issues are resolved. Flash memory can store a database with 3500 users or less; however, a database of more than 3500 users requires external storage.

The Local CA Server

After you configure a local CA server on the ASA, users can enroll for a certificate by logging into a website and entering a username and a one-time password that is provided by the local CA administrator to validate their eligibility for enrollment.

As shown in Figure 49-1, the local CA server resides on the ASA and handles enrollment requests from website users and CRL inquiries coming from other certificate validating devices and ASAs. Local CA database and configuration files are maintained either on the ASA flash memory (default storage) or on a separate storage device.

Figure 49-1 The Local CA



Licensing Requirements for Digital Certificates

The following table shows the licensing requirements for this feature:

Model	License Requirement
All models	Base License.

Prerequisites for Local Certificates

Local certificates have the following prerequisites:

- Make sure that the ASA is configured correctly to support certificates. An incorrectly configured ASA can cause enrollment to fail or request a certificate that includes inaccurate information.
- Make sure that the hostname and domain name of the ASA are configured correctly. To view the currently configured hostname and domain name, enter the **show running-config** command. For information about configuring the hostname and domain name, see the "Configuring the Hostname, Domain Name, and Passwords" section on page 21-1.

- Make sure that the ASA clock is set accurately before configuring the CA. Certificates have a date and time that they become valid and expire. When the ASA enrolls with a CA and obtains a certificate, the ASA checks that the current time is within the valid range for the certificate. If it is outside that range, enrollment fails. For information about setting the clock, see the "Setting the Date and Time" section on page 21-2.

Prerequisites for SCEP Proxy Support

Configuring the ASA as a proxy to submit requests for third-party certificates has the following requirements:

- AnyConnect Secure Mobility Client 3.0 or later must be running at the endpoint.
- The authentication method, configured in the connection profile for your group policy, must be set to use both AAA and certificate authentication.
- An SSL port must be open for IKEv2 VPN connections.
- The CA must be in auto-grant mode.

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

- Supported in single and multiple context mode for a local CA.
- Supported in single context mode only for third-party CAs.

Firewall Mode Guidelines

Supported in routed and transparent firewall mode.

Failover Guidelines

- Does not support replicating sessions in Stateful Failover.
- Does not support Active/Active or Active/Standby failover.

IPv6 Guidelines

Supports IPv6.

Additional Guidelines

- For ASAs that are configured as CA servers or clients, limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038. This guideline also applies to imported certificates from third-party vendors.
- You cannot configure the local CA when failover is enabled. You can only configure the local CA server for standalone ASAs without failover. For more information, see CSCty43366.
- When a certificate enrollment is completed, the ASA stores a PKCS12 file containing the user's keypair and certificate chain, which requires about 2 KB of flash memory or disk space per enrollment. The actual amount of disk space depends on the configured RSA key size and certificate

fields. Keep this guideline in mind when adding a large number of pending certificate enrollments on an ASA with a limited amount of available flash memory, because these PKCS12 files are stored in flash memory for the duration of the configured enrollment retrieval timeout.

- The **lifetime ca-certificate** command takes effect when the local CA server certificate is first generated (that is, when you initially configure the local CA server and issue the **no shutdown** command). When the CA certificate expires, the configured lifetime value is used to generate the new CA certificate. You cannot change the lifetime value for existing CA certificates.
- You should configure the ASA to use an identity certificate to protect ASDM traffic and HTTPS traffic to the management interface. Identity certificates that are automatically generated with SCEP are regenerated after each reboot, so make sure that you manually install your own identity certificates. For an example of this procedure that applies only to SSL, see the following URL: http://www.cisco.com/en/US/products/ps6120/products_configuration_example09186a00809fcf91.shtml.
- The ASA and the AnyConnect clients can only validate certificates in which the X520Serialnumber field (the serial number in the Subject Name) is in PrintableString format. If the serial number format uses encoding such as UTF8, the certificate authorization will fail.

Configuring Digital Certificates

This section describes how to configure local CA certificates. Make sure that you follow the sequence of tasks listed to correctly configure this type of digital certificate. This section includes the following topics:

- Configuring CA Certificate Authentication, page 49-11
- Configuring CA Certificates for Revocation, page 49-19
- Configuring CRL Retrieval Policy, page 49-19
- Configuring CRL Retrieval Methods, page 49-20
- Configuring OCSP Rules, page 49-20
- Configuring Advanced CRL and OCSP Settings, page 49-21

This section describes how to configure digital certificates for the ASA Services Module and includes the following topics:

- Configuring CA Certificate Authentication, page 49-13
- Adding or Installing a CA Certificate, page 49-13
- Editing or Removing a CA Certificate Configuration, page 49-14
- Showing CA Certificate Details, page 49-14
- Configuring CA Certificates for Revocation, page 49-15
- Configuring CRL Retrieval Policy, page 49-15
- Configuring CRL Retrieval Methods, page 49-16
- Configuring OCSP Rules, page 49-16
- Configuring Advanced CRL and OCSP Settings, page 49-17

Configuring CA Certificate Authentication

The CA Certificates pane displays the available certificates, identified by the issued to and issued by CA server, the date that the certificate expires, the associated trustpoints, and the certificate usage or purpose. In the CA Certificates pane, you can perform the following tasks:

- Authenticate self-signed or subordinate CA certificates.
- Install CA certificates on the ASA.
- Create a new certificate configuration.
- Edit an existing certificate configuration.
- Obtain a CA certificate manually and import it.
- Have the ASA use SCEP to contact the CA, and then automatically obtain and install the certificate.
- Display details and issuer information for a selected certificate.
- Access the CRL for an existing CA certificate.
- Remove the configuration of an existing CA certificate.
- Save the new or modified CA certificate configuration.
- Discard any changes and return the certificate configuration to the original settings.

This section includes the following topics:

- Adding or Installing a CA Certificate, page 49-11
- Editing or Removing a CA Certificate Configuration, page 49-12
- Showing CA Certificate Details, page 49-13

Adding or Installing a CA Certificate

You can add a new certificate configuration from an existing file, by manually pasting a certificate in PEM format, or by automatic enrollment using SCEP. SCEP is a secure messaging protocol that requires minimal user intervention and lets you enroll and install certificates using only the VPN Concentrator Manager.

To add or install a CA certificate, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Remote Access VPN > Certificate Management > CA Certificates**.

Step 2 Click **Add**.

The Install Certificate dialog box appears. The selected trustpoint name appears in read-only format.

Step 3 To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting).

Step 4 Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.

Step 5 The Certificate Installation dialog box appears with a confirmation message indicating that the certificate was successfully installed. Click **OK** to close this dialog box.

Step 6 To enroll manually, click the **Paste certificate in PEM format** radio button.

Step 7 Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided, then click **Install Certificate**.

Step 8 The Certificate Installation dialog box appears with a confirmation message indicating that the certificate was successfully installed. Click **OK** to close this dialog box.

Step 9 To enroll automatically, click the **Use SCEP** radio button. The ASA contacts the CA using SCEP, obtains the certificates, and installs them on the device. To use SCEP, you must enroll with a CA that supports SCEP, and you must enroll via the Internet. Automatic enrollment using SCEP requires that you provide the following information:

- The path and file name of the certificate to be automatically installed.
- The maximum number of minutes to retry certificate installation. The default is one minute.
- The number of retries for installing a certificate. The default is zero, which indicates unlimited retries within the retry period.

Note See Prerequisites for SCEP Proxy Support when choosing to use the SCEP method to install certficates.

Step 10 To display additional configuration options for new and existing certificates, click **More Options**.

The Configuration Options for CA Certificates pane appears.

Step 11 To continue, see the "Editing or Removing a CA Certificate Configuration" section on page 49-12.

Editing or Removing a CA Certificate Configuration

To change or remove an existing CA certificate configuration, perform the following steps:

Step 1 To change an existing CA certificate configuration, select it, and then click **Edit**.

The Edit Options for CA Certificates pane appears. To change any of these settings, see the following sections for procedures:

- "Configuring CRL Retrieval Policy" section on page 49-19
- "Configuring CRL Retrieval Methods" section on page 49-20
- "Configuring OCSP Rules" section on page 49-20
- "Configuring Advanced CRL and OCSP Settings" section on page 49-21

Step 2 To remove a CA certificate configuration, select it, and then click **Delete**.

Note After you delete a certificate configuration, it cannot be restored. To recreate the deleted certificate, click **Add** to reenter all of the certificate configuration information.

Showing CA Certificate Details

To show detailed information about the selected CA certificate, click **Show Details** to display the Certificate Details dialog box, which includes the following three *display-only* tabs:

- The General tab displays the values for type, serial number, status, usage, public key type, CRL distribution point, the times within which the certificate is valid, and associated trustpoints. The values apply to both available and pending status.
- The Issued to tab displays the X.500 fields of the subject DN or certificate owner and their values. The values apply only to available status.
- The Issued by tab displays the X.500 fields of the entity granting the certificate. The values apply only to available status.

Configuring CA Certificate Authentication

The CA Certificates pane displays the available certificates, identified by the issued to and issued by CA server, the date that the certificate expires, the associated trustpoints, and the certificate usage or purpose. In the CA Certificates pane, you can perform the following tasks:

- Authenticate self-signed or subordinate CA certificates.
- Install CA certificates on the ASA.
- Create a new certificate configuration.
- Edit an existing certificate configuration.
- Obtain a CA certificate manually and import it.
- Display details and issuer information for a selected certificate.
- Access the CRL for an existing CA certificate.
- Remove the configuration of an existing CA certificate.
- Save the new or modified CA certificate configuration.
- Discard any changes and return the certificate configuration to the original settings.

Adding or Installing a CA Certificate

You can add a new certificate configuration from an existing file, by manually pasting a certificate in PEM format.

To add or install a CA certificate, perform the following steps:

Step 1 In the main ASDM application window, choose **Configuration > Device Management > Certificate Management > CA Certificates**.

Step 2 Click **Add**.

The Install Certificate dialog box appears. The selected trustpoint name appears in read-only format.

Step 3 To add a certificate configuration from an existing file, click the **Install from a file** radio button (this is the default setting).

Step 4 Enter the path and file name, or click **Browse** to search for the file. Then click **Install Certificate**.

Step 5 To enroll manually, click the **Paste certificate in PEM format** radio button.

Step 6 Copy and paste the PEM format (base64 or hexadecimal) certificate into the area provided, then click **Install Certificate**.

Step 7 To display additional configuration options for new and existing certificates, click **More Options**.

The Configuration Options for CA Certificates pane appears.

Step 8 Make your selections, and then click OK. To continue, see the "Editing or Removing a CA Certificate Configuration" section on page 49-14.

Editing or Removing a CA Certificate Configuration

To change or remove an existing CA certificate configuration, perform the following steps:

Step 1 To change an existing CA certificate configuration, select it, and then click **Edit**.

The Edit Options for CA Certificates pane appears. To change any of these settings, see the following sections for procedures:

- "Configuring CRL Retrieval Policy" section on page 49-15
- "Configuring CRL Retrieval Methods" section on page 49-16
- "Configuring OCSP Rules" section on page 49-16
- "Configuring Advanced CRL and OCSP Settings" section on page 49-17

Step 2 To remove a CA certificate configuration, select it, and then click **Delete**.

Note After you delete a certificate configuration, it cannot be restored. To recreate the deleted certificate, click **Add** to reenter all of the certificate configuration information.

Showing CA Certificate Details

To show detailed information about the selected CA certificate, click **Show Details** to display the Certificate Details dialog box, which includes the following three *display-only* tabs:

- The General tab displays the values for type, serial number, status, usage, public key type, CRL distribution point, the times within which the certificate is valid, and associated trustpoints. The values apply to both available and pending status.
- The Issued to tab displays the X.500 fields of the subject DN or certificate owner and their values. The values apply only to available status.
- The Issued by tab displays the X.500 fields of the entity granting the certificate. The values apply only to available status.

Configuring CA Certificates for Revocation

To configure CA certificates for revocation, perform the following site-to-site task in either single or muliple context mode:

Step 1 In the ASDM application window, choose **Configuration > Site-to-Site VPN > Certificate Management > CA Certificates > Add** to display the Install Certificates dialog box. Then click **More Options**.

Step 2 In the Configuration Options for CA Certificates pane, click the **Revocation Check** tab.

Step 3 To disable revocation checking of certificates, click the **Do not check certificates for revocation** radio button.

Step 4 To select one or more revocation checking methods (CRL or OCSP), click the **Check certificates for revocation** radio button.

Step 5 In the Revocation Methods area, available methods appear on the left. Click **Add** to move a method to the right and make it available. Click **Move Up** or **Move Down** to change the method order.

The methods you choose are implemented in the order in which you add them. If a method returns an error, the next revocation checking method activates.

Step 6 Check the **Consider certificate valid if revocation checking returns errors** check box to ignore revocation checking errors during certificate validation.

Step 7 Click **OK** to close the Revocation Check tab. Alternatively, to continue, see the "Configuring CRL Retrieval Policy" section on page 49-15.

Configuring CRL Retrieval Policy

To configure the CRL retrieval policy, perform the following steps:

Step 1 In the ASDM application window, choose **Configuration > Site-to-Site VPN > Certificate Management > CA Certificates > Add** to display the Install Certificates dialog box. Then click **More Options**.

Step 2 Check the **Use CRL Distribution Point from the certificate** check box to direct revocation checking to the CRL distribution point from the certificate being checked.

Step 3 Check the **Use Static URLs configured below** check box to list specific URLs to be used for CRL retrieval. The URLs you select are implemented in the order in which you add them. If an error occurs with the specified URL, the next URL in order is taken.

Step 4 In the Static Configuration area, click **Add**.

The Add Static URL dialog box appears.

Step 5 In the URL field, enter the static URL to use for distributing the CRLs, and then click **OK**.

The URL that you entered appears in the Static URLs list.

Step 6 To change the static URL, select it, and then click **Edit**.

Step 7 To remove an existing static URL, select it, and then click **Delete**.

Step 8 To change the order in which the static URLs appear, click **Move Up** or **Move Down**.

Step 9 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring CRL Retrieval Methods" section on page 49-16.

Configuring CRL Retrieval Methods

To configure CRL retrieval methods, perform the following steps:

Step 1 In the ASDM application window, choose **Configuration > Site-to-Site VPN > Certificate Management > CA Certificates > Add** to display the Install Certificates dialog box. Then click **More Options**.

Step 2 In the Configuration Options for CA Certificates pane, click the **CRL Retrieval Methods** tab.

Step 3 Choose one of the following three retrieval methods:

- To enable LDAP for CRL retrieval, check the **Enable Lightweight Directory Access Protocol (LDAP)** check box. With LDAP, CRL retrieval starts an LDAP session by connecting to a named LDAP server, accessed by a password. The connection is on TCP port 389 by default. Enter the following required parameters:
  - Name
  - Password
  - Confirm Password
  - Default Server (server name)
  - Default Port (389)
- To enable HTTP for CRL retrieval, check the **Enable HTTP** check box.

Step 4 Click **OK** to close this tab. Alternatively, to continue, see the "Configuring OCSP Rules" section on page 49-16.
