show running-config filter	Displays filtering configuration.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

filter java

To remove Java applets from HTTP traffic passing through the ASA, use the **filter java** command in global configuration mode. To remove the configuration, use the **no** form of this command.

filter java {[*port*[**-***port*] | **except** } *local_ip local_mask foreign_ip foreign_mask*]

no filter java {[*port*[**-***port*] | **except** } *local_ip local_mask foreign_ip foreign_mask*]

Syntax Description

except	(Optional) Creates an exception to a previous filter condition.
foreign_ip	The IP address of the lowest security level interface to which access is requested. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
foreign_mask	Network mask of the *foreign_ip* argument. Always specify a specific mask value. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
local_ip	The IP address of the highest security level interface from which access is requested. You can set this address to 0.0.0.0 (or in shortened form, 0) to specify all hosts.
local_mask	Network mask of the *local_ip* argument. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
port	The TCP port to which filtering is applied. Typically, this is port 80, but other values are accepted. The http or url literal can be used for port 80.
*port***-***port*	(Optional) Specifies a port range.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Java applets may pose security risks because they can contain code intended to attack hosts and servers on a protected network. You can remove Java applets with the **filter java** command.

The **filter java** command filters out Java applets that return to the ASA from an outbound connection. The user still receives the HTML page, but the web page source for the applet is commented out so that the applet cannot execute. The **filter java** command does not filter WebVPN traffic.

If the <applet> or </applet> HTML tags split across network packets or if the code in the tags is longer than the number of bytes in the MTU, the ASA cannot block the tag. If Java applets are known to be in <object> tags, use the **filter activex** command to remove them.

Examples

The following example specifies that Java applets are blocked on all outbound connections:

```
hostname(config)# filter java 80 0 0 0 0
```

The following example specifies that the Java applet blocking applies to web traffic on port 80 from any local host and for connections to any foreign host.

The following example blocks the downloading of Java applets to a host on a protected network:

```
hostname(config)# filter java http 192.168.3.3 255.255.255.255 0 0
```

Related Commands

Commands	Description
filter activex	Removes ActiveX objects from HTTP traffic passing through the ASA.
filter url	Directs traffic to a URL filtering server.
show running-config filter	Displays filtering configuration.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

filter url

To direct traffic to a URL filtering server, use the **filter url** command in global configuration mode. To remove the configuration, use the **no** form of this command.

filter url *port* [**-***port*] | **except** *local_ip local_mask foreign_ip foreign_mask* [**allow**] [**cgi-truncate**] [**longurl-truncate** | **longurl-deny**] [**proxy-block**]

no filter url *port* [**-***port*] | **except** *local_ip mask foreign_ip foreign_mask* [**allow**] [**cgi-truncate**] [**longurl-truncate** | **longurl-deny**] [**proxy-block**]

Syntax Description

allow	When the server is unavailable, let outbound connections pass through the ASA without filtering. If you omit this option, and if the N2H2 or Websense server goes off line, the ASA stops outbound port 80 (Web) traffic until the N2H2 or Websense server is back online.
cgi_truncate	When a URL has a parameter list starting with a question mark (?), such as a CGI script, truncate the URL sent to the filtering server by removing all characters after and including the question mark.
except	Creates an exception to a previous **filter** condition.
foreign_ip	The IP address of the lowest security level interface to which access is sought. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
foreign_mask	Network mask of the *foreign_ip* argument. Always specify a specific mask value. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
http	Specifies port 80. You can enter http or www instead of 80 to specify port 80.
local_ip	The IP address of the highest security level interface from which access is sought. You can set this address to 0.0.0.0 (or in shortened form, 0) to specify all hosts.
local_mask	Network mask of the *local_ip* argument. You can use 0.0.0.0 (or in shortened form, 0) to specify all hosts.
longurl-deny	Denies the URL request if the URL is over the URL buffer size limit or the URL buffer is not available.
longurl-truncate	Sends only the originating hostname or IP address to the N2H2 or Websense server if the URL is over the URL buffer limit.
-*port*	(Optional) The TCP port to which filtering is applied. Typically, this is port 80, but other values are accepted. The http or url literal can be used for port 80. Adding a second port after a hyphen optionally identifies a range of ports.
proxy-block	Prevents users from connecting to an HTTP proxy server.
url	Filter URLs from data moving through the ASA.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple	
				Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **filter url** command lets you prevent outbound users from accessing World Wide Web URLs that you designate using the N2H2 or Websense filtering application.

Note The **url-server** command must be configured before issuing the **filter url** command.

The **allow** option of the **filter url** command determines how the ASA behaves if the N2H2 or Websense server goes off line. If you use the **allow** option with the **filter url** command and the N2H2 or Websense server goes offline, port 80 traffic passes through the ASA without filtering. If used without the **allow** option and with the server offline, the ASA stops outbound port 80 (Web) traffic until the server is back online, or if another URL server is available, passes control to the next URL server.

Note With the **allow** option set, the ASA passes control to an alternate server if the N2H2 or Websense server goes offline.

The N2H2 or Websense server works with the ASA to deny users from access to websites based on the company security policy.

Using the Filtering Server

Websense protocol Version 4 enables group and username authentication between a host and an ASA. The ASA performs a username lookup, and then Websense server handles URL filtering and username logging.

The N2H2 server must be a Windows workstation (2000, NT, or XP), running an IFP Server, with a recommended minimum of 512 MB of RAM. Also, the long URL support for the N2H2 service is capped at 3 KB, less than the cap for Websense.

Websense protocol Version 4 contains the following enhancements:

- URL filtering allows the ASA to check outgoing URL requests with the policy defined on the Websense server.
- Username logging tracks username, group, and domain name on the Websense server.
- Username lookup enables the ASA to use the user authentication table to map the host's IP address to the username.

Information on Websense is available at the following website:

http://www.websense.com/

Configuration Procedure

Follow these steps to filter URLs:

1. Designate an N2H2 or Websense server with the appropriate vendor-specific form of the **url-server** command.
2. Enable filtering with the **filter** command.
3. If needed, improve throughput with the **url-cache** command. However, this command does not update Websense logs, which may affect Websense accounting reports. Accumulate Websense run logs before using the **url-cache** command.
4. Use the **show url-cache statistics** and the **show perfmon** commands to view run information.

Working with Long URLs

Filtering URLs up to 4 KB is supported for the Websense filtering server, and up to 3 KB for the N2H2 filtering server.

Use the **longurl-truncate** and **cgi-truncate** options to allow handling of URL requests longer than the maximum permitted size.

If a URL is longer than the maximum, and you do not enable the **longurl-truncate** or **longurl-deny** options, the ASA drops the packet.

The **longurl-truncate** option causes the ASA to send only the hostname or IP address portion of the URL for evaluation to the filtering server when the URL is longer than the maximum length permitted. Use the **longurl-deny** option to deny outbound URL traffic if the URL is longer than the maximum permitted.

Use the **cgi-truncate** option to truncate CGI URLs to include only the CGI script location and the script name without any parameters. Many long HTTP requests are CGI requests. If the parameters list is very long, waiting and sending the complete CGI request including the parameter list can use up memory resources and affect ASA performance.

Buffering HTTP Responses

By default, when a user issues a request to connect to a specific website, the ASA sends the request to the web server and to the filtering server at the same time. If the filtering server does not respond before the web content server, the response from the web server is dropped. This delays the web server response from the point of view of the web client.

By enabling the HTTP response buffer, replies from web content servers are buffered and the responses will be forwarded to the requesting user if the filtering server allows the connection. This prevents the delay that may otherwise occur.

To enable the HTTP response buffer, enter the following command:

```
hostname(config)# url-block block block-buffer-limit
```

Replace the *block-buffer-limit* argument with the maximum number of blocks that will be buffered. The permitted values are from 1 to 128, which specifies the number of 1550-byte blocks that can be buffered at one time.

Examples

The following example filters all outbound HTTP connections except those from the 10.0.2.54 host:

```
hostname(config)# url-server (perimeter) host 10.0.1.1
hostname(config)# filter url 80 0 0 0 0
hostname(config)# filter url except 10.0.2.54 255.255.255.255 0 0
```

The following example blocks all outbound HTTP connections destined to a proxy server that listens on port 8080:

```
hostname(config)# filter url 8080 0 0 0 0 proxy-block
```

Related Commands

Commands	Description
filter activex	Removes ActiveX objects from HTTP traffic passing through the ASA.
filter java	Removes Java applets from HTTP traffic passing through the ASA.
url-block	Manages the URL buffers used for web server responses while waiting for a filtering decision from the filtering server.
url-cache	Enables URL caching while pending responses from an N2H2 or Websense server and sets the size of the cache.
url-server	Identifies an N2H2 or Websense server for use with the **filter** command.

fips enable

To enable policy checking to enforce FIPS compliance on the system or module, use the **fips enable** command in global configuration mode. To disable policy checking, use the **no** form of this command.

fips enable

no fips enable

Syntax Description

enable	Enables or disables policy checking to enforce FIPS compliance.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	—	—	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

To run in a FIPS-compliant mode of operation, you must apply both the **fips enable** command and the correct configuration specified in the security policy. The internal API allows the device to migrate toward enforcing correct configuration at run time.

When the FIPS-compliant mode is present in the startup configuration, FIPS POST will run and print the following console message:

```

```

Examples

The following shows policy checking to enforce FIPS compliance on the system:

```
hostname(config)# fips enable
```

Related Commands

Command	Description
clear configure fips	Clears the system or module FIPS configuration information stored in NVRAM.
crashinfo console disable	Disables the reading, writing and configuration of crash write info to flash.
fips self-test poweron	Executes power-on self-tests.
show crashinfo console	Reads, writes, and configures crash write to flash.
show running-config fips	Displays the FIPS configuration that is running on the ASA.

fips self-test poweron

To execute power-on self-tests, use the **fips self-test powereon** command in privileged EXEC mode.

fips self-test poweron

Syntax Description

poweron	Executes power-on self-tests.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

Entering this command causes the device to run all self-tests required for FIPS 140-2 compliance. Tests include the cryptographic algorithm test, software integrity test, and critical functions test.

Examples

The following example shows the system executing power-on of self-tests:

```
sw8-5520(config)# fips self-test poweron
```

Related Commands

Command	Description
clear configure fips	Clears the system or module FIPS configuration information stored in NVRAM.
crashinfo console disable	Disables the reading, writing, and configuration of crash write info to Flash.
fips enable	Enables or disablea policy checking to enforce FIPS compliance on the system or module.
show crashinfo console	Reads, writes, and configures crash write to flash.
show running-config fips	Displays the FIPS configuration that is running on the ASA.

firewall transparent

To set the firewall mode to transparent mode, use the **firewall transparent** command in global configuration mode. To restore routed mode, use the **no** form of this command.

firewall transparent

no firewall transparent

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA is in routed mode.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.5(1)/9.0(1)	You can set this per context in multiple context mode.

Usage Guidelines

A transparent firewall is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

You can set this command per context in multiple context mode.

When you change modes, the ASA clears the configuration because many commands are not supported for both modes. If you already have a populated configuration, be sure to back up your configuration before changing the mode; you can use this backup for reference when creating your new configuration.

If you download a text configuration to the ASA that changes the mode with the **firewall transparent** command, be sure to put the command at the top of the configuration; the ASA changes the mode as soon as it reads the command and then continues reading the configuration you downloaded. If the command is later in the configuration, the ASA clears all the preceding lines in the configuration.

Examples

The following example changes the firewall mode to transparent:

```
hostname(config)# firewall transparent
```

Related Commands

Command	Description
arp-inspection	Enables ARP inspection, which compares ARP packets to static ARP entries.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning.
show firewall	Shows the firewall mode.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

firewall vlan-group (IOS)

To assign VLANs to a firewall group, enter the **firewall vlan-group** command in global configuration mode. To remove the VLANs, use the **no** form of this command.

firewall vlan-group *firewall_group vlan_range*

no firewall vlan-group *firewall_group vlan_range*

Syntax Description

firewall_group	Specifies the group ID as an integer.
vlan_range	Specifies the VLANs assigned to the group. The *vlan_range* can be one or more VLANs (2 to 1000 and from 1025 to 4094) identified in one of the following ways: • A single number (*n*) • A range (*n-x*) Separate numbers or ranges by commas. For example, enter the following numbers: `5,7-10,13,45-100` **Note** Routed ports and WAN ports consume internal VLANs, so it is possible that VLANs in the 1020-1100 range might already be in use.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In Cisco IOS software, create up to 16 firewall VLAN groups using the **firewall vlan-group** command, and then assign the groups to the ASA (using the **firewall module** command). For example, you can assign all the VLANs to one group, or you can create an inside group and an outside group, or you can create a group for each customer. Each group can contain unlimited VLANs.

You cannot assign the same VLAN to multiple firewall groups; however, you can assign multiple firewall groups to an ASA and you can assign a single firewall group to multiple ASAs. VLANs that you want to assign to multiple ASAs, for example, can reside in a separate group from VLANs that are unique to each ASA.

Examples

The following example shows how you can create three firewall VLAN groups: one for each ASA, and one that includes VLANs assigned to both ASAs.

```
Router(config)# firewall vlan-group 50 55-57
Router(config)# firewall vlan-group 51 70-85
Router(config)# firewall vlan-group 52 100
Router(config)# firewall module 5 vlan-group 50,52
Router(config)# firewall module 8 vlan-group 51,52
```

The following is sample output from the **show firewall vlan-group** command:

```
Router# show firewall vlan-group
Group vlans
----- ------
   50 55-57
   51 70-85
   52 100
```

The following is sample output from the **show firewall module** command, which shows all VLAN groups:

```
Router# show firewall module
Module Vlan-groups
  5    50,52
  8    51,52
```

Related Commands

Command	Description
firewall module	Assigns a VLAN group to an ASA.
show firewall vlan-group	Shows the VLAN groups and the VLANs assigned to them.
show module	Shows all installed modules.

flow-export active refresh-interval

To specify the time interval between flow-update events, use the **flow-export active refresh-interval** command in global configuration mode.

flow-export active refresh-interval *value*

Syntax Description

value	Specifies the time interval between flow-update events in minutes. Valid values are from 1-60 minutes.

Defaults

The default value is 1 minute.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

If you have already configured the **flow-export delay flow-create** command, and you then configure the **flow-export active refresh-interval** command with an interval value that is not at least 5 seconds more than the delay value, the following warning message appears at the console:

```
WARNING: The current delay flow-create value configuration may cause flow-update events to
appear before flow-creation events.
```

If you have already configured the **flow-export active refresh-interval** command, and you then configure the **flow-export delay flow-create** command with a delay value that is not at least 5 seconds less than the interval value, the following warning message appears at the console:

```
WARNING: The current delay flow-create value configuration may cause flow-update events to
appear before flow-creation events.
```

Examples

The following example shows how to configure a time interval of 30 minutes:

```
hostname(config)# flow-export active refresh-interval 30
```

Related Commands

Commands	Description
clear flow-export counters	Resets all runtime counters in NetFlow to zero.
flow-export destination	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

flow-export delay flow-create

To delay export of the flow-create event, use the **flow-export delay flow-create** command in global configuration mode. To export the flow-create event without a delay, use the **no** form of this command.

flow-export delay flow-create *seconds*

no flow-export delay flow-create *seconds*

Syntax Description

seconds	Specifies the delay in seconds for exporting the flow-create event. Valid values are 1-180 seconds.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(2)	This command was introduced.

Usage Guidelines

If the **flow-export delay flow-create** command is not configured, the flow-create event is exported without a delay.

If the flow is torn down before the configured delay, the flow-create event is not sent; an extended flow teardown event is sent instead.

Examples

The following example shows how to delay the export of a flow-create event by ten seconds:

```
hostname(config)# flow-export delay flow-create 10
```

Related Commands

Commands	Description
clear flow-export counters	Resets all runtime counters in NetFlow to zero.
flow-export destination	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

flow-export destination

To configure a collector to which NetFlow packets are sent, use the **flow-export destination** command in global configuration mode. To remove a collector of NetFlow packets, use the **no** form of this command.

flow-export destination *interface-name ipv4-address | hostname udp-port*

no flow-export destination *interface-name ipv4-address | hostname udp-port*

Syntax Description

hostname	Specifies the hostname of the NetFlow collector.
interface-name	Specifies the name of the interface through which the destination can be reached.
ipv4-address	Specifies the IP address of the NetFlow collector. Only IPv4 is supported.
udp-port	Specifies the UDP port on which the NetFlow collector is listening. Valid values are 1-65535.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.
8.1(2)	The maximum number of flow export destinations was increased to five.

Usage Guidelines

You can use the **flow-export destination** command to configure the ASA to export NetFlow data to a NetFlow collector.

Note You can enter a maximum of five export destinations (collectors) per security context. When you enter a new destination, the template records are sent to the newly added collector. If you try to add more than five destinations, the following error message appears:

"ERROR: A maximum of 5 flow-export destinations can be configured."

If the ASA is configured to export NetFlow data, to improve performance, we recommend that you disable redundant syslog messages (those also captured by NetFlow) by entering the **logging flow-export-syslogs disable** command.

Examples

The following example shows how to configure a collector for NetFlow data:

```
hostname(config)# flow-export destination inside 209.165.200.224 2055
```

Related Commands

Commands	Description
clear flow-export counters	Resets all runtime counters in NetFlow to zero.
flow-export delay flow-create	Delays the export of the flow-create event by a specified amount of time.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

flow-export event-type destination

To configure the address of NetFlow collectors and filters to determine which NetFlow records should be sent to each collector, use the **flow-export event-type destination** command in policy-map class configuration mode. To remove the address of NetFlow collectors and filters, use the **no** form of this command.

flow-export event-type {**all** | **flow-create** | **flow-denied** | **flow-update** | **flow-teardown**} **destination**

no flow-export event-type {**all** | **flow-create** | **flow-denied** | **flow-update** | **flow-teardown**} **destination**

Syntax Description

all	Specifies all four event types.
flow-create	Specifies flow-create events.
flow-denied	Specifies flow-denied events.
flow-teardown	Specifies flow-teardown events.
flow-update	Specifies flow-update events.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Policy-map class configuration	•	•	•	•	—

Command History

Release	Modification
8.1(2)	This command was introduced.

Usage Guidelines

NetFlow events are configured through Modular Policy Framework. If Modular Policy Framework is not configured for NetFlow, no events are logged. Traffic is matched based on the order in which classes are configured. After a match is detected, no other classes are checked. For NetFlow events, the configuration requirements are as follows:

- A flow-export destination (that is, a NetFlow collector) is uniquely identified by its IP address.
- Supported event types are flow-create, flow-teardown, flow-denied, flow-update, and all, which include the four previously listed event types.
- Flow-export actions are not supported in interface policies.

- Flow-export actions are only supported in the **class-default** command and in classes with the **match any** or **match access-list** command.
- If no NetFlow collector has been defined, no configuration actions occur.
- NetFlow Secure Event Logging filtering is order-independent.

Note To create a valid NetFlow configuration, you must have both the flow-export destination configuration and the flow-export event-type configuration. The flow-export destination configuration alone does nothing. You must also configure a class map for the flow-export event-type configuration. This can either be the default class map or one that you create.

Examples

The following example exports all NetFlow events between hosts 10.1.1.1 and 20.1.1.1 to the destination 15.1.1.1.

```
hostname(config)# access-list flow_export_acl permit ip host 10.1.1.1 host 20.1.1.1
hostname(config)# class-map flow_export_class
hostname(config-cmap)# match access-list flow_export_acl
hostname(config)# policy-map global_policy
hostname(config-pmap)# class flow_export_class
hostname(config-pmap-c)# flow-export event-type all destination 15.1.1.1
```

Related Commands

flow-export delay flow-create	Delays the export of the flow-create event by a specified amount of time.
flow-export template timeout-rate	Controls the interval at which the template information is sent to the NetFlow collector.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

flow-export template timeout-rate

To control the interval at which the template information is sent to NetFlow collectors, use the **flow-export template timeout-rate** command in global configuration mode. To reset the template timeout to the default value, use the **no** form of this command.

flow-export template timeout-rate *minutes*

no flow-export template timeout-rate *minutes*

Syntax Description

minutes	Specifies the interval in minutes. Valid values are 1-3600 minutes.
template	Enables the **timeout-rate** keyword for configuring export templates.
timeout-rate	Specifies the amount of time elapsed (interval) after the template is initially sent before it is resent.

Defaults

The default value for the interval is 30 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

You should configure the timeout rate based on the collector being used and at what rate the collectors expect the templates to be refreshed.

If the security appliance is configured to export NetFlow data, to improve performance, we recommend that you disable redundant syslog messages (those also captured by NetFlow) by entering the **logging flow-export-syslogs disable** command.

Examples

The following example shows how to configure NetFlow to send template records to all collectors every 60 minutes:

```
hostname(config)# flow-export template timeout-rate 60
```

Related Commands

Commands	Description
clear flow-export counters	Resets all the runtime counters associated with NetFlow data.
flow-export destination	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
logging flow-export-syslogs enable	Enables syslog messages after you have entered the **logging flow-export-syslogs disable** command, and the syslog messages that are associated with NetFlow data.
show flow-export counters	Displays a set of runtime counters for NetFlow.

flowcontrol

To enable pause (XOFF) frames for flow control, use the **flowcontrol** command in interface configuration mode. To disable pause frames, use the **no** form of this command.

flowcontrol send on [*low_water high_water pause_time*] [**noconfirm**]

no flowcontrol send on [*low_water high_water pause_time*] [**noconfirm**]

Syntax Description

high_water	Sets the high-water mark, between 0 and 511 KB for 10 GigabitEthernet, and between 0 and 47 KB for 1 GigabitEthernet. When the buffer usage exceeds the high watermark, the NIC sends a pause frame.
low_water	Sets the low-water mark, between 0 and 511 KB for 10 GigabitEthernet, and between 0 and 47 KB for 1 GigabitEthernet. After the network interface controller (NIC) sends a pause frame, when the buffer usage is reduced below the low watermark, the NIC sends an XON frame. The link partner can resume traffic after receiving an XON frame.
noconfirm	Applies the command without confirmation. Because this command resets the interface, without this option, you are asked to confirm the configuration change.
pause_time	Sets the pause refresh threshold value, between 0 and 65535 slots. Each slot is the amount of time to transmit 64 bytes, so the time per unit depends on your link speed. The link partner can resume traffic after receiving an XON, or after the XOFF expires, as controlled by this timer value in the pause frame. If the buffer usage is consistently above the high watermark, pause frames are sent repeatedly, controlled by the pause refresh threshold value. The default is 26624.

Command Default

Pause frames are disabled by default.

For 10 GigabitEthernet, see the following default settings:

- The default high watermark is 128 KB.
- The default low watermark is 64 KB.
- The default pause refresh threshold value is 26624 slots.

For 1 GigabitEthernet, see the following default settings:

- The default high watermark is 24 KB.
- The default low watermark is 16 KB.
- The default pause refresh threshold value is 26624 slots.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced for 10-GigabitEthernet interfaces on the ASA 5580.
8.2(3)	Added support for the ASA 5585-X.
8.2(5)/8.4(2)	Added support for 1-GigabitEthernet interfaces on all models.

Usage Guidelines

This command is supported on 1-GigabitEthernet and 10-Gigabit Ethernet interfaces. This command does not support management interfaces.

Enter this command for a physical interface.

If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue.

When you enable this command, pause (XOFF) and XON frames are generated automatically by the NIC hardware based on the FIFO buffer usage:

1. The NIC sends a pause frame when the buffer usage exceeds the high watermark.
2. After a pause is sent, the NIC sends an XON frame when the buffer usage is reduced below the low watermark.
3. The link partner can resume traffic after receiving an XON, or after the XOFF expires, as controlled by the timer value in the pause frame.
4. If the buffer usage is consistently above the high watermark, the NIC sends pause frames repeatedly, controlled by the pause refresh threshold value.

When you use this command, the following warning message appears:

```
Changing flow-control parameters will reset the interface. Packets may be lost during the
reset.
Proceed with flow-control changes?
```

To change the parameters without being prompted, use the **noconfirm** keyword.

Note Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Examples

The following example enables pause frames using the default settings:

```
hostname(config)# interface tengigabitethernet 1/0
hostname(config-if)# flowcontrol send on
```

```
Changing flow-control parameters will reset the interface. Packets may be lost during the
reset.
Proceed with flow-control changes?
hostname(config-if)# y
```

Related Commands

Command	Description
interface	Enters interface configuration mode.

format

To erase all files and format the file system, use the **format** command in privileged EXEC mode.

format {**disk0: | disk1: | flash:**}

Syntax Description

disk0*:*	Specifies the internal flash memory, followed by a colon.
disk1:	Specifies the external flash memory card, followed by a colon.
flash:	Specifies the internal flash memory, followed by a colon. In the ASA 5500 series, the **flash** keyword is aliased to **disk0**.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **format** command erases all data on the specified file system and then rewrites the FAT information to the device.

Caution Use the **format** command with extreme caution, only when necessary, to clean up corrupted flash memory.

To delete all visible files (excluding hidden system files), enter the **delete /recursive** command, instead of the **format** command.

Note On the Cisco ASA 5500 series, the **erase** command destroys all user data on the disk with the 0xFF pattern. In contrast, the **format** command only resets the file system control structures. If you used a raw disk read tool, you could still see the information.

To repair a corrupt file system, try entering the **fsck** command before entering the **format** command.

Examples

This example shows how to format the flash memory:

```
hostname# format flash:
```

Related Commands

Command	Description
delete	Removes all user-visible files.
erase	Deletes all files and formats the flash memory.
fsck	Repairs a corrupt file system.

forward interface

For models with a built-in switch, such as the ASA 5505, use the **forward interface** command in interface configuration mode to restore connectivity for one VLAN from initiating contact to one other VLAN. To restrict one VLAN from initiating contact to one other VLAN, use the **no** form of this command.

forward interface vlan *number*

no forward interface vlan *number*

Syntax Description

vlan *number*	Specifies the VLAN ID to which this VLAN interface cannot initiate traffic.

Defaults

By default, all interfaces can initiate traffic to all other interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You might need to restrict one VLAN depending on how many VLANs your license supports.

In routed mode, you can configure up to three active VLANs with the ASA 5505 Base license, and up to five active VLANs with the Security Plus license. An active VLAN is a VLAN with a **nameif** command configured. You can configure up to five inactive VLANs on the ASA 5505 for either license, but if you make them active, be sure to follow the guidelines for your license.

With the Base license, the third VLAN must be configured with the **no forward interface** command to restrict this VLAN from initiating contact to one other VLAN.

For example, you have one VLAN assigned to the outside for Internet access, one VLAN assigned to an inside work network, and a third VLAN assigned to your home network. The home network does not need to access the work network, so you can use the **no forward interface** command on the home VLAN; the work network can access the home network, but the home network cannot access the work network.

If you already have two VLAN interfaces configured with a **nameif** command, be sure to enter the **no forward interface** command before the **nameif** command on the third interface; the ASA does not allow three fully functioning VLAN interfaces with the Base license on the ASA 5505.

Examples

The following example configures three VLAN interfaces. The third home interface cannot forward traffic to the work interface.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address dhcp
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif work
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# no forward interface vlan 200
hostname(config-if)# nameif home
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

...
```

Related Commands

Command	Description
backup interface	Assigns an interface to be a backup link to an ISP, for example.
clear interface	Clears counters for the **show interface** command.
interface vlan	Creates a VLAN interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
switchport access vlan	Assigns a switch port to a VLAN.

fqdn (crypto ca trustpoint)

To include the indicated FQDN in the Subject Alternative Name extension of the certificate during enrollment, use the **fqdn** command in crypto ca trustpoint configuration mode. To restore the default setting of the FQDN, use the **no** form of the command.

fqdn [*fqdn* | **none**]

no fqdn

Syntax Description

fqdn	Specifies the FQDN. The maximum length is 64 characters.
none	Specifies no fully qualified domain name.

Defaults

The default setting does not include the FQDN.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you are configuring the ASA to support authentication of a Nokia VPN Client using certificates, use the **none** keyword. See the **crypto isakmp identity** or **isakmp identity** command for more information about supporting certificate authentication of the Nokia VPN Client.

Examples

The following example enters crypto ca-trustpoint configuration mode for the trustpoint central, and includes the FQDN engineering in the enrollment request for the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)# fqdn engineering
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca-trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.
enrollment retry count	Specifies the number of retries to attempt to send an enrollment request.

Command	Description
enrollment retry period	Specifies the number of minutes to wait before trying to send an enrollment request.
enrollment terminal	Specifies cut-and-paste enrollment with this trustpoint.

fqdn (network object)

To configure a FQDN for a network object, use the **fqdn** command in object configuration mode. To remove the object from the configuration, use the **no** form of this command.

fqdn [**v4** | **v6**] *fqdn*

no fqdn [**v4** | **v6**] *fqdn*

Syntax Description

fqdn	Specifies the FQDN, including the host and domain. The FQDN must begin and end with a digit or letter. Only letters, digits, and hyphens are allowed as internal characters. Labels are separated by a dot (for example, www.cisco.com).
v4	(Optional) Specifies an IPv4 domain name.
v6	(Optional)Specifies an IPv6 domain name.

Defaults

By default, the domain name is an IPv4 domain.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object network configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

If you configure an existing network object with a different value, the new configuration will replace the existing configuration.

Examples

The following example shows how to create a network object:

```
hostname (config)# object network FQDN_1
hostname (config-network-object)# fqdn example.cisco.com
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
description	Adds a description to the network object.

Command	Description
fqdn	Specifies a fully qualified domain name network object.
host	Specifies a host network object.
nat	Enables NAT for the network object.
object network	Creates a network object.
object-group network	Creates a network object group.
range	Specifies a range of addresses for the network object.
show running-config object network	Shows the network object configuration.
subnet	Specifies a subnet network object.

fragment

To provide additional management of packet fragmentation and improve compatibility with NFS, use the **fragment** command in global configuration mode. To return to the default values, use the **no** form of this command.

fragment reassembly {**full** | **virtual**} {**size** | **chain** | **timeout** *limit*} [*interface*]

no fragment reassembly {**full** | **virtual**} {**size** | **chain** | **timeout** *limit*} [*interface*]

Syntax Description

chain *limit*	Specifies the maximum number of fragments into which a full IP packet can be fragmented.
interface	(Optional) Specifies the ASA interface. If an interface is not specified, the command applies to all interfaces.
reassembly full | **virtual**	Specifies the full or virtual reassembly for IP fragments that are routed through the ASA. IP fragments that terminate at the ASA are always fully reassembled.
size *limit*	Sets the maximum number of fragments that can be in the IP reassembly database waiting for reassembly. **Note** The ASA does not accept any fragments that are not part of an existing fabric chain after the queue size reaches 2/3 full. The remaining 1/3 of the queue is used to accept fragments where the source/destination IP addresses and IP identification number are the same as an incomplete fragment chain that is already partially queued. This limit is a DoS protection mechanism to help legitimate fragment chains be reassembled when there is a fragment flooding attack.
timeout *limit*	Specifies the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded.

Defaults

The defaults are as follows:

- **chain** is 24 packets.
- *interface* is all interfaces.
- **size** is 200.
- **timeout** is 5 seconds.
- Virtual reassembly is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified so that you now must choose one of the following keywords: **chain**, **size**, or **timeout**. You can no longer enter the **fragment** command without entering one of these keywords, as was supported in prior releases of the software.
8.0(4)	The **reassembly full** | **virtual** option was added.

Usage Guidelines

By default, the ASA accepts up to 24 fragments to reconstruct a full IP packet. Based on your network security policy, you should consider configuring the ASA to prevent fragmented packets from traversing the ASA by entering the **fragment chain 1** *interface* command on each interface. Setting the limit to 1 means that all packets must be whole; that is, unfragmented.

If a large percentage of the network traffic through the ASA is NFS, additional tuning might be necessary to avoid database overflow.

In an environment where the MTU size is small between the NFS server and client, such as a WAN interface, the **chain** keyword might require additional tuning. In this case, we recommend using NFS over TCP to improve efficiency.

Setting the **size** *limit* to a large value can make the ASA more vulnerable to a DoS attack by fragment flooding. Do not set the **size** *limit* equal to or greater than the total number of blocks in the 1550 or 16384 pool.

The default values will limit DoS attacks caused by fragment flooding.

The following processes are performed regardless of the **reassembly** option setting:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed (see the **timeout** option).
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow (see the **chain** option).

If the **fragment reassembly virtual** command is configured, the fragment set is forwarded to the transport layer for further processing.

If the **fragment reassembly full** command is configured, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

Examples

The following example shows how to prevent fragmented packets on the outside and inside interfaces:

```
hostname(config)# fragment chain 1 outside
hostname(config)# fragment chain 1 inside
```

Continue entering the **fragment chain 1** *interface* command for each additional interface on which you want to prevent fragmented packets.

The following example shows how to configure the fragment database on the outside interface to a maximum size of 2000, a maximum chain length of 45, and a wait time of 10 seconds:

```
hostname(config)# fragment size 2000 outside
hostname(config)# fragment chain 45 outside
hostname(config)# fragment timeout 10 outside
```

The following example displays output from the **show fragment** command that includes the **reassembly virtual** option:

```
hostname(config)# show fragment
Interface: outside
    Size: 200, Chain: 24, Timeout: 5, Reassembly: virtual
    Queue: 0, Assembled: 0, Fail: 0, Overflow: 0
Interface: inside
    Size: 200, Chain: 24, Timeout: 5, Reassembly: virtual
    Queue: 0, Assembled: 0, Fail: 0, Overflow: 0
```

Related Commands

Command	Description
clear configure fragment	Resets all the IP fragment reassembly configurations to defaults.
clear fragment	Clears the operational data of the IP fragment reassembly module.
show fragment	Displays the operational data of the IP fragment reassembly module.
show running-config fragment	Displays the IP fragment reassembly configuration.

frequency

To set the rate at which the selected SLA operation repeats, use the **frequency** command in SLA monitor protocol configuration mode. To restore the default value, use the **no** form of this command.

frequency *seconds*

no frequency

Syntax Description

seconds	The number of seconds between SLA probes. Valid values are from 1 to 604800 seconds. This value cannot be less than the **timeout** value.

Defaults

The default frequency is 60 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
SLA monitor protocol configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

An SLA operation repeats at a given frequency for the lifetime of the operation. For example:

- An **ipIcmpEcho** operation with a frequency of 60 seconds repeats by sending the echo request packets once every 60 seconds for the lifetime of the operation.
- The default number of packets in an echo operation is 1. This packet is sent when the operation is started and is then sent again 60 seconds later.

If an individual SLA operation takes longer to execute than the specified frequency value, a statistics counter called “busy” is increased rather than immediately repeating the operation.

The value specified for the **frequency** command cannot be less than the value specified for the **timeout** command.

Examples

The following example configures an SLA operation with an ID of 123 and creates a tracking entry with the ID of 1 to track the reachability of the SLA. The frequency of the SLA operation is set to 3 seconds, and the timeout value is set to 1000 milliseconds.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
```

```
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
sla monitor	Defines an SLA monitoring operation.
timeout	Defines the amount of time that the SLA operation waits for a response.

fsck

To perform a file system check and to repair corruptions, use the **fsck** command in privileged EXEC mode.

fsck [**/noconfirm**] {**disk0: | disk1: | flash:**}

Syntax Description

/noconfirm	(Optional) Does not prompt for confirmation to repair.
disk0:	Specifies the internal flash memory, followed by a colon.
disk1:	Specifies the external flash memory card, followed by a colon.
flash:	Specifies the internal flash memory, followed by a colon. The **flash** keyword is aliased to **disk0:**.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **fsck** command checks and tries to repair corrupt file systems. Use this command before trying more permanent procedures.

If the FSCK utility fixes an instance of disk corruption (due to a power failure or abnormal shutdown, for example), it creates recovery files named FSCK*xxx*.REC. These files can contain a fraction of a file or a whole file that was recovered while FSCK was running. In rare circumstances, you might need to inspect these files to recover data; generally, these files are not needed, and can be safely deleted.

Note The FSCK utility runs automatically at startup, so you may see these recovery files even if you did not manually enter the **fsck** command.

Examples

The following example shows how to check the file system of the flash memory:

```
hostname# fsck disk0:
```

Related Commands

Command	Description
delete	Removes all user-visible files.
erase	Deletes all files and formats the flash memory.
format	Erases all files on a file system, including hidden system files, and reinstalls the file system.

ftp mode passive

To set the FTP mode to passive, use the **ftp mode passive** command in global configuration mode. To reset the FTP client to active mode, use the **no** form of this command.

ftp mode passive

no ftp mode passive

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **ftp mode passive** command sets the FTP mode to passive.The ASA can use FTP to upload or download image files or configuration files to or from an FTP server. The **ftp mode passive** command controls how the FTP client on the ASA interacts with the FTP server.

In passive FTP, the client initiates both the control connection and the data connection. Passive mode refers to the server state, in that the server is passively accepting both the control connection and the data connection, which are initiated by the client.

In passive mode, both destination and source ports are ephemeral ports (greater than 1023). The mode is set by the client, as the client issues the **passive** command to initiate the setup of the passive data connection. The server, which is the recipient of the data connection in passive mode, responds with the port number to which it is listening for the specific connection.

Examples

The following example sets the FTP mode to passive:

```
hostname(config)# ftp mode passive
```

Related Commands

copy	Uploads or downloads image files or configuration files to or from an FTP server.
debug ftp client	Displays detailed information about FTP client activity.
show running-config ftp mode	Displays FTP client configuration.

functions

You cannot use the **functions** command for Release 8.0(2). It is deprecated and remains in this command reference only for reasons of backward compatibility. Use the **import** and **export** commands to create URL lists for websites, file access, and plug-ins, customizatioin, and language translations.

To configure automatic downloading of the port forwarding Java applet, Citrix support, file access, file browsing, file server entry, application of a webtype ACL, HTTP proxy, port forwarding, or URL entry over WebVPN for this user or group policy, use the **functions** command in webvpn configuration mode. To remove a configured function, use the **no** form of this command.

functions {**auto-download** | **citrix** | **file-access** | **file-browsing** | **file-entry** | **filter** | **http-proxy** | **url-entry** | **port-forward** | **none**}

no functions {**auto-download** | **citrix** | **file-access** | **file-browsing** | **file-entry** | **filter** | **http-proxy** | **url-entry** | **port-forward** | **none**}

Syntax Description

auto-download	Enables or disables automatic download of the port forwarding Java applet after WebVPN login. You must first enable port forwarding, Outlook/Exchange proxy, or HTTP proxy.
citrix	Enables or disables support for terminal services from a MetaFrame Application Server to the remote user. This keyword lets the ASA act as a secure gateway within a secure Citrix configuration. These services provide users with access to MetaFrame applications through a standard Web browser.
file-access	Enables or disables file access. When enabled, the WebVPN home page lists file servers in the server list. You must enable file access to enable file browsing and/or file entry.
file-browsing	Enables or disables browsing for file servers and shares. You must enable file browsing to allow user entry of a file server.
file-entry	Enables or disables user ability to enter names of file servers.
filter	Applies a webtype ACL. When enabled, the ASA applies the webtype ACL defined with the WebVPN **filter** command.
http-proxy	Enables or disables the forwarding of an HTTP applet proxy to the remote user. The proxy is useful for technologies that interfere with proper mangling, such as Java, ActiveX, and flash. It bypasses mangling while ensuring the continued use of the ASA. The forwarded proxy modifies the browser's old proxy configuration automatically and redirects all HTTP and HTTPS requests to the new proxy configuration. It supports virtually all client side technologies, including HTML, CSS, JavaScript, VBScript, ActiveX, and Java. The only browser it supports is Microsoft Internet Explorer.
none	Sets a null value for all WebVPN functions. Prevents inheriting functions from a default or specified group policy.
port-forward	Enables port forwarding. When enabled, the ASA uses the port forwarding list defined with the WebVPN **port-forward** command.
url-entry	Enables or disables user entry of URLs. When enabled, the ASA still restricts URLs with any configured URL or network ACLs. When URL entry is disabled, the ASA restricts WebVPN users to the URLs on the home page.

Defaults

Functions are disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	The **auto-download** and **citrix** keywords were added.
8.0(2)	This command was deprecated.

Usage Guidelines

To remove all configured functions, including a null value created by issuing the **functions none** command, use the **no** form of this command without arguments. The **no** option allows inheritance of a value from another group policy. To prevent inheriting function values, use the **functions none** command.

Examples

The following example shows how to configure file access and file browsing for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# functions file-access file-browsing
```

Related Commands

Command	Description
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.

CHAPTER 23

gateway through hw-module module shutdown Commands

gateway

To specify which group of call agents are managing a particular gateway, use the **gateway** command in mgcp map configuration mode. To remove the configuration, use the **no** form of this command.

gateway *ip_address* [*group_id*]

Syntax Description

gateway	The group of call agents that are managing a particular gateway.
group_id	The ID of the call agent group, from 0 to 2147483647.
ip_address	The IP address of the gateway.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Mgcp map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **gateway** command to specify which group of call agents are managing a particular gateway. The IP address of the gateway is specified with the *ip_address* option. The *group_id* option is a number from 0 to 4294967295 that must correspond with the *group_id* of the call agents that are managing the gateway. A gateway may only belong to one group.

Examples

The following example allows call agents 10.10.11.5 and 10.10.11.6 to control gateway 10.10.10.115, and allows call agents 10.10.11.7 and 10.10.11.8 to control both gateways 10.10.10.116 and 10.10.10.117:

```
hostname(config)# mgcp-map mgcp_policy
hostname(config-mgcp-map)# call-agent 10.10.11.5 101
hostname(config-mgcp-map)# call-agent 10.10.11.6 101
hostname(config-mgcp-map)# call-agent 10.10.11.7 102
hostname(config-mgcp-map)# call-agent 10.10.11.8 102
hostname(config-mgcp-map)# gateway 10.10.10.115 101
hostname(config-mgcp-map)# gateway 10.10.10.116 102
hostname(config-mgcp-map)# gateway 10.10.10.117 102
```

Related Commands

Commands	Description
debug mgcp	Enables the display of debugging information for MGCP.
mgcp-map	Defines an MGCP map and enables mgcp map configuration mode.
show mgcp	Displays MGCP configuration and session information.

gateway-fqdn

To configure the FQDN of the ASA. use the **gateway-fqdn** command. To remove the configuration, use the **no** form of this command.

gateway-fqdn value {**FQDN_Name** | **none**}

no gateway-fqdn

Syntax Description

fqdn-name	Defines the ASA FQDN to push down to the AnyConnect client.
none	Defines the FQDN as null value where the FQDN is not specified. The global FQDN configurd using hostname and domain-name commands will be used if available.

Defaults

The default FQDN name is not set in the default group policy. New group policies are set to inherit this value.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
group-policy configuration	•		•		

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

If you have configured Load Balancing between your ASAs, specify the FQDN of the ASA in order to resolve the ASA IP address used for re-establishing the VPN session. This setting is critical to support client roaming between networks of different IP protocols (such as IPv4 to IPv6).

You cannot use the ASA FQDN present in the AnyConnect profile to derive the ASA IP address after roaming. The addresses may not match the correct device (the one the tunnel was established to) in the load balancing scenario.

If the ASA's FQDN is not pushed to the client, the client will try to reconnect to whatever IP address the tunnel had previously established. In order to support roaming between networks of different IP protocols (from IPv4 to IPv6), AnyConnect must perform name resolution of the device FQDN after roaming, so that it can determine which ASA address to use for re-establishing the tunnel. The client uses the ASA FQDN present in its profile during the initial connection. During subsequent session reconnects, it always uses the device FQDN pushed by ASA (and configured by the administrator in the group policy), when available. If the FQDN is not configured, the ASA derives the device FQDN (and sends it to the client) from whatever is set under Device Setup > Device Name/Password and Domain Name in ASDM.

If the device FQDN is not pushed by the ASA, the client cannot reestablish the VPN session after roaming between networks of different IP protocols.

Examples

The following example defines the FQDN of the ASA as ASAName.example.cisco.com

```
hostname(config-group-policy)# gateway-fqdn value ASAName.example.cisco.com
hostname(config-group-policy)#
```

The following example removes the FQDN of the ASA from the group policy. The group policy then inherits this value from the Default Group Policy.

```
hostname(config-group-policy)# no gateway-fqdn
hostname(config-group-policy)#
```

The following example defines the FQDN as having no value. The global FQDN configurd using hostname and domain-name commands will be used if available.

```
hostname(config-group-policy)# gateway-fqdn none
hostname(config-group-policy)#
```

group

To specify the Diffie-Hellman group in an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **group** command in ikev2 policy configuration mode. To remove the command and use the default setting, use the **no** form of this command:

group {**1** | **2** | **5** | **14** | **19** | **20** | **21** | **24**}

no group {**1** | **2** | **5** | **14** | **19** | **20** | **21** | **24**}

Syntax Description

1	Specifies the 768-bit Diffie-Hellman group 1 (not supported in FIPS mode).
2	Specifies the 1024-bit Diffie-Hellman group 2.
5	Specifies the 1536-bit Diffie-Hellman group 5.
14	Choose ECDH group as the IKEv2 DH key exchange group.
19	Choose ECDH groups as the IKEv2 DH key exchange group.
20	Choose ECDH groups as the IKEv2 DH key exchange group.
21	Choose ECDH groups as the IKEv2 DH key exchange group.
24	Choose ECDH groups as the IKEv2 DH key exchange group.

Defaults

The default Diffie-Hellman group is group 2.

Usage Guidelines

An IKEv2 SA is a key used in Phase 1 to enable IKEv2 peers to communicate securely in Phase 2. After entering the **crypto ikev2 policy** command, you can use the **group** command to set the SA Diffie-Hellman group. The ASA and the AnyConnect client use the group identifier to derive a shared secret without transmitting it to each other. The lower the Diffie-Hellman group number, the less CPU time it requires to execute. The higher the Diffie-Hellman group number, the greater the security.

When the AnyConnect client is operating in non-FIPS mode, the ASA supports Diffie-Hellman groups 1, 2 and 5. In FIPS mode, it supports groups 2 and 5. Therefore, if you configure the ASA to use *only* group 1, the AnyConnect client in FIPS mode will fail to connect.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ikev2 policy configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was added.
9.0(1)	Added the ability to choose an ECDH group as the IKEv2 DH key exchange group.

Examples

The following example enters ikev2 policy configuration mode and sets the Diffie-Hellman group to group 5:

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)# group 5
```

Related Commands

Command	Description
encryption	Specifies the encryption algorithm in an IKEv2 SA for AnyConnect IPsec connections.
group	Specifies the Diffie-Hellman group in an IKEv2 SA for AnyConnect IPsec connections.
lifetime	Specifies the SA lifetime for the IKEv2 SA for AnyConnect IPsec connections.
prf	Specifies the pseudo-random function in an IKEv2 SA for AnyConnect IPsec connections.

group-alias

To create one or more alternate names by which the user can refer to a tunnel group, use the **group-alias** command in tunnel-group webvpn configuration mode. To remove an alias from the list, use the **no** form of this command.

group-alias *name* [**enable | disable**]

no group-alias *name*

Syntax Description

disable	Disables the group alias.
enable	Enables a previously disabled group alias.
name	Specifies the name of a tunnel group alias. This can be any string you choose, except that the string cannot contain spaces.

Defaults

There is no default group alias, but if you do specify a group alias, that alias is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The group alias that you specify appears in the drop-down list on the login page. Each group can have multiple aliases or no alias. This command is useful when the same group is known by several common names, such as “Devtest” and “QA”.

Examples

The following example shows the commands for configuring the tunnel group named “devtest” and establishing the aliases “QA” and “Fra-QA” for the group:

```
hostname(config)# tunnel-group devtest type webvpn
hostname(config)# tunnel-group devtest webvpn-attributes
hostname(config-tunnel-webvpn)# group-alias QA
hostname(config-tunnel-webvpn)# group-alias Fra-QA
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel group database or the named tunnel group configuration.
show webvpn group-alias	Displays the aliases for the specified tunnel group or for all tunnel groups.
tunnel-group webvpn-attributes	Enters the tunnel-group webvpn configuration mode for configuring WebVPN tunnel group attributes.

group-delimiter

To enable group name parsing and specify the delimiter to be used when parsing group names from the user names that are received when tunnels are being negotiated, use the **group-delimiter** command in global configuration mode. To disable this group name parsing, use the **no** form of this command.

group-delimiter *delimiter*

no group-delimiter

Syntax Description

delimiter	Specifies the character to use as the group name delimiter. Valid values are: @, #, and !.

Defaults

By default, no delimiter is specified, disabling group-name parsing.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The delimiter is used to parse tunnel group names from user names when tunnels are negotiated. By default, no delimiter is specified, disabling group name parsing.

Examples

This example shows the **group-delimiter** command to change the group delimiter to the hash mark (#):

```
hostname(config)# group-delimiter #
```

Related Commands

Command	Description
clear configure group-delimiter	Clears the configured group delimiter.
show running-config group-delimiter	Displays the current group delimiter value.
strip-group	Enables or disables strip group processing.

group-lock

To restrict remote users to access through the tunnel group only, issue the **group-lock** command in group-policy configuration mode or username configuration mode. To remove the **group-lock** attribute from the running configuration, use the **no** form of this command.

group-lock {value *tunnel-grp-name* **| none}**

no group-lock

Syntax Description

none	Sets group-lock to a null value, thereby allowing no group lock restriction. Prevents inheriting a group lock value from a default or specified group policy.
value *tunnel-grp-name*	Specifies the name of an existing tunnel group that the ASA requires for the user to connect.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Usage Guidelines

To disable group lock, use the **group-lock none** command. The **no group-lock** command allows inheritance of a value from another group policy.

Group lock restricts users by checking if the group configured in the VPN client is the same as the tunnel group to which the user is assigned. If it is not, the ASA prevents the user from connecting. If you do not configure group lock, the ASA authenticates users without regard to the assigned group.

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set group lock for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# group-lock value tunnel group name
```

group-object

To add object groups, use the **group-object** command in protocol, network, service, and icmp-type, and object-group user configuration modes. To remove network object groups, use the **no** form of this command.

group-object *obj_grp_name*

no group-object *obj_grp_name*

Syntax Description

obj_grp_name	Identifies the object group (one to 64 characters) and can be any combination of letters, digits, and the "_", "-", "." characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Protocol, network, service, icmp-type, and object-group user configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(2)	Add support for adding object groups in the object-group user configuration mode for use with the Identity Firewall feature.

Usage Guidelines

The **group-object** command is used with the **object-group** command to define an object that itself is an object group. It is used in protocol, network, service, and icmp-type, object-group user configuration modes. This sub-command allows logical grouping of the same type of objects and construction of hierarchical object groups for structured configuration.

Duplicate objects are allowed in an object group if they are group objects. For example, if object 1 is in both group A and group B, it is allowed to define a group C which includes both A and B. It is not allowed, however, to include a group object which causes the group hierarchy to become circular. For example, it is not allowed to have group A include group B and then also have group B include group A.

The maximum allowed levels of a hierarchical object group is 10.

See the **user-group object** command for information about using the **group-object** command with the Identity Firewall feature.

Note The security appliance does not support IPv6 nested object groups, so you cannot use the **group-object** command for an object with IPv6 entities in it under another IPv6 object-group.

Examples

The following example shows how to use the **group-object** command in network configuration mode eliminate the need to duplicate hosts:

```
hostname(config)# object-group network host_grp_1
hostname(config-network)# network-object host 192.168.1.1
hostname(config-network)# network-object host 192.168.1.2
hostname(config-network)# exit
hostname(config)# object-group network host_grp_2
hostname(config-network)# network-object host 172.23.56.1
hostname(config-network)# network-object host 172.23.56.2
hostname(config-network)# exit
hostname(config)# object-group network all_hosts
hostname(config-network)# group-object host_grp_1
hostname(config-network)# group-object host_grp_2
hostname(config-network)# exit
hostname(config)# access-list grp_1 permit tcp object-group host_grp_1 any eq ftp
hostname(config)# access-list grp_2 permit tcp object-group host_grp_2 any eq smtp
hostname(config)# access-list all permit tcp object-group all-hosts any eq w
```

The following example shows how to use the **group-object** command with the **object-group user** command to add a locally defined object group for use with the Identity Firewall feature:

```
hostname(config)# object-group user sampleuser1-group
hostname(config-object-group user)# description group members of sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-all
hostname(config-object-group user)# user CSCO\user2
hostname(config-object-group user)# exit
hostname(config)# object-group user sampleuser2-group
hostname(config-object-group user)# description group members of sampleuser2-group
hostname(config-object-group user)# group-object sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-marketing
hostname(config-object-group user)# user CSCO\user3
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object-group** commands from the configuration.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
object-group user	Creates a user group object for the Identity Firewall feature.
port-object	Adds a port object to a service object group.
show running-config object-group	Displays the current object groups.

group-policy

To create or edit a group policy, use the **group-policy** command in global configuration mode. To remove a group policy from the configuration, use the **no** form of this command.

group-policy *name* {**internal [from** *group-policy_name*] | **external server-group** *server_group* **password** *server_password*}

no group-policy *name*

Syntax Description

external server-group *server_group*	Specifies the group policy as external and identifies the AAA server group for the ASA to query for attributes.
from *group-policy_name*	Initializes the attributes of this internal group policy to the values of a preexisting group policy.
internal	Identifies the group policy as internal.
name	Specifies the name of the group policy. The name can be up to 64 characters long and can contain spaces. Group names with spaces must be enclosed in double quotes, for example, “Sales Group”.
password *server_password*	Provides the password to use when retrieving attributes from the external AAA server group. The password can be up to 128 characters long and cannot contain spaces.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0.1	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

A default group policy, named “DefaultGroupPolicy,” always exists on the ASA. However, this default group policy does not take effect unless you configure the ASA to use it. For configuration instructions, see the CLI configuration guide.

Use the **group-policy attributes** command to enter group-policy configuration mode, in which you can configure any of the group-policy Attribute-Value Pairs. The DefaultGroupPolicy has these Attribute-Value Pairs:

Attribute	Default Value
backup-servers	keep-client-config
banner	none
client-access-rules	none
client-firewall	none
default-domain	none
dns-server	none
group-lock	none
ip-comp	disable
ip-phone-bypass	disabled
ipsec-udp	disabled
ipsec-udp-port	10000
leap-bypass	disabled
nem	disabled
password-storage	disabled
pfs	disable
re-xauth	disable
secure-unit-authentication	disabled
split-dns	none
split-tunnel-network-list	none
split-tunnel-policy	tunnelall
user-authentication	disabled
user-authentication-idle-timeout	none
vpn-access-hours	unrestricted
vpn-filter	none
vpn-idle-timeout	30 minutes
vpn-session-timeout	none
vpn-simultaneous-logins	3
vpn-tunnel-protocol	IPsec WebVPN
wins-server	none

In addition, you can configure webvpn configuration mode attributes for the group policy, either by entering the **webvpn** command in group policy configuration mode or by entering the **group-policy attributes** command and then entering the **webvpn** command in group-webvpn configuration mode. See the description of the **group-policy attributes** command for details.

Examples

The following example shows how to create an internal group policy with the name “FirstGroup”:

```
hostname(config)# group-policy FirstGroup internal
```

The following example shows how to create an external group policy with the name “ExternalGroup,” the AAA server group “BostonAAA,” and the password “12345678”:

```
hostname(config)# group-policy ExternalGroup external server-group BostonAAA password
12345678
```

Related Commands

Command	Description
clear configure group-policy	Removes the configuration for a particular group policy or for all group policies.
group-policy attributes	Enters group-policy configuration mode, which lets you configure attributes and values for a specified group policy or lets you enter webvpn configuration mode to configure WebVPN attributes for the group.
show running-config group-policy	Displays the running configuration for a particular group policy or for all group policies.
webvpn	Enters webvpn configuration mode, in which you can configure the WebVPN attributes for the specified group.

group-policy attributes

To enter the group-policy configuration mode, use the **group-policy attributes** command in global configuration mode. To remove all attributes from a group policy, user the **no** form of this command.

group-policy *name* **attributes**

no group-policy *name* **attributes**

Syntax Description

name	Specifies the name of the group policy.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In group-policy configuration mode, you can configure Attribute-Value Pairs for a specified group policy or enter group-policy webvpn configuration mode to configure WebVPN attributes for the group.

The syntax of the commands in attributes mode have the following characteristics in common:

- The **no** form removes the attribute from the running configuration, and enables inheritance of a value from another group policy.
- The **none** keyword sets the attribute in the running configuration to a null value, thereby preventing inheritance.
- Boolean attributes have explicit syntax for enabled and disabled settings.

A default group policy, named DefaultGroupPolicy, always exists on the ASA. However, this default group policy does not take effect unless you configure the ASA to use it. For configuration instructions, see the CLI configuration guide.

The **group-policy attributes** command enters group-policy configuration mode, in which you can configure any of the group-policy Attribute-Value Pairs. The DefaultGroupPolicy has these Attribute-Value Pairs:

Attribute	Default Value
backup-servers	keep-client-config
banner	none
client-access-rule	none
client-firewall	none
default-domain	none
dns-server	none
group-lock	none
ip-comp	disable
ip-phone-bypass	disabled
ipsec-udp	disabled
ipsec-udp-port	10000
leap-bypass	disabled
nem	disabled
password-storage	disabled
pfs	disable
re-xauth	disable
secure-unit-authentication	disabled
split-dns	none
split-tunnel-network-list	none
split-tunnel-policy	tunnelall
user-authentication	disabled
user-authentication-idle-timeout	none
vpn-access-hours	unrestricted
vpn-filter	none
vpn-idle-timeout	30 minutes
vpn-session-timeout	none
vpn-simultaneous-logins	3
vpn-tunnel-protocol	IPsec WebVPN
wins-server	none

In addition, you can configure webvpn-mode attributes for the group policy, by entering the **group-policy attributes** command and then entering the **webvpn** command in group-policy configuration mode. See the description of the **webvpn** command (group-policy attributes and username attributes modes) for details.

Examples

The following example shows how to enter group-policy attributes mode for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)#
```

Related Commands

Command	Description
clear configure group-policy	Removes the configuration for a particular group policy or for all group policies.
group-policy	Creates, edits, or removes a group policy.
show running-config group-policy	Displays the running configuration for a particular group policy or for all group policies.
webvpn	Enters group-webvpn configuration mode, in which you can configure the WebVPN attributes for the specified group.

group-prompt

To customize the group prompt of the WebVPN page login box that is displayed to WebVPN users when they connect to the ASA, use the **group-prompt** command in webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

group-prompt {**text** | **style**} *value*

no group-prompt {**text** | **style**} *value*

Syntax Description

text	Specifies a change to the text.
style	Specifies a change the style.
value	The actual text to display or Cascading Style Sheet (CSS) parameters (the maximum bunber is 256 characters).

Defaults

The default text of the group prompt is “GROUP:”.

The default style of the group prompt is color:black;font-weight:bold;text-align:right.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid CSS parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma-separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

In the following example, the text is changed to "Corporate Group:", and the default style is changed with the font weight increased to bolder:

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# group-prompt text Corporate Group:
F1-asa1(config-webvpn-custom)# group-prompt style font-weight:bolder
```

Related Commands

Command	Description
password-prompt	Customizes the password prompt of the WebVPN page.
username-prompt	Customizes the username prompt of the WebVPN page.

group-search-timeout

To specify the maximum time to wait for a response from an Active Directory server queried using the **show ad-groups** command, use the **group-search-timeout** command in aaa-server host configuration mode. To remove the command from the configuration, use the **no** form of the command:

group-search-timeout *seconds*

no group-search-timeout *seconds*

Syntax Description

seconds	The time to wait for a response from the Active Directory server, from 1 to 300 seconds.

Defaults

The default is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command is introduced.

Usage Guidelines

The **show ad-groups** command applies only to Active Directory servers using LDAP, and displays groups that are listed on an Active Directory server. Use the **group-search-timeout** command to adjust the time to wait for a response from the server.

Examples

The following example sets the timeout to 20 seconds:

```
hostname(config-aaa-server-host)#group-search-timeout 20
```

Related Commands

Command	Description
ldap-group-base-dn	Specifies a level in the Active Directory hierarchy where the server begins searching for groups that are used by dynamic group policies.
show ad-groups	Displays groups that are listed on an Active Directory server.

group-url

To specify incoming URLs or IP addresses for the group, use the **group-url** command in tunnel-group webvpn configuration mode. To remove a URL from the list, use the **no** form of this command.

group-url *url* [**enable** | **disable**]

no group-url *url*

Syntax Description

disable	Disables the URL, but does not remove it from the list.
enable	Enables the URL.
url	Specifies a URL or IP address for this tunnel group.

Defaults

There is no default URL or IP address, but if you do specify a URL or IP address, it is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Specifying a group URL or IP address eliminates the need for the user to select a group at login. When a user logs in, the ASA looks for the user's incoming URL/address in the tunnel group policy table. If it finds the URL/address and if this command is enabled in the tunnel group, then the ASA automatically selects the associated tunnel group and presents the user with only the username and password fields in the login window. This simplifies the user interface and has the added advantage of never exposing the list of groups to the user. The login window that the user sees uses the customizations configured for that tunnel group.

If the URL/address is disabled and the **group-alias** command is configured, then the drop-down list of groups is also displayed, and the user must make a selection.

You can configure multiple URLs/addresses (or none) for a group. Each URL/address can be enabled or disabled individually. You must use a separate **group-url** command for each URL/address specified. You must specify the entire URL/address, including either the HTTP or HTTPS protocol.

You cannot associate the same URL/address with multiple groups. The ASA verifies the uniqueness of the URL/address before accepting it for a tunnel group.

Examples

The following example shows the commands for configuring the WebVPN tunnel group named “test” and establishing two group URLs, “http://www.cisco.com” and “https://supplier.example.com” for the group:

```
hostname(config)# tunnel-group test type webvpn
hostname(config)# tunnel-group test webvpn-attributes
hostname(config-tunnel-webvpn)# group-url http://www.cisco.com
hostname(config-tunnel-webvpn)# group-url https://supplier.example.com
hostname(config-tunnel-webvpn)#
```

The following example enables the group URLs http://www.cisco.com and http://192.168.10.10 for the tunnel group named RadiusServer:

```
hostname(config)# tunnel-group RadiusServer type webvpn
hostname(config)# tunnel-group RadiusServer general-attributes
hostname(config-tunnel-general)# authentication server-group RADIUS
hostname(config-tunnel-general)# accounting-server-group RADIUS
hostname(config-tunnel-general)# tunnel-group RadiusServer webvpn-attributes
hostname(config-tunnel-webvpn)# group-alias “Cisco Remote Access” enable
hostname(config-tunnel-webvpn)# group-url http://www.cisco.com enable
hostname(config-tunnel-webvpn)# group-url http://192.168.10.10 enable
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the entire tunnel group database or the named tunnel group configuration.
show webvpn group-url	Displays the URLs for the specified tunnel group or for all tunnel groups.
tunnel-group webvpn-attributes	Enters the webvpn configuration mode for configuring WebVPN tunnel group attributes.

h245-tunnel-block

To block H.245 tunneling in H.323, use the **h245-tunnel-block** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

h245-tunnel-block action [**drop-connection** | **log**]

no h245-tunnel-block action [**drop-connection** | **log**]

Syntax Description

drop-connection	Drops the call setup connection when an H.245 tunnel is detected.
log	Issues a log when an H.245 tunnel is detected.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to block H.245 tunneling on an H.323 call:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# h245-tunnel-block action drop-connection
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

health-check

To enab;e the cluster health check feature, use the **health-check** command in cluster group configuration mode. To the health check, use the **no** form of this command.

health-check [**holdtime** *timeout*] [**vss-enabled**]

no health-check [**holdtime** *timeout*] [**vss-enabled**]

Syntax Description

holdtime *timeout*	(Optional) Determines the amount of time between keepalive or interface status messages, between .8 and 45 seconds. The default is 3 seconds.
vss-enabled	If you configure the cluster control link as an EtherChannel (recommended), and it is connected to a VSS or vPC pair, then you might need to enable the **vss-enabled** option. For some switches, when one unit in the VSS/vPC is shutting down or booting up, EtherChannel member interfaces connected to that switch may appear to be Up to the ASA, but they are not passing traffic on the switch side. The ASA can be erroneously removed from the cluster if you set the ASA holdtime timeout to a low value (such as .8 seconds), and the ASA sends keepalive messages on one of these EtherChannel interfaces. When you enable **vss-enabled**, the ASA floods the keepalive messages on all EtherChannel interfaces in the cluster control link to ensure that at least one of the switches can receive them.

Command Default

Health check is enabled by default, with a holdtime of 3 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.
9.1(4)	We added the **vss-enabled** keyword.

Usage Guidelines

We recommend that you temporarily disable the health check with the **no health-check** command when any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the ASA or the switch, or adding an additional switch to form a VSS or vPC). After the cluster topology is stable, you must re-enable the cluster health check feature.

Keepalive messages between members determine member health. If a unit does not receive any keepalive messages from a peer unit within the holdtime period, the peer unit is considered unresponsive or dead. Interface status messages detect link failure. If an interface fails on a particular unit, but the same interface is active on other units, then the unit is removed from the cluster.

If a unit does not receive interface status messages within the holdtime, then the amount of time before the ASA removes a member from the cluster depends on the type of interface and whether the unit is an established member or is joining the cluster. For EtherChannels (spanned or not), if the interface is down on an established member, then the ASA removes the member after 9 seconds. If the unit is joining the cluster as a new member, the ASA waits 45 seconds before rejecting the new unit. For non-EtherChannels, the unit is removed after 500 ms, regardless of the member state.

This command is not part of the bootstrap configuration, and is replicated from the master unit to the slave units.

Examples

The following example disables the health check:

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# no health-check
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

hello-interval

To specify the interval between EIGRP hello packets sent on an interface, use the **hello-interval** command in interface configuration mode. To return the hello interval to the default value, use the **no** form of this command.

hello-interval eigrp *as-number seconds*

no hello-interval eigrp *as-number seconds*

Syntax Description

as-number	Specifies the autonomous system number of the EIGRP routing process.
seconds	Specifies the interval between hello packets that are sent on the interface. Valid values are from 1 to 65535 seconds.

Defaults

The default is 5 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The smaller the hello interval, the faster topological changes will be detected, but more routing traffic will occur. This value must be the same for all routers and access servers on a specific network.

Examples

The following example sets the EIGRP hello interval to 10 seconds and the hold time to 30 seconds:

```
hostname(config-if)# hello-interval eigrp 100 10
hostname(config-if)# hold-time eigrp 100 30
```

Related Commands

Command	Description
hold-time	Configures the EIGRP hold time advertised in hello packets.

help

To display help information for the command specified, use the **help** command in user EXEC mode.

help {*command* | **?**}

Syntax Description

?	Displays all commands that are available in the current privilege level and mode.
command	Specifies the command for which to display the CLI help.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **help** command displays help information about all commands. You can see help for an individual command by entering the **help** command followed by the command name. If you do not specify a command name and enter **?** instead, all commands that are available in the current privilege level and mode display.

If you enable the **pager** command and after 24 lines display, the listing pauses, and the following prompt appears:

```
<--- More --->
```

The More prompt uses syntax similar to the UNIX **more** command as follows:

- To see another screen of text, press the **Space** bar.
- To see the next line, press the **Enter** key.
- To return to the command line, press the **q** key.

Examples

The following example shows how to display help for the **rename** command:

```
hostname# help rename

USAGE:

        rename /noconfirm [{disk0:|disk1:|flash:}] <source path> [{disk0:|disk1:
```

```
|flash:}] <destination path>

DESCRIPTION:

rename          Rename a file

SYNTAX:

/noconfirm                      No confirmation
{disk0:|disk1:|flash:} Optional parameter that specifies the filesystem
<source path>           Source file path
<destination path>      Destination file path

hostname#
```

The following examples shows how to display help by entering the command name and a question mark:

```
hostname(config)# enable ?
usage: enable password <pwd> [encrypted]
```

Help is available for the core commands (not the **show**, **no**, or **clear** commands) by entering **?** at the command prompt:

```
hostname(config)# ?
aaa             Enable, disable, or view TACACS+ or RADIUS
                user authentication, authorization and accounting
…
```

Related Commands

Command	Description
show version	Displays information about the operating system software.

hidden-parameter

To specify hidden parameters in the HTTP POST request that the ASA submits to the authenticating web server for SSO authentication, use the **hidden-parameter** command in aaa-server-host configuration mode. To remove all hidden parameters from the running configuration, use the **no** form of this command.

hidden-parameter *string*

no hidden-parameter

Note To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

Syntax Description

string	A hidden parameter embedded in the form and sent to the SSO server. You can enter it on multiple lines. The maximum number of characters for each line is 255. The maximum number of characters for all lines together—the complete hidden parameter—is 2048.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

This is an SSO with HTTP Forms command.

The WebVPN server of the ASA uses an HTTP POST request to submit an SSO authentication request to an authenticating web server. That request may require specific hidden parameters from the SSO HTML form—other then username and password—that are not visible to the user. You can discover hidden parameters that the web server expects in the POST request by using a HTTP header analyzer on a form received from the web server.

The **hidden-parameter** command lets you specify a hidden parameter that the web server requires in the authentication POST request. If you use a header analyzer, you can copy and paste the entire hidden parameter string, including any encoded URL parameters.

For ease of entry, you can enter a hidden parameter on multiple, sequential lines. The ASA then concatenates the lines into a single hidden parameter. While the maximum characters per hidden-parameter line is 255 characters, you can enter fewer characters on each line.

Note Any question mark in the string must be preceded by a **Ctrl+v** escape sequence.

Examples

The following example shows a hidden parameter comprised of four form entries and their values, separated by &. Excerpted from the POST request, the four entries and their values are:

- SMENC with a value of ISO-8859-1
- SMLOCALE with a value of US-EN
- target with a value of https%3A%2F%2Ftools.cisco.com%2Femco%2Fappdir%2FAreaRoot.do %3FEMCOPageCode%3DENG
- smauthreason with a value of 0

SMENC=ISO-8859-1&SMLOCALE=US-EN&target=https%3A%2F%2Ftools.cisco.com%2Femco%2Fappdir%2FAreaRoot.do%3FEMCOPageCode%3DENG&smauthreason=0

```
hostname(config)# aaa-server testgrp1 host example.com
hostname(config-aaa-server-host)# hidden-parameter SMENC=ISO-8859-1&SMLOCALE=US-EN&targe
hostname(config-aaa-server-host)# hidden-parameter t=https%3A%2F%2Ftools.cisco.com%2Femc
hostname(config-aaa-server-host)# hidden-parameter o%2Fappdir%2FAreaRoot.do%3FEMCOPageCo
hostname(config-aaa-server-host)# hidden-parameter de%3DENG&smauthreason=0
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
action-uri	Specifies a web server URI to receive a username and password for SSO authentication.
auth-cookie-name	Specifies a name for the authentication cookie.
password-parameter	Specifies the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication.
start-url	Specifies the URL at which to retrieve a prelogin cookie.
user-parameter	Specifies the name of the HTTP POST request parameter in which a username must be submitted for SSO authentication.

hidden-shares

To control the visibility of hidden shares for CIFS files, use the **hidden-shares** command in group-webvpn configuration mode. To remove the hidden shares option from the configuration, use the **no** form of this command.

hidden-shares {**none** | **visible**}

[no] hidden-shares {**none** | **visible**}

Syntax Description

none	Specifies that no configured hidden shares are visible or accessible to users.
visible	Reveals hidden shares, making them accessible to users.

Defaults

The default behavior for this command is none.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Group-webvpn configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

A hidden share is identified by a dollar sign ($) at the end of the share name. For example, drive C is shared as C$. With hidden shares, a shared folder is not displayed, and users are restricted from browsing or accessing these hidden resources.

The **no** form of the **hidden-shares** command removes the option from the configuration and disables hidden shares as a group policy attribute.

Examples

The following example makes visible WebVPN CIFS hidden-shares related to GroupPolicy2:

```
hostname(config)# webvpn
hostname(config-group-policy)# group-policy GroupPolicy2 attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# hidden-shares visible
hostname(config-group-webvpn)#
```

Related Commands

Command	Description
debug webvpn cifs	Displays debugging messages about the CIFS.
group-policy attributes	Enters group-policy configuration mode, which lets you configure attributes and values for a specified group policy or lets you enter webvpn configuration mode to configure WebVPN attributes for the group.
url-list	Configures a set of URLs for WebVPN users to access.
url-list	Applies a list of WebVPN servers and URLs to a particular user or group policy.

hold-time

To specify the hold time advertised by the ASA in EIGRP hello packets, use the **hold-time** command in interface configuration mode. To return the hello interval to the default value, use the **no** form of this command.

hold-time eigrp *as-number seconds*

no hold-time eigrp *as-number seconds*

Syntax Description

as-number	The autonomous system number of the EIGRP routing process.
seconds	Specifies the hold time, in seconds. Valid values are from 1 to 65535 seconds.

Defaults

The default is 15 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This value is advertised in the EIGRP hello packets sent by the ASA. The EIGRP neighbors on that interface use this value to determine the availability of the ASA. If they do not receive a hello packet from the ASA during the advertised hold time, the EIGRP neighbors will consider the ASA to be unavailable.

On very congested and large networks, the default hold time might not be sufficient time for all routers and access servers to receive hello packets from their neighbors. In this case, you may want to increase the hold time.

We recommend that the hold time be at least three times the hello interval. If the ASA does not receive a hello packet within the specified hold time, routes through this neighbor are considered unavailable.

Increasing the hold time delays route convergence across the network.

Examples

The following example sets the EIGRP hello interval to 10 seconds and the hold time to 30 seconds:

```
hostname(config-if)# hello-interval eigrp 100 10
```

```
hostname(config-if)# hold-time eigrp 100 30
```

Related Commands

Command	Description
hello-interval	Specifies the interval between EIGRP hello packets sent on an interface.

homepage

To specify a URL for the web page that displays upon login for this WebVPN user or group policy, use the **homepage** command in webvpn configuration mode. To remove a configured home page, including a null value created by issuing the **homepage none** command, use the **no** form of this command.

homepage {**value** *url-string* | **none**}

no homepage

Syntax Description

none	Indicates that there is no WebVPN home page. Sets a null value, thereby disallowing a home page. Prevents inheriting a home page.
value *url-string*	Provides a URL for the home page. The string must begin with either http:// or https://.

Defaults

There is no default home page.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To specify a home page URL for users associated with the group policy, enter a value for the URL string in this command. To inherit a home page from the default group policy, use the **no** form of the comand. The **no** option allows inheritance of a value from another group policy. To prevent inheriting a home page, use the **homepage none** command.

Clientless users are immediately brought to this page after successful authentication. AnyConnect launches the default web browser to this URL upon successful establishment of the VPN connection. On Linux platforms, AnyConnect does not currently support this command and ignores it.

Examples

The following example shows how to specify www.example.com as the home page for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# homepage value http://www.example.com
```

Related Commands

Command	Description
webvpn	Lets you enter webvpn configuration mode to configure parameters that apply to group policies or usernames.

homepage use-smart-tunnel

To allow the group policy home page to use the smart tunnel feature when clientless SSL VPN is used, use the **homepage use-smart-tunnel** command in the group-policy webvpn configuration mode.

homepage {**value** *url-string* | **none**}

homepage use-smart-tunnel

Syntax Description

none	Indicates that there is no WebVPN home page. Sets a null value, thereby disallowing a home page. Prevents inheriting a home page.
value *url-string*	Provides a URL for the home page. The string must begin with either http:// or https://.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You can use the HTTP capture tool to monitor the browser session and verify that the smart tunnel was initiated during the WebVPN connection. What you see in the browser capture determines whether the request is forwarded to the web page without degradation and whether the smart tunnel is used. If you see something like https://172.16.16.23/+CSCOE+portal.html, the *+CSCO** indicates that the content is degraded by the ASA. When the smart tunnel is initiated, you see an **http get** command to a specific URL without the +CSCO* (such as GET 200 html http://mypage.example.com).

Examples

If you consider a case where Vendor V wants to provide Partner P with clientless access to their interal inventory server pages, Vendor V's administrator must decide the following:

- Will users have access to the inventory pages after they log into a clientless SSL VPN, whether or not they go through the clientless portal?
- Will the smart tunnel be a good choice for access because the page includes a Microsoft Silverlight component?
- Is a tunnel-all policy suitable because once the browser has been tunneled, all tunnel policy forces all browser traffic to go through Vendor V's ASA, leaving Partner P's users with no access to internal resources?

With the assumption that inventory pages are hosted at inv.example.com (10.0.0.0), the following example creates a tunnel policy that contains only one host:

```
hostname(config-webvpn)# smart-tunnel network inventory ip 10.0.0.0
hostname(config-webvpn)# smart-tunnel network inventory host inv.example.com
```

The following example applies a tunnel-specified tunnel policy to the partner's group policy:

```
hostname(config-group-webvpn)# smart-tunnel tunnel-policy tunnelspecified inventory
```

The following example specifies the group policy home page and enables a smart tunnel on it:

```
hostname(config-group-webvpn)# homepage value http://inv.example.com
hostname(config-group-webvpn)# homepage use-smart-tunnel
```

host (network object)

To configure a host for a network object, use the **host** command in object network configuration mode. To remove the host from the object, use the **no** form of this command.

host *ip_address*

no host *ip_address*

Syntax Description

ip_address	Identifies the host IP address for the object, either IPv4 or IPv6.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

If you configure an existing network object with a different IP address, the new configuration will replace the existing configuration.

Examples

The following example shows how to create a host network object:

```
hostname (config)# object network OBJECT1
hostname (config-network-object)# host 10.1.1.1
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
description	Adds a description to the network object.
fqdn	Specifies a fully qualified domain name network object.
nat	Enables NAT for the network object.
object network	Creates a network object.
object-group network	Creates a network object group.

Command	Description
range	Specifies a range of addresses for the network object.
show running-config object network	Shows the network object configuration.
subnet	Specifies a subnet network object.

host (parameters)

To specify a host to interact with using RADIUS accounting, use the **host** command in radius-accounting parameter configuration mode, which is accessed by using the **parameters** command in the policy-map type inspect radius-accounting submode. To disable the specified host, use the **no** form of this command.

host *address* [**key** *secret*]

no host *address* [**key** *secret*]

Syntax Description

host	Specifies a single endpoint sending the RADIUS accounting messages.
address	The IP address of the client or server sending the RADIUS accounting messages.
key	Optional keyword to specify the secret of the endpoint sending the gratuitous copy of the accounting messages.
secret	The shared secret key of the endpoint sending the accounting messages used to validate the messages. This can be up to 128 alphanumeric characters.

Defaults

The **no** option is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Radius-accounting parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Multiple instances of this command are allowed.

Examples

The following example shows how to specify a host with RADIUS accounting:

```
hostname(config)# policy-map type inspect radius-accounting ra
hostname(config-pmap)# parameters
hostname(config-pmap-p)# host 209.165.202.128 key cisco123
```

Related Commands

Commands	Description
inspect radius-accounting	Sets inspection for RADIUS accounting.
parameters	Sets parameters for an inspection policy map.

hostname

To set the ASA hostname, use the **hostname** command in global configuration mode. To restore the default hostname, use the **no** form of this command.

hostname *name*

no hostname [*name*]

Syntax Description

name	Specifies a hostname up to 63 characters. A hostname must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.

Defaults

The default hostname depends on your platform.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	You can no longer use non-alphanumeric characters (other than a hyphen).

Usage Guidelines

The hostname appears as the command line prompt, and if you establish sessions to multiple devices, the hostname helps you keep track of where you enter commands. For multiple context mode, the hostname that you set in the system execution space appears in the command line prompt for all contexts.

The hostname that you optionally set within a context does not appear in the command line, but can be used for the **banner** command **$(hostname)** token.

Examples

The following example sets the hostname to firewall1:

```
hostname(config)# hostname firewall1
firewall1(config)#
```

Related Commands

Command	Description
banner	Sets a login, message of the day, or enable banner.
domain-name	Sets the default domain name.

hpm topn enable

To enable real-time reports in ASDM of the top hosts connecting through the ASA, use the **hpm topn enable** command in global configuration mode. To disable the hosts reporting, use the **no** form of this command.

hpm topn enable

no hpm topn enable

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You might want to disable this command to maximize system performance. This command populates the ASDM Home > Firewall Dashboard > Top 200 Hosts pane.

Examples

The following example enables the top hosts reporting:

```
hostname(config)# hpm topn enable
```

Related Commands

Command	Description
clear configure hpm	Clears the HPM configuration.
show running-config hpm	Shows the HPM configuration.

hsi

To add an HSI to an HSI group for H.323 protocol inspection, use the **hsi** command in hsi group configuration mode. To disable this feature, use the **no** form of this command.

hsi *ip_address*

no hsi *ip_address*

Syntax Description

ip_address	IP address of the host to add. A maximum of five HSIs per HSI group is allowed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Hsi group configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to add an HSI to an HSI group in an H.323 inspection policy map:

```
hostname(config-pmap-p)# hsi-group 10
hostname(config-h225-map-hsi-grp)# hsi 10.10.15.11
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
endpoint	Adds an endpoint to the HSI group.
hsi-group	Creates an HSI group.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

hsi-group

To define an HSI group for H.323 protocol inspection and to enter hsi group configuration mode, use the **hsi-group** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

hsi-group *group_id*

no hsi-group *group_id*

Syntax Description

group_id	HSI group ID number, from 0 to 2147483647.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure an HSI group in an H.323 inspection policy map:

```
hostname(config-pmap-p)# hsi-group 10
hostname(config-h225-map-hsi-grp)# hsi 10.10.15.11
hostname(config-h225-map-hsi-grp)# endpoint 10.3.6.1 inside
hostname(config-h225-map-hsi-grp)# endpoint 10.10.25.5 outside
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
endpoint	Adds an endpoint to the HSI group.
hsi	Adds an HSI to the HSI group.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

html-content-filter

To filter Java, ActiveX, images, scripts, and cookies for WebVPN sessions for this user or group policy, use the **html-content-filter** command in webvpn configuration mode. To remove a content filter, use the **no** form of this command.

html-content-filter {**java** | **images** | **scripts** | **cookies** | **none**}

no html-content-filter [**java** | **images** | **scripts** | **cookies** | **none**]

Syntax Description

cookies	Removes cookies from images, providing limited ad filtering and privacy.
images	Removes references to images (removes <IMG> tags).
java	Removes references to Java and ActiveX (removes the <EMBED>, <APPLET>, and <OBJECT> tags.
none	Indicates that there is no filtering. Sets a null value, thereby disallowing filtering. Prevents inheriting filtering values.
scripts	Removes references to scripting (removes <SCRIPT> tags).

Defaults

No filtering occurs.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To remove all content filters, including a null value created by issuing the **html-content-filter none** command, use the **no** form of this command without arguments. The **no** option allows inheritance of a value from another group policy. To prevent inheriting an HTML content filter, use the **html-content-filter none** command.

Using the command a second time overrides the previous setting.

Examples

The following example shows how to set filtering of Java and ActiveX, cookies, and images for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
```

```
hostname(config-group-webvpn)# html-content-filter java cookies images
```

Related Commands

Command	Description
webvpn	Lets you enter webvpn configuration mode to configure parameters that apply to group policies or usernames. Lets you enter global configuration mode to configure global settings for WebVPN.

http

To specify hosts that can access the HTTP server internal to the ASA, use the **http** command in global configuration mode. To remove one or more hosts, use the **no** form of this command. To remove the attribute from the configuration, use the **no** form of this command without arguments.

http *ip_address subnet_mask interface_name*

no http

Syntax Description

interface_name	Provides the name of the ASA interface through which the host can access the HTTP server.
ip_address	Provides the IP address of a host that can access the HTTP server.
subnet_mask	Provides the subnet mask of a host that can access the HTTP server.

Defaults

No hosts can access the HTTP server.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to allow the host with the IP address of 10.10.99.1 and the subnet mask of 255.255.255.255 access to the HTTP server via the outside interface:

```
hostname(config)# http 10.10.99.1 255.255.255.255 outside
```

The next example shows how to allow any host access to the HTTP server via the outside interface:

```
hostname(config)# http 0.0.0.0 0.0.0.0 outside
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration: disables the HTTP server and removes hosts that can access the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.

Command	Description
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
http server enable	Enables the HTTP server.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

http authentication-certificate

To require a certficate for authentication with ASDM HTTPS connections, use the **http authentication-certificate** command in global configuration mode. To remove the attribute from the configuration, use the **no** version of this command. To remove all **http authentication-certificate** commands from the configuration, use the **no** version without arguments.

The ASA validates certificates against the PKI trust points. If a certificate does not pass validation, the ASA closes the SSL connection.

http authentication-certificate *interface*

no http authentication-certificate [*interface*]

Syntax Description

interface	Specifies the interface on the ASA that requires certificate authentication.

Defaults

HTTP certificate authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0.3	This command was deprecated in favor of the **ssl certificate-authentication** command.
8.2.1	This command was re-added; the global **ssl certificate-authentication** command was kept for backwards compatibility.
8.4.7, 9.1.3	Certificate-only authentication was enabled. Previously, this command only added certificate authentication to user authentication when you enabled the **aaa authentication http console** command.

Usage Guidelines

You configure certificate authentication for each interface, so that connections on a trusted/inside interface do not have to provide a certificate. You can use the command multiple times to enable certificate authentication on multiple interfaces.

Examples

The following example shows how to require certificate authentication for clients connecting to the interfaces named outside and external:

```
hostname(config)# http authentication-certificate inside
hostname(config)# http authentication-certificate external
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration: disables the HTTP server and removes hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask. Specifies the ASA interface through which the host accesses the HTTP server.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
http server enable	Enables the HTTP server.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.
ssl authentication-certificate	To require a certificate for SSL connections.

http[s] (parameters)

To specify the service type for the scansafe inspection policy map, use the **http**[**s**] command in parameters configuration mode. To remove the service type, use the **no** form of this command. You can access the parameters configuration mode by first entering the the **policy-map type inspect scansafe** command.

{**http** | **https**}

no {**http** | **https**}

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You can only specify one service type for a scansafe inspection policy map, either **http** or **https**. There is no default; you must specify a type.

Examples

The following example creates an inspection policy map, and sets the service type to HTTP:

```
hostname(config)# policy-map type inspect scansafe cws_inspect_pmap1
hostname(config-pmap)# parameters
hostname(config-pmap-p)# http
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.

Command	Description
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

http-comp

To enable compression of HTTP data over a WebVPN connection for a specific group or user, use the **http-comp** command in the group-policy webvpn and username webvpn configuration modes. To remove the command from the configuration and have the value be inherited, use the **no** form of this command.

http-comp {**gzip** | **none**}

no http-comp {**gzip** | **none**}

Syntax Description

gzip	Specifies compression is enabled for the group or user.
none	Specifies compression is disabled for the group or user.

Defaults

By default, compression is set to enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

For WebVPN connections, the **compression** command configured in global configuration mode overrides the **http-comp** command configured in group policy and username webvpn configuration modes.

Examples

The following example disables compression for the group-policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# http-comp none
```

Related Commands

Command	Description
compression	Enables compression for all SVC, WebVPN, and IPsec VPN connections.

http-proxy

To configure the ASA to use an external proxy server to handle HTTP requests, use the **http-proxy** command in webvpn configuration mode. To remove the HTTP proxy server from the configuration, use the **no** form of this command.

http-proxy {*host* [*port*] [**exclude** `url`] | **pac** *pacfile*} [**username** *username* {**password** *password*}]

no http-proxy

Syntax Description

host	Hostname or IP address for the external HTTP proxy server.
pac *pacfile*	Identifies the PAC file that contains a JavaScript function that specifies one or more proxies.
password	(Optional, and available only if you specify a username) Enter this keyword to accompany each HTTP proxy request with a password to provide basic, proxy authentication.
password	Password to send to the proxy server with each HTTP request.
port	(Optional) Port number used by the HTTP proxy server. The default port is 80, which is the port that the ASA uses if you do not supply a value. The range is 1-65535.
url	Enter a URL or a comma-delimited list of several URLs to exclude from those that can be sent to the proxy server. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards: • ***** to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string. • **?** to match any single character, including slashes and periods. • [*x*-*y*] to match any single character in the range of *x* and *y*, where *x* represents one character and *y* represents another character in the ANSI character set. • [**!***x*-*y*] to match any single character that is not in the range.
username	(Optional) Enter this keyword to accompany each HTTP proxy request with a username to provide basic, proxy authentication.
username	Username to send to the proxy server with each HTTP request.

Defaults

By default, no HTTP proxy server is configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Added the **exclude**, **username**, and **password** keywords.

Usage Guidelines

Requiring Internet access via a server that the organization controls provides another opportunity for filtering to assure secure Internet access and administrative control.

The ASA supports only one instance of the **http-proxy** command. If one instance of this command is already present in the running configuration and you enter another instance, the CLI overwrites the previous instance. The CLI lists any **http-proxy** commands in the running configuration if you enter the **show running-config webvpn** command. If the response does not list an **http -proxy** command, then none is present.

Note Proxy NTLM authentication is not supported in **http-proxy**. Only proxy without authentication and basic authentication are supported.

Examples

The following example shows how to configure use of an HTTP proxy server with an IP address of 209.165. 201.2 using the default port, 443:

```
hostname(config)# webvpn
hostname(config-webvpn)# http-proxy 209.165.201.2
hostname(config-webvpn)
```

The following example shows how to configure use of the same proxy server, and send a username and password with each HTTP request:

```
hostname(config-webvpn)# http-proxy 209.165.201.2 jsmith password mysecretdonttell
hostname(config-webvpn)
```

The following example shows the same command, except when the ASA receives the specific URL www.example.com in an HTTP request, it resolves the request instead of passing it on to the proxy server:

```
hostname(config-webvpn)# http-proxy 209.165.201.2 exclude www.example.com username jsmith
password mysecretdonttell
hostname(config-webvpn)
```

The followiing example shows how to use the **exclude** option:

```
hostname(config-webvpn)# http-proxy 10.1.1.1 port 8080 exclude *.com username John pasword
12345678
hostname(config-webvpn)
```

The followiing example shows how to use the **pac** option:

```
hostname(config-webvpn)# http-proxy pac http://10.1.1.1/pac.js
hostname(config-webvpn)
```

Related Commands

Command	Description
https-proxy	Configures the use of an external proxy server to handle HTTPS requests.
show running-config webvpn	Displays the running configuration for SSL VPN, including any HTTP and HTTPS proxy servers.

http-proxy (dap)

To enable or disable HTTP proxy port forwarding, use the **http-proxy** command in dap-webvpn configuration mode.To remove the attribute from the configuration, use the **no** form of this command.

http-proxy {**enable** | **disable** | **auto-start**}

no http-proxy

Syntax Description

auto-start	Enables and automatically starts HTTP proxy port forwarding for the DAP record.
enable/disable	Enables or disables HTTP proxy port forwarding for the DAP record.

Defaults

No default value or behaviors.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Dap-webvpn configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The ASA can apply attribute values from a variety of sources. It applies them according to the following hierarchy:

1. DAP record
2. Username
3. Group policy
4. Group policy for the tunnel group
5. Default group policy

It follows that DAP values for an attribute have a higher priority than those configured for a user, group policy, or tunnel group.

When you enable or disable an attribute for a DAP record, the ASA applies that value and enforces it. For example, when you disable HTTP proxy in dap-webvpn configuration mode, the ASA looks no further for a value. When you instead use the **no** value for the **http-proxy** command, the attribute is not present in the DAP record, so the ASA moves down to the AAA attribute in the username, and if necessary, the group policy to find a value to apply.

Examples

The following example shows how to enable HTTP proxy port forwarding for the DAP record named Finance.

```
hostname (config)# dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# webvpn
hostname(config-dap-webvpn)# http-proxy enable
hostname(config-dap-webvpn)#
```

Related Commands

Command	Description
dynamic-access-policy-record	Creates a DAP record.
show running-config dynamic-access-policy-record	Displays the running configuration for all DAP records, or for the named DAP record.

http redirect

To specify that the ASA redirect HTTP connections to HTTPS, use the **http redirect** command in global configuration mode. To remove a specified **http redirect** command from the configuration, use the **no** form of this command. To remove all **http redirect** commands from the configuration, use the **no** form of this command without arguments.

http redirect *interface* [*port*]

no http redirect [*interface*]

Syntax Description

interface	Identifies the interface for which the ASA should redirect HTTP requests to HTTPS.
port	Identifies the port that the ASA listens on for HTTP requests, which it then redirects to HTTPS. By default, it listens on port 80,

Defaults

HTTP redirect is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The interface requires an access list that permits HTTP. Otherwise the ASA does not listen to port 80, or to any other port that you configure for HTTP.

If the **http redirect** command fails, the following message appears:

```
"TCP port <port_number> on interface <interface_name> is in use by another feature. Please
choose a different port for the HTTP redirect service"
```

Use a different port for the HTTP redirect service.

Examples

The following example shows how to configure HTTP redirect for the inside interface, keeping the default port 80:

```
hostname(config)# http redirect inside
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration: disables the HTTP server and removes hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask. Specifies the ASA interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http server enable	Enables the HTTP server.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

http server enable

To enable the ASA HTTP server, use the **http server enable** command in global configuration mode. To disable the HTTP server, use the **no** form of this command.

http server enable [*port*]

Syntax Description

port	The port to use for HTTP connections. The range is 1-65535. The default port is 443.

Defaults

The HTTP server is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to enable the HTTP server.

```
hostname(config)# http server enable
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration: disables the HTTP server and removes hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask. Specifies the ASA interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

http server idle-timeout

To set an idle timeout for ASDM connections to the ASA, use the **http server idle-timeout** command in global configuration mode. To disable the timeout, use the **no** form of this command.

http server idle-timeout [*minutes*]

no http server idle-timeout [*minutes*]

Syntax Description

minutes	The idle timeout, from 1-1440 minutes.

Defaults

The default setting is 20 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example sets the idle timeout for ASDM sessions to 500 minutes:

```
hostname(config)# http server idle-timeout 500
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration, disables the HTTP server, and removes hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask and the interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http server enable	Enables the HTTP server for ASDM sessions.
http server session-timeout	Limits the session time of ASDM sessions to the ASA.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

http server session-timeout

To set a session timeout for ASDM connections to the ASA, use the **http server session-timeout** command in global configuration mode. To disable the timeout, use the **no** form of this command.

http server session-timeout [*minutes*]

no http server session-timeout [*minutes*]

Syntax Description

minutes	The session timeout, from 1-1440 minutes.

Defaults

The session timeout is disabled. ASDM connections have no session time limit.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Examples

The following example sets a session timeout for ASDM connections to 1000 minutes:

```
hostname(config)# http server session-timeout 1000
```

Related Commands

Command	Description
clear configure http	Removes the HTTP configuration: disables the HTTP server and removes hosts that can access the HTTP server.
http	Specifies hosts that can access the HTTP server by IP address and subnet mask and the interface through which the host accesses the HTTP server.
http authentication-certificate	Requires authentication via certificate from users who are establishing HTTPS connections to the ASA.
http server enable	Enables the HTTP server for ASDM sessions.
http server idle-timeout	Limits the idle time of ASDM sessions to the ASA.
http redirect	Specifies that the ASA redirect HTTP connections to HTTPS.
show running-config http	Displays the hosts that can access the HTTP server, and whether or not the HTTP server is enabled.

https-proxy

To configure the ASA to use an external proxy server to handle HTTPS requests, use the **https-proxy** command in webvpn configuration mode. To remove the HTTPS proxy server from the configuration, use the **no** form of this command.

https-proxy {*host* [*port*] [**exclude** `url`] | [**username** *username* {**password** *password*}]

no https-proxy

Syntax Description

host	Hostname or IP address for the external HTTPS proxy server.
password	(Optional, and available only if you specify a username) Enter this keyword to accompany each HTTPS proxy request with a password to provide basic, proxy authentication.
password	Password to send to the proxy server with each HTTPS request.
port	(Optional) Port number used by the HTTPS proxy server. The default port is 443, which is the port the ASA uses if you do not supply a value. The range is 1-65535.
url	Enter a URL or a comma-delimited list of several URLs to exclude from those that can be sent to the proxy server. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards: • ***** to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string. • **?** to match any single character, including slashes and periods. • [*x*-*y*] to match any single character in the range of *x* and *y*, where *x* represents one character and *y* represents another character in the ANSI character set. • [**!***x*-*y*] to match any single character that is not in the range.
username	(Optional) Enter this keyword to accompany each HTTPS proxy request with a username to provide basic, proxy authentication.
username	Username to send to the proxy server with each HTTPS request.

Defaults

By default, no HTTPS proxy server is configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Added the **exclude**, **username**, and **password** keywords.

Usage Guidelines

Requiring Internet access via a server that the organization controls provides another opportunity for filtering to assure secure Internet access and administrative control.

The ASA supports only one instance of the **https-proxy** command. If one instance of this command is already present in the running configuration and you enter another instance, the CLI overwrites the previous instance. The CLI lists any **https-proxy** commands in the running configuration if you enter the **show running-config webvpn** command. If the response does not list an **https-proxy** command, then none is present.

Examples

The following example shows how to configure use of an HTTPS proxy server with an IP address of 209.165. 201.2 using the default port, 443:

```
hostname(config)# webvpn
hostname(config-webvpn)# https-proxy 209.165.201.2
hostname(config-webvpn)
```

The following example shows how to configure use of the same proxy server, and send a username and password with each HTTPS request:

```
hostname(config-webvpn)# https-proxy 209.165.201.2 jsmith password mysecretdonttell
hostname(config-webvpn)
```

The following example shows the same command, except that when the ASA receives the specific URL www.example.com in an HTTPS request, it resolves the request instead of passing it on to the proxy server:

```
hostname(config-webvpn)# https-proxy 209.165.201.2 exclude www.example.com username jsmith
password mysecretdonttell
hostname(config-webvpn)
```

The followiing example shows how to use the **exclude** option:

```
hostname(config-webvpn)# https-proxy 10.1.1.1 port 8080 exclude *.com username John
pasword 12345678
hostname(config-webvpn)
```

The followiing example shows how to use the **pac** option:

```
hostname(config-webvpn)# https-proxy pac http://10.1.1.1/pac.js
hostname(config-webvpn)
```

Related Commands

Command	Description
http-proxy	Configures the use of an external proxy server to handle HTTP requests.
show running-config webvpn	Displays the running configuration for SSL VPN, including any HTTP and HTTPS proxy servers.

hw-module module allow-ip

For the AIP SSC on the ASA 5505, to set the hosts that are allowed to access the management IP address, use the **hw-module module allow-ip** command in privileged EXEC mode.

hw-module module 1 allow-ip *ip_address netmask*

Syntax Description

1	Specifies the slot number, which is always 1.
ip_ address	Specifies the host IP address(es).
netmask	Specifies the subnet mask.

Defaults

In the factory default configuration, the following hosts are allowed to manage the IPS module: 192.168.1.5 through 192.168.1.254.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command is only valid when the SSC status is Up.

These settings are written to the IPS application configuration, not the ASA configuration. You can view these settings from the ASA using the **show module details** command.

You can alternatively use the IPS application **setup** command to configure this setting from the IPS CLI.

Examples

The following example shows how to configure host parameters on the SSC:

```
hostname# hw-module module 1 allow-ip 209.165.201.29 255.255.255.0
```

Related Commands

Command	Description
hw-module module ip	Configures the AIP SSC management address.
show module	Shows module status information.

hw-module module ip

For the AIP SSC on the ASA 5505, to configure the management IP address, use the **hw-module module ip** command in privileged EXEC mode.

hw-module module 1 ip *ip_address netmask gateway*

Syntax Description

1	Specifies the slot number, which is always 1.
gateway	Specifies the gateway IP address.
ip_address	Specifies the management IP address.
netmask	Specifies the subnet mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Make sure this address is on the same subnet as the ASA VLAN IP address. For example, if you assigned 10.1.1.1 to the VLAN for the ASA, then assign another address on that network, such as 10.1.1.2, for the IPS management address.

If the management station is on a directly connected ASA network, then set the gateway to be the ASA IP address assigned to the IPS management VLAN. In the example decribed, set the gateway to 10.1.1.1. If the management station is on a remote network, then set the gateway to be the address of an upstream router on the IPS management VLAN.

Note These settings are written to the IPS application configuration, not the ASA configuration. You can view these settings from the ASA using the **show module details** command.

You can alternatively use the IPS application **setup** command to configure this setting from the IPS CLI.

Examples

The following example shows how to configure a management address for the IPS module:

```
hostname# hw-module module 1 ip 209.165.200.254 255.255.255.224 209.165.200.225
```

Related Commands

Command	Description
hw-module module allow-ip	Configures the AIP SSC management host addresses.
show module	Shows module status information.

hw-module module password-reset

To reset the password for the default admin user on the hardware module to the default value, use the **hw-module module password-reset** command in privileged EXEC mode.

hw-module module 1 password-reset

Syntax Description

1	Specifies the slot number, which is always 1.

Defaults

The default username and password depends on your module:

- IPS module—username: **cisco**; password: **cisco**
- CSC module—username: **cisco**; password: **cisco**
- ASA CX module—username: **admin**; password: **Admin123**

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.2(2)	This command was introduced.
8.4(4.1)	We added support for the ASA CX module.

Usage Guidelines

This command is only valid when the hardware module is in the Up state and supports password reset. For IPS, password reset is supported if the module is running IPS Version 6.0 or later. After resetting the password, you should change it to a unique value using the module application. Resetting the module password causes the module to reboot. Services are not available while the module is rebooting, which may take several minutes. You can run the **show module** command to monitor the module state.

The command always prompts for confirmation. If the command succeeds, no other output appears. If the command fails, an error message appears that explains why the failure occurred. The possible error messages are as follows:

```
Unable to reset the password on the module in slot 1

Unable to reset the password on the module in slot 1 - unknown module state

Unable to reset the password on the module in slot 1 - no module installed

Failed to reset the password on the module in slot 1 - module not in Up state

Unable to reset the password on the module in slot 1 - unknown module type

The module in slot 1 does not support password reset

Unable to reset the password on the module in slot 1 - no application found

The SSM application version does not support password reset

Failed to reset the password on the module in slot 1
```

Examples

The following example resets a password on a hardware module in slot 1:

```
hostname(config)# hw-module module 1 password-reset
Reset the password on module in slot 1? [confirm] y
```

Related Commands

Command	Description
hw-module module recover	Recovers a module by loading a recovery image from a TFTP server.
hw-module module reload	Reloads the module software.
hw-module module reset	Shuts down and resets the module hardware.
hw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

hw-module module recover

To load a recovery software image from a TFTP server to an installed module, or to configure network settings to access the TFTP server, use the **hw-module module recover** command in privileged EXEC mode. You might need to recover a module using this command if, for example, the module is unable to load a local image.

hw-module module 1 recover {**boot** | **stop** | **configure** [**url** *tfp_url* | **ip** *module_address* | **gateway** *gateway_ip_address* | **vlan** *vlan_id*]}

Syntax Description

1	Specifies the slot number, which is always 1.
boot	Initiates recovery of this module and downloads a recovery image according to the **configure** keyword settings. The module then reboots from the new image.
configure	Configures the network parameters to download a recovery image. If you do not enter a network parameter after the **configure** keyword, you are prompted for all parameters. This command prompts you for the URL for the TFTP server, the management interface IP address and netmask, gateway address, and VLAN ID. These network parameters are configured in ROMMON; the network parameters you configured in the module application configuration are not available to ROMMON, so you must set them separately here.
gateway *gateway_ip_address*	(Optional) The gateway IP address for access to the TFTP server through the SSM management interface.
ip *module_address*	(Optional) The IP address of the module management interface.
stop	Stops the recovery action, and stops downloading the recovery image. The module boots from the original image. You must enter this command within 30 to 45 seconds after starting recovery using the **hw-module module recover boot** command. If you issue the **stop** command after this period, it might cause unexpected results, such as the module becoming unresponsive.
url *tfp_url*	(Optional) The URL for the image on a TFTP server, in the following format: **tftp://***server*/[*path*/]*filename*
vlan *vlan_id*	(Optional) Specifies the VLAN ID for the management interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the module suffers a failure, and the module application image cannot run, you can reinstall a new image on the module from a TFTP server.

Note Do not use the **upgrade** command within the module software to install the image.

Be sure the TFTP server that you specify can transfer files up to 60 MB in size. This process can take approximately 15 minutes to complete, depending on your network and the size of the image.

This command is only available when the module is in the Up, Down, Unresponsive, or Recovery state. See the **show module** command for state information.

You can view the recovery configuration using the **show module 1 recover** command.

Note This command is not supported on the ASA CX module.

Examples

The following example sets the module to download an image from a TFTP server:

```
hostname# hw-module module 1 recover configure
Image URL [tftp://127.0.0.1/myimage]: tftp://10.1.1.1/ids-newimg
Port IP Address [127.0.0.2]: 10.1.2.10
Port Mask [255.255.255.254]: 255.255.255.0
Gateway IP Address [1.1.2.10]: 10.1.2.254
VLAN ID [0]: 100
```

The following example recovers the module:

```
hostname# hw-module module 1 recover boot
The module in slot 1 will be recovered.  This may
erase all configuration and all data on that device and
attempt to download a new image for it.
Recover module in slot 1? [confirm]
```

Related Commands

Command	Description
debug module-boot	Shows debug messages about the module booting process.
hw-module module reset	Shuts down a module and performs a hardware reset.
hw-module module reload	Reloads the module software.
hw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

hw-module module reload

To reload module software for a physical module, use the **hw-module module reload** command in privileged EXEC mode.

hw-module module 1 reload

Syntax Description

1	Specifies the slot number, which is always 1.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(4.1)	We added support for the ASA CX module.

Usage Guidelines

This command differs from the **hw-module module reset** command, which also performs a hardware reset before reloading the module.

This command is only valid when the module status is Up. See the **show module** command for state information.

Examples

The following example reloads the module in slot 1:

```
hostname# hw-module module 1 reload
Reload module in slot 1? [confirm] y
Reload issued for module in slot 1
%XXX-5-505002: Module in slot 1 is reloading.  Please wait...
%XXX-5-505006: Module in slot 1 is Up.
```

Related Commands

Command	Description
debug module-boot	Shows debugging messages about the module booting process.
hw-module module recover	Recovers a module by loading a recovery image from a TFTP server.
hw-module module reset	Shuts down a module and performs a hardware reset.
hw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

hw-module module reset

To reset the module hardware and then reload the module software, use the **hw-module module reset** command in privileged EXEC mode.

hw-module module 1 reset

Syntax Description

1	Specifies the slot number, which is always 1.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(4.1)	We added support for the ASA CX module.

Usage Guidelines

When the module is in an Up state, the **hw-module module reset** command prompts you to shut down the software before resetting.

You can recover a module (if supported) using the **hw-module module recover** command. If you enter the **hw-module module reset** command while the module is in a Recover state, the module does not interrupt the recovery process. The **hw-module module reset** command performs a hardware reset of the module, and the module recovery continues after the hardware reset. You might want to reset the module during recovery if the module hangs; a hardware reset might resolve the issue.

This command differs from the **hw-module module reload** command, which only reloads the software and does not perform a hardware reset.

This command is only valid when the module status is Up, Down, Unresponsive, or Recover. See the **show module** command for state information.

Examples

The following example resets an module in slot 1 that is in the Up state:

```
hostname# hw-module module 1 reset
The module in slot 1 should be shut down before
resetting it or loss of configuration may occur.
Reset module in slot 1? [confirm] y
Reset issued for module in slot 1
%XXX-5-505001: Module in slot 1 is shutting down.  Please wait...
```

```
%XXX-5-505004: Module in slot 1 shutdown is complete.
%XXX-5-505003: Module in slot 1 is resetting.  Please wait...
%XXX-5-505006: Module in slot 1 is Up.
```

Related Commands

Command	Description
debug module-boot	Shows debugging messages about the module booting process.
hw-module module recover	Recovers a module by loading a recovery image from a TFTP server.
hw-module module reload	Reloads the module software.
hw-module module shutdown	Shuts down the module software in preparation for being powered off without losing configuration data.
show module	Shows module information.

hw-module module shutdown

To shut down the module software, use the **hw-module module shutdown** command in privileged EXEC mode.

hw-module module 1 shutdown

Syntax Description

1	Specifies the slot number, which is always 1.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(4.1)	We added support for the ASA CX module.

Usage Guidelines

Shutting down the module software prepares the module to be safely powered off without losing configuration data.

This command is only valid when the module status is Up or Unresponsive. See the **show module** command for state information.

Examples

The following example shuts down a module in slot 1:

```
hostname# hw-module module 1 shutdown
Shutdown module in slot 1? [confirm] y
Shutdown issued for module in slot 1
hostname#
%XXX-5-505001: Module in slot 1 is shutting down.  Please wait...
%XXX-5-505004: Module in slot 1 shutdown is complete.
```

Related Commands

Command	Description

hw-module module reload	Reloads the module software.
hw-module module reset	Shuts down a module and performs a hardware reset.
show module	Shows module information.

icmp through import webvpn webcontent Commands

icmp

To configure access rules for ICMP traffic that terminates at an ASA interface, use the **icmp** command. To remove the configuration, use the **no** form of this command.

icmp {**permit** | **deny**} *ip_address net_mask* [*icmp_type*] *if_name*

no icmp {**permit** | **deny**} *ip_address net_mask* [*icmp_type*] *if_name*

Syntax Description

deny	Deny access if the conditions are matched.
icmp_type	(Optional) ICMP message type (see Table 24-1).
if_name	The interface name.
ip_address	The IP address of the host sending ICMP messages to the interface.
net_mask	The network mask to be applied to the IP address of the host.
permit	Permit access if the conditions are matched.

Defaults

The default behavior of the ASA is to allow all ICMP traffic to the ASA interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **icmp** command controls ICMP traffic that terminates on any ASA interface. If no ICMP control list is configured, then the ASA accepts all ICMP traffic that terminates at any interface, including the outside interface. However, by default, the ASA does not respond to ICMP echo requests directed to a broadcast address.

The ASA only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

The **icmp deny** command disables pinging to an interface, and the **icmp permit** command enables pinging to an interface. With pinging disabled, the ASA cannot be detected on the network. This is also referred to as configurable proxy pinging.

Use the **access-list extended** or **access-group** command for ICMP traffic that is routed through the ASA for destinations on a protected interface.

We recommend that you grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. See RFC 1195 and RFC 1435 for details about path MTU discovery.

If an ICMP control list is configured for an interface, then the ASA first matches the specified ICMP traffic and then applies an implicit deny for all other ICMP traffic on that interface. That is, if the first matched entry is a permit entry, the ICMP packet continues to be processed. If the first matched entry is a deny entry or an entry is not matched, the ASA discards the ICMP packet and generates a syslog message. An exception is when an ICMP control list is not configured; in that case, a permit statement is assumed.

Table 24-1 lists the supported ICMP type values.

Table 24-1 ICMP Types and Literals

ICMP Type	Literal
0	echo-reply
3	unreachable
8	echo
11	time-exceeded

Examples

The following example denies all ping requests and permits all unreachable messages at the outside interface:

```
hostname(config)# icmp permit any unreachable outside
```

Continue entering the **icmp deny any** *interface* command for each additional interface on which you want to deny ICMP traffic.

The following example permits host 172.16.2.15 or hosts on subnet 172.22.1.0/16 to ping the outside interface:

```
hostname(config)# icmp permit host 172.16.2.15 echo-reply outside
hostname(config)# icmp permit 172.22.1.0 255.255.0.0 echo-reply outside
hostname(config)# icmp permit any unreachable outside
```

Related Commands

Commands	Description
clear configure icmp	Clears the ICMP configuration.
debug icmp	Enables the display of debug information for ICMP.
show icmp	Displays ICMP configuration.
timeout icmp	Configures the idle timeout for ICMP.

icmp unreachable

To configure the unreachable ICMP message rate limit for ICMP traffic that terminates at an ASA interface, use the **icmp unreachable** command. To remove the configuration, use the **no** form of this command.

icmp unreachable rate-limit *rate* **burst-size** *size*

no icmp unreachable rate-limit *rate* **burst-size** *size*

Syntax Description

rate-limit *rate*	Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
burst-size *size*	Sets the burst rate, between 1 and 10. This keyword is not currently used by the system, so you can choose any value.

Defaults

The default rate limit is 1 message per second.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(2)	This command was introduced.

Usage Guidelines

If you allow ICMP messages, including unreachable messages, to terminate on an ASA interface (see the **icmp** command), then you can control the rate of unreachable messages.

This command, along with the **set connection decrement-ttl** command, is required to allow a traceroute through the ASA that shows the ASA as one of the hops.

Examples

The following example enables time to live decrements and sets the ICMP unreachable rate limit:

```
hostname(config)# policy-map localpolicy1
hostname(config-pmap)# class local_server
hostname(config-pmap-c)# set connection decrement-ttl
hostname(config-pmap-c)# exit
hostname(config)# icmp permit host 172.16.2.15 echo-reply outside
hostname(config)# icmp permit 172.22.1.0 255.255.0.0 echo-reply outside
hostname(config)# icmp permit any unreachable outside
hostname(config)# icmp unreachable rate-limit 50 burst-size 1
```

Related Commands

Commands	Description
clear configure icmp	Clears the ICMP configuration.
debug icmp	Enables the display of debug information for ICMP.
set connection decrement-ttl	Decrements the time to live value for a packet.
show icmp	Displays ICMP configuration.
timeout icmp	Configures the idle timeout for ICMP.

icmp-object

To add icmp-type object groups, use the **icmp-object** command in icmp-type configuration mode. To remove network object groups, use the **no** form of this command.

icmp-object *icmp_type*

no group-object *icmp_type*

Syntax Description

icmp_type	Specifies an ICMP type name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Icmp-type configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **icmp-object** command is used with the **object-group** command to define an icmp-type object. It is used in icmp-type configuration mode.

ICMP type numbers and names include:

Number	ICMP Type Name
0	**echo-reply**
3	**unreachable**
4	**source-quench**
5	**redirect**
6	**alternate-address**
8	**echo**
9	**router-advertisement**
10	**router-solicitation**
11	**time-exceeded**
12	**parameter-problem**

Number	ICMP Type Name
13	**timestamp-request**
14	**timestamp-reply**
15	**information-request**
16	**information-reply**
17	**address-mask-request**
18	**address-mask-reply**
31	**conversion-error**
32	**mobile-redirect**

Examples

The following example shows how to use the **icmp-object** command in icmp-type configuration mode:

```
hostname(config)# object-group icmp-type icmp_allowed
hostname(config-icmp-type)# icmp-object echo
hostname(config-icmp-type)# icmp-object time-exceeded
hostname(config-icmp-type)# exit
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object-group** commands from the configuration.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
port-object	Adds a port object to a service object group.
show running-config object-group	Displays the current object groups.

id-cert-issuer

To indicate whether the system accepts peer certificates issued by the CA associated with this trustpoint, use the **id-cert-issuer** command in crypto ca-trustpoint configuration mode. To disallow certificates that were issued by the CA associated with the trustpoint, use the **no** form of this command. This is useful for trustpoints that represent widely used root CAs.

id-cert-issuer

no id-cert-issuer

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is enabled (identity certificates are accepted).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca-trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use this command to limit certificate acceptance to those issued by the subordinate certificate of a widely used root certificate. If you do not allow this feature, the ASA rejects any IKE peer certificate signed by this issuer.

Examples

The following example enters crypto ca trustpoint configuration mode for the trustpoint central, and lets an administrator accept identity certificates signed by the issuer for the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# id-cert-issuer
hostname(ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.
enrollment retry count	Specifies the number of retries to attempt to send an enrollment request.

Command	Description
enrollment retry period	Specifies the number of minutes to wait before trying to send an enrollment request.
enrollment terminal	Specifies cut-and-paste enrollment with this trustpoint.

id-mismatch

To enable logging for excessive DNS ID mismatches, use the **id-mismatch** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

id-mismatch [**count** *number* **duration** *seconds*] **action log**

no id-mismatch [**count** *number* **duration** *seconds*] **action log**]

Syntax Description

count *number*	The maximum number of mismatch instances before a system message log is sent.
duration *seconds*	The period, in seconds, to monitor.

Defaults

This command is disabled by default. The default rate is 30 in the a period of 3 seconds if the options are not specified when the command is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

A high rate of DNS ID mismatches may indicate a cache poisoning attack. This command can be enabled to monitor and alert such attempts. A summarized system message log will be printed if the mismatch rate exceeds the configured value. The **id-mismatch** command provides the system administrator with additional information to the regular event-based system message log.

Examples

The following example shows how to enable ID mismatch in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# id-mismatch action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

id-randomization

To randomize the DNS identifier for a DNS query, use the **id-randomization** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

id-randomization

no id-randomization

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled by default. The DNS identifier from the DNS query does not get modified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

ID randomization helps protect against cache poisening attacks.

Examples

The following example shows how to enable ID randomization in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# id-randomization
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

id-usage

To specify how the enrolled identity of a certificate can be used, use the **id-usage** command in crypto ca trustpoint configuration mode. To set the usage of the certificate to the default, use the **no** form of this command.

id-usage {**ssl-ipsec** | **code-signer**}

no id-usage {**ssl-ipsec** | **code-signer**}

Syntax Description

code-signer	The device identity represented by this certificate is used as a Java code signer to verify applets provided to remote users.
ssl-ipsec	(Default) The device identity represented by this certificate can be used as the server-side identity for SSL or IPsec-encrypted connections.

Defaults

The **id-usage** command default is **ssl-ipsec**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Remote-access VPNs can use SSL, IPsec, or both protocols, depending on deployment requirements, to permit access to virtually any network application or resource. The **id-usage** command allows you to specify the type of access to various certificate-protected resources.

A CA identity and in some cases, a device identity, is based on a certificate issued by the CA. All of the commands within the crypto ca trustpoint configuration mode control CA-specific configuration parameters, which specify how the ASA obtains the CA certificate, how the ASA obtains its certificate from the CA, and the authentication policies for user certificates issued by the CA.

Only a single instance of the **id-usage** command can be present in a trustpoint configuration. To enable the trustpoint for the **code-signer** and/or **ssl-ipsec** options, use a single instance which can specify either or both options.

Examples

The following example enters crypto ca trustpoint configuration mode for the trustpoint central, and designates it as a code-signer certificate:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)# id-usage code-signer
hostname(config-ca-trustpoint)#
```

The following example enters crypto ca trustpoint configuration mode for the trustpoint general, and designates it as both a code-signer certificate and as a server side identity for SSL or IPsec connections:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)# id-usage code-signer ssl-ipsec
hostname(config-ca-trustpoint)#
```

The following example enters crypto ca trustpoint configuration mode for the trustpoint checkin1, and resets it to limit its use to SSL or IPsec connections:

```
hostname(config)# crypto ca trustpoint checkin1
hostname(config-ca-trustpoint)# no id-usage ssl-ipsec
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.
java-trustpoint	Configures the WebVPN Java object signing facility to use a PKCS12 certificate and keying material from a specified trustpoint location.
ssl trust-point	Specifies the certificate that represents the SSL certificate for an interface.
trust-point (tunnel-group ipsec-attributes mode)	Specifies the name that identifies the certificate to be sent to the IKE peer,
validation-policy	Specifies conditions for validating certificates associated with user connections.

igmp

To reinstate IGMP processing on an interface, use the **igmp** command in interface configuration mode. To disable IGMP processing on an interface, use the **no** form of this command.

igmp

no igmp

Syntax Description

This command has no arguments or keywords.

Defaults

Enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Only the **no** form of this command appears in the running configuration.

Examples

The following example disables IGMP processing on the selected interface:

```
hostname(config-if)# no igmp
```

Related Commands

Command	Description
show igmp groups	Displays the multicast groups with receivers that are directly connected to the ASA and that were learned through IGMP.
show igmp interface	Displays multicast information for an interface.

igmp access-group

To control the multicast groups that hosts on the subnet serviced by an interface can join, use the **igmp access-group** command in interface configuration mode. To disable groups on the interface, use the **no** form of this command.

igmp access-group *acl*

no igmp access-group *acl*

Syntax Description

acl	Name of an IP access list. You can specify a standard or and extended access list. However, if you specify an extended access list, only the destination address is matched; you should specify **any** for the source.

Defaults

All groups are allowed to join on an interface.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Examples

The following example limits hosts permitted by access list 1 to join the group:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp access-group 1
```

Related Commands

Command	Description
show igmp interface	Displays multicast information for an interface.

igmp forward interface

To enable forwarding of all IGMP host reports and leave messages received to the interface specified, use the **igmp forward interface** command in interface configuration mode. To remove the forwarding, use the **no** form of this command.

igmp forward interface *if-name*

no igmp forward interface *if-name*

Syntax Description

if-name	Logical name of the interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Usage Guidelines

Enter this command on the input interface. This command is used for stub multicast routing and cannot be configured concurrently with PIM.

Examples

The following example forwards IGMP host reports from the current interface to the specified interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp forward interface outside
```

Related Commands

Command	Description
show igmp interface	Displays multicast information for an interface.

igmp join-group

To configure an interface to be a locally connected member of the specified group, use the **igmp join-group** command in interface configuration mode. To cancel membership in the group, use the **no** form of this command.

igmp join-group *group-address*

no igmp join-group *group-address*

Syntax Description

group-address	IP address of the multicast group.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Usage Guidelines

This command configures an ASA interface to be a member of a multicast group. The **igmp join-group** command causes the ASA to both accept and forward multicast packets destined for the specified multicast group.

To configure the ASA to forward the multicast traffic without being a member of the multicast group, use the **igmp static-group** command.

Examples

The following example configures the selected interface to join the IGMP group 255.2.2.2:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp join-group 225.2.2.2
```

Related Commands

Command	Description
igmp static-group	Configure the interface to be a statically connected member of the specified multicast group.

igmp limit

To limit the number of IGMP states on a per-interface basis, use the **igmp limit** command in interface configuration mode. To restore the default limit, use the **no** form of this command.

igmp limit *number*

no igmp limit [*number*]

Syntax Description

number	Number of IGMP states allowed on the interface. Valid values range from 0 to 500. The default value is 500. Setting this value to 0 prevents learned groups from being added, but manually defined memberships (using the **igmp join-group** and **igmp static-group** commands) are still permitted.

Defaults

The default is 500.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced. It replaced the **igmp max-groups** command.

Examples

The following example limits the number of IGMP states on the interface to 250:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp limit 250
```

Related Commands

Command	Description
igmp	Reinstates IGMP processing on an interface.
igmp join-group	Configure an interface to be a locally connected member of the specified group.
igmp static-group	Configure the interface to be a statically connected member of the specified multicast group.

igmp query-interval

To configure the frequency at which IGMP host query messages are sent by the interface, use the **igmp query-interval** command in interface configuration mode. To restore the default frequency, use the **no** form of this command.

igmp query-interval *seconds*

no igmp query-interval *seconds*

Syntax Description

seconds	Frequency, in seconds, at which to send IGMP host query messages. Valid values range from 1 to 3600. The default is 125 seconds.

Defaults

The default query interval is 125 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Usage Guidelines

Multicast routers send host query messages to discover which multicast groups have members on the networks attached to the interface. Hosts respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Host query messages are addressed to the all-hosts multicast group, which has an address of 224.0.0.1 TTL value of 1.

The designated router for a LAN is the only router that sends IGMP host query messages:

- For IGMP Version 1, the designated router is elected according to the multicast routing protocol that runs on the LAN.
- For IGMP Version 2, the designated router is the lowest IP-addressed multicast router on the subnet.

If the router hears no queries for the timeout period (controlled by the **igmp query-timeout** command), it becomes the querier.

Caution Changing this value may severely impact multicast forwarding.

Examples

The following example changes the IGMP query interval to 120 seconds:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp query-interval 120
```

Related Commands

Command	Description
igmp query-max-response-time	Configures the maximum response time advertised in IGMP queries.
igmp query-timeout	Configures the timeout period before the router takes over as the querier for the interface after the previous querier has stopped querying.

igmp query-max-response-time

To specify the maximum response time advertised in IGMP queries, use the **igmp query-max-response-time** command in interface configuration mode. To restore the default response time value, use the **no** form of this command.

igmp query-max-response-time *seconds*

no igmp query-max-response-time *seconds*

Syntax Description

seconds	Maximum response time, in seconds, advertised in IGMP queries. Valid values are from 1 to 25. The default value is 10 seconds.

Defaults

10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Usage Guidelines

This command is valid only when IGMP Version 2 or 3 is running.

This command controls the period during which the responder can respond to an IGMP query message before the router deletes the group.

Examples

The following example changes the maximum query response time to 8 seconds:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp query-max-response-time 8
```

Related Commands

Command	Description
igmp query-interval	Configures the frequency at which IGMP host query messages are sent by the interface.
igmp query-timeout	Configures the timeout period before the router takes over as the querier for the interface after the previous querier has stopped querying.

igmp query-timeout

To configure the timeout period before the interface takes over as the querier after the previous querier has stopped querying, use the **igmp query-timeout** command in interface configuration mode. To restore the default value, use the **no** form of this command.

igmp query-timeout *seconds*

no igmp query-timeout *seconds*

Syntax Description

seconds	Number of seconds that the router waits after the previous querier has stopped querying and before it takes over as the querier. Valid values are from 60 to 300 seconds. The default value is 255 seconds.

Defaults

The default query interval is 255 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command requires IGMP Version 2 or 3.

Examples

The following example configures the router to wait 200 seconds from the time it received the last query before it takes over as the querier for the interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp query-timeout 200
```

Related Commands

Command	Description
igmp query-interval	Configures the frequency at which IGMP host query messages are sent by the interface.
igmp query-max-response-time	Configures the maximum response time advertised in IGMP queries.

igmp static-group

To configure the interface to be a statically connected member of the specified multicast group, use the **igmp static-group** command in interface configuration mode. To remove the static group entry, use the **no** form of this command.

igmp static-group *group*

no igmp static-group *group*

Syntax Description

group	IP multicast group address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When configured with the **igmp static-group** command, the ASA interface does not accept multicast packets destined for the specified group itself; it only forwards them. To configure the ASA to both accept and forward multicast packets for a speific multicast group, use the **igmp join-group** command. If the **igmp join-group** command is configured for the same group address as the **igmp static-group** command, the **igmp join-group** command takes precedence, and the group behaves like a locally joined group.

Examples

The following example adds the selected interface to the multicast group 239.100.100.101:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp static-group 239.100.100.101
```

Related Commands

Command	Description
igmp join-group	Configures an interface to be a locally connected member of the specified group.

igmp version

To configure which version of IGMP the interface uses, use the **igmp version** command in interface configuration mode. To restore version to the default, use the **no** form of this command.

igmp version {**1** | **2**}

no igmp version [**1** | **2**]

Syntax Description

1	IGMP Version 1.
2	IGMP Version 2.

Defaults

IGMP Version 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was moved to interface configuration mode. Earlier versions required you to enter multicast interface configuration mode, which is no longer available.

Usage Guidelines

All routers on the subnet must support the same version of IGMP. Hosts can have any IGMP version (1 or 2), and the ASA will correctly detect their presence and query them appropriately.

Some commands require IGMP Version 2, including as the **igmp query-max-response-time** and **igmp query-timeout** commands.

Examples

The following example configures the selected interface to use IGMP Version 1:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# igmp version 1
```

Related Commands

Command	Description
igmp query-max-response-time	Configures the maximum response time advertised in IGMP queries.
igmp query-timeout	Configures the timeout period before the router takes over as the querier for the interface after the previous querier has stopped querying.

ignore-ipsec-keyusage

To suppress key usage checking on IPsec client certificates, use the **ignore-ipsec-keyusage** command in ca-trustpoint configuration mode. To resume key usage checking, use the **no** form of this command.

ignore-ipsec-keyusage

no ignore-ipsec-keyusage

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-trustpoint configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced as a safety measure and was deprecated at the same time. Note that future releases might not offer suppression of key usage checking.

Usage Guidelines

Use of this command indicates that the values in the Key Usage and extended Key Usage extensions of IPsec remote client certificates are not to be validated. This command ignores key usage checking and is useful for noncompliant deployments.

Examples

The following example shows how to ignore the results of key usage checking:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)#
hostname(config-ca-trustpoint)# ignore-ipsec-keyusage
Notice: This command has been deprecated
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.

ignore lsa mospf

To suppress the sending of syslog messages when the router receives LSA Type 6 MOSPF packets, use the **ignore lsa mospf** command in router configuration mode. To restore the sending of the syslog messages, use the **no** form of this command.

ignore lsa mospf

no ignore lsa mospf

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Type 6 MOSPF packets are unsupported.

Examples

The following example causes LSA Type 6 MOSPF packets to be ignored:

```
hostname(config-router)# ignore lsa mospf
```

Related Commands

Command	Description
show running-config router ospf	Displays the OSPF router configuration.

ignore-ssl-keyusage

To suppress key usage checking on SSL client certificates, use the **ignore-ssl-keyusage** command in ca-trustpoint configuration mode. To resume key usage checking, use the **no** form of this command.

ignore-ssl-keyusage

no ignore-ssl-keyusage

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-trustpoint configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced as a safety measure and was deprecated at the same time. Note that future releases might not offer suppression of key usage checking.

Usage Guidelines

Use of this command indicates that the values in the Key Usage and extended Key Usage extensions of IPsec remote client certificates are not to be validated. This command ignores key usage checking and is useful for noncompliant deployments.

Examples

The following example shows how to ignore the results of key usage checking:

```
hostname(config)# crypto ca trustpoint central
hostname(config-ca-trustpoint)#
hostname(config-ca-trustpoint)# ignore-ssl-keyusage
Notice: This command has been deprecated
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.

ike-retry-count

To configure the maximum number of connection retry attempts a Cisco AnyConnect VPN Client using IKE should make before falling back to SSL to attempt the connection, use the **ike-retry-count** command in group-policy webvpn configuration mode or username webvpn configuration mode. To remove this command from the configuration and reset the maximum number of retry attempts to the default value, use the **no** form of this command.

ike-retry-count {**none** | *value*}

no ike-retry-count [**none** | *value*]

Syntax Description

none	Specifies that no retry attempts are allowed.
value	Specify the maximum number of connection retry atttempts (1-10) for the Cisco AnyConnect VPN Client to perform after an inital connection failure.

Defaults

The default number of allowed retry attempts is 3.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy webvpn configuration	•	—	•	—	—
Username webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced

Usage Guidelines

Use the **ike-retry-count** command to control the number of times that the Cisco AnyConnect VPN Client should attempt to connect using IKE. If the client fails to connect using IKE after the number of retries specified in this command, it falls back to SSL to attempt the connection. This value overrides any value that exists in the Cisco AnyConnect VPN Client.

Note To support fallback from IPsec to SSL, the **vpn-tunnel-protocol** command must be have with both the **svc** and **ipsec** arguments configured.

Examples

The following example sets the IKE retry count to 7 for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
```

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# ike-retry-count 7
hostname(config-group-webvpn)#
```

The following example sets the IKE retry count to 9 for the username Finance:

```
hostname(config)# username Finance attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# ike-retry-count 9
hostname(config-group-webvpn)#
```

Related Commands

Command	Description
group-policy	Creates or edits a group policy.
ike-retry-timeout	Specifies the number of seconds between IKE retry attempts.
username	Adds a user to the ASA database.
vpn-tunnel-protocol	Configures a VPN tunnel type (IPsec, L2TP over IPsec, or WebVPN).
webvpn	Enters group-policy webvpn configuration mode or username webvpn configuration mode.

ikev1 pre-shared-key

To specify a preshared key to support IKEv1 connections based on preshared keys, use the **pre-shared-key** command in tunnel-group ipsec-attributes configuration mode. To return to the default value, use the **no** form of this command.

pre-shared-key *key*

no pre-shared-key

Syntax Description

key	Specifies an alphanumeric key between 1 and 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The command name was modified from **pre-shared-key** to **ikev1 pre-shared-key**.

Usage Guidelines

You can apply this attribute to all IPsec tunnel-group types.

Examples

The following command entered in config-ipsec configuration mode, specifies the preshared key XYZX to support IKE connections for the IPSec LAN-to-LAN tunnel group named 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# pre-shared-key xyzx
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel group IPsec attributes for this group.

ikev1 trust-point

To specify the name of a trustpoint that identifies the certificate to be sent to the IKEv1 peer, use the **trust-point** command in tunnel-group ipsec-attributes mode. To eliminate a trustpoint specification, use the **no** form of this command.

trust-point *trust-point-name*

no trust-point *trust-point-name*

Syntax Description

trust-point-name	Specifies the name of the trustpoint to use.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec attributes	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	The command name was changed from **trust-point** to **ikev1 trust-point**.

Usage Guidelines

You can apply this attribute to all IPsec tunnel group types.

Examples

The following example entered in tunnel-ipsec configuration mode, configures a trustpoint for identifying the certificate to be sent to the IKEv1 peer for the IPsec LAN-to-LAN tunnel group named 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# ikev1 trust-point mytrustpoint
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.

Command	Description
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel group IPsec attributes for this group.

ikev1 user-authentication

To configure hybrid authentication during IKE, use the **ikev1 user-authentication** command in tunnel-group ipsec-attributes configuration mode. To disable hybrid authentication, use the **no** form of this command.

ikev1 user-authentication [*interface*] {**none** | **xauth** | **hybrid**}

no ikev1 user-authentication [*interface*] {**none** | **xauth** | **hybrid**}

Syntax Description

hybrid	Specifies hybrid XAUTH authentication during IKE.
interface	(Optional) Specifies the interface on which the user authentication method is configured.
none	Disables user authentication during IKE.
xauth	Specifies XAUTH, also called extended user authentication.

Defaults

The default authentication method is XAUTH or extended user authentication. The default is all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.4(1)	The command name was changed from **isakmp ikev1-user-authentication** to **ikev1 user-authentication**.

Usage Guidelines

You use this command when you need to use digital certificates for ASA authentication and a different, legacy method for remote VPN user authentication, such as RADIUS, TACACS+, or SecurID. This command breaks Phase 1 of IKE down into the following two steps, together called hybrid authentication:

1. The ASA authenticates to the remote VPN user with standard public key techniques. This establishes an IKE security association that is unidirectionally authenticated.
2. An XAUTH exchange then authenticates the remote VPN user. This extended authentication can use one of the supported legacy authentication methods.

Note Before the authentication type can be set to hybrid, you must configure the authentication server, create a preshared key, and configure a trustpoint.

An IPsec hybrid RSA authentication type is rejected when the exchange type is main mode.

When you omit the optional *interface* argument, the command applies to all the interfaces and serves as a backup when the per-interface command is not specified. When there are two **ikev1 user-authentication** commands specified for a tunnel group, and one uses the *interface* argument and one does not, the one specifying the interface takes precedence for that particular interface.

Examples

The following example commands enable hybrid XAUTH on the inside interface for a tunnel group called example-group:

```
hostname(config)# tunnel-group example-group type ipsec-ra
hostname(config)# tunnel-group example-group ipsec-attributes
hostname(config-tunnel-ipsec)# ikev1 user-authentication (inside) hybrid
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
aaa-server	Defines a AAA server.
pre-shared-key	Creates a preshared key for supporting IKE connections.
tunnel-group	Creates and manages the database of connection specific records for IPsec, L2TP/IPsec, and WebVPN connections.

ikev2 local-authentication

To specify local authentication for IKEv2 LAN-to-LAN connections, use the **ikev2 local-authentication** command in tunnel-group ipsec-attributes configuration mode. To return to the default value, use the no form of this command.

ikev2 local-authentication {**certificate** *trustpoint* | **pre-shared-key** *key-value*}

no ikev2 local-authentication {**certificate** *trustpoint* | **pre-shared-key** *key-value*}

Syntax Description

certificate	Specifies certificate authentication.
trustpoint	Specifies the trustpoint that identifies the certificate to send to the remote peer.
pre-shared-key	Specifies using a local preshared key used to authenticate the remote peer.
key-value	The key value, from 1 to 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

The setting applies to IPsec IKEv2 LAN-to-LAN tunnel groups only.

Examples

The following command entered in tunnel-group ipsec-attributes configuration mode, specifies the preshared key XYZX to support IKE connections for the IPsec LAN-to-LAN tunnel group named 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# ikev2 local-authentication pre-shared-key XYZX
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel group IPsec attributes for this group.

ikev2 remote-authentication

To specify remote authentication for IPsec IKEv2 LAN-to-LAN connections, use the **ikev2 local-authentication** command in tunnel-group ipsec-attributes configuration mode. To return to the default value, use the no form of this command.

ikev2 remote-authentication {**certificate** *trustpoint* | **pre-shared-key** *key-value*}

no ikev2 remote-authentication {**certificate** *trustpoint* | **pre-shared-key** *key-value*}

Syntax Description

certificate	Specifies certificate authentication.
trustpoint	Specifies the trustpoint that identifies the certificate to send to the remote peer.
pre-shared-key	Specifies using a local preshared key used to authenticate the remote peer.
key-value	The key value, from 1 to 128 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

The setting applies to IPsec IKEv2 LAN-to-LAN tunnel groups only.

Examples

The following command entered in tunnel-group ipsec-attributes configuration mode, specifies the preshared key XYZX to support IKEv2 connections for the IPsec LAN-to-LAN tunnel group named 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# ikev2 remote-authentication pre-shared-key xyzx
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel group IPsec attributes for this group.

im

To enable instant messaging over SIP, use the **im** command in parameters configuration mode, which is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

im

no im

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable instant messaging over SIP in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# im
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

imap4s

To enter IMAP4S configuration mode, use the **imap4s** command in global configuration mode. To remove any commands entered in IMAP4S command mode, use the **no** form of this command.

imap4s

no imap4s

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

IMAP4 is a client/server protocol in which your Internet server receives and holds e-mail for you. You (or your e-mail client) can view just the heading and the sender of the letter and then decide whether to download the mail. You can also create and manipulate multiple folders or mailboxes on the server, delete messages, or search for certain parts or an entire note. IMAP requires continual access to the server during the time that you are working with your mail. IMAP4S lets you receive e-mail over an SSL connection.

Examples

The following example shows how to enter IMAP4S configuration mode:

```
hostname(config)# imap4s
hostname(config-imap4s)#
```

Related Commands

Command	Description
clear configure imap4s	Removes the IMAP4S configuration.
show running-config imap4s	Displays the running configuration for IMAP4S.

import webvpn customization

To load a customization object onto the flash device of the ASA, enter the **import webvpn customization** command in privileged EXEC mode.

import webvpn customization *name URL*

Syntax Description

name	The name that identifies the customization object. The maximum number is 64 characters.
URL	Remote path to the source of the XML customization object. The maximum number is 255 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Make sure WebVPN is enabled on an ASA interface before you enter the **import customization** command. To do so, enter the **show running-config** command.

The ASA does the following when you import a customization object:

- Copies the customization object from the URL to the ASA file system disk0:/csco_config/customization as MD5*name*.
- Performs a basic XML syntax check on the file. If it is invalid, the ASA deletes the file.
- Checks that the file in index.ini contains the record MD5*name*. If not, the ASA adds MD5*name* to the file.
- Copies the MD5*name* file to RAMFS /csco_config/customization/ with as ramfs *name*.

Examples

The following example imports to the ASA a customization object, *General.xml*, from the URL 209.165.201.22/customization and names it *custom1*.

```
hostname# import webvpn customization custom1 tftp://209.165.201.22/customization
/General.xml
```

```
Accessing
tftp://209.165.201.22/customization/General.xml...!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Writing file disk0:/csco_config/97/custom1...
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
329994 bytes copied in 5.350 secs (65998 bytes/sec)
```

Related Commands

Command	Description
revert webvpn customization	Removes the specified customization object from the flash device of the ASA.
show import webvpn customization	Lists the customization objects present on the flash device of the ASA.

import webvpn plug-in protocol

To install a plug-in onto the flash device of the ASA, enter the **import webvpn plug-in protocol** command in privileged EXEC mode.

import webvpn plug-in protocol *protocol URL*

Syntax Description

protocol	• **rdp—**The Remote Desktop Protocol plug-in lets the remote user connect to a computer running Microsoft Terminal Services. Cisco redistributes this plug-in without any changes. The website containing the original is http://properjavardp.sourceforge.net/. • **ssh,telnet—**The Secure Shell plug-in lets the remote user establish a secure channel to a remote computer, or lets the remote user use Telnet to connect to a remote computer. Cisco redistributes this plug-in without any changes. The website containing the original is http://javassh.org/. **Caution** The **import webvpn plug-in protocol ssh,telnet** *URL* command installs *both* the SSH and Telnet plug-ins. Do *not* enter this command once for SSH and once for Telnet. When typing the **ssh,telnet** string, do *not* insert a space. Use the **revert webvpn plug-in protocol** command to remove any **import webvpn plug-in protocol** commands that deviate from these requirements. • **vnc—**The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing turned on. Cisco redistributes this plug-in without any changes. The website containing the original is http://www.tightvnc.com/.
URL	Remote path to the source of the plug-in.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Before installing a plug-in, do the following:

- Make sure Clientless SSL VPN ("webvpn") is enabled on an interface on the ASA. To do so, enter the **show running-config** command.
- Create a temporary directory named "plugins" on a local TFTP server (for example, with the hostname "local_tftp_server"), and download the plug-ins from the Cisco website to the "plugins" directory. Enter the hostname or address of the TFTP server and the path to the plug-in that you need into the URL field of the **import webvpn plug-in protocol** command.

The ASA does the following when you import a plug-in:

- Unpacks the .jar file specified in the *URL*.
- Writes the file to the csco-config/97/plugin directory on the ASA file system.
- Populates the drop-down menu next to the URL attributes in ASDM.
- Enables the plug-in for all future Clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down menu next to the Address field of the portal page. The following table shows the changes to the main menu and address field of the portal page.

Plug-in	Main Menu Option Added to Portal Page	Address Field Option Added to Portal Page
rdp	Terminal Servers	rdp://
ssh,telnet	SSH	ssh://
	Telnet	telnet://
vnc	VNC Client	vnc://

The ASA does not retain the **import webvpn plug-in protocol** command in the configuration. Instead, it loads the contents of the csco-config/97/plugin directory automatically. A secondary ASA obtains the plug-ins from the primary ASA.

When the user in a Clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can select the protocol displayed in the drop-down menu and enter the URL in the Address field to establish a connection.

Note Support has been added for SSH V2 in addition to previous SSH V1 and Telnet. The plug-in protocol is still the same (ssh and telnet), and the URL formats are as follows:
ssh://<target> — uses SSH V2
ssh://<target>/?version=1 — uses SSH V1
telnet://<target> — uses telnet

To remove the respective **import webvpn plug-in protocol** command and disable support for the protocol, use the **revert webvpn plug-in protocol** command.

Examples

The following command adds Clientless SSL VPN support for RDP:

```
hostname# import webvpn plug-in protocol rdp tftp://209.165.201.22/plugins/rdp-plugin.jar
Accessing
tftp://209.165.201.22/plugins/rdp-plugin.jar...!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Writing file disk0:/csco_config/97/plugin/rdp...
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
329994 bytes copied in 5.350 secs (65998 bytes/sec)
```

The following command adds Clientless SSL VPN support for SSH and Telnet:

```
hostname# import webvpn plug-in protocol ssh,telnet
tftp://209.165.201.22/plugins/ssh-plugin.jar

Accessing
tftp://209.165.201.22/plugins/ssh-plugin.jar...!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!
Writing file disk0:/csco_config/97/plugin/ssh...
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
238510 bytes copied in 3.650 secs (79503 bytes/sec)
```

The following command adds Clientless SSL VPN support for VNC:

```
hostname# import webvpn plug-in protocol vnc tftp://209.165.201.22/plugins/vnc-plugin.jar

Accessing tftp://209.165.201.22/plugins/vnc-plugin.jar...!!!!!!!!!!!!!!!!
Writing file disk0:/csco_config/97/plugin/vnc...
!!!!!!!!!!!!!!!!
58147 bytes copied in 2.40 secs (29073 bytes/sec)
hostname#
```

Related Commands

Command	Description
revert webvpn plug-in protocol	Removes the specified plug-in from the flash device of the ASA.
show import webvpn plug-in	Lists the plug-ins present on the flash device of the ASA.

import webvpn translation-table

To import a translation table used to translate terms displayed to remote users establishing SSL VPN connections, use the **import webvpn translation-table** command in privileged EXEC mode.

import webvpn translation-table *translation_domain* **language** *language url*

Syntax Description

language	Specifies a language for the translation table. Enter the value for *language* in the manner expressed by your browser language options.
translation_domain	Specifies the functional area and associated messages visible to remote users.
url	Specifies the URL of the XML file used to create the customization object.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The ASA provides language translation for the portal and screens displayed to users that initiate browser-based, clientless SSL VPN connections, as well as the user interface displayed to AnyConnect VPN Client users.

Each functional area and its messages that is visible to remote users has its own translation domain and is specified by the *translation_domain* argument. The following table shows the translation domains and the functional areas translated.

Translation Domain	Functional Areas Translated
AnyConnect	Messages displayed on the user interface of the Cisco AnyConnect VPN Client.
banners	Banners displayed to remote users and messages when VPN access is denied.
CSD	Messages for the Cisco Secure Desktop (CSD).
customization	Messages on the login and logout pages, portal page, and all the messages customizable by the user.

Translation Domain (continued)	Functional Areas Translated (continued)
plugin-ica	Messages for the Citrix plug-in.
plugin-rdp	Messages for the Remote Desktop Protocol plug-in.
plugin-telnet,ssh	Messages for the Telnet and SSH plug-in.
plugin-vnc	Messages for the VNC plug-in.
PortForwarder	Messages displayed to port forwarding users.
url-list	Text that user specifies for URL bookmarks on the portal page.
webvpn	All the layer 7, AAA, and portal messages that are not customizable.

A translation template is an XML file in the same format as the translation table, but has all the translations empty. The software image package for the ASA includes a template for each domain that is part of the standard functionality. Templates for plug-ins are included with the plug-ins and define their own translation domains. Because you can customize the login and logout pages, portal page, and URL bookmarks for clientless users, the ASA generates the **customization** and **url-list** translation domain templates dynamically, and the template automatically reflects your changes to these functional areas.

Download the template for the translation domain using the **export webvpn translation-table** command, make changes to the messages, and use the **import webvpn translation-table** command to create the object. You can view available objects with the **show import webvpn translation-table** command.

Be sure to specify language in the manner expressed by your browser language options. For example, Microsoft Internet Explorer uses the abbreviation *zh* for the Chinese language. The translation table imported to the ASA must also be named *zh*.

With the exception of the AnyConnect translation domain, a translation table has no affect, and messages are not translated until you create a customization object, identify a translation table to use in that object, and specify the customization for the group policy or user. Changes to the translation table for the AnyConnect domain are immediately visible to AnyConnect client users. See the **import webvpn customization** command for more information.

Examples

The following example imports a translation-table for the translation domain affecting the AnyConnect client user interface, and specifies the translation table is for the Chinese language. The **show import webvpn translation-table** command displays the new object:

```
hostname# import webvpn translation-table anyconnect language zh
tftp://209.165.200.225/anyconnect
hostname# !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
hostname# show import webvpn translation-table
Translation Tables' Templates:
customization
AnyConnect
CSD
PortForwarder
url-list
webvpn
Citrix-plugin
RPC-plugin
Telnet-SSH-plugin
VNC-plugin
```

```
Translation Tables:
zh AnyConnect
```

Related Commands

Command	Description
export webvpn translation-table	Exports a translation table.
import webvpn customization	Imports a customization object that references the translation table.
revert	Removes translation tables from flash.
show import webvpn translation-table	Displays available translation table templates and translation tables.

import webvpn url-list

To load a URL list onto the flash device of the ASA, enter the **import webvpn url-list** command in privileged EXEC mode.

import webvpn url-list *name URL*

Syntax Description

name	The name that identifies the URL list. The maximum number is 64 characters.
URL	Remote path to the source of the URL list. The maximum number is 255 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Make sure that WebVPN is enabled on a ASA interface before you enter the **import url-list** command. To do so, enter the **show running-config** command.

The ASA does the following when you import a URL list:

- Copies the URL list from the URL to the ASA file system disk0:/csco_config/url-lists as *name on flash* = base 64*name*.
- Performs a basic XML syntax check on the file. If the syntax is invalid, the ASA deletes the file.
- Checks that the file in index.ini contains the record base 64*name*. If not, the ASA adds base 64*name* to the file.
- Copies the *name* file to RAMFS /csco_config/url-lists/ with ramfs name = *name*.

Examples

The following example imports a URL list, *NewList.xml*, from the URL 209.165.201.22/url-lists to the ASA and names it *ABCList*.

```
hostname# import webvpn url-list ABCList tftp://209.165.201.22/url-lists/NewList.xml
```

```
Accessing
tftp://209.165.201.22/url-lists/NewList.xml...!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Writing file disk0:/csco_config/97/ABClist...
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
329994 bytes copied in 5.350 secs (65998 bytes/sec)
```

Related Commands

Command	Description
revert webvpn url-list	Removes the specified URL list from the flash device of the ASA.
show import webvpn url-list	Lists the URL lists present on the flash device of the ASA.

import webvpn webcontent

To import content to flash memory that is visible to remote Clientless SSL VPN users, use the **import webvpn webcontent** command in privileged EXEC mode.

import webvpn webcontent *destination url source url*

Syntax Description

destination url	The URL to export to. The maximum number is 255 characters.
source url	The URL in the ASA flash memory in which the content resides. The maximum number is 64 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•		—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Content imported with the **webcontent** option is visible to remote Clientless users. This includes help content visible on the Clientless portal and logos used by customization objects that customize user screens.

Content imported to URLs with the path /+CSCOE+/ is visible only to authorized users.

Content imported to URLs with the path /+CSCOU+/ is visible to both unauthorized and authorized users.

For example, a corporate logo imported as /+CSCOU+/logo.gif could be used in a portal customization object and be visible on the logon page and the portal page. The same logo.gif file imported as /+CSCOE+/logo.gif would only be visible to remote users after they have logged in successfully.

Help content that appears on the various application screens must be imported to specific URLs. The following table shows the URLs and screen areas for the help content displayed for standard Clientless applications:

URL	Clientless Screen Area
/+CSCOE+/help/*language*/app-access-hlp.inc	Application Access
/+CSCOE+/help/*language*/file-access-hlp.inc	Browse Networks

URL (continued)	Clientless Screen Area (continued)
/+CSCOE+/help/*language*/net_access_hlp.html	AnyConnect Client
/+CSCOE+/help/*language*/web-access-help.inc	Web Access

The following table shows the URLs and screen areas for the help content displayed for optional plug-in Clientless applications:

URL	Clientless Screen Area
/+CSCOE+/help/*language*/ica-hlp.inc	MetaFrame Access
/+CSCOE+/help/*language*/rdp-hlp.inc	Terminal Servers
/+CSCOE+/help/*language*/ssh,telnet-hlp.inc	Telnet/SSH Servers
/+CSCOE+/help/*language*/vnc-hlp.inc	VNC Connections

The *language* entry in the URL path is the language abbreviation that you designate for the help content. The ASA does not actually translate the file into the language you specify, but labels the file with the language abbreviation.

Examples

The following example imports the HTML file *application_access_help.html,* from a TFTP server at 209.165.200.225, to the URL that stores the Application Access help content in flash memory. The URL includes the abbrevation *en* for the English language:

```
hostname# import webvpn webcontent /+CSCOE+/help/en/app-access-hlp.inc
tftp://209.165.200.225/application_access_help.html
!!!!* Web resource `+CSCOE+/help/en/ap-access-hlp.inc' was successfully initialized
hostname#
```

The following example imports the HTML file *application_access_help.html,* from a tftp server at 209.165.200.225, to the URL that stores the Application Access help content in flash memory. The URL includes the abbrevation *en* for the English language:

```
hostname# import webvpn webcontent /+CSCOE+/help/en/app-access-hlp.inc
tftp://209.165.200.225/application_access_help.html
!!!!* Web resource `+CSCOE+/help/en/ap-access-hlp.inc' was successfully initialized
hostname#
```

Related Commands

Command	Description
export webvpn webcontent	Exports previously imported content visible to Clientless SSL VPN users.
revert webvpn webcontent	Removes content from flash memory.
show import webvpn webcontent	Displays information about imported content.

inspect ctiqbe through inspect xdmcp Commands

inspect ctiqbe

To enable CTIQBE protocol inspection, use the **inspect ctiqbe** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To disable inspection, use the **no** form of this command.

inspect ctiqbe

no inspect ctiqbe

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced and replaces the previously existing **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect ctiqbe** command enables CTIQBE protocol inspection, which supports NAT, PAT, and bidirectional NAT. This enables Cisco IP SoftPhone and other Cisco TAPI/JTAPI applications to work successfully with Cisco CallManager for call setup across the ASA.

The Telephony Application Programming Interface (TAPI) and Java Telephony Application Programming Interface (JTAPI) are used by many Cisco VoIP applications. Computer Telephony Interface Quick Buffer Encoding (CTIQBE) is used by Cisco TAPI Service Provider (TSP) to communicate with Cisco CallManager.

The following summarizes limitations that apply when using CTIQBE application inspection:

- CTIQBE application inspection does not support configurations using the **alias** command.
- Stateful Failover of CTIQBE calls is *not* supported.
- Using the **debug ctiqbe** command may delay message transmission, which may have a performance impact in a real-time environment. When you enable this debugging or logging and Cisco IP SoftPhone seems unable to complete call setup through the ASA, increase the timeout values in the Cisco TSP settings on the system running Cisco IP SoftPhone.
- CTIQBE application inspection does *not* support CTIQBE messages fragmented in multiple TCP packets.

The following summarizes special considerations when using CTIQBE application inspection in specific scenarios:

- If two Cisco IP SoftPhones are registered with different Cisco CallManagers, which are connected to different interfaces of the ASA, calls between these two phones will fail.
- When Cisco CallManager is located on the higher security interface compared to Cisco IP SoftPhones, if NAT or outside NAT is required for the Cisco CallManager IP address, the mapping must be static as Cisco IP SoftPhone requires the Cisco CallManager IP address to be specified explicitly in its Cisco TSP configuration on the PC.
- When using PAT or Outside PAT, if the Cisco CallManager IP address is to be translated, its TCP port 2748 must be statically mapped to the same port of the PAT (interface) address for Cisco IP SoftPhone registrations to succeed. The CTIQBE listening port (TCP 2748) is fixed and is not user-configurable on Cisco CallManager, Cisco IP SoftPhone, or Cisco TSP.

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect ctiqbe** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect ctiqbe** command does not use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect ctiqbe** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

Examples

The following example enables the CTIQBE inspection engine, which creates a class map to match CTIQBE traffic on the default port (2748). The service policy is then applied to the outside interface.

```
hostname(config)# class-map ctiqbe-port
hostname(config-cmap)# match port tcp eq 2748
hostname(config-cmap)# exit
hostname(config)# policy-map ctiqbe_policy
hostname(config-pmap)# class ctiqbe-port
hostname(config-pmap-c)# inspect ctiqbe
hostname(config-pmap-c)# exit
hostname(config)# service-policy ctiqbe_policy interface outside
```

To enable CTIQBE inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
show conn	Displays the connection state for different connection types.
show ctiqbe	Displays information regarding the CTIQBE sessions established across the ASA and the media connections allocated by the CTIQBE inspection engine.
timeout	Sets the maximum idle time duration for different protocols and session types.

inspect dcerpc

To enable inspection of DCERPC traffic destined for the endpoint-mapper, use the **inspect dcerpc** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect dcerpc [*map_name*]

no inspect dceprc [*map_name*]

Syntax Description

map_name	(Optional) The name of the DCERPC map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **inspect dcerpc** command enables or disables application inspection for the DCERPC protocol.

Examples

The following example shows how to define a DCERPC inspection policy map with the timeout configured for DCERPC pinholes.

```
hostname(config)# policy-map type inspect dcerpc dcerpc_map
hostname(config-pmap)# timeout pinhole 0:10:00

hostname(config)# class-map dcerpc
hostname(config-cmap)# match port tcp eq 135

hostname(config)# policy-map global-policy
hostname(config-pmap)# class dcerpc
hostname(config-pmap-c)# inspect dcerpc dcerpc_map

hostname(config)# service-policy global-policy global
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.
timeout pinhole	Configures the timeout for DCERPC pinholes and overrides the global system pinhole timeout.

inspect dns

To enable DNS inspection (if it has been previously disabled) or to configure DNS inspection parameters, use the **inspect dns** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To disable DNS inspection, use the **no** form of this command.

inspect dns [*map_name*] [**dynamic-filter-snoop**]

no inspect dns [*map_name*] [**dynamic-filter-snoop**]

Syntax Description

dynamic-filter-snoop	(Optional) Enables DNS inspection with Botnet Traffic Filter snooping.
map_name	(Optional) Specifies the name of the DNS map.

Defaults

This command is enabled by default. Botnet Traffic Filter snooping is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.
7.2(1)	This command was modified to allow configuration of additional DNS inspection parameters.
8.2(1)	The **dynamic-filter-snoop** keyword was added.

Usage Guidelines

DNS guard tears down the DNS session associated with a DNS query as soon as the DNS reply is forwarded by the ASA. DNS guard also monitors the message exchange to ensure that the ID of the DNS reply matches the ID of the DNS query.

When DNS inspection is enabled, which it is the default, the ASA performs the following additional tasks:

- Translates the DNS record based on the configuration completed using the **alias**, **static** and **nat** commands (DNS rewrite). Translation only applies to the A-record in the DNS reply. Therefore, reverse lookups, which request the PTR record, are not affected by DNS rewrite.

Note DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A-record, and the PAT rule to use is ambiguous.

- Enforces the maximum DNS message length (the default is 512 bytes and the maximum length is 65535 bytes). Reassembly is performed as necessary to verify that the packet length is less than the maximum length configured. The packet is dropped if it exceeds the maximum length.
- Enforces a domain-name length of 255 bytes and a label length of 63 bytes.
- Verifies the integrity of the domain name referred to by the pointer if compression pointers are encountered in the DNS message.
- Checks to see if a compression pointer loop exists.

A single connection is created for multiple DNS sessions, as long as they are between the same two hosts, and the sessions have the same 5-tuple (source/destination IP address, source/destination port, and protocol). DNS identification is tracked by *app_id*, and the idle timer for each *app_id* runs independently.

Because the *app_id* expires independently, a legitimate DNS response can only pass through the ASA within a limited period of time and there is no resource buildup. However, if you enter the **show conn** command, you will see the idle timer of a DNS connection being reset by a new DNS session. This is due to the nature of the shared DNS connection and is by design.

How DNS Rewrite Works

When DNS inspection is enabled, DNS rewrite provides full support for NAT of DNS messages originating from any interface.

If a client on an inside network requests DNS resolution of an inside address from a DNS server on an outside interface, the DNS A-record is translated correctly. If the DNS inspection engine is disabled, the A-record is not translated.

DNS rewrite performs two functions:

- Translating a public address (the routable or “mapped” address) in a DNS reply to a private address (the “real” address) when the DNS client is on a private interface.
- Translating a private address to a public address when the DNS client is on the public interface.

As long as DNS inspection remains enabled, you can configure DNS rewrite using the **alias**, **static**, or **nat** commands. For details about the syntax and function of these commands, see the appropriate command page.

Botnet Traffic Filter Snooping and the DNS Reverse Lookup Cache

Botnet Traffic Filter snooping compares the domain name with those on the dynamic database or the static database, and adds the name and IP address to the Botnet Traffic Filter DNS reverse lookup cache. This cache is then used by the Botnet Traffic Filter when connections are made to the suspicious address.

We suggest that you enable Botnet Traffic Filter snooping only on interfaces where external DNS requests are going. Enabling Botnet Traffic Filter snooping on all UDP DNS traffic, including that going to an internal DNS server, creates unnecessary load on the ASA.

When you use the dynamic database with DNS snooping, entries are added to the DNS reverse lookup cache. If you use the static database, entries are added to the DNS host cache.

Entries in the DNS reverse lookup cache and the DNS host cache have a time-to-live (TTL) value provided by the DNS server. The largest TTL value allowed is 1 day (24 hours); if the DNS server provides a larger TTL, it is truncated to the 1-day maximum.

For the DNS reverse lookup cache, after an entry times out, the ASA renews the entry when an infected host initiates a connection to a known address, and DNS snooping occurs.

For the DNS host cache, after an entry times out, the ASA periodically requests a refresh for the entry.

For the DNS host cache, the maximum number of blacklist entries and whitelist entries is 1000 each.

Table 25-1 lists the maximum number of entries in the DNS reverse lookup cache per model.

Table 25-1 DNS Reverse Lookup Cache Entries Per Model

ASA Model	Maximum Entries
ASA 5505	5000
ASA 5510	10,000
ASA 5520	20,000
ASA 5540	40,000
ASA 5550	40,000
ASA 5580	100,000

Examples

The following example shows how to set the maximum DNS message length:

```
hostname(config)# policy-map type inspect dns dns-inspect
hostname(config-pmap)# parameters
hostname(config-pmap-p)# message-length maximum 1024
```

The following example creates a class map for all UDP DNS traffic, enables DNS inspection and Botnet Traffic Filter snooping with the default DNS inspection policy map, and applies it to the outside interface:

```
hostname(config)# class-map dynamic-filter_snoop_class
hostname(config-cmap)# match port udp eq domain
hostname(config-cmap)# policy-map dynamic-filter_snoop_policy
hostname(config-pmap)# class dynamic-filter_snoop_class
hostname(config-pmap-c)# inspect dns preset_dns_map dynamic-filter-snoop
hostname(config-pmap-c)# service-policy dynamic-filter_snoop_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug dns	Enables debugging information for DNS.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
name	Adds a name to the blacklist or whitelist.

Commands	Description
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect esmtp

To enable SMTP application inspection or to change the ports to which the ASA listens, use the **inspect esmtp** command in class configuration mode. The class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect esmtp [*map_name*]

no inspect esmtp [*map_name*]

Syntax Description

map_name	(Optional) The name of the ESMTP map.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

ESMTP application inspection provides improved protection against SMTP-based attacks by restricting the types of SMTP commands that can pass through the ASA and by adding monitoring capabilities.

ESMTP is an enhancement to the SMTP protocol and is similar in most respects to SMTP. For convenience, the term SMTP is used in this document to refer to both SMTP and ESMTP. The application inspection process for extended SMTP is similar to SMTP application inspection and includes support for SMTP sessions. Most commands used in an extended SMTP session are the same as those used in an SMTP session but an ESMTP session is considerably faster and offers more options related to reliability and security, such as delivery status notification.

The **inspect esmtp** command includes the functionality previously provided by the **fixup smtp** command, and provides additional support for some extended SMTP commands. Extended SMTP application inspection adds support for these extended SMTP commands, including AUTH, EHLO, ETRN, HELP, SAML, SEND, SOML, STARTLS, and VRFY. Along with the support for seven RFC 821 commands (DATA, HELO, MAIL, NOOP, QUIT, RCPT, RSET), the ASA supports a total of fifteen SMTP commands.

Other extended SMTP commands, such as ATRN, ONEX, VERB, CHUNKING, and private extensions and are not supported. Unsupported commands are translated into Xs, which are rejected by the internal server. This results in a message such as “500 Command unknown: 'XXX'.” Incomplete commands are discarded.

The **inspect esmtp** command changes the characters in the server SMTP banner to asterisks except for the “2”, “0”, “0” characters. Carriage return (CR) and linefeed (LF) characters are ignored.

With SMTP inspection enabled, a Telnet session used for interactive SMTP waits for a valid command and the firewall esmtp state machine keeps the correct states for the session if the following rules are not observed: SMTP commands must be at least four characters in length; must be terminated with carriage return and line feed; and must wait for a response before issuing the next reply.

An SMTP server responds to client requests with numeric reply codes and optional human readable strings. SMTP application inspection controls and reduces the commands that the user can use as well as the messages that the server returns. SMTP inspection performs three primary tasks:

- Restricts SMTP requests to seven basic SMTP commands and eight extended commands.
- Monitors the SMTP command-response sequence.
- Generates an audit trail—Audit record 108002 is generated when invalid character embedded in the mail address is replaced. For more information, see RFC 821.

SMTP inspection monitors the command and response sequence for the following anomalous signatures:

- Truncated commands.
- Incorrect command termination (not terminated with <CR><LR>).
- The MAIL and RCPT commands specify who are the sender and the receiver of the mail. Mail addresses are scanned for strange characters. The pipeline character (|) is deleted (changed to a blank space) and “<” ,”>” are only allowed if they are used to define a mail address (“>” must be preceded by “<”). To close the session when the PIPE character is found as a parameter to a MAIL from or RCPT to command, include the **special-character** command in the configuration as part of the inspection parameters (**parameters** command).
- Unexpected transition by the SMTP server.
- For unknown commands, the ASA changes all the characters in the packet to X. In this case, the server will generate an error code to the client. Because of the change in the packet, the TCP checksum has to be recalculated or adjusted.
- TCP stream editing.
- Command pipelining.

To enable SMTP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the SMTP inspection engine, which creates a class map to match SMTP traffic on the default port (25). The service policy is then applied to the outside interface.

```
hostname(config)# class-map smtp-port
hostname(config-cmap)# match port tcp eq 25
hostname(config-cmap)# exit
hostname(config)# policy-map smtp_policy
hostname(config-pmap)# class smtp-port
hostname(config-pmap-c)# inspect esmtp
hostname(config-pmap-c)# exit
hostname(config)# service-policy smtp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug esmtp	Enables debugging information for SMTP.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.
show conn	Displays the connection state for different connection types, including SMTP.

inspect ftp

To configure the port for FTP inspection or to enable enhanced inspection, use the **inspect ftp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect ftp [**strict** [*map_name*]]

no inspect ftp [**strict** [*map_name*]]

Syntax Description

map_name	The name of the FTP map.
strict	(Optional) Enables enhanced inspection of FTP traffic and forces compliance with RFC standards.

Caution Use caution when moving FTP to a higher port. For example, if you set the FTP port to 2021, all connections that initiate to port 2021 will have their data payload interpreted as FTP commands.

Defaults

The ASA listens to port 21 for FTP by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated. The *map_name* option was added.

Usage Guidelines

The FTP application inspection inspects the FTP sessions and performs four tasks:

- Prepares dynamic secondary data connections
- Tracks **ftp** command-response sequence
- Generates an audit trail
- NATs embedded IP addresses

Note Except for the banner, **inspect ftp** does not support FTP servers that segment FTP command or response.

FTP application inspection prepares secondary channels for FTP data transfer. The channels are allocated in response to a file upload, a file download, or a directory listing event and must be prenegotiated. The port is negotiated through the PORT or PASV commands.

Note Only specify the port for the FTP control connection and not the data connection. The ASA stateful inspection engine dynamically prepares the data connection as necessary.

Note If you disable FTP inspection engines with the **no inspect ftp** command, outbound users can start connections only in passive mode, and all inbound FTP is disabled.

Using the strict Option

The **strict** option prevents web browsers from sending embedded commands in FTP requests. Each **ftp** command must be acknowledged before a new command is allowed. Connections sending embedded commands are dropped. The **strict** option only lets an FTP server generate the 227 command and only lets an FTP client generate the PORT command. The 227 and PORT commands are checked to ensure they do not appear in an error string.

To enable strict FTP application inspection for all interfaces, use the **global** parameter in place of **interface** command.

Caution The use of the **strict** option may break FTP clients that do not comply with the RFC standards.

If the **strict** option is enabled, each **ftp** command and response sequence is tracked for the following anomalous activity:

- Truncated command—Number of commas in the PORT and PASV reply command is checked to see if it is five. If it is not five, then the PORT command is assumed to be truncated and the TCP connection is closed.
- Incorrect command—Checks the **ftp** command to see if it ends with <CR><LF> characters, as required by the RFC. If it does not, the connection is closed.
- Size of RETR and STOR commands—These are checked against a fixed constant. If the size is greater, then an error message is logged and the connection is closed.
- Command spoofing—The PORT command should always be sent from the client. The TCP connection is denied if a PORT command is sent from the server.
- Reply spoofing—PASV reply command (227) should always be sent from the server. The TCP connection is denied if a PASV reply command is sent from the client. This prevents the security hole when the user executes “227 xxxxx a1, a2, a3, a4, p1, p2.”
- TCP stream editing.
- Invalid port negotiation—The negotiated dynamic port value is checked to see if it is less than 1024. As port numbers in the range from 1 to 1024 are reserved for well-known connections, if the negotiated port falls in this range, then the TCP connection is freed.
- Command pipelining—The number of characters present after the port numbers in the PORT and PASV reply command is cross checked with a constant value of 8. If it is more than 8, then the TCP connection is closed.
- The ASA replaces the FTP server response to the SYST command with a series of Xs. to prevent the server from revealing its system type to FTP clients. To override this default behavior, use the **no mask-syst-reply** command in FTP map configuration mode.

Note To identify specific FTP commands that are not permitted to pass through the ASA, identify an FTP map and use the **request-command deny** command. For details, see the **ftp-map** and the **request-command deny** command pages.

FTP Log Messages

FTP application inspection generates the following log messages:

- An Audit record 302002 is generated for each file that is retrieved or uploaded.
- The **ftp** command is checked to see if it is RETR or STOR and the retrieve and store commands are logged.
- The username is obtained by looking up a table providing the IP address.
- The username, source IP address, destination IP address, NAT address, and the file operation are logged.
- Audit record 201005 is generated if the secondary dynamic channel preparation failed due to memory shortage.

In conjunction with NAT, the FTP application inspection translates the IP address within the application payload. This is described in detail in RFC 959.

Examples

Before submitting a username and password, all FTP users are presented with a greeting banner. By default, this banner includes version information useful to hackers trying to identify weaknesses in a system. The following example shows how to mask this banner:

```
hostname(config)# policy-map type inspect ftp mymap
hostname(config-pmap)# parameters
hostname(config-pmap-p)# mask-banner
hostname(config-pmap-p)# exit
hostname(config-pmap)# exit
hostname(config)# class-map match-all ftp-traffic
hostname(config-cmap)# match port tcp eq ftp
hostname(config-cmap)# exit
hostname(config)# policy-map ftp-policy
hostname(config-pmap)# class ftp-traffic
hostname(config-pmap-c)# inspect ftp strict mymap
hostname(config-pmap-c)# exit
hostname(config-pmap)# exit
hostname(config)# service-policy ftp-policy interface inside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
mask-syst-reply	Hides the FTP server response from clients.
policy-map	Associates a class map with specific security actions.
request-command deny	Specifies FTP commands to disallow.
service-policy	Applies a policy map to one or more interfaces.

inspect gtp

To enable or disable GTP inspection or to define a GTP map for controlling GTP traffic or tunnels, use the **inspect gtp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. Use the **no** form of this command to remove the command.

inspect gtp [*map_name*]

no inspect gtp [*map_name*]

Note GTP inspection requires a special license. If you enter the **inspect gtp** command on an ASA without the required license, the ASA displays an error message.

Syntax Description

map_name	(Optional) Name for the GTP map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

GTP is the tunnelling protocol for GPRS, and helps provide secure access over wireless networks. GPRS is a data network architecture that is designed to integrate with existing GSM networks. It offers mobile subscribers uninterrupted, packet-switched data services to corporate networks and the Internet. For an overview of GTP, see the the CLI configuration guide**.**

Use the **gtp-map** command to identify a specific map to use for defining the parameters for GTP. When you enter this command, the system enters a configuration mode that lets you enter the different commands used for defining the specific map. The actions that you can specify for messages that fail the criteria set using the different configuration commands include **drop** and **rate-limit**. In addition to these actions, you can specify to **log** the event or not.

After defining the GTP map, you use the **inspect gtp** command to enable the map. Then you use the **class-map**, **policy-map**, and **service-policy** commands to define a class of traffic, to apply the **inspect** command to the class, and to apply the policy to one or more interfaces.

The well-known ports for GTP are as follows:

- 3386
- 2123

The following features are not supported in 7.0(1):

- NAT, PAT, Outside NAT, alias, and Policy NAT
- Ports other than 3386, 2123, and 2152
- Validating the tunneled IP packet and its contents

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect gtp** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect gtp** command does **not** use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect gtp** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

Examples

The following example shows how to use access lists to identify GTP traffic, define a GTP map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# access-list gtp-acl permit udp any any eq 3386
hostname(config)# access-list gtp-acl permit udp any any eq 2123
hostname(config)# class-map gtp-traffic
hostname(config)# match access-list gtp-acl
hostname(config)# gtp-map gtp-policy
hostname(config)# policy-map inspection_policy
hostname(config-pmap)# class gtp-traffic
hostname(config-pmap-c)# inspect gtp gtp-policy
hostname(config)# service-policy inspection_policy interface outside
```

Note This example enables GTP inspection with the default values. To change the default values, refer to the **gtp-map** command page and to the command pages for each command that is entered from GTP map configuration mode.

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.
service-policy	Applies a policy map to one or more interfaces.
show service-policy inspect gtp	Shows that status and statistics of the **inspect gtp** policy.

inspect h323

To enable H.323 application inspection or to change the ports to which the ASA listens, use the **inspect h323** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect h323 {**h225** | **ras**} [*map_name*]

no inspect h323 {**h225** | **ras**} [*map_name*]

Syntax Description

h225	Enables H.225 signalling inspection.
map_name	(Optional) The name of the H.323 map.
ras	Enables RAS inspection.

Defaults

The default port assignments are as follows:

- h323 h225 1720
- h323 ras 1718-1719

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect h323** command provides support for H.323 compliant applications such as Cisco CallManager and VocalTec Gatekeeper. H.323 is a suite of protocols defined by the International Telecommunication Union (ITU) for multimedia conferences over LANs. The ASA supports H.323 through Version 6, including the H.323 v3 feature Multiple Calls on One Call Signaling Channel.

With H.323 inspection enabled, the ASA supports multiple calls on the same call signaling channel, a feature introduced with H.323 Version 3. This feature reduces call setup time and reduces the use of ports on the ASA.

The two major functions of H.323 inspection are as follows:

- NAT the necessary embedded IPv4 addresses in the H.225 and H.245 messages. Because H.323 messages are encoded in PER encoding format, the ASA uses an ASN.1 decoder to decode the H.323 messages.

- Dynamically allocate the negotiated H.245 and RTP/RTCP connections.

How H.323 Works

The H.323 collection of protocols collectively may use up to two TCP connection and four to six UDP connections. FastStart uses only one TCP connection, and RAS uses a single UDP connection for registration, admissions, and status.

An H.323 client may initially establish a TCP connection to an H.323 server using TCP port 1720 to request Q.931 call setup. As part of the call setup process, the H.323 terminal supplies a port number to the client to use for an H.245 TCP connection. The H.245 connection is for call negotiation and media channel setup. In environments where H.323 gatekeeper is in use, the initial packet is transmitted using UDP.

H.323 inspection monitors the Q.931 TCP connection to determine the H.245 port number. If the H.323 terminals are not using FastStart, the ASA dynamically allocates the H.245 connection based on the inspection of the H.225 messages.

Note The H.225 connection can also be dynamically allocated when using RAS.

Within each H.245 message, the H.323 endpoints exchange port numbers that are used for subsequent UDP data streams. H.323 inspection inspects the H.245 messages to identify these ports and dynamically creates connections for the media exchange. Real-Time Transport Protocol (RTP) uses the negotiated port number, while RTP Control Protocol (RTCP) uses the next higher port number.

The H.323 control channel handles H.225 and H.245 and H.323 RAS. H.323 inspection uses the following ports.

- 1718—UDP port used for gatekeeper discovery
- 1719—UDP port used for RAS and for gatekeeper discovery
- 1720—TCP Control Port

If the ACF message from the gatekeeper goes through the ASA, a pinhole will be opened for the H.225 connection. The H.245 signaling ports are negotiated between the endpoints in the H.225 signaling. When an H.323 gatekeeper is used, the ASA opens an H.225 connection based on inspection of the ACF message. If | the ASA does not see the ACF message, you might need to open an access list for the well-known H.323 port 1720 for the H.225 call signaling.

The ASA dynamically allocates the H.245 channel after inspecting the H.225 messages and then hooks up to the H.245 channel to be fixed up as well. That means whatever H.245 messages pass through the ASA pass through the H.245 application inspection, NATing embedded IP addresses and opening the negotiated media channels.

The H.323 ITU standard requires that a TPKT header, defining the length of the message, precede the H.225 and H.245, before being passed on to the reliable connection. Because the TPKT header does not necessarily need to be sent in the same TCP packet as the H.225/H.245 message, the ASA must remember the TPKT length to process/decode the messages properly. The ASA keeps a data structure for each connection and that data structure contains the TPKT length for the next expected message.

If the ASA needs to NAT any IP addresses, then it will have to change the checksum, the UUIE (user-user information element) length, and the TPKT, if included in the TCP packet with the H.225 message. If the TPKT is sent in a separate TCP packet, then the ASA will proxy ACK that TPKT and append a new TPKT to the H.245 message with the new length.

Note The ASA does not support TCP options in the Proxy ACK for the TPKT.

Each UDP connection with a packet going through H.323 inspection is marked as an H.323 connection and will time out with the H.323 timeout as configured using the **timeout** command.

H.239 Support in H.245 Messages

The ASA sits between two H.323 endpoints. When the two H.323 endpoints set up a telepresentation session so that the endpoints can send and receive a data presentation, such as spreadsheet data, the ASA ensures successful H.239 negotiation between the endpoints.

H.239 is a standar that provides the ability for H.300 series endpoints can to open an additional video channel in a single call. In a call, an endpoint (such as a video phone), sends a channel for video and a channel for data presentation. The H.239 negotiation occurs on the H.245 channel.

The ASA opens a pinhole for the additional media channel. The endpoints use open logical channel message (OLC) to signal a new channel creation. The message extension is part of H.245 version 13.

The decoding and encoding of of the telepresentation session is enabled by default. H.239 encoding and decoding is preformed by ASN.1 coder.

Limitations and Restrictions

The following are some of the known issues and limitations when using H.323 application inspection:

- Static PAT may not properly translate IP addresses embedded in optional fields within H.323 messages. If you experience this kind of problem, do not use static PAT with H.323.
- H.323 application inspection is not supported with NAT between same-security-level interfaces.
- It has been observed that when a NetMeeting client registers with an H.323 gatekeeper and tries to call an H.323 gateway that is also registered with the H.323 gatekeeper, the connection is established but no voice is heard in either direction. This problem is unrelated to the ASA.
- If you configure a network static where the network static is the same as a third-party netmask and address, then any outbound H.323 connection fails.
- To enable H.323 inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect h323** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect h323** command does **not** use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect h323** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

Examples

The following example enables the H.323 inspection engine, which creates a class map to match H.323 traffic on the default port (1720). The service policy is then applied to the outside interface.

```
hostname(config)# class-map h323-port
hostname(config-cmap)# match port tcp eq 1720
hostname(config-cmap)# exit
hostname(config)# policy-map h323_policy
hostname(config-pmap)# class h323-port
hostname(config-pmap-c)# inspect h323
hostname(config-pmap-c)# exit
```

```
hostname(config)# service-policy h323_policy interface outside
```

Related Commands

Commands	Description
debug h323	Enables the display of debugging information for H.323.
show h225	Displays information for H.225 sessions established across the ASA.
show h245	Displays information for H.245 sessions established across the ASA by endpoints using slow start.
show h323-ras	Displays information for H.323 RAS sessions established across the ASA.
timeout {**h225** | **h323**}	Configures idle time after which an H.225 signalling connection or an H.323 control connection will be closed.

inspect http

To enable HTTP application inspection or to change the ports to which the ASA listens, use the **inspect http command** in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect http [*map_name*]

no inspect http [*map_name*]

Syntax Description

map_name	(Optional) The name of the HTTP map.

Defaults

The default port for HTTP is 80.

Enhanced HTTP inspection is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect http** command protects against specific attacks and other threats that may be associated with HTTP traffic. HTTP inspection performs several functions:

- Enhanced HTTP inspection
- URL screening through N2H2 or Websense
- Java and ActiveX filtering

The latter two features are configured in conjunction with the **filter** command.

Enhanced HTTP inspection verifies that HTTP messages conform to RFC 2616, use RFC-defined methods or supported extension methods, and comply with various other criteria. In many cases, you can configure these criteria and the system response when the criteria are not met. The actions that you can specify for messages that fail the criteria set using the different configuration commands include **allow**, **reset**, or **drop**. In addition to these actions, you can specify to log the event or not.

The criteria that you can apply to HTTP messages include the following:

- Does not include any method on a configurable list.

- Specific transfer encoding method or application type.
- HTTP transaction adheres to RFC specification.
- Message body size is within configurable limits.
- Request and response message header size is within a configurable limit.
- URI length is within a configurable limit.
- The content type in the message body matches the header.
- The content type in the response message matches the *accept-type* field in the request message.
- The content type in the message is included in a predefined internal list.
- Message meets HTTP RFC format criteria.
- Presence or absence of selected supported applications.
- Presence or absence of selected encoding types.

Note The actions that you can specify for messages that fail the criteria set using the different configuration commands include **allow**, **reset**, or **drop**. In addition to these actions, you can specify to log the event or not.

To enable enhanced HTTP inspection, enter the **inspect http** *http-map* command. The rules that this applies to HTTP traffic are defined by the specific HTTP map, which you configure by entering the **http-map** command and HTTP map configuration mode commands.

Note When you enable HTTP inspection with an HTTP map, strict HTTP inspection with the action reset and log is enabled by default. You can change the actions performed in response to inspection failure, but you cannot disable strict inspection as long as the HTTP map remains enabled.

Examples

The following example shows how to identify HTTP traffic, define an HTTP map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# class-map http-port
hostname(config-cmap)# match port tcp eq 80
hostname(config-cmap)# exit
hostname(config)# http-map inbound_http
hostname(config-http-map)# content-length min 100 max 2000 action reset log
hostname(config-http-map)# content-type-verification match-req-rsp reset log
hostname(config-http-map)# max-header-length request bytes 100 action log reset
hostname(config-http-map)# max-uri-length 100 action reset log
hostname(config-http-map)# exit
hostname(config)# policy-map inbound_policy
hostname(config-pmap)# class http-port
hostname(config-pmap-c)# inspect http inbound_http
hostname(config-pmap-c)# exit
hostname(config-pmap)# exit
hostname(config)# service-policy inbound_policy interface outside
```

The following example causes the ASA to reset the connection and create a syslog entry when it detects any traffic that contains the following:

- Messages less than 100 bytes or exceeding 2000 bytes

- Unsupported content types
- HTTP headers exceeding 100 bytes
- URIs exceeding 100 bytes

Related Commands

Commands	Description

inspect icmp

To configure the ICMP inspection engine, use the **inspect icmp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect icmp

no inspect icmp

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The ICMP inspection engine allows ICMP traffic to be inspected like TCP and UDP traffic. Without the ICMP inspection engine, we recommend that you do not allow ICMP through the ASA in an ACL. Without stateful inspection, ICMP can be used to attack your network. The ICMP inspection engine ensures that there is only one response for each request, and that the sequence number is correct

When ICMP inspection is disabled, which is the default configuration, ICMP echo reply messages are denied from a lower security interface to a higher security interface, even if it is in response to an ICMP echo request.

To enable ICMP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

You enable the ICMP application inspection engine as shown in the following example, which creates a class map to match ICMP traffic using the ICMP protocol ID, which is 1 for IPv4 and 58 for IPv6. The service policy is then applied to the outside interface.

```
hostname(config)# class-map icmp-class
hostname(config-cmap)# match default-inspection-traffic
hostname(config-cmap)# exit
hostname(config)# policy-map icmp_policy
hostname(config-pmap)# class icmp-class
hostname(config-pmap-c)# inspect icmp
hostname(config-pmap-c)# exit
hostname(config)# service-policy icmp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
icmp	Configures access rules for ICMP traffic that terminates at an ASA interface.
policy-map	Defines a policy that associates security actions with one or more traffic classes.
service-policy	Applies a policy map to one or more interfaces.

inspect icmp error

To enable application inspection for ICMP error messages, use the **inspect icmp error** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect icmp error

no inspect icmp error

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

Use the **inspect icmp error** command to create xlates for intermediate hops that send ICMP error messages, based on the static/NAT configuration. By default, the ASA hides the IP addresses of intermediate hops. However, using the **inspect icmp error** command makes the intermediate hop IP addresses visible. The ASA overwrites the packet with the translated IP addresses.

Cisco ASA 5500 Series software uses the egress interface address as the source address when generating ICMP error messages for path MTU discovery or hop-by-hop discovery. If you enable application inspection for ICMP error messages using the **inspect icmp error** command, NAT is also independently applied to this source address.

When enabled, the ICMP error inspection engine makes the following changes to the ICMP packet:

- In the IP Header, the NAT IP is changed to the Client IP (Destination Address and Intermediate Hop Address) and the IP checksum is modified.
- In the ICMP Header, the ICMP checksum is modified due to the changes in the ICMP packet.
- In the Payload, the following changes are made:
  - Original packet NAT IP is changed to the Client IP
  - Original packet NAT port is changed to the Client Port
  - Original packet IP checksum is recalculated

When an ICMP error message is retrieved, whether ICMP error inspection is enabled or not, the ICMP payload is scanned to retrieve the five-tuple (src ip , dest ip, src port, dest port, and ip protocol) from the original packet. A lookup is performed, using the retrieved five-tuple, to determine the original address of the client and to locate an existing session associated with the specific five-tuple. If the session is not found, the ICMP error message is dropped.

To enable ICMP error inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the ICMP error application inspection engine, which creates a class map to match ICMP traffic using the ICMP protocol ID, which is 1 for IPv4 and 58 for IPv6. The service policy is then applied to the outside interface.

```
hostname(config)# class-map icmp-class
hostname(config-cmap)# match default-inspection-traffic
hostname(config-cmap)# exit
hostname(config)# policy-map icmp_policy
hostname(config-pmap)# class icmp-class
hostname(config-pmap-c)# inspect icmp error
hostname(config-pmap-c)# exit
hostname(config)# service-policy icmp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
icmp	Configures access rules for ICMP traffic that terminates at an ASA interface.

policy-map	Defines a policy that associates security actions with one or more traffic classes.
service-policy	Applies a policy map to one or more interfaces.

inspect ils

To enable ILS application inspection, use the **inspect ils command** in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect ils

no inspect ils

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect ils** command provides NAT support for Microsoft NetMeeting, SiteServer, and Active Directory products that use LDAP to exchange directory information with an ILS server.

The ASA supports NAT for ILS, which is used to register and locate endpoints in the ILS or SiteServer Directory. PAT cannot be supported because only IP addresses are stored by an LDAP database.

For search responses, when the LDAP server is located outside, NAT should be considered to allow internal peers to communicate locally while registered to external LDAP servers. For such search responses, xlates are searched first, and then DNAT entries to obtain the correct address. If both of these searches fail, then the address is not changed. For sites using NAT 0 (no NAT) and not expecting DNAT interaction, we recommend that the inspection engine be turned off to provide better performance.

Additional configuration may be necessary when the ILS server is located inside the ASA border. This would require a hole for outside clients to access the LDAP server on the specified port, typically TCP 389.

Because ILS traffic only occurs on the secondary UDP channel, the TCP connection is disconnected after the TCP inactivity interval. By default, this interval is 60 minutes and can be adjusted using the **timeout** command.

ILS/LDAP follows a client/server model with sessions handled over a single TCP connection. Depending on the client's actions, several of these sessions may be created.

During connection negotiation time, a BIND PDU is sent from the client to the server. Once a successful BIND RESPONSE from the server is received, other operational messages may be exchanged (such as ADD, DEL, SEARCH, or MODIFY) to perform operations on the ILS Directory. The ADD REQUEST and SEARCH RESPONSE PDUs may contain IP addresses of NetMeeting peers, used by H.323 (SETUP and CONNECT messages) to establish the NetMeeting sessions. Microsoft NetMeeting v2.X and v3.X provides ILS support.

The ILS inspection performs the following operations:

- Decodes the LDAP REQUEST/RESPONSE PDUs using the BER decode functions.
- Parses the LDAP packet.
- Extracts IP addresses.
- Translates IP addresses as necessary.
- Encodes the PDU with translated addresses using BER encode functions.
- Copies the newly encoded PDU back to the TCP packet.
- Performs incremental TCP checksum and sequence number adjustment.

ILS inspection has the following limitations:

- Referral requests and responses are not supported.
- Users in multiple directories are not unified.
- Single users having multiple identities in multiple directories cannot be recognized by NAT.

Note Because H.225 call signalling traffic only occurs on the secondary UDP channel, the TCP connection is disconnected after the interval specified by the TCP **timeout** command. By default, this interval is set at 60 minutes.

To enable ILS inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

You enable the ILS inspection engine as shown in the following example, which creates a class map to match ILS traffic on the default port (389). The service policy is then applied to the outside interface.

```
hostname(config)# class-map ils-port
hostname(config-cmap)# match port tcp eq 389
hostname(config-cmap)# exit
hostname(config)# policy-map ils_policy
hostname(config-pmap)# class ils-port
hostname(config-pmap-c)# inspect ils
hostname(config-pmap-c)# exit
hostname(config)# service-policy ils_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.

inspect im

To enable inspection of IM traffic, use the **inspect im** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect im *map_name*

no inspect im *map_name*

Syntax Description

map_name	The name of the IM map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **inspect im** command enables or disables application inspection for the IM protocol.

Examples

The following example shows how to define an IM inspection policy map:

```
hostname(config)# regex loginname1 "user1\@example.com"
hostname(config)# regex loginname2 "user2\@example.com"
hostname(config)# regex loginname3 "user3\@example.com"
hostname(config)# regex loginname4 "user4\@example.com"
hostname(config)# regex yahoo_version_regex "1\.0"
hostname(config)# regex gif_files ".*\.gif"
hostname(config)# regex exe_files ".*\.exe"

hostname(config)# class-map type regex match-any yahoo_src_login_name_regex
hostname(config-cmap)# match regex loginname1
hostname(config-cmap)# match regex loginname2

hostname(config)# class-map type regex match-any yahoo_dst_login_name_regex
hostname(config-cmap)# match regex loginname3
hostname(config-cmap)# match regex loginname4

hostname(config)# class-map type inspect im match-any yahoo_file_block_list
```

```
hostname(config-cmap)# match filename regex gif_files
hostname(config-cmap)# match filename regex exe_files

hostname(config)# class-map type inspect im match-all yahoo_im_policy
hostname(config-cmap)# match login-name regex class yahoo_src_login_name_regex
hostname(config-cmap)# match peer-login-name regex class yahoo_dst_login_name_regex

hostname(config)# class-map type inspect im match-all yahoo_im_policy2
hostname(config-cmap)# match version regex yahoo_version_regex

hostname(config)# class-map im_inspect_class_map
hostname(config-cmap)# match default-inspection-traffic

hostname(config)# policy-map type inspect im im_policy_all
hostname(config-pmap)# class yahoo_file_block_list
hostname(config-pmap-c)# match service file-transfer
hostname(config-pmap)# class yahoo_im_policy
hostname(config-pmap-c)# drop-connection
hostname(config-pmap)# class yahoo_im_policy2
hostname(config-pmap-c)# reset
hostname(config)# policy-map global_policy_name
hostname(config-pmap)# class im_inspect_class_map
hostname(config-pmap-c)# inspect im im_policy_all
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

show running-config policy-map	Display all current policy map configurations.
match protocol	Matches a specific IM protocol in an inspection class or policy map.

inspect ip-options

To enable inspection of IP options in a packet, use the **inspect ip-options** command in class or policy map type inspect configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect ip-options *map_name*

no inspect ip-options *map_name*

Syntax Description

map_name	The name of the IP Options map.

Defaults

This command is enabled by default the global policy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy or class map configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

In a packet, the IP header contains the Options field. The Options field, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for most common communications. In particular, IP Options include provisions for time stamps, security, and special routing. Use of IP Options is optional and the field can contain zero, one, or more options.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the ASA. Configuring this inspection instructs the ASA to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

IP Options inspection can check for the following three IP options in a packet:

- End of Options List (EOOL) or IP Option 0—This option, which contains just a single zero byte, appears at the end of all options to mark the end of a list of options. This might not coincide with the end of the header according to the header length.
- No Operation (NOP) or IP Option 1—The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the NOP option is used as “internal padding” to align the options on a 32-bit boundary.

- Router Alert (RTRALT) or IP Option 20—This option notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

You configure inspection of these three IP options by using the **parameter** command in the policy-map type inspect configuration mode. For details about the syntax of these commands, see the **eool**, **nop**, and **router-alert** command pages.

Note IP Options inspection is included by default in the global inspection policy. Therefore, the ASA allows RSVP traffic that contains packets with the Router Alert option (option 20) when the ASA is in routed mode.

Dropping RSVP packets containing the Router Alert option can cause problems in VoIP implementations.

When you configure ASA to clear the Router Alert option from IP headers, the IP header changes in the following ways:

- The Options field is padded so that the field ends on a 32 bit boundary.
- Internet header length (IHL) changes.
- The total length of the packet changes.
- The checksum is recomputed.

If an IP header contains additional options other than EOOL, NOP, or RTRALT, regardless of whether the ASA is configured to allow these options, the ASA will drop the packet.

Examples

The following example shows how to define an IP Options inspection policy map that allows the ASA to pass packets that contain the EOOL, NOP, and RTRALT options in the packet header.

```
hostname(config)# policy-map type inspect ip-options ip-options-map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# eool action allow
hostname(config-pmap-p)# nop action allow
hostname(config-pmap-p)# router-alert action allow
```

Entering the **clear** command clears the IP option from the packet before allowing the packet through the ASA.

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.

inspect ipsec-pass-thru

To enable IPsec pass-through inspection, use the **inspect ipsec-pass-thru** command in class map configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect ipsec-pass-thru [*map_name*]

no inspect ipsec-pass-thru [*map_name*]

Syntax Description

map_name	(Optional) The name of the IPsec pass-through map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **inspect ipsec-pass-thru** command enables or disables application inspection. IPsec pass-through application inspection provides convenient traversal of ESP (IP protocol 50) and/or AH (IP protocol 51) traffic associated with an IKE UDP port 500 connection. It avoids lengthy access list configuration to permit ESP and AH traffic and also provides security using timeout and maximum connections.

Use the IPsec pass-through parameter map to identify a specific map to use for defining the parameters for the inspection. Use the **policy-map type inspect** command to access the parameters configuration, which lets you specify the restrictions for ESP or AH traffic. You can set the per-client maximum connections and the idle timeout in parameters configuration mode.

Use the **class-map**, **policy-map**, and **service-policy** commands to define a class of traffic, to apply the **inspect** command to the class, and to apply the policy to one or more interfaces. The parameter map defined is enabled when used with the **inspect ipsec-pass-thru** command.

NAT and non-NAT traffic is permitted. However, PAT is not supported.

Note In ASA 7.0(1), the **inspect ipsec-pass-thru** command allowed only ESP traffic to pass through. To retain the same behavior in later versions, a default map that permits ESP is created and attached if the **inspect ipsec-pass-thru** command is specified without any arguments. This map can be seen in the output of the **show running-config all** command.

Examples

The following example shows how to use access lists to identify IKE traffic, define an IPsec pass-through parameter map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# access-list ipsecpassthruacl permit udp any any eq 500
hostname(config)# class-map ipsecpassthru-traffic
hostname(config-cmap)# match access-list ipsecpassthruacl
hostname(config)# policy-map type inspect ipsec-pass-thru iptmap
hostname(config-pmap)# parameters
hostname(config-pmap-p)# esp per-client-max 10 timeout 0:11:00
hostname(config-pmap-p)# ah per-client-max 5 timeout 0:06:00
hostname(config)# policy-map inspection_policy
hostname(config-pmap)# class ipsecpassthru-traffic
hostname(config-pmap-c)# inspect ipsec-pass-thru iptmap
hostname(config)# service-policy inspection_policy interface outside
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.
match protocol	Matches a specific IM protocol in an inspection class or policy map.

inspect ipv6

To enable IPv6 inspection, use the **inspect ipv6** command in class configuration mode. Class configuration mode is accessible from policy-map configuration mode. To remove the configuration, use the **no** form of this command.

inspect ipv6 [*map_name*]

no inspect ipv6 [*map_name*]

Syntax Description

map_name	The name of the IPv6 inspection policy map.

Defaults

IPv6 inspection is disabled by default. If you enable IPv6 inspection and do not specify an inspection policy map, then the default IPv6 inspection policy map is used, and the following actions are taken:

- Allows only known IPv6 extension headers
- Enforces the order of IPv6 extension headers as defined in the RFC 2460 specification

If you create an inspection policy map, the above actions are taken by default unless you explicitly disable them.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

IPv6 inspection lets you selectively log or drop IPv6 traffic based on the extension header. In addition, IPv6 inspection can check conformance to RFC 2460 for type and order of extension headers in IPv6 packets.

Examples

The following example drops all IPv6 traffic with the hop-by-hop, destination-option, routing-address, and routing type 0 headers:

```
policy-map type inspect ipv6 ipv6-pm
 parameters
 match header hop-by-hop
  drop
 match header destination-option
  drop
```

```
 match header routing-address count gt 0
  drop
 match header routing-type eq 0
  drop
policy-map global_policy
 class class-default
  inspect ipv6 ipv6-pm
!
service-policy global_policy global
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
match header	Matches IPv6 headers in an IPv6 inspection policy map.
policy-map type inspect ipv6	Creates an inspection class map to match traffic specific to IPv6.
policy-map	Creates a Layer 3/4 policy map.
verify-header	Configures IPv6 inspection parameters.

inspect mgcp

To enable MGCP application inspection or to change the ports to which the ASA listens, use the **inspect mgcp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect mgcp [*map_name*]

no inspect mgcp [*map_name*]

Syntax Description

map_name	(Optional) The name of the MGCP map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

To use MGCP, you usually need to configure at least two **inspect** commands: one for the port on which the gateway receives commands, and one for the port on which the Call Agent receives commands. Normally, a Call Agent sends commands to the default MGCP port for gateways, 2427, and a gateway sends commands to the default MGCP port for Call Agents, 2727.

MGCP is used for controlling media gateways from external call control elements called media gateway controllers or call agents. A media gateway is typically a network element that provides conversion between the audio signals carried on telephone circuits and data packets carried over the Internet or over other packet networks. Using NAT and PAT with MGCP lets you support a large number of devices on an internal network with a limited set of external (global) addresses.

Examples of media gateways are:

- Trunking gateways, that interface between the telephone network and a Voice over IP network. Such gateways typically manage a large number of digital circuits.
- Residential gateways, that provide a traditional analog (RJ11) interface to a Voice over IP network. Examples of residential gateways include cable modem/cable set-top boxes, xDSL devices, and broad-band wireless devices.

- Business gateways, that provide a traditional digital PBX interface or an integrated soft PBX interface to a Voice over IP network.

MGCP messages are transmitted over UDP. A response is sent back to the source address (IP address and UDP port number) of the command, but the response may not arrive from the same address as the command was sent to. This can happen when multiple call agents are being used in a failover configuration and the call agent that received the command has passed control to a backup call agent, which then sends the response.

Note MGCP call agents send AUEP messages to determine if MGCP end points are present. This establishes a flow through the ASA and allows MGCP end points to register with the call agent.

Use the **call-agent** and **gateway** commands in MGCP map configuration mode to configure the IP addresses of one or more call agents and gateways. Use the **command-queue** command in MGCP map configuration mode to specify the maximum number of MGCP commands that will be allowed in the command queue at one time.

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect mgcp** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access-control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect mgcp** command does **not** use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect mgcp** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

To enable MGCP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

The maximum number of MGCP commands that can be queued is 150.

Examples

The following example shows how to identify MGCP traffic, define a MGCP map, define a policy, and apply the policy to the outside interface. This creates a class map to match MGCP traffic on the default ports (2427 and 2727). The service policy is then applied to the outside interface. This configuration allows call agents 10.10.11.5 and 10.10.11.6 to control gateway 10.10.10.115, and allows call agents 10.10.11.7 and 10.10.11.8 to control both gateways 10.10.10.116 and 10.10.10.117.

```
hostname(config)# access-list mgcp_acl permit tcp any any eq 2427
hostname(config)# access-list mgcp_acl permit tcp any any eq 2727
hostname(config)# class-map mgcp_port
hostname(config-cmap)# match access-list mgcp_acl
hostname(config-cmap)# exit
hostname(config)# mgcp-map inbound_mgcp
hostname(config-mgcp-map)# call-agent 10.10.11.5 101
hostname(config-mgcp-map)# call-agent 10.10.11.6 101
hostname(config-mgcp-map)# call-agent 10.10.11.7 102
hostname(config-mgcp-map)# call-agent 10.10.11.8 102
hostname(config-mgcp-map)# gateway 10.10.10.115 101
hostname(config-mgcp-map)# gateway 10.10.10.116 102
hostname(config-mgcp-map)# gateway 10.10.10.117 102
hostname(config-mgcp-map)# command-queue 150
hostname(config-mgcp-map)# exit
hostname(config)# policy-map inbound_policy
```

```
hostname(config-pmap)# class mgcp_port
hostname(config-pmap-c)# inspect mgcp mgcp-map inbound_mgcp
hostname(config-pmap-c)# exit
hostname(config)# service-policy inbound_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug mgcp	Enables MGCP debugging information.
mgcp-map	Defines an MGCP map and enables mgcp map configuration mode.
show mgcp	Displays information about MGCP sessions established through the ASA.
timeout	Sets the maximum idle time duration for different protocols and session types.

inspect mmp

To configure the MMP inspection engine, use the **inspect mmp** command in class configuration mode. To remove MMP inspection, use the **no** form of this command.

inspect mmp tls-proxy [*name*]

no inspect mmp tls-proxy [*name*]

Syntax Description

name	Species the TLS proxy instance name.
tls-proxy	Enables the TLS proxy for MMP inspection. The MMP protocol can additionally use the TCP transport; however, the CUMA client only supports the TLS transport. Therefore, the **tls-proxy** keyword is required to enable MMP inspection.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

The ASA includes an inspection engine to validate the CUMA Mobile Multiplexing Protocol (MMP). MMP is a data transport protocol for transmitting data entities between CUMA clients and servers. Use the **inspect mmp** command when the ASA is deployed between CUMA clients and servers and inspection of MMP packets is required.

MMP inspection must be enabled with the TLS proxy because MMP traffic is transported only over a TLS connection.

Note While configuring the MMP inspection engine, please note that it can only be added under a non-deafult inspection class. If you attempt to add the inspect mmp <tls-proxy> command under the default inspection class, it will generate an error.

Examples

The following example shows the use of the **inspect mmp** command to inspect MMP traffic:

```
hostname(config)# class-map mmp
```

```
hostname(config-cmap)# match port tcp eq 5443
hostname(config-cmap)# exit
hostname(config)# policy-map mmp-policy
hostname(config-pmap)# class mmp
hostname(config-pmap-c)# inspect mmp tls-proxy myproxy
hostname(config-pmap-c)# exit
hostname(config-pmap)# exit
hostname(config)# service-policy mmp-policy interface outside
```

Related Commands

Command	Description
tls-proxy	Configures the TLS proxy instance.
debug mmp	Displays inspect MMP events.

inspect netbios

To enable NetBIOS application inspection or to change the ports to which the ASA listens, use the **inspect netbios command** in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect netbios [*map_name*]

no inspect netbios [*map_name*]

Syntax Description

map_name	(Optional) The name of the NetBIOS map.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect netbios** command enables or disables application inspection for the NetBIOS protocol.

Examples

The following example shows how to define a NetBIOS inspection policy map:

```
hostname(config)# policy-map type inspect netbios netbios_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# protocol-violation drop
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect pptp

To enable PPTP application inspection or to change the ports to which the ASA listens, use the **inspect pptp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect pptp

no inspect pptp

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The Point-to-Point Tunneling Protocol (PPTP) is a protocol for tunneling PPP traffic. A PPTP session is composed of one TCP channel and usually two PPTP GRE tunnels. The TCP channel is the control channel used for negotiating and managing the PPTP GRE tunnels. The GRE tunnels carries PPP sessions between the two hosts.

When enabled, PPTP application inspection inspects PPTP protocol packets and dynamically creates the GRE connections and xlates necessary to permit PPTP traffic. Only Version 1, as defined in RFC 2637, is supported.

PAT is only performed for the modified version of GRE [RFC 2637] when negotiated over the PPTP TCP control channel. Port Address Translation is *not* performed for the unmodified version of GRE [RFC 1701, RFC 1702].

Specifically, the ASA inspects the PPTP version announcements and the outgoing call request/response sequence. Only PPTP Version 1, as defined in RFC 2637, is inspected. Further inspection on the TCP control channel is disabled if the version announced by either side is not Version 1. In addition, the outgoing-call request and reply sequence are tracked. Connections and xlates are dynamic allocated as necessary to permit subsequent secondary GRE data traffic.

The PPTP inspection engine must be enabled for PPTP traffic to be translated by PAT. Additionally, PAT is only performed for a modified version of GRE (RFC2637) and only if it is negotiated over the PPTP TCP control channel. PAT is not performed for the unmodified version of GRE (RFC 1701 and RFC 1702).

As described in RFC 2637, the PPTP protocol is mainly used for the tunneling of PPP sessions initiated from a modem bank PAC (PPTP Access Concentrator) to the headend PNS (PPTP Network Server). When used this way, the PAC is the remote client and the PNS is the server.

However, when used for VPN by Windows, the interaction is inverted. The PNS is a remote single-user PC that initiates connection to the head-end PAC to gain access to a central network.

To enable PPTP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

You enable the PPTP inspection engine as shown in the following example, which creates a class map to match PPTP traffic on the default port (1723). The service policy is then applied to the outside interface.

```
hostname(config)# class-map pptp-port
hostname(config-cmap)# match port tcp eq 1723
hostname(config-cmap)# exit
hostname(config)# policy-map pptp_policy
hostname(config-pmap)# class pptp-port
hostname(config-pmap-c)# inspect pptp
hostname(config-pmap-c)# exit
hostname(config)# service-policy pptp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug pptp	Enables debugging information for PPTP.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect radius-accouting

To enable or disable RADIUS accounting inspection or to define a map for controlling traffic or tunnels, use the **inspect radius-accounting** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect radius-accounting [*map_name*]

no inspect radius-accounting [*map_name*]

Syntax Description

map_name	(Optional) Name for the RADIUS accounting map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use the **radius-accounting** command to create a specific map to use for defining the parameters for RADIUS accounting. When you enter this command, the system enters a configuration mode that lets you enter the different commands used for defining the specific map. The actions that you can specify for messages that fail the criteria set using the different configuration commands include **send**, **host**, **validate-attribute**, **enable gprs**, and **timeout users**. You can access these commands from **parameter** mode.

After defining the RADIUS accounting map, you use the **inspect gtp** command to enable the map. Then you use the **class-map**, **policy-map**, and **service-policy** commands to define a class of traffic, to apply the **inspect** command to the class, and to apply the policy to one or more interfaces.

Note The **inspect radius-accounting** command can only be used with the **class-map type management** command.

Examples

The following example shows how to use access lists to identify RADIUS accounting traffic, define a RADIUS accounting map, define a policy, and apply the policy to the outside interface:

```
hostname(config)# policy-map type inspect radius-accountin ra
```

Note This example enables RADIUS accounting inspection with the default values. To change the default values, see the **parameters** command and each command that is entered from RADIUS accounting configuration mode.

Related Commands

Commands	Description
parameters	Defines the traffic class to which to apply security actions.
class-map type management	Lets you identify Layer 3 or 4 management traffic destined for the ASA to which you want to apply actions.
show and **clear service-policy**	Lets you view and clear service policy settings.
debug inspect radius-accounting	Lets you debug RADIUS accounting inspection.
service-policy	Applies a policy map to one or more interfaces.

inspect rsh

To enable RSH application inspection or to change the ports to which the ASA listens, use the **inspect rsh** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect rsh

no inspect rsh

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The RSH protocol uses a TCP connection from the RSH client to the RSH server on TCP port 514. The client and server negotiate the TCP port number where the client listens for the STDERR output stream. RSH inspection supports NAT of the negotiated port number if necessary.

To enable RSH inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the RSH inspection engine, which creates a class map to match RSH traffic on the default port (514). The service policy is then applied to the outside interface.

```
hostname(config)# class-map rsh-port
hostname(config-cmap)# match port tcp eq 514
hostname(config-cmap)# exit
hostname(config)# policy-map rsh_policy
hostname(config-pmap)# class rsh-port
hostname(config-pmap-c)# inspect rsh
hostname(config-pmap-c)# exit
hostname(config)# service-policy rsh_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect rtsp

To enable RTSP application inspection or to change the ports to which the ASA listens, use the **inspect rtsp** command in class configuration mode. Class configuration mode is accessible from policy-map configuration mode. To remove the configuration, use the **no** form of this command.

inspect rtsp [*map_name*]

no inspect rtsp [*map_name*]

Syntax Description

map_name	(Optional) The name of the RTSP map.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect rtsp** command lets the ASA pass RTSP packets. RTSP is used by RealAudio, RealNetworks, Apple QuickTime 4, RealPlayer, and Cisco IP/TV connections.

Note For Cisco IP/TV, use RTSP TCP port 554 and TCP 8554.

RTSP applications use the well-known port 554 with TCP (rarely UDP) as a control channel. The ASA only supports TCP, in conformity with RFC 2326. This TCP control channel is used to negotiate the data channels that will be used to transmit audio/video traffic, depending on the transport mode that is configured on the client.

The supported RDT transports are: rtp/avp, rtp/avp/udp, x-real-rdt, x-real-rdt/udp, and x-pn-tng/udp.

The ASA parses setup response messages with a status code of 200. If the response message is traveling inbound, the server is outside relative to the ASA and dynamic channels need to be opened for connections coming inbound from the server. If the response message is outbound, then the ASA does not need to open dynamic channels.

Because RFC 2326 does not require that the client and server ports must be in the setup response message, the ASA will need to keep state and remember the client ports in the setup message. QuickTime places the client ports in the setup message and then the server responds with only the server ports.

Using RealPlayer

When using RealPlayer, it is important to properly configure transport mode. For the ASA, add an **access-list** command statement from the server to the client or vice versa. For RealPlayer, change transport mode by choosing **Options > Preferences > Transport > RTSP Settings**.

If using TCP mode on the RealPlayer, check the **Use TCP to Connect to Server** and **Attempt to use TCP for all content** check boxes. On the ASA, there is no need to configure the inspection engine.

If using UDP mode on the RealPlayer, check the **Use TCP to Connect to Server** and **Attempt to use UDP for static content** check boxes, and for live content not available via Multicast. On the ASA, add a **inspect rtsp** *port* command statement.

Restrictions and Limitations

The following restrictions apply to the **inspect rtsp** command:

- The ASA does not support multicast RTSP or RTSP messages over UDP.
- The ASA does not have the ability to recognize HTTP cloaking where RTSP messages are hidden in the HTTP messages.
- The ASA cannot perform NAT on RTSP messages because the embedded IP addresses are contained in the SDP files as part of HTTP or RTSP messages. Packets could be fragmented and the ASA cannot perform NAT on fragmented packets.
- With Cisco IP/TV, the number of NATs the ASA performs on the SDP part of the message is proportional to the number of program listings in the Content Manager (each program listing can have at least six embedded IP addresses).
- You can configure NAT for Apple QuickTime 4 or RealPlayer. Cisco IP/TV only works with NAT if the Viewer and Content Manager are on the outside network and the server is on the inside network.
- Media streams delivered over HTTP are not supported by RTSP application inspection. This is because RTSP inspection does not support HTTP cloaking (RTSP wrapped in HTTP).
- To enable RTSP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the RTSP inspection engine, which creates a class map to match RTSP traffic on the default ports (554 and 8554). The service policy is then applied to the outside interface.

```
hostname(config)# access-list rtsp-acl permit tcp any any eq 554
hostname(config)# access-list rtsp-acl permit tcp any any eq 8554
hostname(config)# class-map rtsp-traffic
hostname(config-cmap)# match access-list rtsp-acl
hostname(config-cmap)# exit
hostname(config)# policy-map rtsp_policy
hostname(config-pmap)# class rtsp-traffic
hostname(config-pmap-c)# inspect rtsp
hostname(config-pmap-c)# exit
hostname(config)# service-policy rtsp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug rtsp	Enables debugging information for RTSP.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect scansafe

To enables Cloud Web Security inspection on the traffic in a class, use the **inspect scansafe** command in class configuration mode. You can access the class configuration mode by first entering the **policy-map** command. To remove the inspect action, use the **no** form of this command.

inspect scansafe *scansafe_policy_name* [**fail-open** | **fail-close**]

no inspect scansafe *scansafe_policy_name* [**fail-open** | **fail-close**]

Syntax Description

scansafe_policy_name	Specifies the inspection class map name defined by the **policy-map type inspect scansafe** command.
fail-open	(Optional) Allows traffic to pass through the ASA if the Cloud Web Security servers are unavailable.
fail-close	(Optional) Drops all traffic if the Cloud Web Security servers are unavailable. **fail-close** is the default.

Command Default

fail-close is the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Cisco Cloud Web Security provides web security and web filtering services through the Software-as-a-Service (SaaS) model. Enterprises with the ASA in their network can use Cloud Web Security services without having to install additional hardware.

Note This feature is also called “ScanSafe,” so the ScanSafe name appears in some commands.

Configure this command using Modular Policy Framework:

1. Create inspection policy maps using the **policy-map type inspect scansafe** command, at least one for HTTP and one for HTTPS (assuming you want to inspect both types of traffic).
2. (Optional) Configure a whitelist using the **class-map type inspect scansafe** command.

3. Define the traffic that you want to inspect using the **class-map** command. You must configure separate class maps for HTTP and HTTPS traffic.
4. Enter the **policy-map** command to define the policy.
5. For HTTP, enter the **class** command to reference the HTTP class map.
6. Enter the **inspect scansafe** command, referencing the HTTP inspection policy map.
7. For HTTPS, enter the **class** command to reference the HTTPS class map.
8. Enter the **inspect scansafe** command, referencing the HTTPS inspection policy map.
9. Finally, apply the policy map to an interface using the **service-policy** command.

For more information about how Modular Policy Framework works, see the CLI configuration guide.

Examples

The following example configures two classes: one for HTTP and one for HTTPS. Each ACL exempts traffic to www.cisco.com and to tools.cisco.com, and to the DMZ network, for both HTTP and HTTPS. All other traffic is sent to Cloud Web Security, except for traffic from several whitelisted users and groups. The policy is then applied to the inside interface.

```
hostname(config)# class-map type inspect scansafe match-any whitelist1
hostname(config-cmap)# match user user1 group cisco
hostname(config-cmap)# match user user2
hostname(config-cmap)# match group group1
hostname(config-cmap)# match user user3 group group3

hostname(config)# policy-map type inspect scansafe cws_inspect_pmap1
hostname(config-pmap)# parameters
hostname(config-pmap-p)# http
hostname(config-pmap-p)# default group default_group
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist

hostname(config)# policy-map type inspect scansafe cws_inspect_pmap2
hostname(config-pmap)# parameters
hostname(config-pmap-p)# https
hostname(config-pmap-p)# default group2 default_group2
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist

hostname(config)# object network cisco1
hostname(config-object-network)# fqdn www.cisco.com
hostname(config)# object network cisco2
hostname(config-object-network)# fqdn tools.cisco.com
hostname(config)# object network dmz_network
hostname(config-object-network)# subnet 10.1.1.0 255.255.255.0

hostname(config)# access-list SCANSAFE_HTTP extended deny tcp any4 object cisco1 eq 80
hostname(config)# access-list SCANSAFE_HTTP extended deny tcp any4 object cisco2 eq 80
hostname(config)# access-list SCANSAFE_HTTP extended deny tcp any4 object dmz_network eq
80
hostname(config)# access-list SCANSAFE_HTTP extended permit tcp any4 any4 eq 80

hostname(config)# access-list SCANSAFE_HTTPS extended deny tcp any4 object cisco1 eq 443
hostname(config)# access-list SCANSAFE_HTTPS extended deny tcp any4 object cisco2 eq 443
hostname(config)# access-list SCANSAFE_HTTP extended deny tcp any4 object dmz_network eq
443
hostname(config)# access-list SCANSAFE_HTTPS extended permit tcp any4 any4 eq 443

hostname(config)# class-map cws_class1
hostname(config-cmap)# match access-list SCANSAFE_HTTP
```

```
hostname(config)# class-map cws_class2
hostname(config-cmap)# match access-list SCANSAFE_HTTPS

hostname(config)# policy-map cws_policy
hostname(config-pmap)# class cws_class1
hostname(config-pmap-c)# inspect scansafe cws_inspect_pmap1 fail-open
hostname(config-pmap)# class cws_class2
hostname(config-pmap-c)# inspect scansafe cws_inspect_pmap2 fail-open
hostname(config)# service-policy cws_policy inside
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

inspect sip

To enable SIP application inspection or to change the ports to which the ASA listens, use the **inspect sip** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect sip [*sip_map*] [**tls-proxy** *proxy_name*] [**phone-proxy** *proxy_name*] [**uc-ime** *proxy_name*]

no inspect sip [*sip_map*] [**tls-proxy** *proxy_name*] [**phone-proxy** *proxy_name*] [**uc-ime** *proxy_name*]

Syntax Description

phone-proxy *proxy_name*	Enables the phone proxy for the specified inspection session.
sip_map	Specifies a SIP policy map name.
tls-proxy *proxy_name*	Enables TLS proxy for the specified inspection session. The keyword **tls-proxy** cannot be used as a Layer 7 policy map name.
uc-ime *proxy_name*	Enable the Cisco Intercompany Media Engine Proxy for SIP inspection.

Defaults

This command is enabled by default.

The default port assignment for SIP is 5060.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	The **tls-proxy** keyword was added.
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

SIP, as defined by the IETF, enables VoIP calls. SIP works with SDP for call signaling. SDP specifies the details of the media stream. Using SIP, the ASA can support any SIP Voice over IP (VoIP) gateways and VoIP proxy servers. SIP and SDP are defined in the following RFCs:

- SIP: Session Initiation Protocol, RFC 2543
- SDP: Session Description Protocol, RFC 2327

To support SIP calls through the ASA, signaling messages for the media connection addresses, media ports, and embryonic connections for the media must be inspected, because while the signaling is sent over a well-known destination port (UDP/TCP 5060), the media streams are dynamically allocated. Also, SIP embeds IP addresses in the user-data portion of the IP packet. SIP inspection applies NAT for these embedded IP addresses.

Note If a remote endpoint tries to register with a SIP proxy on a network protected by the security appliance, the registration will fail under very specific conditions. These conditions are when PAT is configured for the remote endpoint, the SIP registrar server is on the outside network, and when the port is missing in the contact field in the REGISTER message sent by the endpoint to the proxy server.

Instant Messaging

Instant Messaging refers to the transfer of messages between users in near real-time. The MESSAGE/INFO methods and 202 Accept response are used to support IM as defined in the following RFCs:

- Session Initiation Protocol (SIP)-Specific Event Notification, RFC 3265
- Session Initiation Protocol (SIP) Extension for Instant Messaging, RFC 3428

MESSAGE/INFO requests can come in at any time after registration/subscription. For example, two users can be online at any time, but not chat for hours. Therefore, the SIP inspection engine opens pinholes, which will time out according to the configured SIP timeout value. This value must be configured at least five minutes longer than the subscription duration. The subscription duration is defined in the Contact Expires value and is typically 30 minutes.

Because MESSAGE/INFO requests are typically sent using a dynamically allocated port other than port 5060, they are required to go through the SIP inspection engine.

Note Only the Chat feature is currently supported. Whiteboard, File Transfer, and Application Sharing are not supported. RTC Client 5.0 is not supported.

Technical Details

SIP inspection NATs the SIP text-based messages, recalculates the content length for the SDP portion of the message, and recalculates the packet length and checksum. It dynamically opens media connections for ports specified in the SDP portion of the SIP message as address/ports on which the endpoint should listen.

SIP inspection has a database with indices CALL_ID/FROM/TO from the SIP payload that identifies the call, as well as the source and destination. Contained within this database are the media addresses and media ports that were contained in the SDP media information fields and the media type. There can be multiple media addresses and ports for a session. RTP/RTCP connections are opened between the two endpoints using these media addresses/ports.

The well-known port 5060 must be used on the initial call setup (INVITE) message. However, subsequent messages may not have this port number. The SIP inspection engine opens signaling connection pinholes, and marks these connections as SIP connections. This is done for the messages to reach the SIP application and be NATed.

As a call is set up, the SIP session is considered in the “transient” state. This state remains until a Response message is received indicating the RTP media address and port on which the destination endpoint is listening. If there is a failure to receive the response messages within one minute, the signaling connection will be torn down.

Once the final handshake is made, the call state is moved to active and the signaling connection will remain until a BYE message is received.

If an inside endpoint initiates a call to an outside endpoint, a media hole is opened to the outside interface to allow RTP/RTCP UDP packets to flow to the inside endpoint media address and media port specified in the INVITE message from the inside endpoint. Unsolicited RTP/RTCP UDP packets to an inside interface will not traverse the ASA, unless the ASA configuration specifically allows it.

The media connections are torn down within two minutes after the connection becomes idle. This is, however, a configurable timeout and can be set for a shorter or longer period of time.

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect sip** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access-control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect sip** command does **not** use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect sip** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

To enable SIP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the SIP inspection engine, which creates a class map to match SIP traffic on the default port (5060). The service policy is then applied to the outside interface.

```
hostname(config)# class-map sip-port
hostname(config-cmap)# match port tcp eq 5060
hostname(config-cmap)# exit
hostname(config)# policy-map sip_policy
hostname(config-pmap)# class sip-port
hostname(config-pmap-c)# inspect sip
hostname(config-pmap-c)# exit
hostname(config)# service-policy sip_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
show sip	Displays information about SIP sessions established through the ASA.
debug sip	Enables debugging information for SIP.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

inspect skinny

T o enable SCCP (Skinny) application inspection or to change the ports to which the ASA listens, use the **inspect skinny** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect skinny [*skinny_map*] [**tls-proxy** *proxy_name*] [**phone-proxy** *proxy_name*]

no inspect skinny [*skinny_map*] [**tls-proxy** *proxy_name*] [**phone-proxy** *proxy_name*]

Syntax Description

phone-proxy *proxy_name*	Enables the phone proxy for the specified inspection session.
skinny_map	Specifies a skinny policy map name.
tls-proxy *proxy_name*	Enables TLS proxy for the specified inspection session. The keyword **tls-proxy** cannot be used as a Layer 7 policy map name.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	The keyword **tls-proxy** was added.
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

Skinny (or Simple) Client Control Protocol (SCCP) is a simplified protocol used in VoIP networks. Cisco IP Phones using SCCP can coexist in an H.323 environment. When used with Cisco CallManager, the SCCP client can interoperate with H.323-compliant terminals. Application layer functions in the ASA recognize SCCP Version 3.3. The functionality of the application layer software ensures that all SCCP signaling and media packets can traverse the ASA by providing NAT of the SCCP Signaling packets.

There are 5 versions of the SCCP protocol: 2.4, 3.0.4, 3.1.1, 3.2, and 3.3.2. The ASA supports all versions through Version 3.3.2. The ASA provides both PAT and NAT support for SCCP. PAT is necessary if you have limited numbers of global IP addresses for use by IP phones.

Normal traffic between the Cisco CallManager and Cisco IP Phones uses SCCP and is handled by SCCP inspection without any special configuration.The ASA also supports DHCP options 150 and 66, which allow the ASA to send the location of a TFTP server to Cisco IP Phones and other DHCP clients. For more information, see the **dhcp-server** command.

Supporting Cisco IP Phones

In topologies where Cisco CallManager is located on the higher security interface with respect to the Cisco IP Phones, if NAT is required for the Cisco CallManager IP address, the mapping must be static, because a Cisco IP Phone requires the Cisco CallManager IP address to be specified explicitly in its configuration. An identity static entry allows the Cisco CallManager on the higher security interface to accept registrations from the Cisco IP Phones.

Cisco IP Phones require access to a TFTP server to download the configuration information they need to connect to the Cisco CallManager server.

When the Cisco IP Phones are on a lower security interface compared to the TFTP server, you must use an access list to connect to the protected TFTP server on UDP port 69. While you do need a static entry for the TFTP server, this does not have to be an identity static entry. When using NAT, an identity static entry maps to the same IP address. When using PAT, it maps to the same IP address and port.

When the Cisco IP Phones are on a higher security interface compared to the TFTP server and Cisco CallManager, no access list or static entry is required to allow the Cisco IP Phones to initiate the connection.

Restrictions and Limitations

The following are limitations that apply to the current version of PAT and NAT support for SCCP:

- PAT will not work with configurations using the **alias** command.
- Outside NAT or PAT is not supported.

Note Stateful Failover of SCCP calls is supported, except for calls that are in the middle of call setup.

If the address of an internal Cisco CallManager is configured for NAT or PAT to a different IP address or port, registrations for external Cisco IP Phones will fail because the ASA currently does not support NAT or PAT for the file content transferred via TFTP. Although the ASA does support NAT of TFTP messages, and opens a pinhole for the TFTP file to traverse the ASA, the ASA cannot translate the Cisco CallManager IP address and port embedded in the Cisco IP Phone's configuration files that are being transferred using TFTP during phone registration.

Inspecting Signaling Messages

For inspecting signaling messages, the **inspect skinny** command often needs to determine locations of the media endpoints (for example, IP phones).

This information is used to prepare access-control and NAT state for media traffic to traverse the firewall transparently without manual configuration.

In determining these locations, the **inspect skinny** command does **not** use the tunnel default gateway route. A tunnel default gateway route is a route of the form **route** *interface* **0 0** *metric* **tunneled**. This route overrides the default route for packets that egress from IPsec tunnels. Therefore, if the **inspect skinny** command is desired for VPN traffic, do not configure the tunnel default gateway route. Instead, use other static routing or dynamic routing.

To enable SCCP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the SCCP inspection engine, which creates a class map to match SCCP traffic on the default port (2000). The service policy is then applied to the outside interface.

```
hostname(config)# class-map skinny-port
hostname(config-cmap)# match port tcp eq 2000
```

```
hostname(config-cmap)# exit
hostname(config)# policy-map skinny_policy
hostname(config-pmap)# class skinny-port
hostname(config-pmap-c)# inspect skinny
hostname(config-pmap-c)# exit
hostname(config)# service-policy skinny_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug skinny	Enables SCCP debugging information.
show skinny	Displays information about SCCP sessions established through the ASA.
show conn	Displays the connection state for different connection types.
timeout	Sets the maximum idle time duration for different protocols and session types.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

inspect snmp

To enable SNMP application inspection or to change the ports to which the ASA listens, use the **inspect snmp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect snmp *map_name*

no inspect snmp *map_name*

Syntax Description

map_name	The name of the SNMP map.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **inspect snmp** command to enable SNMP inspection, using the settings configured with an SNMP map, which you create using the **snmp-map** command. Use the **deny version** command in SNMP map configuration mode to restrict SNMP traffic to a specific version of SNMP.

Earlier versions of SNMP are less secure so restricting SNMP traffic to Version 2 may be required by your security policy. To deny a specific version of SNMP, use the **deny version** command within an SNMP map, which you create using the **snmp-map** command. After configuring the SNMP map, you enable the map using the **inspect snmp** command and then apply it to one or more interfaces using the **service-policy** command.

To enable strict snmp application inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example identifies SNMP traffic, defines an SNMP map, defines a policy, enables SNMP inspection, and applies the policy to the outside interface:

```
hostname(config)# access-list snmp-acl permit tcp any any eq 161
hostname(config)# access-list snmp-acl permit tcp any any eq 162
hostname(config)# class-map snmp-port
hostname(config-cmap)# match access-list snmp-acl
```

```
hostname(config-cmap)# exit
hostname(config)# snmp-map inbound_snmp
hostname(config-snmp-map)# deny version 1
hostname(config-snmp-map)# exit
hostname(config)# policy-map inbound_policy
hostname(config-pmap)# class snmp-port
hostname(config-pmap-c)# inspect snmp inbound_snmp
hostname(config-pmap-c)# exit
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
deny version	Disallows traffic using a specific version of SNMP.
snmp-map	Defines an SNMP map and enables SNMP map configuration mode.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect sqlnet

To enable Oracle SQL*Net application inspection, use the **inspect sqlnet** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect sqlnet

no inspect sqlnet

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

The default port assignment is 1521.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The SQL*Net protocol consists of different packet types that the ASA handles to make the data stream appear consistent to the Oracle applications on either side of the ASA.

The default port assignment for SQL*Net is 1521. This is the value used by Oracle for SQL*Net, but this value does not agree with IANA port assignments for Structured Query Language (SQL). Use the **class-map** command to apply SQL*Net inspection to a range of port numbers.

Note Disable SQL*Net inspection when SQL data transfer occurs on the same port as the SQL control TCP port 1521. The ASA acts as a proxy when SQL*Net inspection is enabled and reduces the client window size from 65000 to about 16000 causing data transfer issues.

The ASA NATs all addresses and looks in the packets for all embedded ports to open for SQL*Net Version 1.

For SQL*Net Version 2, all DATA or REDIRECT packets that immediately follow REDIRECT packets with a zero data length will be fixed up.

The packets that need fix-up contain embedded host/port addresses in the following format:

```
(ADDRESS=(PROTOCOL=tcp)(DEV=6)(HOST=a.b.c.d)(PORT=a))
```

SQL*Net Version 2 TNSFrame types (Connect, Accept, Refuse, Resend, and Marker) will not be scanned for addresses to NAT nor will inspection open dynamic connections for any embedded ports in the packet.

SQL*Net Version 2 TNSFrames, Redirect, and Data packets will be scanned for ports to open and addresses to NAT, if preceded by a REDIRECT TNSFrame type with a zero data length for the payload. When the Redirect message with data length zero passes through the ASA, a flag will be set in the connection data structure to expect the Data or Redirect message that follows to be NATed and ports to be dynamically opened. If one of the TNS frames in the preceding paragraph arrive after the Redirect message, the flag will be reset.

The SQL*Net inspection engine will recalculate the checksum, change IP, TCP lengths, and readjust Sequence Numbers and Acknowledgment Numbers using the delta of the length of the new and old message.

SQL*Net Version 1 is assumed for all other cases. TNSFrame types (Connect, Accept, Refuse, Resend, Marker, Redirect, and Data) and all packets will be scanned for ports and addresses. Addresses will be NATed and port connections will be opened.

To enable SQL*Net inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the SQL*Net inspection engine, which creates a class map to match SQL*Net traffic on the default port (1521). The service policy is then applied to the outside interface.

```
hostname(config)# class-map sqlnet-port
hostname(config-cmap)# match port tcp eq 1521
hostname(config-cmap)# exit
hostname(config)# policy-map sqlnet_policy
hostname(config-pmap)# class sqlnet-port
hostname(config-pmap-c)# inspect sqlnet
hostname(config-pmap-c)# exit
hostname(config)# service-policy sqlnet_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug sqlnet	Enables debugging information for SQL*Net.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.
show conn	Displays the connection state for different connection types, including SQL*net.

inspect sunrpc

To enable Sun RPC application inspection or to change the ports to which the ASA listens, use the **inspect sunrpc** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect sunrpc

no inspect sunrpc

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

To enable Sun RPC application inspection or to change the ports to which the ASA listens, use the **inspect sunrpc** command in policy map class configuration mode, which is accessible by using the **class** command within policy map configuration mode. To remove the configuration, use the **no** form of this command.

The **inspect sunrpc** command enables or disables application inspection for the Sun RPC protocol. Sun RPC is used by NFS and NIS. Sun RPC services can run on any port on the system. When a client attempts to access an Sun RPC service on a server, it must find out which port that service is running on. It does this by querying the portmapper process on the well-known port of 111.

The client sends the Sun RPC program number of the service, and gets back the port number. From this point on, the client program sends its Sun RPC queries to that new port. When a server sends out a reply, the ASA intercepts this packet and opens both embryonic TCP and UDP connections on that port.

Note NAT or PAT of Sun RPC payload information is not supported.

To enable RPC inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the RPC inspection engine, which creates a class map to match RPC traffic on the default port (111). The service policy is then applied to the outside interface.

```
hostname(config)# class-map sunrpc-port
hostname(config-cmap)# match port tcp eq 111
hostname(config-cmap)# exit
hostname(config)# policy-map sample_policy
hostname(config-pmap)# class sunrpc-port
hostname(config-pmap-c)# inspect sunrpc
hostname(config-pmap-c)# exit
hostname(config)# service-policy sample_policy interface outside
```

Related Commands

Commands	Description
clear configure sunrpc_server	Removes the configuration performed using the **sunrpc-server** command.
clear sunrpc-server active	Clears the pinholes that are opened by Sun RPC application inspection for specific services, such as NFS or NIS.
show running-config sunrpc-server	Displays the information about the Sun RPC service table configuration.
sunrpc-server	Allows pinholes to be created with a specified timeout for Sun RPC services, such as NFS or NIS.
show sunrpc-server active	Displays the pinholes open for Sun RPC services.

inspect tftp

To disable TFTP application inspection, or to enable it if it has been previously disabled, use the **inspect tftp** command in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect tftp

no inspect tftp

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

The default port assignment is 69.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

Trivial File Transfer Protocol (TFTP), described in RFC 1350, is a simple protocol to read and write files between a TFTP server and client.

The ASA inspects TFTP traffic and dynamically creates connections and translations, if necessary, to permit file transfer between a TFTP client and server. Specifically, the inspection engine inspects TFTP read request (RRQ), write request (WRQ), and error notification (ERROR).

A dynamic secondary channel and a PAT translation, if necessary, are allocated on a reception of a valid read (RRQ) or write (WRQ) request. This secondary channel is subsequently used by TFTP for file transfer or error notification.

Only the TFTP server can initiate traffic over the secondary channel, and at most one incomplete secondary channel can exist between the TFTP client and server. An error notification from the server closes the secondary channel.

TFTP inspection must be enabled if static PAT is used to redirect TFTP traffic.

To enable TFTP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the TFTP inspection engine, which creates a class map to match TFTP traffic on the default port (69). The service policy is then applied to the outside interface.

```
hostname(config)# class-map tftp-port
hostname(config-cmap)# match port udp eq 69
hostname(config-cmap)# exit
hostname(config)# policy-map tftp_policy
hostname(config-pmap)# class tftp-port
hostname(config-pmap-c)# inspect tftp
hostname(config-pmap-c)# exit
hostname(config)# service-policy tftp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect waas

To enable WAAS application inspection, use the **inspect waas** command in class configuration mode. The class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect waas

no inspect waas

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable WAAS application inspection:

```
hostname(config-pmap-c)# inspect waas
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

inspect xdmcp

To enable XDMCP application inspection or to change the ports to which the ASA listens, use the **inspect xdmcp command** in class configuration mode. Class configuration mode is accessible from policy map configuration mode. To remove the configuration, use the **no** form of this command.

inspect xdmcp

no inspect xdmcp

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced, replacing the **fixup** command, which has been deprecated.

Usage Guidelines

The **inspect xdmcp** command enables or disables application inspection for the XDMCP protocol.

XDMCP is a protocol that uses UDP port 177 to negotiate X sessions, which use TCP when established.

For successful negotiation and start of an XWindows session, the ASA must allow the TCP back connection from the Xhosted computer. To permit the back connection, use the **established** command on the ASA. Once XDMCP negotiates the port to send the display, The **established** command is consulted to verify if this back connection should be permitted.

During the XWindows session, the manager talks to the display Xserver on the well-known port 6000 | n. Each display has a separate connection to the Xserver, as a result of the following terminal setting:

```
setenv DISPLAY Xserver:n
```

where *n* is the display number.

When XDMCP is used, the display is negotiated using IP addresses, which the ASA can NAT if needed. XDCMP inspection does not support PAT.

To enable XDMCP inspection for all interfaces, use the **global** parameter in place of **interface outside**.

Examples

The following example enables the XDMCP inspection engine, which creates a class map to match XDMCP traffic on the default port (177). The service policy is then applied to the outside interface.

```
hostname(config)# class-map xdmcp-port
hostname(config-cmap)# match port tcp eq 177
hostname(config-cmap)# exit
hostname(config)# policy-map xdmcp_policy
hostname(config-pmap)# class xdmcp-port
hostname(config-pmap-c)# inspect xdmcp
hostname(config-pmap-c)# exit
hostname(config)# service-policy xdmcp_policy interface outside
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug xdmcp	Enables debugging information for XDMCP.
policy-map	Associates a class map with specific security actions.
service-policy	Applies a policy map to one or more interfaces.

CHAPTER 26

integrity through ip verify reverse-path Commands

integrity

To specify the ESP integrity algorithm in an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **integrity** command in IKEv2 policy configuration mode. To remove the command and use the default setting, use the **no** form of this command:

integrity {**md5** | **sha** | **sha256** | **sha384** | **sha512** | **null**}

no integrity {**md5** | **sha** | **sha256** | **sha384** | **sha512** | **null**}

Syntax Description

md5	Specifies the MD5 algorithm for the ESP integrity protection.
null	Allows an administrator to choose null as the IKEv2 integrity algorithm when AES-GCM is specified as the encryption algorithm.
sha	(Default) Specifies the Secure Hash Algorithm (SHA) SHA 1, defined in the U.S. Federal Information Processing Standard (FIPS), for ESP integrity protection.
sha256	Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
sha384	Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
sha512	Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

Defaults

The default is **sha (**SHA 1 algorithm).

Usage Guidelines

An IKEv2 SA is a key used in phase 1 to enable IKEv2 peers to communicate securely in phase 2. After entering the **crypto ikev2 policy** command, use the **integrity** command to set the integrity algorithm for the ESP protocol.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was added.
8.4(2)	The **sha256**, **sha384**, and **sha512** keywords were added for SHA 2 support.
9.0(1)	Added the null option as an IKEv2 integrity algorithm.

Examples

The following example enters IKEv2 policy configuration mode and sets the integrity algorithm to MD5:

```
hostname(config)# crypto ikev2 policy 1
```

```
hostname(config-ikev2-policy)# integrity md5
```

Related Commands

Command	Description
encryption	Specifies the encryption algorithm in an IKEv2 SA for AnyConnect IPsec connections.
group	Specifies the Diffie-Hellman group in an IKEv2 SA for AnyConnect IPsec connections.
lifetime	Specifies the SA lifetime for the IKEv2 SA for AnyConnect IPsec connections.
prf	Specifies the pseudo-random function in an IKEv2 SA for AnyConnect IPsec connections.

intercept-dhcp

To enable DHCP Intercept, use the **intercept-dhcp enable** command in group-policy configuration mode. To remove the **intercept-dhcp** attribute from the running configuration and allow the users to inherit a DHCP Intercept configuration from the default or other group policy, use the **no** form of this command.

intercept-dhcp *netmask* {**enable | disable**}

no intercept-dhcp

Syntax Description

disable	Disables DHCP Intercept.
enable	Enables DHCP Intercept.
netmask	Provides the subnet mask for the tunnel IP address.

Defaults

DHCP Intercept is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To disable DHCP Intercept, use the **intercept-dhcp disable** command.

A Microsoft XP anomaly results in the corruption of domain names if split tunnel options exceed 255 bytes. To avoid this problem, the ASA limits the number of routes it sends to 27 to 40 routes, with the number of routes dependent on the classes of the routes.

DHCP Intercept lets Microsoft XP clients use split-tunneling with the ASA. The ASA replies directly to the Microsoft Windows XP client DHCP Inform message, providing that client with the subnet mask, domain name, and classless static routes for the tunnel IP address. For Windows clients prior to XP, DHCP Intercept provides the domain name and subnet mask. This is useful in environments in which using a DHCP server is not advantageous.

Examples

The following example shows how to set DHCP Intercepts for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# intercept-dhcp enable
```

interface

To configure an interface and enter interface configuration mode, use the **interface** command in global configuration mode. To remove a subinterface, use the **no** form of this command; you cannot remove a physical interface or a mapped interface.

For physical interfaces (for all models except the ASASM):

interface *physical_interface*

For subinterfaces (not available for the ASA 5505 or the ASASM, or for the Management interface on the ASA 5512-X through ASA 5555-X):

interface {*physical_interface* | **redundant** *number* | **port-channel** *number*}**.***subinterface*

no interface {*physical_interface* | **redundant** *number* | **port-channel** *number*}**.***subinterface*

For multiple context mode when a mapped name is assigned:

interface *mapped_name*

Syntax Description

mapped_name	In multiple context mode, specifies the mapped name if it was assigned using the **allocate-interface** command.
physical_interface	Specifies the physical interface type, slot, and port number as *type*[*slot*/]*port*. A space between the type and slot/port is optional. The physical interface types include the following: • **ethernet** • **gigabitethernet** • **tengigabitethernet** • **management** Enter the type followed by slot/port, for example, **gigabitethernet 0/1**. The management interface is meant for management traffic only. You can, however, use it for through traffic if desired, depending on your model (see the **management-only** command). See the hardware documentation that came with your model to identify the interface type, slot, and port number.
subinterface	Specifies an integer between 1 and 4294967293 designating a logical subinterface. The maximum number of subinterfaces varies depending on your ASA model. Subinterfaces are not available for the ASA 5505, ASASM, or for the management interface on the ASA 5512-X through ASA 5555-X. See the configuration guide for the maximum subinterfaces (or VLANs) per platform. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk.

Defaults

By default, the ASA automatically generates **interface** commands for all physical interfaces.

In multiple context mode, the ASA automatically generates **interface** commands for all interfaces allocated to the context using the **allocate-interface** command.

The default state of an interface depends on the type and the context mode:

- Multiple context mode, context—All allocated interfaces are enabled by default, no matter what the state of the interface is in the system execution space. However, for traffic to pass through the interface, the interface also has to be enabled in the system execution space. If you shut down an interface in the system execution space, then that interface is down in all contexts that share it.
- Single mode or multiple context mode, system—Interfaces have the following default states:
  - Physical interfaces—Disabled.
  - Subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was modified to allow for new subinterface naming conventions and to change arguments to be separate commands under interface configuration mode.

Usage Guidelines

In interface configuration mode, you can configure hardware settings (for physical interfaces), assign a name, assign a VLAN, assign an IP address, and configure many other settings, depending on the type of interface and the security context mode.

For an enabled interface to pass traffic, configure the following interface configuration mode commands: **nameif**, and, for routed mode, **ip address**. For subinterfaces, also configure the **vlan** command.

If you change interface settings, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

The Management 0/0 interface on the ASA 5512-X through ASA 5555-X has the following characteristics:

- No through traffic support
- No subinterface support
- No priority queue support
- No multicast MAC support
- The IPS SSP software module shares the Management 0/0 interface. Separate MAC addresses and IP addresses are supported for the ASA and IPS module. You must perform configuration of the IPS IP address within the IPS operating system. However, physical characteristics (such as enabling the interface) are configured on the ASA.

Examples

The following example configures parameters for the physical interface in single mode:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

The following example configures parameters for a subinterface in single mode:

```
hostname(config)# interface gigabitethernet0/1.1
hostname(config-subif)# vlan 101
hostname(config-subif)# nameif dmz1
hostname(config-subif)# security-level 50
hostname(config-subif)# ip address 10.1.2.1 255.255.255.0
hostname(config-subif)# no shutdown
```

The following example configures interface parameters in multiple context mode for the system configuration, and allocates the gigabitethernet 0/1.1 subinterface to contextA:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# speed 1000
hostname(config-if)# duplex full
hostname(config-if)# no shutdown
hostname(config-if)# interface gigabitethernet0/1.1
hostname(config-subif)# vlan 101
hostname(config-subif)# no shutdown
hostname(config-subif)# context contextA
hostname(config-ctx)# ...
hostname(config-ctx)# allocate-interface gigabitethernet0/1.1
```

The following example configures parameters in multiple context mode for the context configuration:

```
hostname/contextA(config)# interface gigabitethernet0/1.1
hostname/contextA(config-if)# nameif inside
hostname/contextA(config-if)# security-level 100
hostname/contextA(config-if)# ip address 10.1.2.1 255.255.255.0
hostname/contextA(config-if)# no shutdown
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
member-interface	Assigns interfaces to a redundant interface.
clear interface	Clears counters for the **show interface** command.
show interface	Displays the runtime status and statistics of interfaces.
vlan	Assigns a VLAN to a subinterface.

interface bvi

To configure the bridge virtual interface (BVI) for a bridge group, use the **interface bvi** command in global configuration mode. To remove the BVI configuration, use the **no** form of this command.

interface bvi *bridge_group_number*

no interface bvi *bridge_group_number*

Syntax Description

bridge_group_number	Specifies the bridge group number as an integer between 1 and 100.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

Use this command to enter interface configuration mode so you can configure a management IP address for the bridge group. If you do not want the overhead of security contexts, or want to maximize your use of security contexts, you can group interfaces together in a bridge group, and then configure multiple bridge groups, one for each network. Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the ASA, and traffic must exit the ASA before it is routed by an external router back to another bridge group in the ASA. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration. For complete security policy separation, use security contexts with one bridge group in each context. At least one bridge group is required per context or in single mode.

Each bridge group requires a management IP address. The ASA uses this IP address as the source address for packets originating from the bridge group. The management IP address must be on the same subnet as the connected network. For IPv4 traffic, the management IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations. For another method of management, you can configure the Management interface, separate from any bridge groups.

You can configure up to 8 bridge groups in single mode or per context in multiple mode. Note that you must use at least one bridge group; data interfaces must belong to a bridge group. Each bridge group can include up to four interfaces.

Note (ASA 5510 and higher appliances) For a separate management interface, a non-configurable bridge group (ID 101) is automatically added to your configuration. This bridge group is not included in the bridge group limit.

Note The ASA does not support traffic on secondary networks; only traffic on the same network as the management IP address is supported.

Examples

The following example includes two bridge groups of three interfaces each, plus a management-only interface:

```
interface gigabitethernet 0/0
    nameif inside
    security-level 100
    bridge-group 1
    no shutdown
interface gigabitethernet 0/1
    nameif outside
    security-level 0
    bridge-group 1
    no shutdown
interface gigabitethernet 0/2
    nameif dmz
    security-level 50
    bridge-group 1
    no shutdown
interface bvi 1
    ip address 10.1.3.1 255.255.255.0 standby 10.1.3.2

interface gigabitethernet 1/0
    nameif inside
    security-level 100
    bridge-group 2
    no shutdown
interface gigabitethernet 1/1
    nameif outside
    security-level 0
    bridge-group 2
    no shutdown
interface gigabitethernet 1/2
    nameif dmz
    security-level 50
    bridge-group 2
    no shutdown
interface bvi 2
    ip address 10.3.5.8 255.255.255.0 standby 10.3.5.9

interface management 0/0
    nameif mgmt
    security-level 100
    ip address 10.2.1.1 255.255.255.0 standby 10.2.1.2
    no shutdown
```

Related Commands

Command	Description
ace/bvi	Clears the bridge virtual interface configuration.
bridge-group	Groups transparent firewall interfaces into a bridge group.
interface	Configures an interface.
ip address	Sets the management IP address for a bridge group.
show bridge-group	Shows bridge group information, including member interfaces and IP addresses.
show running-config interface bvi	Shows the bridge group interface configuration.

interface port-channel

To configure an EtherChannel interface and enter interface configuration mode, use the **interface port-channel** command in global configuration mode. To remove an EtherChannel interface, use the **no** form of this command.

interface port-channel *number*

no interface port-channel *number*

Syntax Description

number	Specifies the EtherChannel channel group ID, between 1 and 48. This interface was created automatically when you added an interface to the channel group. If you have not yet added an interface, then this command creates the port-channel interface. **Note** You need to add at least one member interface to the port-channel interface before you can configure logical parameters for it, such as a name.

Defaults

By default, port-channel interfaces are enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

In interface configuration mode, you can assign a name, assign an IP address, and configure many other settings.

For an enabled interface to pass traffic, configure the following interface configuration mode commands: **nameif**, and, for routed mode, **ip address**.

If you change interface settings, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Note This command is not supported on the ASA 5505 or the ASASM. You cannot use interfaces on the 4GE SSM, including the integrated 4GE SSM in slot 1 on the ASA 5550, as part of an EtherChannel.

For more information about interfaces, see the CLI configuration guide.

Examples

The following example configures three interfaces as part of an EtherChannel. It also sets the system priority to be a higher priority, and GigabitEthernet 0/2 to be a higher priority than the other interfaces in case more than eight interfaces are assigned to the EtherChannel.

```
hostname(config)# lacp system-priority 1234
hostname(config-if)# interface GigabitEthernet0/0
hostname(config-if)# channel-group 1 mode active
hostname(config-if)# interface GigabitEthernet0/1
hostname(config-if)# channel-group 1 mode active
hostname(config-if)# interface GigabitEthernet0/2
hostname(config-if)# lacp port-priority 1234
hostname(config-if)# channel-group 1 mode passive
hostname(config-if)# interface Port-channel1
hostname(config-if)# lacp max-bundle 4
hostname(config-if)# port-channel min-bundle 2
hostname(config-if)# port-channel load-balance dst-ip
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

interface redundant

To configure a redundant interface and enter interface configuration mode, use the **interface redundant** command in global configuration mode. To remove a redundant interface, use the **no** form of this command.

interface redundant *number*

no interface redundant *number*

Syntax Description

number	Specifies a logical redundant interface ID, between 1 and 8. A space between **redundant** and the ID is optional.

Defaults

By default, redundant interfaces are enabled. However, for traffic to pass through the redundant interface, the member physical interfaces must also be enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
8.0(2)	We introduced this command.

Usage Guidelines

A redundant interface pairs an active and a standby physical interface (see the **member-interface** command). When the active interface fails, the standby interface becomes active and starts passing traffic.

All ASA configuration refers to the logical redundant interface instead of the member physical interfaces.

In interface configuration mode, you can assign a name, assign an IP address, and configure many other settings.

For an enabled interface to pass traffic, configure the following interface configuration mode commands: **nameif**, and, for routed mode, **ip address**.

If you change interface settings, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Note This command is not supported on the ASA 5505 or the ASASM.

For more information about interfaces, see the CLI configuration guide.

Examples

The following example creates two redundant interfaces:

```
hostname(config)# interface redundant 1
hostname(config-if)# member-interface gigabitethernet 0/0
hostname(config-if)# member-interface gigabitethernet 0/1
hostname(config-if)# interface redundant 2
hostname(config-if)# member-interface gigabitethernet 0/2
hostname(config-if)# member-interface gigabitethernet 0/3
```

Related Commands

Command	Description
clear interface	Clears counters for the **show interface** command.
debug redundant-interface	Displays debug messages related to redundant interface events or errors.
member-interface	Assigns a physical interface to a redundant interface.
redundant-interface	Changes the active member interface.
show interface	Displays the runtime status and statistics of interfaces.

interface vlan

For the ASA 5505 and ASASM, to configure a VLAN interface and enter interface configuration mode, use the **interface vlan** command in global configuration mode. To remove a VLAN interface, use the **no** form of this command.

interface vlan *number*

no interface vlan *number*

Syntax Description

number	Specifies a VLAN ID. For the ASA 5505, use an ID between 1 and 4090. The VLAN interface ID is enabled by default on VLAN 1. For the ASASM, use an ID between 2 to 1000 and from 1025 to 4094.

Defaults

By default, VLAN interfaces are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	We introduced this command.
8.4(1)M	We introduced ASASM support.

Usage Guidelines

For the ASASM, you can add any VLAN ID to the configuration, but only VLANs that are assigned to the ASA by the switch can pass traffic. To view all VLANs assigned to the ASA, use the **show vlan** command. If you add an interface for a VLAN that is not yet assigned to the ASA by the switch, the interface will be in the down state. When you assign the VLAN to the ASA, the interface changes to an up state. See the **show interface** command for more information about interface states.

In interface configuration mode, you can assign a name, assign an IP address, and configure many other settings.

For an enabled interface to pass traffic, configure the following interface configuration mode commands: **nameif**, and, for routed mode, **ip address**. For the ASA 5505 switch physical interfaces, assign the physical interface to the VLAN interface using the **switchport access vlan** command.

If you change interface settings, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

For more information about interfaces, see the CLI configuration guide.

Examples

The following example configures three VLAN interfaces. The third home interface cannot forward traffic to the work inteface.

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address dhcp
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif work
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# no forward interface vlan 200
hostname(config-if)# nameif home
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown
```

The following example configures five VLAN interfaces, including the failover interface, which is configured separately using the **failover lan** command:

```
hostname(config)# interface vlan 100
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 200
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.2.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 300
hostname(config-if)# nameif dmz
hostname(config-if)# security-level 50
```

```
hostname(config-if)# ip address 10.3.1.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# interface vlan 400
hostname(config-if)# nameif backup-isp
hostname(config-if)# security-level 50
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown

hostname(config-if)# failover lan faillink vlan500
hostname(config)# failover interface ip faillink 10.4.1.1 255.255.255.0 standby 10.4.1.2
255.255.255.0

hostname(config)# interface ethernet 0/0
hostname(config-if)# switchport access vlan 100
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/1
hostname(config-if)# switchport access vlan 200
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/2
hostname(config-if)# switchport access vlan 300
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/3
hostname(config-if)# switchport access vlan 400
hostname(config-if)# no shutdown

hostname(config-if)# interface ethernet 0/4
hostname(config-if)# switchport access vlan 500
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
allocate-interface	Assigns interfaces and subinterfaces to a security context.
clear interface	Clears counters for the **show interface** command.
show interface	Displays the runtime status and statistics of interfaces.

interface (vpn load-balancing)

To specify a non-default public or private interface for VPN load-balancing in the VPN load-balancing virtual cluster, use the **interface** command in vpn load-balancing mode. To remove the interface specification and revert to thte default interface, use the **no** form of this command.

interface {**lbprivate** | **lbpublic**} *interface-name*

no interface {**lbprivate** | **lbpublic**}

Syntax Description

interface-name	The name of the interface to be configured as the public or private interface for the VPN load-balancing cluster.
lbprivate	Specifies that this command configures the private interface for VPN load-balancing.
lbpublic	Specifies that this command configures the public interface for VPN load-balancing.

Defaults

If you omit the **interface** command, the **lbprivate** interface defaults to **inside**, and the **lbpublic** interface defaults to **outside**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
vpn load-balancing	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must have first used the **vpn load-balancing** command to enter vpn load-balancing configuration mode.

You must also have previously used the **interface**, **ip address** and **nameif** commands to configure and assign a name to the interface that you are specifying in this command.

Examples

The following is an example of a **vpn load-balancing** command sequence that includes an **interface** command that specifies the public interface of the cluster as “test” one that reverts the private interface of the cluster to the default (inside):

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
```

```
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# no interface lbprivate
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# participate
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
vpn load-balancing	Enters vpn load-balancing configuration mode.

interface-policy

To specify the policy for failover when monitoring detects an interface failure, use the **interface-policy** command in failover group configuration mode. To restore the default values, use the **no** form of this command.

interface-policy *num*[**%**]

no interface-policy *num*[**%**]

Syntax Description

num	Specifies a number from 1 to 100 when used as a percentage, or 1 to the maximum number of interfaces.
%	(Optional) Specifies that the number *num* is a percentage of the monitored interfaces.

Defaults

If the **failover interface-policy** command is configured for the unit, then the default for the **interface-policy failover group** command assumes that value. If not, then *num* is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

There is no space between the *num* argument and the optional **%** keyword.

If the number of failed interfaces meets the configured policy and the other ASA is functioning correctly, the ASA will mark itself as failed and a failover may occur (if the active ASA is the one that fails). Only interfaces that are designated as monitored by the **monitor-interface** command count towards the policy.

Examples

The following partial example shows a possible configuration for a failover group:

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# interface-policy 25%
hostname(config-fover-group)# exit
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
failover interface-policy	Configures the interface monitoring policy.
monitor-interface	Specifies the interfaces being monitored for failover.

internal-password

To display an additional password field on the clientless SSL VPN portal page, use the **internal-password** command in webvpn configuration mode. This additional password is used by the ASA to authenticate users to file servers for whom SSO is allowed.

To disable the ability to use an internal password, use the **no** version of the command.

internal-password enable

no internal password

Syntax Description

enable	Enables use of an internal password.

Defaults

The default is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

If enabled, end users type a second password when logging in to a clientless SSL VPN session. The clientless SSL VPN server sends an SSO authentication request, including the username and password, to the authenticating server using HTTPS. If the authenticating server approves the authentication request, it returns an SSO authentication cookie to the clientless SSL VPN server. This cookie is kept on the ASA on behalf of the user and used to authenticate the user to secure websites within the domain protected by the SSO server.

The internal password feature is useful if you require that the internal password be different from the SSL VPN password. In particular, you can use one-time passwords for authentication to the ASA, and another password for internal sites.

Examples

The following example shows how to enable the internal password:

```
hostname(config)# webvpn
hostname(config-webvpn)# internal password enable
hostname(config-webvpn)#
```

Related Commands

Command	Description
webvpn	Enters webvpn configuration mode, which lets you configure attributes for clientless SSL VPN connections.

interval maximum

To configure the maximum interval between update attempts by a DDNS update method, use the **interval** command in DDNS-update-method mode. To remove an interval for a DDNS update method from the running configuration, use the **no** form of this command.

interval maximum *days hours minutes seconds*

no interval maximum *days hours minutes seconds*

Syntax Description

days	Specifies the number of days between update attempts with a range of 0 to 364.
hours	Specifies the number of hours between update attempts with a range of 0 to 23.
minutes	Specifies the number of minutes between update attempts with a range of 0 to 59.
seconds	Specifies the number of seconds between update attempts with a range of 0 to 59.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ddns-update-method configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The days, hours, minutes, and seconds are added together to arrive at the total interval.

Examples

The following example configures a method called ddns-2 to attempt an update every 3 minutes and 15 seconds:

```
hostname(config)# ddns update method ddns-2
hostname(DDNS-update-method)# interval maximum 0 0 3 15
```

Related Commands

Command	Description
ddns	Specifies a DDNS update method type for a created DDNS method.
ddns update	Associates a DDNS update method with an ASA interface or a DDNS update hostname.
ddns update method	Creates a method for dynamically updating DNS resource records.
dhcp-client update dns	Configures the update parameters that the DHCP client passes to the DHCP server.
dhcpd update dns	Enables a DHCP server to perform DDNS updates.

invalid-ack

To set the action for packets with an invalid ACK, use the **invalid-ack** command in tcp-map configuration mode. To set the value back to the default, use the **no** form of this command. This command is part of the TCP normalization policy enabled using the **set connection advanced-options** command.

invalid-ack {**allow** | **drop**}

no invalid-ack

Syntax Description

allow	Allows packets with an invalid ACK.
drop	Drops packets with an invalid ACK.

Defaults

The default action is to drop packets with an invalid ACK.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.

Usage Guidelines

To enable TCP normalization, use the Modular Policy Framework:

1. **tcp-map**—Identifies the TCP normalization actions.
   a. **invalid-ack**—In tcp-map configuration mode, you can enter the **invalid-ack** command and many others.
2. **class-map**—Identify the traffic on which you want to perform TCP normalization.
3. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced-options**—Identify the TCP map you created.
4. **service-policy**—Assigns the policy map to an interface or globally.

You might see invalid ACKs in the following instances:

- In the TCP connection SYN-ACK-received status, if the ACK number of a received TCP packet is not exactly the same as the sequence number of the next TCP packet sending out, it is an invalid ACK.

- Whenever the ACK number of a received TCP packet is greater than the sequence number of the next TCP packet sending out, it is an invalid ACK.

Note TCP packets with an invalid ACK are automatically allowed for WAAS connections.

Examples

The following example sets the ASA to allow packets with an invalid ACK:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# invalid-ack allow
hostname(config)# class-map cmap
hostname(config-cmap)# match any
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class-map	Identifies traffic for a service policy.
policy-map	dentifies actions to apply to traffic in a service policy.
set connection advanced-options	Enables TCP normalization.
service-policy	Applies a service policy to interface(s).
show running-config tcp-map	Shows the TCP map configuration.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

ip address

To set the IP address for an interface (in routed mode) or for the bridge virtual interface (BVI) or management interface (transparent mode), use the **ip address** command in interface configuration mode. To remove the IP address, use the **no** form of this command.

ip address *ip_address* [*mask*] [**standby** *ip_address* | **cluster-pool** *poolname*]

no ip address [*ip_address*]

Syntax Description

cluster-pool *poolname*	(Optional) For ASA clustering, sets the cluster pool of addresses defined by the **ip local pool** command. The main cluster IP address defined by the *ip_address* argument belongs to the current master unit only. Each cluster member receives a local IP address from this pool. You cannot determine the exact address assigned to each unit in advance; to see the address used on each unit, enter the **show ip local pool** *poolname* command. Each cluster member is assigned a member ID when it joins the cluster. The ID determines the local IP used from the pool.
ip_address	The IP address for the interface.
mask	(Optional) The subnet mask for the IP address. If you do not set the mask, the ASA uses the default mask for the IP address class.
standby *ip_address*	(Optional) For failover, sets the IP address for the standby unit.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	For routed mode, this command was changed from a global configuration command to an interface configuration mode command.
8.4(1)	For transparent mode, bridge groups were introduced. You now set the IP address for the BVI, and not globally.
9.0(1)	The **cluster-pool** keyword was introduced to support ASA clustering.

Usage Guidelines

This command also sets the standby address for failover.

Multiple Context Mode Guidelines

In single context routed firewall mode, each interface address must be on a unique subnet. In multiple context mode, if this interface is on a shared interface, then each IP address must be unique but on the same subnet. If the interface is unique, this IP address can be used by other contexts if desired.

Transparent Firewall Guidelines

A transparent firewall does not participate in IP routing. The only IP configuration required for the ASA is to set the BVI address. This address is required because the ASA uses this address as the source address for traffic originating on the ASA, such as system messages or communications with AAA servers. You can also use this address for remote management access. This address must be on the same subnet as the upstream and downstream routers. For multiple context mode, set the management IP address within each context. For models that include a Management interface, you can also set an IP address for this interface for management purposes.

Failover Guidelines

The standby IP address must be on the same subnet as the main IP address.

ASA Clustering Guidelines

You can only set the cluster pool for an individual interface after you configure the cluster interface mode to be individual (**cluster-interface mode individual** command). The only exception is for the management-only interface(s):

- You can always configure the management-only interface as an individual interface, even in spanned EtherChannel mode. The management interface can be an individual interface even in transparent firewall mode.
- In spanned EtherChannel mode, if you configure the management interface as an individual interface, you cannot enable dynamic routing for the management interface. You must use a static route.

Examples

The following example sets the IP addresses and standby addresses of two interfaces:

```
hostname(config)# interface gigabitethernet0/2
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0 standby 10.1.1.2
hostname(config-if)# no shutdown
hostname(config-if)# interface gigabitethernet0/3
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.2.1 255.255.255.0 standby 10.1.2.2
hostname(config-if)# no shutdown
```

The following example sets the management address and standby address of bridge group 1:

```
hostname(config)# interface bvi 1
hostname(config-if)# ip address 10.1.3.1 255.255.255.0 standby 10.1.3.2
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.

Command	Description
ip address dhcp	Sets the interface to obtain an IP address from a DHCP server.
show ip address	Shows the IP address assigned to an interface.

ip address dhcp

To use DHCP to obtain an IP address for an interface, use the **ip address dhcp** command in interface configuration mode. To disable the DHCP client for this interface, use the **no** form of this command.

ip address dhcp [**setroute**]

no ip address dhcp

Syntax Description

setroute	(Optional) Allows the ASA to use the default route supplied by the DHCP server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from a global configuration command to an interface configuration mode command. You can also enable this command on any interface, instead of only the outside interface.

Usage Guidelines

Reenter this command to reset the DHCP lease and request a new lease.

If you do not enable the interface using the **no shutdown** command before you enter the **ip address dhcp** command, some DHCP requests might not be sent.

Note The ASA rejects any leases that have a timeout of less than 32 seconds.

Examples

The following example enables DHCP on the Gigabitethernet0/1 interface:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# no shutdown
hostname(config-if)# ip address dhcp
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
ip address	Sets the IP address for the interface or sets the management IP address for a transparent firewall.
show ip address dhcp	Shows the IP address obtained from the DHCP server.

ip address pppoe

To enable PPPoE, use the **ip address pppoe** command in interface configuration mode. To disable PPPoE, use the **no** form of this command.

ip address [*ip_address* [*mask*]] **pppoe** [**setroute**]

no ip address [*ip_address* [*mask*]] **pppoe**

Syntax Description

ip_address	Manually sets the IP address instead of receiving an address from the PPPoE server.
mask	Specifies the subnet mask for the IP address. If you do not set the mask, the ASA uses the default mask for the IP address class.
setroute	Lets the ASA use the default route supplied by the PPPoE server. If the PPPoE server does not send a default route, the ASA creates a default route with the address of the access concentrator as the gateway.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

PPPoE combines two widely accepted standards, Ethernet and PPP, to provide an authenticated method of assigning IP addresses to client systems. ISPs deploy PPPoE because it supports high-speed broadband access using their existing remote access infrastructure and because it is easier for customers to use.

Before you set the IP address using PPPoE, configure the **vpdn** commands to set the username, password, and authentication protocol. If you enable this command on more than one interface, for example for a backup link to your ISP, then you can assign each interface to a different VPDN group if necessary using the **pppoe client vpdn group** command.

The maximum transmission unit (MTU) size is automatically set to 1492 bytes, which is the correct value to allow PPPoE transmission within an Ethernet frame.

Reenter this command to reset and restart the PPPoE session.

You cannot set this command at the same time as the **ip address** command or the **ip address dhcp** command.

Examples

The following example enables PPPoE on the Gigabitethernet 0/1 interface:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address pppoe
hostname(config-if)# no shutdown
```

The following example manually sets the IP address for a PPPoE interface:

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.1.1 255.255.255.0 pppoe
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
ip address	Sets the IP address for an interface.
pppoe client vpdn group	Assigns this interface to a particular VPDN group.
show ip address pppoe	Shows the IP address obtained from the PPPoE server.
vpdn group	Creates a vpdn group and concfigures PPPoE client settings.

ip-address-privacy

To enable IP address privacy, use the **ip-address-privacy** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

ip-address-privacy

no ip-address-privacy

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to enable IP address privacy over SIP in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# ip-address-privacy
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

ip audit attack

To set the default actions for packets that match an attack signature, use the **ip audit attack** command in global configuration mode. To restore the default action (to reset the connection), use the **no** form of this command.

ip audit attack [**action** [**alarm**] [**drop**] [**reset**]]

no ip audit attack

Syntax Description

action	(Optional) Specifies that you are defining a set of default actions. If you do not follow this keyword with any actions, then the ASA takes no action. If you do not enter the **action** keyword, the ASA assumes you entered it, and the **action** keyword appears in the configuration.
alarm	(Default) Generates a system message showing that a packet matched a signature.
drop	(Optional) Drops the packet.
reset	(Optional) Drops the packet and closes the connection.

Defaults

The default action is to send and alarm.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can specify multiple actions, or no actions. You can override the action you set with this command when you configure an audit policy using the **ip audit name** command. If you do not specify the action in the **ip audit name** command, then the action you set with this command is used.

For a list of signatures, see the **ip audit signature** command.

Examples

The following example sets the default action to alarm and reset for packets that match an attack signature. The audit policy for the inside interface overrides this default to be alarm only, while the policy for the outside interface uses the default setting set with the **ip audit attack** command.

```
hostname(config)# ip audit attack action alarm reset
```

```
hostname(config)# ip audit name insidepolicy attack action alarm
hostname(config)# ip audit name outsidepolicy attack
hostname(config)# ip audit interface inside insidepolicy
hostname(config)# ip audit interface outside outsidepolicy
```

Related Commands

Command	Description
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.
show running-config ip audit attack	Shows the configuration for the **ip audit attack** command.

ip audit info

To set the default actions for packets that match an informational signature, use the **ip audit info** command in global configuration mode. To restore the default action (to generate an alarm), use the **no** form of this command. You can specify multiple actions, or no actions.

ip audit info [**action** [**alarm**] [**drop**] [**reset**]]

no ip audit info

Syntax Description

action	(Optional) Specifies that you are defining a set of default actions. If you do not follow this keyword with any actions, then the ASA takes no action. If you do not enter the **action** keyword, the ASA assumes you entered it, and the **action** keyword appears in the configuration.
alarm	(Default) Generates a system message showing that a packet matched a signature.
drop	(Optional) Drops the packet.
reset	(Optional) Drops the packet and closes the connection.

Defaults

The default action is to generate an alarm.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can override the action you set with this command when you configure an audit policy using the **ip audit name** command. If you do not specify the action in the **ip audit name** command, then the action you set with this command is used.

For a list of signatures, see the **ip audit signature** command.

Examples

The following example sets the default action to alarm and reset for packets that match an informational signature. The audit policy for the inside interface overrides this default to be alarm and drop, while the policy for the outside interface uses the default setting set with the **ip audit info** command.

```
hostname(config)# ip audit info action alarm reset
```

```
hostname(config)# ip audit name insidepolicy info action alarm drop
hostname(config)# ip audit name outsidepolicy info
hostname(config)# ip audit interface inside insidepolicy
hostname(config)# ip audit interface outside outsidepolicy
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
ip audit signature	Disables a signature.
show running-config ip audit info	Shows the configuration for the **ip audit info** command.

ip audit interface

To assign an audit policy to an interface, use the **ip audit interface** command in global configuration mode. To remove the policy from the interface, use the **no** form of this command.

ip audit interface *interface_name policy_name*

no ip audit interface *interface_name policy_name*

Syntax Description

interface_name	Specifies the interface name.
policy_name	The name of the policy you added with the **ip audit name** command. You can assign an info policy and an attack policy to each interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example applies audit policies to the inside and outside interfaces:

```
hostname(config)# ip audit name insidepolicy1 attack action alarm
hostname(config)# ip audit name insidepolicy2 info action alarm
hostname(config)# ip audit name outsidepolicy1 attack action reset
hostname(config)# ip audit name outsidepolicy2 info action alarm
hostname(config)# ip audit interface inside insidepolicy1
hostname(config)# ip audit interface inside insidepolicy2
hostname(config)# ip audit interface outside outsidepolicy1
hostname(config)# ip audit interface outside outsidepolicy2
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.

Command	Description
ip audit signature	Disables a signature.
show running-config ip audit interface	Shows the configuration for the **ip audit interface** command.

ip audit name

To create a named audit policy that identifies the actions to take when a packet matches a predefined attack signature or informational signature, use the **ip audit name** command in global configuration mode. To remove the policy, use the **no** form of this command.

ip audit name *name* {**info** | **attack**} [**action** [**alarm**] [**drop**] [**reset**]]

no ip audit name *name* {**info** | **attack**} [**action** [**alarm**] [**drop**] [**reset**]]

Syntax Description

action	(Optional) Specifies that you are defining a set of actions. If you do not follow this keyword with any actions, then the ASA takes no action. If you do not enter the **action** keyword, then the ASA uses the default action set by the **ip audit attack** and **ip audit info** commands.
alarm	(Optional) Generates a system message showing that a packet matched a signature.
attack	Creates an audit policy for attack signatures; the packet might be part of an attack on your network, such as a DoS attack or illegal FTP commands.
drop	(Optional) Drops the packet.
info	Creates an audit policy for informational signatures; the packet is not currently attacking your network, but could be part of an information-gathering activity, such as a port sweep.
name	Sets the name of the policy.
reset	(Optional) Drops the packet and closes the connection.

Defaults

If you do not change the default actions using the **ip audit attack** and **ip audit info** commands, then the default action for attack signatures and informational signatures is to generate an alarm.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Signatures are activities that match known attack patterns. For example, there are signatures that match DoS attacks. To apply the policy, assign it to an interface using the **ip audit interface** command. You can assign an info policy and an attack policy to each interface.

For a list of signatures, see the **ip audit signature** command.

If traffic matches a signature, and you want to take action against that traffic, use the **shun** command to prevent new connections from the offending host and to disallow packets from any existing connection.

Examples

The following example sets an audit policy for the inside interface to generate an alarm for attack and informational signatures, while the policy for the outside interface resets the connection for attacks:

```
hostname(config)# ip audit name insidepolicy1 attack action alarm
hostname(config)# ip audit name insidepolicy2 info action alarm
hostname(config)# ip audit name outsidepolicy1 attack action reset
hostname(config)# ip audit name outsidepolicy2 info action alarm
hostname(config)# ip audit interface inside insidepolicy1
hostname(config)# ip audit interface inside insidepolicy2
hostname(config)# ip audit interface outside outsidepolicy1
hostname(config)# ip audit interface outside outsidepolicy2
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit signature	Disables a signature.
shun	Blocks packets with a specific source and destination address.

ip audit signature

To disable a signature for an audit policy, use the **ip audit signature** command in global configuration mode. To reenable the signature, use the **no** form of this command.

ip audit signature *signature_number* **disable**

no ip audit signature *signature_number*

Syntax Description

disable	Disables the signature.
signature_number	Specifies the signature number to disable. See Table 26-1 for a list of supported signatures.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You might want to disable a signature if legitimate traffic continually matches a signature, and you are willing to risk disabling the signature to avoid large numbers of alarms. Table 26-1 lists supported signatures and system message numbers.

Table 26-1 Signature IDs and System Message Numbers

Signature ID	Message Number	Signature Title	Signature Type	Description
1000	400000	IP options-Bad Option List	Informational	Triggers on receipt of an IP datagram where the list of IP options in the IP datagram header is incomplete or malformed. The IP options list contains one or more options that perform various network management or debugging tasks.
1001	400001	IP options-Record Packet Route	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 7 (Record Packet Route).

Table 26-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
1002	400002	IP options-Timestamp	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 4 (Timestamp).
1003	400003	IP options-Security	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 2 (Security options).
1004	400004	IP options-Loose Source Route	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 3 (Loose Source Route).
1005	400005	IP options-SATNET ID	Informational	Triggers on receipt of an IP datagram where the IP option list for the datagram includes option 8 (SATNET stream identifier).
1006	400006	IP options-Strict Source Route	Informational	Triggers on receipt of an IP datagram in which the IP option list for the datagram includes option 2 (Strict Source Routing).
1100	400007	IP Fragment Attack	Attack	Triggers when any IP datagram is received with an offset value less than 5 but greater than 0 indicated in the offset field.
1102	400008	IP Impossible Packet	Attack	Triggers when an IP packet arrives with source equal to destination address. This signature will catch the so-called Land Attack.
1103	400009	IP Overlapping Fragments (Teardrop)	Attack	Triggers when two fragments contained within the same IP datagram have offsets that indicate that they share positioning within the datagram. This could mean that fragment A is being completely overwritten by fragment B, or that fragment A is partially being overwritten by fragment B. Some operating systems do not properly handle fragments that overlap in this manner and may throw exceptions or behave in other undesirable ways upon receipt of overlapping fragments, which is how the Teardrop attack works to create a DoS.
2000	400010	ICMP Echo Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 0 (Echo Reply).
2001	400011	ICMP Host Unreachable	Informational	Triggers when an IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 3 (Host Unreachable).

Table 26-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
2002	400012	ICMP Source Quench	Informational	Triggers when an IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 4 (Source Quench).
2003	400013	ICMP Redirect	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 5 (Redirect).
2004	400014	ICMP Echo Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 8 (Echo Request).
2005	400015	ICMP Time Exceeded for a Datagram	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 11(Time Exceeded for a Datagram).
2006	400016	ICMP Parameter Problem on Datagram	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 12 (Parameter Problem on Datagram).
2007	400017	ICMP Timestamp Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 13 (Timestamp Request).
2008	400018	ICMP Timestamp Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 14 (Timestamp Reply).
2009	400019	ICMP Information Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 15 (Information Request).
2010	400020	ICMP Information Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 16 (ICMP Information Reply).
2011	400021	ICMP Address Mask Request	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 17 (Address Mask Request).
2012	400022	ICMP Address Mask Reply	Informational	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and the type field in the ICMP header set to 18 (Address Mask Reply).

Table 26-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
2150	400023	Fragmented ICMP Traffic	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1 (ICMP) and either the more fragments flag is set to 1 (ICMP) or there is an offset indicated in the offset field.
2151	400024	Large ICMP Traffic	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1(ICMP) and the IP length > 1024.
2154	400025	Ping of Death Attack	Attack	Triggers when a IP datagram is received with the protocol field of the IP header set to 1(ICMP), the Last Fragment bit is set, and (IP offset * 8) + (IP data length) > 65535 that is to say, the IP offset (which represents the starting position of this fragment in the original packet, and which is in 8 byte units) plus the rest of the packet is greater than the maximum size for an IP packet.
3040	400026	TCP NULL flags	Attack	Triggers when a single TCP packet with none of the SYN, FIN, ACK, or RST flags set has been sent to a specific host.
3041	400027	TCP SYN+FIN flags	Attack	Triggers when a single TCP packet with the SYN and FIN flags are set and is sent to a specific host.
3042	400028	TCP FIN only flags	Attack	Triggers when a single orphaned TCP FIN packet is sent to a privileged port (having port number less than 1024) on a specific host.
3153	400029	FTP Improper Address Specified	Informational	Triggers if a port command is issued with an address that is not the same as the requesting host.
3154	400030	FTP Improper Port Specified	Informational	Triggers if a port command is issued with a data port specified that is <1024 or >65535.
4050	400031	UDP Bomb attack	Attack	Triggers when the UDP length specified is less than the IP length specified. This malformed packet type is associated with a denial of service attempt.
4051	400032	UDP Snork attack	Attack	Triggers when a UDP packet with a source port of either 135, 7, or 19 and a destination port of 135 is detected.
4052	400033	UDP Chargen DoS attack	Attack	This signature triggers when a UDP packet is detected with a source port of 7 and a destination port of 19.
6050	400034	DNS HINFO Request	Informational	Triggers on an attempt to access HINFO records from a DNS server.

Table 26-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
6051	400035	DNS Zone Transfer	Informational	Triggers on normal DNS zone transfers, in which the source port is 53.
6052	400036	DNS Zone Transfer from High Port	Informational	Triggers on an illegitimate DNS zone transfer, in which the source port is not equal to 53.
6053	400037	DNS Request for All Records	Informational	Triggers on a DNS request for all records.
6100	400038	RPC Port Registration	Informational	Triggers when attempts are made to register new RPC services on a target host.
6101	400039	RPC Port Unregistration	Informational	Triggers when attempts are made to unregister existing RPC services on a target host.
6102	400040	RPC Dump	Informational	Triggers when an RPC dump request is issued to a target host.
6103	400041	Proxied RPC Request	Attack	Triggers when a proxied RPC request is sent to the portmapper of a target host.
6150	400042	ypserv (YP server daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP server daemon (ypserv) port.
6151	400043	ypbind (YP bind daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP bind daemon (ypbind) port.
6152	400044	yppasswdd (YP password daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP password daemon (yppasswdd) port.
6153	400045	ypupdated (YP update daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP update daemon (ypupdated) port.
6154	400046	ypxfrd (YP transfer daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the YP transfer daemon (ypxfrd) port.
6155	400047	mountd (mount daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the mount daemon (mountd) port.
6175	400048	rexd (remote execution daemon) Portmap Request	Informational	Triggers when a request is made to the portmapper for the remote execution daemon (rexd) port.

Table 26-1 Signature IDs and System Message Numbers (continued)

Signature ID	Message Number	Signature Title	Signature Type	Description
6180	400049	rexd (remote execution daemon) Attempt	Informational	Triggers when a call to the rexd program is made. The remote execution daemon is the server responsible for remote program execution. This may be indicative of an attempt to gain unauthorized access to system resources.
6190	400050	statd Buffer Overflow	Attack	Triggers when a large statd request is sent. This could be an attempt to overflow a buffer and gain access to system resources.

Examples

The following example disables signature 6100:

```
hostname(config)# ip audit signature 6100 disable
```

Related Commands

Command	Description
ip audit attack	Sets the default actions for packets that match an attack signature.
ip audit info	Sets the default actions for packets that match an informational signature.
ip audit interface	Assigns an audit policy to an interface.
ip audit name	Creates a named audit policy that identifies the actions to take when a packet matches an attack signature or an informational signature.
show running-config ip audit signature	Shows the configuration for the **ip audit signature** command.

ip-comp

To enable LZS IP compression, use the **ip-comp enable** command in group-policy configuration mode. To disable IP compression, use the **ip-comp disable** command.To remove the **ip-comp** attribute from the running configuration, use the **no** form of this command.

ip-comp {**enable | disable**}

no ip-comp

Syntax Description

disable	Disables IP compression.
enable	Enables IP compression.

Defaults

IP compression is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **no** form of this command enables inheritance of a value from another group policy. Enabling data compression might speed up data transmission rates for remote dial-in users connecting with modems.

Caution Data compression increases the memory requirement and CPU utilization for each user session and consequently decreases the overall throughput of the ASA. For this reason, we recommend that you enable data compression only for remote users connecting with a modem. Design a group policy specific to modem users, and enable compression only for them.

If the endpoints generate IP compression traffic, you should disable IP compression to prevent improper decompression of the packets. If IP compression is enabled on a particular LAN to LAN tunnel, host A cannot communicate with host B when trying to pass IP compression data from one side of the tunnel to other side.

Note When the **ip-comp** command is enabled and IPsec fragmentation is configured for "before-encryption," you cannot have IPsec compression (ip-comp_option and pre-encryption). The IP header sent to the crypto chip becomes obfuscated (because of the compression), causing the crypto chip to generate an error when processing the supplied outbound packet. You might also check your MTU level to ensure that it is a small amount (such as 600 bytes).

Examples

The following example shows how to enable IP compression for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ip-comp enable
```

ip local pool

To configure IP address pools, use the **ip local pool** command in global configuration mode. To delete the address pool, use the **no** form of this command.

ip local pool *poolname first-address—last-address* [**mask** *mask*]

no ip local pool *poolname*

Syntax Description

first-address	Specifies the starting address in the range of IP addresses.
last-address	Specifies the final address in the range of IP addresses.
mask *mask*	(Optional) Specifies a subnet mask for the pool of addresses.
poolname	Specifies the name of the IP address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	You can use an IP local pool for the cluster pool in the **ip address** command to support ASA clustering.

Usage Guidelines

You must supply the mask value when the IP addresses assigned to VPN clients belonging to a non-standard network and the data could be routed incorrectly if you use the default mask. A typical example is when the IP local pool contains 10.10.10.0/255.255.255.0 addresses, since this is a Class A network by default. This could cause some routing issues when the VPN client needs to access different subnets within the 10 network over different interfaces. For example, if a printer, address 10.10.100.1/255.255.255.0 is available via interface 2, but the 10.10.10.0 network is available over the VPN tunnel and therefore interface 1, the VPN client would be confused as to where to route data destined for the printer. Both the 10.10.10.0 and 10.10.100.0 subnets fall under the 10.0.0.0 Class A network so the printer data may be sent over the VPN tunnel.

Examples

The following example configures an IP address pool named firstpool. The starting address is 10.20.30.40 and the ending address is 10.20.30.50. The network mask is 255.255.255.0.

```
hostname(config)# ip local pool firstpool 10.20.30.40-10.20.30.50 mask 255.255.255.0
```

Related Commands

Command	Description
clear configure ip local pool	Removes all IP local pools.
show running-config ip local pool	Displays the IP pool configuration. To specify a specific IP address pool, include the name in the command.

ip-phone-bypass

To enable IP Phone Bypass, use the **ip-phone-bypass enable** command in group-policy configuration mode.To remove the IP phone Bypass attribute from the running configuration, use the **no** form of this command.

ip-phone-bypass {**enable** | **disable**}

no ip-phone-bypass

Syntax Description

disable	Disables IP Phone Bypass.
enable	Enables IP Phone Bypass.

Defaults

IP Phone Bypass is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To disable IP Phone Bypass, use the **ip-phone-bypass disable** command. The **no** form of this command option allows inheritance of a value for IP Phone Bypass from another group policy.

IP Phone Bypass lets IP phones behind hardware clients connect without undergoing user authentication processes. If enabled, secure unit authentication remains in effect.

You need to configure IP Phone Bypass only if you have enabled user authentication.

You also need to configure the **mac-exempt** option to exempt the clients from authentication. See the **vpnclient mac-exempt** command for more information.

Examples

The following example shows how to enable IP Phone Bypass for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ip-phone-bypass enable
```

Related Commands

Command	Description
user-authentication	Requires users behind a hardware client to identify themselves to the ASA before connecting.

ips

To divert traffic from the ASA to the AIP SSM for inspection, use the **ips** command in class configuration mode. To remove this command, use the **no** form of this command.

ips {**inline** | **promiscuous**} {**fail-close** | **fail-open**} [**sensor** {*sensor_name* | *mapped_name*}]

no ips {**inline** | **promiscuous**} {**fail-close** | **fail-open**} [**sensor** {*sensor_name* | *mapped_name*}]

Syntax Description

fail-close	Blocks traffic if the AIP SSM fails.
fail-open	Permits traffic if the AIP SSM fails.
inline	Directs packets to the AIP SSM; the packet might be dropped as a result of IPS operation.
promiscuous	Duplicates packets for the AIP SSM; the original packet cannot be dropped by the AIP SSM.
sensor {*sensor_name* | *mapped_name*}	Sets the virtual sensor name for this traffic. If you use virtual sensors on the AIP SSM (using Version 6.0 or above), you can specify a sensor name using this argument. To see available sensor names, enter the **ips ... sensor ?** command. Available sensors are listed. You can also use the **show ips** command. If you use multiple context mode on the adaptive security appliance, you can only specify sensors that you assigned to the context (see the **allocate-ips** command). Use the *mapped_name* argument if configured in the context. If you do not specify a sensor name, then the traffic uses the default sensor. In multiple context mode, you can specify a default sensor for the context. In single mode or if you do not specify a default sensor in multiple mode, the traffic uses the default sensor that is set on the AIP SSM. If you enter a name that does not yet exist on the AIP SSM, you get an error, and the command is rejected.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	Virtual sensor support was added.

Usage Guidelines

The ASA 5500 series supports the AIP SSM, which runs advanced IPS software that provides proactive, full-featured intrusion prevention services to stop malicious traffic, including worms and network viruses, before they can affect your network. Before or after you configure the **ips** command on the ASA, configure the security policy on the AIP SSM. You can either session to the AIP SSM from the ASA (the **session** command) or you can connect directly to the AIP SSM using SSH or Telnet on its mangement interface. Alternatively, you can use ASDM. For more information about configuring the AIP SSM, see *Configuring the Cisco Intrusion Prevention System Sensor Using the Command Line Interface*.

To configure the **ips** command, you must first configure the **class-map** command, **policy-map** command, and the **class** command.

The AIP SSM runs a separate application from the ASA. It is, however, integrated into the ASA traffic flow. The AIP SSM does not contain any external interfaces itself, other than a management interface. When you apply the **ips** command for a class of traffic on the ASA, traffic flows through the ASA and the AIP SSM in the following way:

1. Traffic enters the ASA.
2. Firewall policies are applied.
3. Traffic is sent to the AIP SSM over the backplane (using the **inline** keyword; See the **promiscuous** keyword for information about only sending a copy of the traffic to the AIP SSM).
4. The AIP SSM applies its security policy to the traffic, and takes appropriate actions.
5. Valid traffic is sent back to the ASA over the backplane; the AIP SSM might block some traffic according to its security policy, and that traffic is not passed on.
6. VPN policies are applied (if configured).
7. Traffic exits the ASA.

Examples

The following example diverts all IP traffic to the AIP SSM in promiscuous mode, and blocks all IP traffic if the AIP SSM card fails for any reason:

```
hostname(config)# access-list IPS permit ip any any
hostname(config)# class-map my-ips-class
hostname(config-cmap)# match access-list IPS
hostname(config-cmap)# policy-map my-ips-policy
hostname(config-pmap)# class my-ips-class
hostname(config-pmap-c)# ips promiscuous fail-close
hostname(config-pmap-c)# service-policy my-ips-policy global
```

The following example diverts all IP traffic destined for the 10.1.1.0 network and the 10.2.1.0 network to the AIP SSM in inline mode, and allows all traffic through if the AIP SSM card fails for any reason. For the my-ips-class traffic, sensor1 is used; for the my-ips-class2 traffic, sensor2 is used.

```
hostname(config)# access-list my-ips-acl permit ip any 10.1.1.0 255.255.255.0
hostname(config)# access-list my-ips-acl2 permit ip any 10.2.1.0 255.255.255.0
hostname(config)# class-map my-ips-class
hostname(config-cmap)# match access-list my-ips-acl
hostname(config)# class-map my-ips-class2
hostname(config-cmap)# match access-list my-ips-acl2
hostname(config-cmap)# policy-map my-ips-policy
```

```
hostname(config-pmap)# class my-ips-class
hostname(config-pmap-c)# ips inline fail-open sensor sensor1
hostname(config-pmap)# class my-ips-class2
hostname(config-pmap-c)# ips inline fail-open sensor sensor2
hostname(config-pmap-c)# service-policy my-ips-policy interface outside
```

Related Commands

Command	Description
allocate-ips	Assigns a virtual sensor to a security context.
class	Specifies a class map to use for traffic classification.
class-map	Identifies traffic for use in a policy map.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Displays all current policy map configurations.

ipsec-udp

To enable IPsec over UDP, use the **ipsec-udp enable** command in group-policy configuration mode. To remove the IPsec over UDP attribute from the current group policy, use the **no** form of this command.

ipsec-udp {**enable** | **disable**}

no ipsec-udp

Syntax Description

disable	Disables IPsec over UDP.
enable	Enables IPsec over UDP.

Defaults

IPsec over UDP is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **no** form of this command enables inheritance of a value for IPsec over UDP from another group policy.

IPsec over UDP, sometimes called IPsec through NAT, lets a Cisco VPN Client or hardware client connect via UDP to an ASA that is running NAT.

To disable IPsec over UDP, use the **ipsec-udp disable** command.

To use IPsec over UDP, you must also configure the **ipsec-udp-port** command.

The Cisco VPN Client must also be configured to use IPsec over UDP (it is configured to use it by default). The VPN 3002 requires no configuration to use IPsec over UDP.

IPsec over UDP is proprietary, applies only to remote access connections, and requires mode configuration, which means that the ASA exchanges configuration parameters with the client while negotiating SAs.

Using IPsec over UDP may slightly degrade system performance.

The ipsec-udp-port command is not supported on an ASA5505 operating as a VPN client. The ASA 5505 in client mode can initiate IPsec sessions on UDP ports 500 and/or 4500.

Examples

The following example shows how to configure IPsec over UDP for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipsec-udp enable
```

Related Commands

Command	Description
ipsec-udp-port	Specifies the port on which the ASA listens for UDP traffic.

ipsec-udp-port

To set a UDP port number for IPsec over UDP, use the **ipsec-udp-port** command in group-policy configuration mode. To disable the UDP port, use the **no** form of this command.

ipsec-udp-port *port*

no ipsec-udp-port

Syntax Description

port	Identifies the UDP port number using an integer in the range of 4001 through 49151.

Defaults

The default port is 10000.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **no** form of this command enables inheritance of a value for the IPsec over UDP port from another group policy.

In IPsec negotiations. the ASA listens on the configured port and forwards UDP traffic for that port even if other filter rules drop UDP traffic.

You can configure multiple group policies with this feature enabled, and each group policy can use a different port number.

Examples

The following example shows how to set an IPsec UDP port to port 4025 for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipsec-udp-port 4025
```

Related Commands

Command	Description
ipsec-udp	Lets a Cisco VPN Client or hardware client connect via UDP to an ASA that is running NAT.

ip verify reverse-path

To enable Unicast RPF, use the **ip verify reverse-path** command in global configuration mode. To disable this feature, use the **no** form of this command.

ip verify reverse-path interface *interface_name*

no ip verify reverse-path interface *interface_name*

Syntax Description

interface_name	The interface on which you want to enable Unicast RPF.

Defaults

This feature is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the ASA only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the ASA to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the ASA, the ASA routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the ASA can use the default route to satisfy Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the ASA uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the ASA drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the ASA drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.

- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure that they arrived on the same interface used by the initial packet.

Examples

The following example enables Unicast RPF on the outside interface:

```
hostname(config)# ip verify reverse-path interface outside
```

Related Commands

Command	Description
clear configure ip verify reverse-path	Clears the configuration set using the **ip verify reverse-path** command.
clear ip verify statistics	Clears the Unicast RPF statistics.
show ip verify statistics	Shows the Unicast RPF statistics.
show running-config ip verify reverse-path	Shows the configuration set using the **ip verify reverse-path** command.

ipv6 address through ipv6-vpn-filter Commands

ipv6 address

To enable IPv6 and configure the IPv6 addresses on an interface (in routed mode) or for the management address (transparent mode), use the **ipv6 address** command. To remove the IPv6 addresses, use the **no** form of this command.

ipv6 address {**autoconfig** | *ipv6-address*/*prefix-length* [**standby** *ipv6-prefix* | **cluster-pool** *poolname*] | *ipv6-prefix*/*prefix-length* **eui-64** | *ipv6-address* **link-local** [**standby** *ipv6-address*]}

no ipv6 address {**autoconfig** | *ipv6-address*/*prefix-length* [**standby** *ipv6-address* | **cluster-pool** *poolname*] | *ipv6-prefix*/*prefix-length* **eui-64** | *ipv6-address* **link-local** [**standby** *ipv6-address*]}

Syntax Description

autoconfig	Enables stateless autoconfiguration on the interface. Enabling stateless autoconfiguration on the interface configures IPv6 addresses based on prefixes received in router advertisement messages. A link-local address, based on the modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled. Not supported for transparent firewall mode. **Note** Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send router advertisement messages, the ASA does send router advertisement messages in this case. See the **ipv6 nd suppress-ra** command to suppress messages.
cluster-pool *poolname*	(Optional) For ASA clustering, sets the cluster pool of addresses defined by the **ipv6 local pool** command. The main cluster IP address defined by the argument belongs to the current master unit only. Each cluster member receives a local IP address from this pool. You cannot determine the exact address assigned to each unit in advance; to see the address used on each unit, enter the **show ipv6 local pool** *poolname* command. Each cluster member is assigned a member ID when it joins the cluster. The ID determines the local IP used from the pool.
ipv6-address/prefix-length	Assigns a global address to the interface. When you assign a global address, the link-local address is automatically created for the interface.

ipv6-prefix/prefix-length **eui-64**	Assigns a global address to the interface by combining the specified prefix with an interface ID generated from the interface MAC address using the modified EUI-64 format. When you assign a global address, the link-local address is automatically created for the interface. If the value specified for the *prefix-length* argument is greater than 64 bits, the prefix bits have precedence over the interface ID. An error message will be displayed if another host is using the specified address. You do not need to specify the standby address; the interface ID will be generated automatically. The modified EUI-64 format interface ID is derived from the 48-bit link-layer (MAC) address by inserting the hexadecimal number FFFE between the upper three bytes (OUI field) and the lower three bytes (serial number) of the link layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.
ipv6-address **link-local**	Manually configures the link-local address only. The *ipv6-address* specified with this command overrides the link-local address that is automatically generated for the interface. The link-local address is composed of the link-local prefix FE80::/64 and the interface ID in modified EUI-64 format. An interface with a MAC address of 00E0.B601.3B7A would have a link-local address of FE80::2E0:B6FF:FE01:3B7A. An error message will be displayed if another host is using the specified address.
standby *ipv6-address*	(Optional) Specifies the interface address used by the secondary unit or failover group in a failover pair.

Defaults

IPv6 is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.
8.2(2)	Support for a standby address was added to the command.

Release	Modification
8.4(1)	For transparent mode, bridge groups were introduced. You set the IP address for the BVI, and not globally.
9.0(1)	The **cluster-pool** keyword was introduced to support ASA clustering.

Usage Guidelines

Configuring an IPv6 address on an interface enables IPv6 on that interface; you do not need to use the **ipv6 enable** command after specifying an IPv6 address.

Multiple Context Mode Guidelines

In single context routed firewall mode, each interface address must be on a unique subnet. In multiple context mode, if this interface is on a shared interface, then each IP address must be unique but on the same subnet. If the interface is unique, this IP address can be used by other contexts if desired.

Transparent Firewall Guidelines

A transparent firewall does not participate in IP routing. The only IP configuration required for the ASA is to set the BVI address. This address is required because the ASA uses this address as the source address for traffic originating on the ASA, such as system messages or communications with AAA servers. You can also use this address for remote management access. This address must be on the same subnet as the upstream and downstream routers. For multiple context mode, set the management IP address within each context. For models that include a Management interface, you can also set an IP address for this interface for management purposes.

Failover Guidelines

The standby IP address must be on the same subnet as the main IP address.

ASA Clustering Guidelines

You can only set the cluster pool for an individual interface after you configure the cluster interface mode to be individual (**cluster-interface mode individual**). The only exception is for the management-only interface(s):

- You can always configure the management-only interface as an individual interface, even in spanned EtherChannel mode. The management interface can be an individual interface even in transparent firewall mode.
- In spanned EtherChannel mode, if you configure the management interface as an individual interface, you cannot enable dynamic routing for the management interface. You must use a static route.

Examples

The following example assigns 3FFE:C00:0:1::576/64 as the global address for the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 address 3ffe:c00:0:1::576/64
```

The following example assigns an IPv6 address automatically for the selected interface:

```
hostname(config)# interface gigabitethernet 0/1
hostname(config-if)# ipv6 address autoconfig
```

The following example assigns IPv6 address 3FFE:C00:0:1::/64 to the selected interface and specifies an EUI-64 interface ID in the low order 64 bits of the address. If this device is part of a failover pair, you do not need to specify the **standby** keyword; the standby address will be automatically created using the modified EUI-64 interface ID.

```
hostname(config)# interface gigabitethernet 0/2
hostname(onfig-if)# ipv6 address 3FFE:C00:0:1::/64 eui-64
```

The following example assigns FE80::260:3EFF:FE11:6670 as the link-level address for the selected interface:

```
hostname(config)# interface gigabitethernet 0/3
hostname(config-if)# ipv6 address FE80::260:3EFF:FE11:6670 link-local
```

The following example assigns 3FFE:C00:0:1::576/64 as the global address for the selected interface and 3FFE:C00:0:1::575 as the address for the corresponding interface on the standby unit:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 address 3ffe:c00:0:1::576/64 standby 3ffe:c00:0:1::575
```

The following example assigns FE80::260:3EFF:FE11:6670 as the link-level address for the selected interface on the primary unit in a failover pair, and FE80::260:3EFF:FE11:6671 as the link-level address for the corresponding interface on the secondary unit.

```
hostname(config)# interface gigabitethernet 0/3
hostname(config-if)# ipv6 address FE80::260:3EFF:FE11:6670 link-local standby
FE80::260:3EFF:FE11:6671
```

Related Commands

Command	Description
debug ipv6 interface	Displays debugging information for IPv6 interfaces.
show ipv6 interface	Displays the status of interfaces configured for IPv6.

ipv6 dhcprelay enable

To enable DHCPv6 relay service on an interface, use the **ipv6 dhcprelay enable** command in global configuration mode. To disable the DHCPv6 relay service, use the **no** form of this command.

ipv6 dhcprelay enable *interface*

no ipv6 dhcprelay enable *interface*

Syntax Description

interface	Specifies the output interface for a destination.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command allows you to enable DHCPv6 relay service on an interface.When the service is enabled, incoming DHCPv6 messages from a client on the interface, which may have been relayed by another relay agent, are forwarded to all configured relay destinations through all configured outgoing links. For multiple context mode, you cannot enable DHCP relay service on an interface that is used by more than one context (that is, a shared interface).

Examples

The following example shows how to configure the DHCPv6 relay agent for a DHCPv6 server with an IP address of 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 on the ASA outside interface. Client requests are from the ASA inside interface, with a binding timeout value of 90 seconds.

```
hostname(config)# ipv6 dhcprelay server 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 outside
hostname(config)# ipv6 dhcprelay timeout 90
hostname(config)# ipv6 dhcprelay enable inside
```

Related Commands

Command	Description
ipv6 dhcprelay server	Specifies the IPv6 DHCP server destination address to which client messages are forwarded.
ipv6 dhcprelay timeout	Sets the amount of time in seconds that is allowed for responses from the DHCPv6 server to pass to the DHCPv6 client through the relay binding structure.

ipv6 dhcprelay server

To specify the IPv6 DHCP server destination address to which client messages are forwarded, use the **ipv6 dhcprelay server** command in global configuration mode. To remove the IPv6 DHCP server destination address, use the **no** form of this command.

ipv6 dhcprelay server *ipv6-address* [*interface*]

no ipv6 dhcprelay server *ipv6-address* [*interface*]

Syntax Description

interface	(Optional) Specifies the output interface for a destination.
ipv6-address	Can be a link-scoped unicast, multicast, site-scoped unicast, or global IPV6 address.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command enables you to specify the IPv6 DHCP server destination address to which client messages are forwarded. Client messages are forwarded to the destination address through the link to which the output interface is connected. If the specified address is a link-scoped address, then you must specify the interface. Unspecified, loopback, and node-local multicast addresses are not allowed as the relay destination. You can specify a maximum of ten servers per context.

Examples

The following example shows how to configure the DHCPv6 relay agent for a DHCPv6 server with an IP address of 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 on the ASA outside interface. Client requests are from the ASA inside interface, with a binding timeout value of 90 seconds.

```
hostname(config)# ipv6 dhcprelay server 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 outside
hostname(config)# ipv6 dhcprelay timeout 90
hostname(config)# ipv6 dhcprelay enable inside
```

Related Commands

Command	Description
ipv6 dhcprelay enable	Enables IPv6 DHCP relay service on an interface.
ipv6 dhcprelay timeout	Sets the amount of time in seconds that is allowed for responses from the DHCPv6 server to pass to the DHCPv6 client through the relay binding structure.

ipv6 dhcprelay timeout

To set the amount of time in seconds that are allowed for responses from the DHCPv6 server to pass to the DHCPv6 client through the relay binding structure, use the **ipv6 dhcprelay timeout** command in global configuration mode. To return to the default setting, use the **no** form of this command.

ipv6 dhcprelay timeout *seconds*

no ipv6 dhcprelay timeout *seconds*

Syntax Description

seconds	Sets the number of seconds that are allowed for DHCPv6 relay address negotiation. Valid values range from 1 to 3600.

Defaults

The default is 60 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command allows you to set the amount of time in seconds that are allowed for responses from the DHCPv6 server to pass to the DHCPv6 client through the relay binding structure.

Examples

The following example shows how to configure the DHCPv6 relay agent for a DHCPv6 server with an IP address of 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 on the ASA outside interface. Client requests are from the ASA inside interface, with a binding timeout value of 90 seconds.

```
hostname(config)# ipv6 dhcprelay server 3FFB:C00:C18:6:A8BB:CCFF:FE03:2701 outside
hostname(config)# ipv6 dhcprelay timeout 90
hostname(config)# ipv6 dhcprelay enable inside
```

Related Commands

Command	Description
ipv6 dhcprelay server	Specifies the IPv6 DHCP server destination address to which client messages are forwarded.
ipv6 dhcprelay enable	Specifies the IPv6 DHCP server destination address to which client messages are forwarded.

ipv6 enable

To enable IPv6 processing and you have not already configured an explicit IPv6 address, use the **ipv6 enable** command in global configuration mode. To disable IPv6 processing on an interface that has not been configured with an explicit IPv6 address, use the **no** form of this command.

ipv6 enable

no ipv6 enable

Syntax Description

This command has no arguments or keywords.

Defaults

IPv6 is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

The **ipv6 enable** command automatically configures an IPv6 link-local unicast address on the interface, while also enabling the interface for IPv6 processing.

The **no ipv6 enable** command does not disable IPv6 processing on an interface that is configured with an explicit IPv6 address.

Examples

The following example enables IPv6 processing on the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 enable
```

Related Commands

Command	Description
ipv6 address	Configures an IPv6 address for an interface and enables IPv6 processing on the interface.
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 enforce-eui64

To enforce the use of modified EUI-64 format interface identifiers in IPv6 addresses on a local link, use the **ipv6 enforce-eui64** command in global configuration mode. To disable modified EUI-64 address format enforcement, use the **no** form of this command.

ipv6 enforce-eui64 *if_name*

no ipv6 enforce-eui64 *if_name*

Syntax Description

if_name	Specifies the name of the interface, as designated by the **nameif** command, for which you are enabling modified EUI-64 address format enforcement.

Defaults

Modified EUI-64 format enforcement is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

When this command is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the modified EUI-64 format. If the IPv6 packets do not use the modified EUI-64 format for the interface identifier, the packets are dropped and the following syslog message is generated:

```
%ASA-3-325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link. Packets received from hosts behind a router will fail the address format verification, and be dropped, because their source MAC address will be the router MAC address and not the host MAC address.

The modified EUI-64 format interface identifier is derived from the 48-bit link-layer (MAC) address by inserting the hexadecimal number FFFE between the upper three bytes (OUI field) and the lower three bytes (serial number) of the link layer address. To ensure the chosen address is from a unique Ethernet MAC address, the next-to-lowest order bit in the high-order byte is inverted (universal/local bit) to indicate the uniqueness of the 48-bit address. For example, an interface with a MAC address of 00E0.B601.3B7A would have a 64-bit interface ID of 02E0:B6FF:FE01:3B7A.

Examples

The following example enables modified EUI-64 format enforcement for IPv6 addresses received on the inside interface:

```
hostname(config)# ipv6 enforce-eui64 inside
```

Related Commands

Command	Description
ipv6 address	Configures an IPv6 address on an interface.
ipv6 enable	Enables IPv6 on an interface.

ipv6 icmp

To configure ICMP access rules for an interface, use the **ipv6 icmp** command in global configuration mode. To remove an ICMP access rule, use the **no** form of this command.

ipv6 icmp {**permit | deny**} {*ipv6-prefix/prefix-length* | **any** | **host** *ipv6-address*} [*icmp-type*] *if-name*

no ipv6 icmp {**permit | deny**} {*ipv6-prefix/prefix-length* | **any** | **host** *ipv6-address*} [*icmp-type*] *if-name*

Syntax Description

any	Keyword specifying any IPv6 address. An abbreviation for the IPv6 prefix ::/0.
deny	Prevents the specified ICMP traffic on the selected interface.
host	Indicates that the address refers to a specific host.
icmp-type	Specifies the ICMP message type being filtered by the access rule. The value can be a valid ICMP type number (from 0 to 255) or one of the following ICMP type literals: • destination-unreachable • packet-too-big • time-exceeded • parameter-problem • echo-request • echo-reply • membership-query • membership-report • membership-reduction • router-renumbering • router-solicitation • router-advertisement • neighbor-solicitation • neighbor-advertisement • neighbor-redirect
if-name	The name of the interface, as designated by the **nameif** command, to which the access rule applies.
ipv6-address	The IPv6 address of the host sending ICMPv6 messages to the interface.
ipv6-prefix	The IPv6 network that is sending ICMPv6 messages to the interface.
permit	Allows the specified ICMP traffic on the selected interface.
prefix-length	The length of the IPv6 prefix. This value indicates how many of the high-order, contiguous bits of the address comprise the network portion of the prefix. The slash (/) must precede the prefix length.

Defaults

If no ICMP access rules are defined, all ICMP traffic is permitted.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

ICMP in IPv6 functions the same as ICMP in IPv4. ICMPv6 generates error messages, such as ICMP destination unreachable messages and informational messages like ICMP echo request and reply messages. Additionally, ICMP packets in IPv6 are used in the IPv6 neighbor discovery process and path MTU discovery.

The minimum MTU allowed on an IPv6 enabled interface is 1280 bytes; however, if IPsec is enabled on the interface, the MTU value should not be set below 1380 because of the overhead of IPsec encryption. Setting the interface below 1380 bytes may result in dropped packets.

If there are no ICMP rules defined for an interface, all IPv6 ICMP traffic is permitted.

If there are ICMP rules defined for an interface, then the rules are processed in order on a first-match basis followed by an implicit deny all rule. For example, if the first matched rule is a permit rule, the ICMP packet is processed. If the first matched rule is a deny rule, or if the ICMP packet did not match any rule on that interface, then the ASA discards the ICMP packet and generates a syslog message.

For this reason, the order that you enter the ICMP rules is important. If you enter a rule denying all ICMP traffic from a specific network, and then follow it with a rule permitting ICMP traffic from a particular host on that network, the host rule will never be processed. The ICMP traffic is blocked by the network rule. However, if you enter the host rule first, followed by the network rule, the host ICMP traffic will be allowed, while all other ICMP traffic from that network is blocked.

The **ipv6 icmp** command configures access rules for ICMP traffic that terminates at the ASA interfaces. To configure access rules for pass-through ICMP traffic, see the **ipv6 access-list** command.

Examples

The following example denies all ping requests and permits all packet-too-big messages (to support path MTU discovery) at the outside interface:

```
hostname(config)# ipv6 icmp deny any echo-reply outside
hostname(config)# ipv6 icmp permit any packet-too-big outside
```

The following example permits host 2000:0:0:4::2 or hosts on prefix 2001::/64 to ping the outside interface:

```
hostname(config)# ipv6 icmp permit host 2000:0:0:4::2 echo-reply outside
hostname(config)# ipv6 icmp permit 2001::/64 echo-reply outside
hostname(config)# ipv6 icmp permit any packet-too-big outside
```

Related Commands

Command	Description
ipv6 access-list	Configures access lists.

ipv6 local pool

To configure an IPv6 address pool, use the **ipv6 local pool** command in global configuration mode. To delete the pool, use the **no** form of this command.

ipv6 local pool *pool_name ipv6_address/prefix_length number_of_addresses*

no ipv6 local pool *pool_name ipv6_address/prefix_length number_of_addresses*

Syntax Description

ipv6_address	Specifies the starting IPv6 address for the pool.
number_of_addresses	Range: 1-16384.
pool_name	Specifies the name to assign to this IPv6 address pool.
prefix_length	Range: 0-128.

Defaults

By default, the IPv6 local address pool is not configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	You can use an IPv6 local pool for the cluster pool in the **ipv6 address** command to support ASA clustering.

Usage Guidelines

For VPN, to assign IPv6 local pools, use either the **ipv6-local-pool** command in the tunnel group or the **ipv6-address-pools** command (note the "s" on this command) in the group policy. The ipv6-address-pools setting in the group policy overrides the ipv6-address-pools setting in the tunnel group.

Examples

The following example configures an IPv6 address pool named firstipv6pool for use in allocating addresses to remote clients:

```
hostname(config)# ipv6 local pool firstipv6pool 2001:DB8::1001/32 100
hostname(config)#
```

Related Commands

Command	Description
ipv6-address-pool	Associates IPv6 address pools with a VPN tunnel group policy.
ipv6-address-pools	Associates IPv6 address pools with a VPN group policy.
clear configure ipv6 local pool	Clears all configured IPv6 local pools.
show running-config ipv6	Shows the configuration for IPv6.

ipv6 nd dad attempts

To configure the number of consecutive neighbor solicitation messages that are sent on an interface during duplicate address detection, use the **ipv6 nd dad attempts** command in interface configuration mode. To return to the default number of duplicate address detection messages sent, use the **no** form of this command.

ipv6 nd dad attempts *value*

no ipv6 nd dad attempts *value*

Syntax Description

value	A number from 0 to 600. Entering 0 disables duplicate address detection on the specified interface. Entering 1 configures a single transmission without follow-up transmissions. The default value is 1 message.

Defaults

The default number of attempts is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

Duplicate address detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces (the new addresses remain in a tentative state while duplicate address detection is performed). Duplicate address detection uses neighbor solicitation messages to verify the uniqueness of unicast IPv6 addresses. The frequency at which the neighbor solicitation messages are sent is configured using the **ipv6 nd ns-interval** command.

Duplicate address detection is suspended on interfaces that are administratively down. While an interface is administratively down, the unicast IPv6 addresses assigned to the interface are set to a pending state.

Duplicate address detection is automatically restarted on an interface when the interface returns to being administratively up. An interface returning to administratively up restarts duplicate address detection for all of the unicast IPv6 addresses on the interface.

Note While duplicate address detection is performed on the link-local address of an interface, the state for the other IPv6 addresses is still set to tentative. When duplicate address detection is completed on the link-local address, duplicate address detection is performed on the remaining IPv6 addresses.

When duplicate address detection identifies a duplicate address, the state of the address is set to DUPLICATE and the address is not used. If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface and an error message similar to the following is issued:

```
%ASA-4-DUPLICATE: Duplicate address FE80::1 on outside
```

If the duplicate address is a global address of the interface, the address is not used and an error message similar to the following is issued:

```
%ASA-4-DUPLICATE: Duplicate address 3000::4 on outside
```

All configuration commands associated with the duplicate address remain as configured while the state of the address is set to DUPLICATE.

If the link-local address for an interface changes, duplicate address detection is performed on the new link-local address and all of the other IPv6 address associated with the interface are regenerated (duplicate address detection is performed only on the new link-local address).

Examples

The following example configures 5 consecutive neighbor solicitation messages to be sent when duplicate address detection is being performed on the tentative unicast IPv6 address of the interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd dad attempts 5
```

The following example disables duplicate address detection on the selected interface:

```
hostname(config)# interface gigabitethernet 0/1
hostname(config-if)# ipv6 nd dad attempts 0
```

Related Commands

Command	Description
ipv6 nd ns-interval	Configures the interval between IPv6 neighbor solicitation transmissions on an interface.
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd managed-config-flag

To configure the ASA to set the managed address config flag in the IPv6 router advertisement packet, use the **ipv6 nd managed config-flag** command in interface configuration mode. To restore the default setting, use the **no** form of this command.

ipv6 nd managed-config-flag

no ipv6 managed-config-flag

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The IPv6 autoconfiguration client host can use this flag to indicate that it must use the stateful address configuration protocol (DHCPv6) to obtain addresses in addition to the derived stateless autoconfiguration address.

Examples

The following example sets the managed address config flag in the IPv6 router advertisement packet for the interface GigabitEthernet 0/0:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd managed config-flag
```

Related Commands

Command	Description
ipv6 nd other-config-flag	Configures the ASA to set the other config flag in the IPv6 router advertisement packet.

ipv6 nd ns-interval

To configure the interval between IPv6 neighbor solicitation retransmissions on an interface, use the **ipv6 nd ns-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

ipv6 nd ns-interval *value*

no ipv6 nd ns-interval [*value*]

Syntax Description

value	The interval between IPv6 neighbor solicitation transmissions, in milliseconds. Valid values range from 1000 to 3600000 milliseconds. The default value is 1000 milliseconds.

Defaults

The default is 1000 milliseconds between neighbor solicitation transmissions.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

This value will be included in all IPv6 router advertisements sent out this interface.

Examples

The following example configures an IPv6 neighbor solicitation transmission interval of 9000 milliseconds for GigabitEthernet 0/0:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd ns-interval 9000
```

Related Commands

Command	Description
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd other-config-flag

To configure the ASA to set the other config flag in the IPv6 router advertisement packet, use the **ipv6 nd other-config-flag** command in interface configuration mode. To restore the default setting, use the **no** form of this command.

ipv6 nd other-config-flag

no ipv6 other-config-flag

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The IPv6 autoconfiguration client host can use this flag to indicate that it must use the stateful address configuration protocol (DHCPv6) to obtain non-address configuration information such as DNS server information.

Examples

The following example sets the other config flag in the IPv6 router advertisement packet for the interface GigabitEthernet 0/0:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd other-config-flag
```

Related Commands

Command	Description
ipv6 nd managed-config-flag	Configures the ASA to set the managed address config flag in the IPv6 router advertisement packet.

ipv6 nd prefix

To configure which IPv6 prefixes are included in IPv6 router advertisements, use the **ipv6 nd prefix** command in interface configuration mode. To remove the prefixes, use the **no** form of this command.

ipv6 nd prefix *ipv6-prefix/prefix-length* | **default** [[*valid-lifetime preferred-lifetime*] | [**at** *valid-date preferred-date*] | **infinite** | **no-advertise** | **off-link** | **no-autoconfig**]

no ipv6 nd prefix *ipv6-prefix/prefix-length* | **default** [[*valid-lifetime preferred-lifetime*] | [**at** *valid-date preferred-date*] | **infinite** | **no-advertise** | **off-link** | **no-autoconfig**]

Syntax Description

at *valid-date preferred-date*	The date and time at which the lifetime and preference expire. The prefix is valid until this specified date and time are reached. Dates are expressed in the form *date-valid-expire month-valid-expire hh:mm-valid-expire date-prefer-expire month-prefer-expire hh:mm-prefer-expire*.
default	Default values are used.
infinite	(Optional) The valid lifetime does not expire.
ipv6-prefix	The IPv6 network number to include in router advertisements. This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal format using 16-bit values between colons.
no-advertise	(Optional) Indicates to hosts on the local link that the specified prefix is not to be used for IPv6 autoconfiguration.
no-autoconfig	(Optional) Indicates to hosts on the local link that the specified prefix cannot be used for IPv6 autoconfiguration.
off-link	(Optional) Indicates that the specified prefix is not used for on-link determination.
preferred-lifetime	The amount of time (in seconds) that the specified IPv6 prefix is advertised as being preferred. Valid values range from 0 to 4294967295 seconds. The maximum value represents infinity, which can also be specified with the **infinite** keyword. The default is 604800 (7 days).
prefix-length	The length of the IPv6 prefix. This value indicates how many of the high-order, contiguous bits of the address comprise the network portion of the prefix. The slash (/) must precede the prefix length.
valid-lifetime	The amount of time that the specified IPv6 prefix is advertised as being valid. Valid values range from 0 to 4294967295 seconds. The maximum value represents infinity, which can also be specified with the **infinite** keyword. The default is 2592000 (30 days).

Defaults

All prefixes configured on interfaces that originate IPv6 router advertisements are advertised with a valid lifetime of 2592000 seconds (30 days) and a preferred lifetime of 604800 seconds (7 days), and with both the “onlink” and “autoconfig” flags set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command allows control over the individual parameters per prefix, including whether or not the prefix should be advertised.

By default, prefixes configured as addresses on an interface using the **ipv6 address** command are advertised in router advertisements. If you configure prefixes for advertisement using the **ipv6 nd prefix** command, then only these prefixes are advertised.

The **default** keyword can be used to set default parameters for all prefixes.

A date can be set to specify the expiration of a prefix. The valid and preferred lifetimes are counted down in real time. When the expiration date is reached, the prefix will no longer be advertised.

When onlink is “on” (by default), the specified prefix is assigned to the link. Nodes sending traffic to such addresses that contain the specified prefix consider the destination to be locally reachable on the link.

When autoconfig is “on” (by default), it indicates to hosts on the local link that the specified prefix can be used for IPv6 autoconfiguration.

Examples

The following example includes the IPv6 prefix 2001:200::/35, with a valid lifetime of 1000 seconds and a preferred lifetime of 900 seconds in router advertisements sent out on the specified interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd prefix 2001:200::/35 1000 900
```

Related Commands

Command	Description
ipv6 address	Configures an IPv6 address and enables IPv6 processing on an interface.
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd ra-interval

To configure the interval between IPv6 router advertisement transmissions on an interface, use the **ipv6 nd ra-interval** command in interface configuration mode. To restore the default interval, use the **no** form of this command.

ipv6 nd ra-interval [**msec**] *value*

no ipv6 nd ra-interval [[**msec**] *value*]

Syntax Description

msec	(Optional) indicates that the value provided is in milliseconds. If this keyword is not present, the value provided is seconds.
value	The interval between IPv6 router advertisement transmissions. Valid values range from 3 to 1800 seconds, or from 500 to 1800000 milliseconds if the **msec** keyword is provided. The default is 200 seconds.

Defaults

200 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The interval between transmissions should be less than or equal to the IPv6 router advertisement lifetime if the ASA is configured as a default router by using the **ipv6 nd ra-lifetime** command. To prevent synchronization with other IPv6 nodes, randomly adjust the actual value used to within 20 percent of the specified value.

Examples

The following example configures an IPv6 router advertisement interval of 201 seconds for the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd ra-interval 201
```

Related Commands

Command	Description
ipv6 nd ra-lifetime	Configures the lifetime of an IPv6 router advertisement.
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd ra-lifetime

To configure the "router lifetime" value in IPv6 router advertisements on an interface, use the **ipv6 nd ra-lifetime** command in interface configuration mode. To restore the default value, use the **no** form of this command.

ipv6 nd ra-lifetime *seconds*

no ipv6 nd ra-lifetime [*seconds*]

Syntax Description

seconds	The validity of the ASA as a default router on this interface. Valid values range from 0 to 9000 seconds. The default is 1800 seconds. 0 indicates that the ASA should not be considered a default router on the selected interface.

Defaults

1800 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The "router lifetime" value is included in all IPv6 router advertisements sent out an interface. The value indicates the usefulness of the ASA as a default router on this interface.

Setting the value to a non-zero value to indicates that the ASA should be considered a default router on this interface. The non-zero value for the "router lifetime" value should not be less than the router advertisement interval.

Setting the value to 0 indicates that the ASA should not be considered a default router on this interface.

Examples

The following example configures an IPv6 router advertisement lifetime of 1801 seconds for the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd ra-lifetime 1801
```

Related Commands

Command	Description
ipv6 nd ra-interval	Configures the interval between IPv6 router advertisement transmissions on an interface.
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd reachable-time

To configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, use the **ipv6 nd reachable-time** command in interface configuration mode. To restore the default time, use the **no** form of this command.

ipv6 nd reachable-time *value*

no ipv6 nd reachable-time [*value*]

Syntax Description

value	The amount of time, in milliseconds, that a remote IPv6 node is considered reachable. Valid values range from 0 to 3600000 milliseconds. The default value is 0. When 0 is used for the *value* argument, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

Defaults

Zero milliseconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

The configured time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly; however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

To see the reachable time used by the ASA, including the actual value when this comamnd is set to 0, use the **show ipv6 interface** command to display information about the IPv6 interface, including the ND reachable time being used.

Examples

The following example configures an IPv6 reachable time of 1700000 milliseconds for the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd reachable-time 1700000
```

Related Commands

Command	Description
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 nd suppress-ra

To suppress IPv6 router advertisement transmissions on a LAN interface, use the **ipv6 nd suppress-ra** command in interface configuration mode. To reenable the sending of IPv6 router advertisement transmissions on a LAN interface, use the **no** form of this command.

ipv6 nd suppress-ra

no ipv6 nd suppress-ra

Syntax Description

This command has no arguments or keywords.

Defaults

Router advertisements are automatically sent on LAN interfaces if IPv6 unicast routing is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **no ipv6 nd suppress-ra** command to enable the sending of IPv6 router advertisement transmissions on non-LAN interface types (for example serial or tunnel interfaces).

Examples

The following example suppresses IPv6 router advertisements on the selected interface:

```
hostname(config)# interface gigabitethernet 0/0
hostname(config-if)# ipv6 nd suppress-ra
```

Related Commands

Command	Description
show ipv6 interface	Displays the usability status of interfaces configured for IPv6.

ipv6 neighbor

To configure a static entry in the IPv6 neighbor discovery cache, use the **ipv6 neighbor** command in global configuration mode. To remove a static entry from the neighbor discovery cache, use the **no** form of this command.

ipv6 neighbor *ipv6_address if_name mac_address*

no ipv6 neighbor *ipv6_address if_name* [*mac_address*]

Syntax Description

if_name	The internal or external interface name designated by the **nameif** command.
ipv6_address	The IPv6 address that corresponds to the local data link address.
mac_address	The local data line (hardware MAC) address.

Defaults

Static entries are not configured in the IPv6 neighbor discovery cache.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

The **ipv6 neighbor** command is similar to the **arp** command. If an entry for the specified IPv6 address already exists in the neighbor discovery cache—learned through the IPv6 neighbor discovery process—the entry is automatically converted to a static entry. These entries are stored in the configuration when the **copy** command is used to store the configuration.

Use the **show ipv6 neighbor** command to view static entries in the IPv6 neighbor discovery cache.

The **clear ipv6 neighbors** command deletes all entries in the IPv6 neighbor discovery cache except static entries. The **no ipv6 neighbor** command deletes a specified static entry from the neighbor discovery cache; the command does not remove dynamic entries—entries learned from the IPv6 neighbor discovery process—from the cache. Disabling IPv6 on an interface by using the **no ipv6 enable** command deletes all IPv6 neighbor discovery cache entries configured for that interface except static entries (the state of the entry changes to INCMP [Incomplete]).

Static entries in the IPv6 neighbor discovery cache are not modified by the neighbor discovery process.

Examples

The following example adds a static entry for the an inside host with an IPv6 address of 3001:1::45A and a MAC address of 0002.7D1A.9472 to the neighbor discovery cache:

```
hostname(config)# ipv6 neighbor 3001:1::45A inside 0002.7D1A.9472
```

Related Commands

Command	Description
clear ipv6 neighbors	Deletes all entries in the IPv6 neighbor discovery cache, except static entries.
show ipv6 neighbor	Displays IPv6 neighbor cache information.

ipv6 ospf

To enable the OSPFv3 interface configuration for IPv6, use the **ipv6 ospf** command in global configuration mode. To disable the OSPFv3 interface configuration for IPv6, use the **no** form of this command.

ipv6 ospf [*process-id*] [**cost** | **database-filter** | **dead-interval** *seconds* | **flood-reduction** | **hello-interval** *seconds* | **mtu-ignore** | **neighbor** | **network** | **priority** | **retransmit-interval** *seconds* | **transmit-delay** *seconds*]

no ipv6 ospf [*process-id*] [**cost** | **database-filter** | **dead-interval** *seconds* | **flood-reduction** | **hello-interval** *seconds* | **mtu-ignore** | **neighbor** | **network** | **priority** | **retransmit-interval** *seconds* | **transmit-delay** *seconds*]

Syntax Description

cost	Explicitly specifies the cost of sending a packet on an interface.
database-filter	Filters outgoing LSAs to an OSPFv3 interface.
dead-interval *seconds*	Sets the time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535. The default is four times the interval set by the **ipv6 ospf hello-interval** command.
flood-reduction	Specifies the flood reduction of LSAs to the interface.
hello-interval *seconds*	Specifies the interval in seconds between hello packets sent on the interface. The value must be the same for all nodes on a specific network and can range from 1 to 65535. The default interval is 10 seconds for Ethernet interfaces and 30 seconds for non-broadcast interfaces.
mtu-ignore	Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.
neighbor	Configures OSPFv3 router interconnections to non-broadcast networks.
network	Sets the OSPF network type to a type other than the default, which depends on the network type.
priority	Sets the router priority, which helps determine the designated router for a network. Valid values range from 0 to 255.
process-id	Specifies the OSPFv3 process to be enabled. Valid values range from 1 to 65535.
retransmit-interval *seconds*	Specifies the time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
transmit-delay *seconds*	Sets the estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.

Defaults

All IPv6 addresses are included by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

You must enable an OSPFv3 routing process before you can create an OSPFv3 area.

Examples

The following example enables OSPFv3 interface configuration:

```
hostname(config)# ipv6 ospf 3
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf area

To create an OSPFv3 area for IPv6, use the **ipv6 ospf area** command in global configuration mode. To disable the OSPFv3 area configuration for IPv6, use the **no** form of this command.

ipv6 ospf area [*area-num*] [**instance**]

no ipv6 ospf area [*area-num*] [**instance**]

Syntax Description

area-num	Specifies the OSPFv3 area to be enabled.
instance	Specifies the area instance ID that is to be assigned to an interface.

Defaults

All IPv6 addresses are included by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

You must configure OSPFv3 routing on each interface separately. An interface can have only one OSPFv3 area, and OSPFv3 for the ASA supports only one instance per interface. Each interface uses a different area instance ID. The area instance ID only affects the receipt of OSPF packets, and applies to normal OSPF interfaces and virtual links.

Examples

The following example enables OSPFv3 interface configuration:

```
hostname(config)# ipv6 ospf 3 area 2
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf cost

To explicitly specify the cost of sending a packet on an interface, use the **ipv6 ospf cost** command in interface configuration mode. To reset the cost of sending a packet on an interface to the default value, use the **no** form of this command.

ipv6 ospf cost *interface-cost*

no ipv6 ospf cost *interface-cost*

Syntax Description

interface-cost	Specifies an unsigned integer value expressed as the link-state metric, which can range from 1 to 65535.

Defaults

The default cost is based on the bandwidth.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to explicitly specify the packet cost for an interface.

Examples

The following example sets the packet cost to 65:

```
hostname(config-if)# ipv6 ospf cost 65
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf database-filter all out

To filter outgoing LSAs to an OSPFv3 interface, use the **ipv6 ospf databse-filter all out** command in interface configuration mode. To restore the forwarding of LSAs to the interface, use the **no** form of this command.

ipv6 ospf database-filter all out

no ipv6 ospf database-filter all out

Syntax Description

This command has no arguments or keywords.

Defaults

All outgoing LSAs are flooded to the interface.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to filter outgoing LSAs to an OSPFv3 interface.

Examples

The following example filters outgoing LSAs to the specified interface:

```
hostname(config)# interface ethernet 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf database-filter all out
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf dead-interval

To set the time period for which hello packets must not be seen before neighbors declare that the router is down, use the **ipv6 ospf dead-interval** command in interface configuration mode. To return to the default time, use the **no** form of this command.

ipv6 ospf dead-interval *seconds*

no ipv6 ospf dead-interval *seconds*

Syntax Description

seconds	Specifies the interval in seconds. The value must be the same for all nodes in the network. Valid values range from 1 to 65535.

Defaults

The default is four times the interval that is set by the **ipv6 ospf hello-interval** command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to specify the interval during which hello packets are not seen before neighbors notify that the router is down.

Examples

The following example sets the dead interval to 60:

```
hostname(config)# interface ethernet 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf dead-interval 60
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf encryption

To specify the encryption type for an interface, use the **ipv6 ospf encryption** command in interface configuration mode. To remove the encryption type for an interface, use the **no** form of this command.

ipv6 ospf encryption {**ipsec spi** *spi* **esp** *encryption-algorithm* [[*key-encryption-type*] *key*] *authentication-algorithm* [*key-encryption-type*] *key* | **null**}

no ipv6 ospf encryption {**ipsec spi** *spi* **esp** *encryption-algorithm* [[*key-encryption-type*] *key*] *authentication-algorithm* [*key-encryption-type*] *key* | **null**}

Syntax Description

authentication-algorithm	Specifies the encryption algorithm to be used. Valid values are one of the following: • **md5**—Enables message digest 5 (MD5). • **sha1**—Enables SHA-1.
encryption-algorithm	Specifies the encryption algorithm to be used with ESP. Valid values are the following: • **aes-cdc**—Enables AES-CDC encryption. • **3des**—Enables 3DES encryption. • **des**—Enables DES encryption. • **null**—Specifies ESP with no encryption.
esp	Specifies the encapsulating security payload (ESP).
ipsec	Specifies the IP security protocol.
key	Specifies the number used in the calculation of the message digest. When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
key-encryption-type	(Optional) Specifes the key encryption type, which can be one of the following values: • **0**—The key is not encrypted. • **7**—The key is encrypted.
null	Overrides area authentication.
spi *spi*	Specifies the security policy index (SPI) value. The *spi* value must be a number from 256 to 4294967295, which is entered as a decimal.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to specify the encryption type for an interface.

Examples

The following example enables SHA-1 encryption on the interface:

```
hostname(config)# interface ethernet 0/0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf encryption ipsec spi 1001 esp null sha1
123456789A123456789B123456789C123456789D
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf flood-reduction

To specify the flood reduction of LSAs to the interface, use the **ipv6 ospf flood-reduction** command in interface configuration mode. To remove the flood reduction of LSAs to the interface, use the **no** form of this command.

ipv6 ospf flood-reduction

no ipv6 ospf flood-reduction

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to specify the flood reduction of LSAs to an interface.

Examples

The following example enables flood reduction of LSAs to the interface:

```
hostname(config-if)# interface GigabitEthernet3/2.200
 vlan 200
 nameif outside
 security-level 100
 ip address 20.20.200.30 255.255.255.0 standby 20.20.200.31
 ipv6 address 3001::1/64 standby 3001::8
 ipv6 address 6001::1/64 standby 6001::8
 ipv6 enable
 ospf priority 255
 ipv6 ospf cost 100
 ipv6 ospf 100 area 10 instance 200
ipv6 ospf flood reduction
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf hello-interval

To set the time period for which hello packets must not be seen before neighbors declare that the router is down, use the **ipv6 ospf dead-interval** command in interface configuration mode. To return to the default time, use the **no** form of this command.

ipv6 ospf dead-interval *seconds*

no ipv6 ospf dead-interval *seconds*

Syntax Description

seconds	Specifies the interval in seconds. The value must be the same for all nodes in the network. Valid values range from 1 to 65535.

Defaults

The default interval is 10 seconds if you are using Ethernet and 30 seconds if you are using non-broadcast.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to specify the interval during which hello packets are not seen before neighbors notify that the router is down.

Examples

The following example sets the dead interval to 60:

```
hostname(config)# interface ethernet 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf dead-interval 60
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf mtu-ignore

To disable OSPFv3 maximum transmission unit (MTU) mismatch detection when the ASA receives database descriptor (DBD) packets, use the **ipv6 ospf mtu-ignore** command in interface configuration mode. To reset the MTU mismatch detection when the ASA receives DBD packets to the default, use the **no** form of this command.

ipv6 ospf mtu-ignore

no ipv6 ospf mtu-ignore

Syntax Description

This command has no arguments or keywords.

Defaults

OSPFv3 MTU mismatch detection is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to disable OSPFv3 MTU mismatch detection when the ASA receives DBD packets.

Examples

The following example disables OSPFv3 MTU mismatch detection when the ASA receives DBD packets:

```
hostname(config)# interface serial 0/0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf mtu-ignore
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6 ospf neighbor

To configure OSPFv3 router interconnections to nonbroadcast networks, use the **ipv6 ospf neighbor** command in interface configuration mode. To remove a configuration, use the **no** form of this command.

ipv6 ospf neighbor *ipv6-address* [**priority** *number*] [**poll-interval** *seconds*] [**cost** *number*] [**database-filter**]

no ipv6 ospf neighbor *ipv6-address* [**priority** *number*] [**poll-interval** *seconds*] [**cost** *number*] [**database-filter**]

Syntax Description

cost *number*	(Optional) Assigns a cost to the neighbor in the form of an integer from 1 to 65535. Neighbors with no specific cost configured assume the cost of the interface, based on the **ipv6 ospf cost** command.
database-filter	(Optional) Filters outgoing link-state advertisements (LSAs) to an OSPF neighbor.
ipv6-address	Link-local IPv6 address of the neighbor. This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal format using 16-bit values between colons.
poll-interval *seconds*	(Optional) A number value that represents the poll interval time in seconds. RFC 2328 recommends that this value be much larger than the hello interval. The default is 120 seconds (two minutes). This keyword does not apply to point-to-multipoint interfaces.
priority *number*	(Optional) A number that indicates the router priority value of the nonbroadcast neighbor associated with the IPv6 prefix specified. The default is 0.

Defaults

The default depends on the network type.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to configure OSPFv3 router interconnections to nonbroadcast networks.

Examples

The following example configures an OSPFv3 neighboring router:

```
hostname(config)# interface serial 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf 1 area 0
hostname(config-if)# ipv6 ospf neighbor FE80::A8BB:CCFF:FE00:C01
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
ipv6 ospf priority	Determines the designated router for a specified network.

ipv6 ospf network

To configure the OSPFv3 network type to a type other than the default, use the **ipv6 ospf network** command in interface configuration mode. To return to the default type, use the **no** form of this command.

ipv6 ospf network {**broadcast** | **point-to-point non-broadcast**}

no ipv6 ospf network {**broadcast** | **point-to-point non-broadcast**}

Syntax Description

broadcast	Sets the network type to broadcast.
point-to-point non-broadcast	Sets the network type to point-to-point non-broadcast.

Defaults

The default depends on the network type.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to configure the OSPFv3 network type to a type that is different from the default.

Examples

The following example sets the OSPFv3 network to a broadcast network:

```
hostname(config)# interface serial 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf 1 area 0
hostname(config-if)# ipv6 ospf network broadcast
hostname(config-if)# encapsulation frame-relay
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
ipv6 ospf priority	Determines the designated router for a specified network.

ipv6 ospf priority

To set the router priority, which helps determine the designated router for a specified network, use the **ipv6 ospf priority** command in interface configuration mode. To return to the default value, use the **no** form of this command.

ipv6 ospf priority *number-value*

no ipv6 ospf priority *number-value*

Syntax Description

number-value	Sets the number value that specifies the priority of the router. Valid values range from 0 to 255.

Defaults

The default priority is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to set the priority of the router.

Examples

The following example sets the priority of the router to 4:

```
hostname(config)# interface ethernet 0
hostname(config-if)# ipv6 ospf priority 4
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
ipv6 ospf retransmit-interval	Specifies the time between LSA retransmissions for adjacencies that belong to the interface.

ipv6 ospf retransmit-interval

To specify the time between LSA retransmissions for adjacencies that belong to the interface, use the **ipv6 ospf retransmit-interval** command in interface configuration mode. To return to the default value, use the **no** form of this command.

ipv6 ospf retransmit-interval *seconds*

no ipv6 ospf retransmit-interval *seconds*

Syntax Description

seconds	Specifies the time in seconds between retransmissions. The interval must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds.

Defaults

The default is 5 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to specify the time between LSA retransmissions for adjacencies that belong to the interface.

Examples

The following example sets the retransmission interval to 8 seconds:

```
hostname(config)# interface ethernet 2
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf retransmit-interval 8
```

Related Commands

Command	Description
ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
ipv6 ospf priority	Determines the designated router for a specified network.

ipv6 ospf transmit-delay

To set the estimated time that is required to send a link-state update packet on the interface, use the **ipv6 ospf transmit-delay** command in interface configuration mode. To return to the default value, use the **no** form of this command.

ipv6 ospf transmit-delay *seconds*

no ipv6 ospf transmit-delay *seconds*

Syntax Description

seconds	Specifies the time in seconds that is required to send a link-state update. Valid values range from 1 to 65535 seconds.

Defaults

The default is 1 second.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Use this command to set the estimated time that is required to send a link-state update packet on the interface.

Examples

The following example sets the transmission delay to 3 seconds:

```
hostname(config)# interface ethernet 0
hostname(config)# ipv6 enable
hostname(config-if)# ipv6 ospf transmit-delay 3
```

Related Commands

Command	Description
clear ipv6 ospf	Deletes all IPv6 settings in the OSPFv3 routing process.
ipv6 ospf priority	Determines the designated router for a specified network.

ipv6 route

To add an IPv6 route to the IPv6 routing table, use the **ipv6 route** command in global configuration mode. To remove an IPv6 default route, use the **no** form of this command.

ipv6 route *if_name ipv6-prefix/prefix-length ipv6-address* [*administrative-distance* | **tunneled**]

no ipv6 route *if_name ipv6-prefix/prefix-length ipv6-address* [*administrative-distance* | **tunneled**]

Syntax Description

administrative-distance	(Optional) The administrative distance of the route. The default value is 1, which gives static routes precedence over any other type of routes except connected routes.
if_name	The name of the interface for which the route is being configured.
ipv6-address	The IPv6 address of the next hop that can be used to reach the specified network.
ipv6-prefix	The IPv6 network that is the destination of the static route. This argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal format using 16-bit values between colons.
prefix-length	The length of the IPv6 prefix. This value indicates how many of the high-order, contiguous bits of the address comprise the network portion of the prefix. The slash (/) must precede the prefix length.
tunneled	(Optional) Specifies the route as the default tunnel gateway for VPN traffic.

Defaults

By default, the administrative distance is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(1)	Support for transparent firewall mode was introduced.

Usage Guidelines

Use the **show ipv6 route** command to view the contents of the IPv6 routing table.

You can define a separate default route for tunneled traffic along with the standard default route. When you create a default route with the **tunneled** option, all traffic from a tunnel terminating on the ASA that cannot be routed using learned or static routes, is sent to this route. For traffic emerging from a tunnel, this route overrides over any other configured or learned default routes.

The following restrictions apply to default routes with the **tunneled** option:

- Do not enable unicast RPF (**ip verify reverse-path** command) on the egress interface of the tunneled route. Enabling uRPF on the egress interface of a tunneled route causes the session to fail.
- Do not enable TCP intercept on the egress interface of the tunneled route. Doing so causes the session to fail.
- Do not use the VoIP inspection engines (CTIQBE, H.323, GTP, MGCP, RTSP, SIP, or SKINNY), the DNS inspect engine, or the DCE RPC inspection engine with tunneled routes. These inspection engines ignore the tunneled route.

You cannot define more than one default route with the **tunneled** option; ECMP for tunneled traffic is not supported.

Examples

The following example routes packets for network 7fff::0/32 to a networking device on the inside interface at 3FFE:1100:0:CC00::1 with an administrative distance of 110:

```
hostname(config)# ipv6 route inside 7fff::0/32 3FFE:1100:0:CC00::1 110
```

Related Commands

Command	Description
debug ipv6 route	Displays debugging messages for IPv6 routing table updates and route cache updates.
show ipv6 route	Displays the current contents of the IPv6 routing table.

ipv6 router ospf

To create an OSPFv3 routing process and enter IPv6 router configuration mode, use the **ipv6 router ospf** command in global configuration mode.

ipv6 router ospf *process-id*

Syntax Description

process-id	Specifies the internal identification, which is locally assigned and can be a positive integer from 1 to 65535. The number used is the number that is assigned administratively when you enable the OSPFv3 for IPv6 routing process.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **ipv6 router ospf** command is the global configuration command for OSPFv3 routing processes running on the ASA. After you enter the **ipv6 router ospf** command, the command prompt appears as (config-rtr)#, indicating that you are in IPv6 router configuration mode.

When using the **no ipv6 router ospf** command, you do not need to specify optional arguments unless they provide necessary information. The **no ipv6 router ospf** command terminates the OSPFv3 routing process specified by its *process-id* argument. You assign the *process-id* value locally on the ASA. You must assign a unique value for each OSPFv3 routing process. You can use a maximum of two processes.

Use the **ipv6 router ospf** command in IPv6 router configuration mode to configure OSPFv3 routing processes with the following OSPFv3-specific options:

- **area**—Configures OSPFv3 area parameters. Supported parameters include the area ID as a decimal value from 0 to 4294967295 and the area ID in the IP address format of **A.B.C.D**.
- **default**—Sets a command to its default value. The **originate** parameter distributes the default route.
- **default-information**—Controls distribution of default information.
- **distance**—Defines the OSPFv3 route administrative distance based on the route type. Supported parameters include the administrative distance with values from 1 to 254 and **ospf** for the OSPF distance.

- **exit—**Exits IPv6 router configuration mode.
- **ignore**—Suppresses the sending of syslog messages with the **lsa** parameter when the router receives a link-state advertisement (LSA) for Type 6 Multicast OSPF (MOSPF) packets.
- **log-adjacency-changes**—Configures the router to send a syslog message when an OSPFv3 neighbor goes up or down. With the **detail** parameter, all state changes are logged.
- **passive-interface**—Suppresses routing updates on an interface with the following parameters:
  - **GigabitEthernet**—Specifies the GigabitEthernet IEEE 802.3z interface.
  - **Management**—Specifies the management interface.
  - **Port-channel**—Specifies the Ethernet channel of an interface.
  - **Redundant**—Specifies the redundant interface.
  - **default**—Suppresses routing updates on all interfaces.
- **redistribute**—Configures the redistribution of routes from one routing domain into another according to the following parameters:
  - **connected**—Specifies connected routes.
  - **ospf**—Specifies OSPF routes.
  - **static**—Specifies static routes.
- **router-id**—Creates a fixed router ID for a specified process with the following parameters:
  - **A.B.C.D**—Specifies the OSPF router ID in IP address format.
  - **cluster-pool**—Configures an IP address pool when Layer 3 clustering is configured.
- **summary-prefix**—Configures IPv6 address summaries with valid values from 0 to 128. The **X:X:X:X::X/** parameter specifies the IPv6 prefix.
- **timers—**Adjusts routing timers with the following parameters:
  - **lsa**—Specifies OSPF LSA timers.
  - **pacing**—Specifies OSPF pacing timers.
  - **throttle**—Specifies OSPF throttle timers.

Examples

The following example enables an OSPFv3 routing process and enters IPv6 router configuration mode:

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)#
```

Related Commands

Command	Description
clear ipv6 ospf	Removes all IPv6 settings in the OSPFv3 routing process.
debug ospfv3	Provides debugging information for troubleshooting OSPFv3 routing processes.

ipv6-address-pool (tunnel-group general attributes mode)

To specify a list of IPv6 address pools for allocating addresses to remote clients, use the **ipv6-address-pool** command in tunnel-group general-attributes configuration mode. To eliminate IPv6 address pools, use the **no** form of this command.

ipv6-address-pool [(*interface_name*)] *ipv6_address_pool1* [*...ipv6_address_pool6*]

no ipv6-address-pool [(*interface_name*)] *ipv6_address_pool1* [*...ipv6_address_pool6*]

Syntax Description

interface_name	(Optional) Specifies the interface to be used for the address pool.
ipv6_address_pool	Specifies the name of the address pool configured with the **ipv6 local pool** command. You can specify up to six local address pools.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You can enter multiples of each of these commands, one per interface. If an interface is not specified, then the command specifies the default for all interfaces that are not explicitly referenced.

The IPv6 address-pool settings in the group-policy **ipv6-address-pools** command override the IPv6 address pool settings in the tunnel group **ipv6-address-pool** command.

The order in which you specify the pools is significant. The ASA allocates addresses from these pools in the order in which the pools appear in this command.

Examples

The following example entered in tunnel-group general-attributes configuration mode, specifies a list of IPv6 address pools for allocating addresses to remote clients for an IPsec remote access tunnel group test:

```
hostname(config)# tunnel-group test type remote-access
hostname(config)# tunnel-group test general-attributes
hostname(config-tunnel-general)# ipv6-address-pool (inside) ipv6addrpool1 ipv6addrpool2
ipv6addrpool3
```

```
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
ipv6-address-pools	Configures the IPv6 address pools settings for the group policy, which override those settings for the tunnel group.
ipv6 local pool	Configures IP address pools to be used for VPN remote access tunnels.
clear configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group	Configures a tunnel group.

ipv6-address-pools

To specify a list of up to six IPv6 address pools from which to allocate addresses to remote clients, use the **ipv6-address-pools** command in group-policy attributes configuration mode. To remove the attribute from the group policy and enable inheritance from other sources of group policy, use the **no** form of this command.

ipv6-address-pools value *ipv6_address_pool1* [*...ipv6_address_pool6*]

no ipv6-address-pools value *ipv6_address_pool1* [*...ipv6_address_pool6*]

ipv6-address-pools none

no ipv6-address-pools none

Syntax Description

ipv6_address_pool	Specifies the names of the up to six IPv6 address pools configured with the **ipv6 local pool** command. Use spaces to separate the IPv6 address pool names.
none	Specifies that no IPv6 address pools are configured and disables inheritance from other sources of group policy.
value	Specifies a list of up to six IPv6 address pools from which to assign addresses.

Defaults

By default, the IPv6 address pools attribute is not configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

To configure IPv6 address pools, use the **ipv6 local pool** command.

The order in which you specify the pools in the **ipv6-address-pools** command is significant. The ASA allocates addresses from these pools in the order in which the pools appear in this command.

The **ipv6-address-pools none** command disables this attribute from being inherited from other sources of policy, such as the DefaultGrpPolicy. The **no ipv6-address-pools none** command removes the **ipv6-address-pools none** command from the configuration, restoring the default value, which is to allow inheritance.

Examples

The following example, entered in group-policy attributes configuration mode, configures an IPv6 address pool named firstipv6pool for use in allocating addresses to remote clients, then associates that pool with GroupPolicy1:

```
hostname(config)# ipv6 local pool firstipv6pool 2001:DB8::1000/32 100
hostname(config)# group-policy GroupPolicy1 attributes
hostname(config-group-policy)# ipv6-address-pools value firstipv6pool
hostname(config-group-policy)#
```

Related Commands

Command	Description
ipv6 local pool	Configures an IPv6 address pool to be used for VPN group policies.
clear configure group-policy	Clears all configured group policies.
show running-config group-policy	Shows the configuration for all group policies or for a particular group policy.

ipv6-split-tunnel-policy

To set a IPv6 split tunneling policy, use the **ipv6-split-tunnel-policy** command in group-policy configuration mode. To remove the ipv6-split-tunnel-policy attribute from the running configuration, use the **no** form of this command. This enables inheritance of a value for IPv6 split tunneling from another group policy.

IPv6 split tunneling lets a remote-access VPN client conditionally direct packets over an IPsec or SSL IPv6 tunnel in encrypted form, or to a network interface in cleartext form. With IPv6 split-tunneling enabled, packets not bound for destinations on the other side of the IPsec or SSL VPN tunnel endpoint do not have to be encrypted, sent across the tunnel, decrypted, and then routed to a final destination.

This command applies IPv6 split tunneling policy to a specific network.

ipv6-split-tunnel-policy {tunnelall | tunnelspecified | excludespecified}

no ipv6-split-tunnel-policy

Syntax Description

excludespecified	Defines a list of networks to which traffic goes in the clear. This feature is useful for remote users who want to access devices on their local network, such as printers, while they are connected to the corporate network through a tunnel.
ipv6-split-tunnel-policy	Indicates that you are setting rules for tunneling traffic.
tunnelall	Specifies that no traffic goes in the clear or to any other destination than the ASA. Remote users reach internet networks through the corporate network and do not have access to local networks.
tunnelspecified	Tunnels all traffic from or to the specified networks. This option enables split tunneling. It lets you create a network list of addresses to tunnel. Data to all other addresses travels in the clear, and is routed by the remote user's internet service provider.

Defaults

IPv6 split tunneling is disabled by default, which is tunnelall.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

IPv6 split tunneling is primarily a traffic management feature, not a security feature. In fact, for optimum security, we recommend that you not enable IPv6 split tunneling.

Examples

The following example shows how to set a split tunneling policy of tunneling only specified networks for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipv6-split-tunnel-policy tunnelspecified
```

Related Commands

Command	Description
split-tunnel-network-list none	Indicates that no access list exists for split tunneling. All traffic travels across the tunnel.
split-tunnel-network-list value	Identifies the access list the ASA uses to distinguish networks that require tunneling and those that do not.

ipv6-vpn-address-assign

To specify a method for assigning IPv6 addresses to remote access clients, use the **ipv6-vpn-addr-assign** command in global configuration mode. To remove the attribute from the configuration, use the **no** version of this command. To remove all configured VPN address assignment methods from the ASA, user the **no** version of this command. without arguments.

ipv6-vpn-addr-assign {**aaa | local** }

no ipv6-vpn-addr-assign {**aaa | local** }

Syntax Description

aaa	The ASA retrieves addresses from an external or internal (LOCAL) AAA (authentication, authorization, and accounting) server on a per-user basis. If you are using an authentication server that has IP addresses configured, we recommend using this method.
local	The ASA distributes IPv6 addresses from internally configured address pools.

Defaults

Both the AAA and local vpn address assignment options are enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The ASA can use either the AAA or local methods for assigning IPv6 addresses to remote access clients. If you configure more than one address assignment method, the ASA searches each of the options until it finds an IPv6 address.

Examples

The following example shows how to configure AAA as the address assignment method.

```
Example:
hostname(config)# ipv6-vpn-addr-assign aaa
```

The following example shows how to configure the use of a local address pool for the address assignment method.

Example:

```
hostname(config)# no ipv6-vpn-addr-assign local
```

Related Commands

Command	Description
ipv6 local pool	Configures an IPv6 address pool to be used for VPN group policies.
show running-config group-policy	Shows the configuration for all group policies or for a particular group policy.
vpn-addr-assign	Specifies a method for assigning IPv4 addresses to remote access clients.

ipv6-vpn-filter

To specify the name of the IPv6 ACL to use for VPN connections, use the **ipv6-vpn-filter** command in group-policy configuration or username configuration mode. To remove the ACL, including a null value created by issuing the **ipv6-vpn-filter none** command, use the **no** form of this command.

ipv6-vpn-filter {**value** *IPV6-ACL-NAME* | **none**}

no ipv6-vpn-filter

Syntax Description

none	Indicates that there is no access list. Sets a null value, thereby disallowing an access list. Prevents inheriting an access list from another group policy.
value *IPV6-ACL-NAME*	Provides the name of the previously configured access list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	The **ipv6-vpn-filter** command was deprecated. The **vpn-filter** command should be used to configure unified filters with either IPv4 and IPv6 entries. This IPv6 filter will only be used if there are no IPv6 entries in the access list specified by the **vpn-filter** command.
9.1(4)	The **ipv6-vpn-filter** command has been disabled, only the "no" form of the command will be allowed. The **vpn-filter** command should be used to configure unified filters for IPv4 and IPv6 entries. If this command is mistakenly used to specify IPv6 ACLs the connection will be terminated.

Usage Guidelines

Clientless SSL VPN does not use the ACL defined in the **ipv6-vpn-filter** command.

The **no** option allows inheritance of a value from another group policy. To prevent inheriting values, use the **ipv6-vpn-filter none** command.

You configure ACLs to permit or deny various types of traffic for this user or group policy. You then use the **ipv6-vpn-filter** command to apply those ACLs.

Examples

The following example shows how to set a filter that invokes an access list named ipv6_acl_vpn for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipv6-vpn-filter value ipv6_acl_vpn
```

Related Commands

Command	Description
access-list	Creates an access list, or uses a downloadable access list.
vpn-filter	Specifies the names of an IPv4 or IPv6 ACL to use for VPN connections.

CHAPTER 28

isakmp am-disable through issuer-name Commands

isakmp am-disable

To disable inbound aggressive mode connections, use the **isakmp am-disable** command in global configuration mode. To enable inbound aggressive mode connections, use the **no** form of this command.

isakmp am-disable

no isakmp am-disable

Syntax Description

This command has no arguments or keywords.

Defaults

The default value is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp am-disable** command replaced it.

Examples

The following example, entered in global configuration mode, disables inbound aggressive mode connections:

```
hostname(config)# isakmp am-disable
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp disconnect-notify

To enable disconnect notification to peers, use the **isakmp disconnect-notify** command in global configuration mode. To disable disconnect notification, use the **no** form of this command.

isakmp disconnect-notify

no isakmp disconnect-notify

Syntax Description

This command has no arguments or keywords.

Defaults

The default value is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp disconnect-notify** command replaced it.

Examples

The following example, entered in global configuration mode, enables disconnect notification to peers:

```
hostname(config)# isakmp disconnect-notify
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp enable

To enable ISAKMP negotiation on the interface on which the IPsec peer communicates with the ASA, use the **isakmp enable** command in global configuration mode. To disable ISAKMP on the interface, use the **no** form of this command.

isakmp enable *interface-name*

no isakmp enable *interface-name*

Syntax Description

interface-name	Specifies the name of the interface on which to enable or disable ISAKMP negotiation.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp enable** command replaced it.

Examples

The following example, entered in global configuration mode, shows how to disable ISAKMP on the inside interface:

```
hostname(config)# no isakmp enable inside
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp identity

To set the Phase 2 ID to be sent to the peer, use the **isakmp identity** command in global configuration mode. To return to the default setting, use the **no** form of this command.

isakmp identity {**address** | **hostname** | **key-id** *key-id-string* | **auto**}

no isakmp identity {**address** | **hostname** | **key-id** *key-id-string* | **auto**}

Syntax Description

address	Uses the IP address of the host exchanging ISAKMP identity information.
auto	Determines ISKMP negotiation by connection type; IP address for the preshared key or certificate DN for certificate authentication.
hostname	Uses the fully qualified domain name of the host exchanging ISAKMP identity information (default). This name comprises the hostname and the domain name.
key-id *key_id_string*	Specifies the string used by the remote peer to look up the preshared key.

Defaults

The default ISAKMP identity is the **isakmp identity hostname** command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp identity** command replaced it.

Examples

The following example, entered in global configuration mode, enables ISAKMP negotiation on the interface for communicating with the IPsec peer, depending on connection type:

```
hostname(config)# isakmp identity auto
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.

Command	Description
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp ipsec-over-tcp

To enable IPsec over TCP, use the **isakmp ipsec-over-tcp** command in global configuration mode. To disable IPsec over TCP, use the **no** form of this command.

isakmp ipsec-over-tcp [**port** *port1...port10*]

no isakmp ipsec-over-tcp [**port** *port1...port10*]

Syntax Description

port *port1...port10*	(Optional) Specifies the ports on which the device accepts IPsec over TCP connections. You can list up to 10 ports. Port numbers can be in the range of 1-65535. The default port number is 10000.

Defaults

The default value is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp ipsec-over-tcp** command replaces it.

Examples

This example, entered in global configuration mode, enables IPsec over TCP on port 45:

```
hostname(config)# isakmp ipsec-over-tcp port 45
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp keepalive

To configure IKE keepalives, use the **isakmp keepalive** command in tunnel-group ipsec-attributes configuration mode. To return the keepalive parameters to enabled with default threshold and retry values, use the **no** form of this command.

isakmp keepalive [**threshold** *seconds* | **infinite**] [**retry** *seconds*] [**disable**]

no isakmp keepalive disable [**threshold** *seconds* | **infinite**] [**retry** *seconds*] [**disable**]

Syntax Description

disable	Disables IKE keepalive processing, which is enabled by default.
infinite	The ASA never initiates keepalive monitoring.
retry *seconds*	Specifies the interval in seconds between retries after a keepalive response has not been received. The range is 2-10 seconds. The default is 2 seconds.
threshold *seconds*	Specifies the number of seconds that the peer can idle before beginning keepalive monitoring. The range is 10-3600 seconds. The default is 10 seconds for a LAN-to-LAN group, and 300 second for a remote access group.

Defaults

The default for a remote access group is a threshold of 300 seconds and a retry of 2 seconds.

For a LAN-to-LAN group, the default is a threshold of 10 seconds and a retry of 2 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In every tunnel group, IKE keepalives are enabled by default with default threshold and retry values. You can apply this attribute only to IPsec remote access and IPsec LAN-to-LAN tunnel group types.

Examples

The following example entered in tunnel-group ipsec-attributes configuration mode, configures IKE DPD, establishes a threshold of 15, and specifies a retry interval of 10 for the IPsec LAN-to-LAN tunnel group with the IP address 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPSec_L2L
```

```
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# isakmp keepalive threshold 15 retry 10
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel group IPsec attributes for this group.

isakmp nat-traversal

To enable NAT traversal globally, check that ISAKMP is enabled (you can enable it with the **isakmp enable** command) in global configuration mode and then use the **isakmp nat-traversal** command. If you have enabled NAT traversal, you can disable it with the **no** form of this command.

isakmp nat-traversal *natkeepalive*

no isakmp nat-traversal *natkeepalive*

Syntax Description

natkeepalive	Sets the NAT keepalive interval, from 10 to 3600 seconds. The default is 20 seconds.

Defaults

By default, NAT traversal (**isakmp nat-traversal** command) is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp nat-traversal** command replaced it.

Usage Guidelines

Network Address Translation (NAT), including Port Address Translation (PAT), is used in many networks where IPsec is also used, but there are a number of incompatibilities that prevent IPsec packets from successfully traversing NAT devices. NAT traversal enables ESP packets to pass through one or more NAT devices.

The ASA supports NAT traversal as described by Version 2 and Version 3 of the IETF "UDP Encapsulation of IPsec Packets" draft, available at http://www.ietf.org/html.charters/ipsec-charter.html, and NAT traversal is supported for both dynamic and static crypto maps.

This command enables NAT-T globally on the ASA. To disable in a crypto-map entry, use the **crypto map set nat-t-disable** command.

Examples

The following example, entered in global configuration mode, enables ISAKMP and then enables NAT traversal with an interval of 30 seconds:

```
hostname(config)# isakmp enable
hostname(config)# isakmp nat-traversal 30
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp policy authentication

To specify an authentication method within an IKE policy, use the **isakmp policy authentication** command in global configuration mode. To remove the ISAKMP authentication method, use the **clear configure** command.

isakmp policy *priority* **authentication** {**crack** | **pre-share** | **rsa-sig**}

Syntax Description

crack	Specifies IKE Challenge/Response for Authenticated Cryptographic Keys (CRACK) as the authentication method.
pre-share	Specifies preshared keys as the authentication method.
priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
rsa-sig	Specifies RSA signatures as the authentication method. RSA signatures provide non-repudiation for the IKE negotiation. This means you can prove to a third party whether or not you had an IKE negotiation with the peer.

Defaults

The default ISAKMP policy authentication is the **pre-share** option.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

IKE policies define a set of parameters for IKE negotiation. If you specify RSA signatures, you must configure the ASA and its peer to obtain certificates from a certification authority (CA). If you specify preshared keys, you must separately configure these preshared keys within the ASA and its peer.

Examples

The following example, entered in global configuration mode, sets the authentication method of RSA signatures to be used within the IKE policy with the priority number of 40:

```
hostname(config)# isakmp policy 40 authentication rsa-sig
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp policy encryption

To specify the encryption algorithm to use within an IKE policy, use the **isakmp policy encryption** command in global configuration mode. To reset the encryption algorithm to the default value, use the **no** form of this command.

isakmp policy *priority* **encryption** {**aes | aes-192| aes-256 | des | 3des**}

no isakmp policy *priority* **encryption** {**aes | aes-192| aes-256 | des | 3des**}

Syntax Description

3des	Specifies that the triple DES encryption algorithm be used in the IKE policy.
aes	Specifies that the encryption algorithm to use in the IKE policy is AES with a 128-bit key.
aes-192	Specifies that the encryption algorithm to use in the IKE policy is AES with a 192-bit key.
aes-256	Specifies that the encryption algorithm to use in the IKE policy is AES with a 256-bit key.
des	Specifies that the encryption algorithm to use in the IKE policy is 56-bit DES-CBC.
priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.

Defaults

The default ISAKMP policy encryption is **3des**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp policy encryption** command replaced it.

Examples

The following example, entered in global configuration mode, sets 128-bit key AES encryption as the algorithm to be used within the IKE policy with the priority number of 25:

```
hostname(config)# isakmp policy 25 encryption aes
```

The following example, entered in global configuration mode, sets the 3DES algorithm to be used within the IKE policy with the priority number of 40:

```
hostname(config)# isakmp policy 40 encryption 3des
hostname(config)#
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp policy group

To specify the Diffie-Hellman group for an IKE policy, use the **isakmp policy group** command in global configuration mode.To reset the Diffie-Hellman group identifier to the default value, use the **no** form of this command.

isakmp policy *priority* **group** {**1** | **2** | **5**}

no isakmp policy *priority* **group**

Syntax Description

group 1	Specifies that the 768-bit Diffie-Hellman group be used in the IKE policy. This is the default value.
group 2	Specifies that the 1024-bit Diffie-Hellman group 2 be used in the IKE policy.
group 5	Specifies that the 1536-bit Diffie-Hellman group 5 be used in the IKE policy.
priority	Uniquely identifies the Internet Key Exchange (IKE) policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.

Defaults

The default is group 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced. Group 7 was added.
7.2(1)	This command was deprecated. The **crypto isakmp policy group** command replaced it.
8.0(4)	The **group 7** command option was deprecated. Attempts to configure group 7 will generate an error message and use group 5 instead.

Usage Guidelines

IKE policies define a set of parameters to use during IKE negotiation.

There are three group options: 768-bit (DH Group 1), 1024-bit (DH Group 2), and 1536-bit (DH Group 5). The 1024-bit and 1536-bit Diffie-Hellman Groups provide stronger security, but require more CPU time to execute.

Note The Cisco VPN Client Version 3.x or higher requires ISAKMP policy to have DH group 2 configured. (If you have DH group 1 configured, the Cisco VPN Client cannot connect.)

AES support is available on ASAs licensed for VPN-3DES only. Due to the large key sizes provided by AES, ISAKMP negotiation should use Diffie-Hellman (DH) group 5 instead of group 1 or group 2. This is done with the **isakmp policy priority group 5** command.

Examples

The following example, entered in global configuration mode, sets group 2, the 1024-bit Diffie Hellman, to use for the IKE policy with the priority number of 40:

```
hostname(config)# isakmp policy 40 group 2
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp policy hash

To specify the hash algorithm for an IKE policy, use the **isakmp policy hash** command in global configuration mode.To reset the hash algorithm to the default value of SHA-1, use the **no** form of this command.

isakmp policy *priority* **hash** {**md5** | **sha**}

no isakmp policy *priority* **hash**

Syntax Description

md5	Specifies that MD5 (HMAC variant) be used as the hash algorithm in the IKE policy.
priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
sha	Specifies that SHA-1 (HMAC variant) be used as the hash algorithm in the IKE policy.

Defaults

The default hash algorithm is SHA-1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp policy hash** command replaces it.

Usage Guidelines

IKE policies define a set of parameters to be used during IKE negotiation.

There are two hash algorithm options: SHA-1 and MD5. MD5 has a smaller digest and is considered to be slightly faster than SHA-1.

Examples

The following example, entered in global configuration mode, specifies that the MD5 hash algorithm be used within the IKE policy, with the priority number of 40:

```
hostname(config)# isakmp policy 40 hash md5
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp policy lifetime

To specify the lifetime of an IKE security association before it expires, use the **isakmp policy lifetime** command in global configuration mode. To reset the security association lifetime to the default value of 86,400 seconds (one day), use the **no** form of this command .

isakmp policy *priority* **lifetime** *seconds*

no isakmp policy *priority* **lifetime**

Syntax Description

priority	Uniquely identifies the IKE policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.
seconds	Specifies how many seconds each security association should exist before expiring. To propose a finite lifetime, use an integer from 120 to 2147483647 seconds. Use 0 seconds for an infinite lifetime.

Defaults

The default value is 86,400 seconds (one day).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp policy lifetime** command replaced it.

Usage Guidelines

When IKE begins negotiations, it seeks to agree upon the security parameters for its own session. Then the security association at each peer refers to the agreed-upon parameters. The peers retain the security association until the lifetime expires. Before a security association expires, subsequent IKE negotiations can use it, which can save time when setting up new IPsec security associations. The peers negotiate new security associations before current security associations expire.

With longer lifetimes, the ASA sets up future IPsec security associations more quickly. Encryption strength is great enough to ensure security without using very fast rekey times, on the order of every few minutes. We recommend that you accept the default, but you can specify an infinite lifetime if the peer does not propose a lifetime.

Note If the IKE security association is set to an infinite lifetime, but the peer proposes a finite lifetime, then the negotiated finite lifetime from the peer is used.

Examples

The following example, entered in global configuration mode, sets the lifetime of the IKE security association to 50,4000 seconds (14 hours) within the IKE policy with the priority number of 40:

```
hostname(config)# isakmp policy 40 lifetime 50400
```

The following example, entered in global configuration mode, sets the IKE security association to an infinite lifetime.

```
hostname(config)# isakmp policy 40 lifetime 0
```

Related Commands

clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

isakmp reload-wait

To enable waiting for all active sessions to voluntarily terminate before rebooting the ASA, use the **isakmp reload-wait** command in global configuration mode. To disable waiting for active sessions to terminate and to proceed with a reboot of the ASA, use the **no** form of this command.

isakmp reload-wait

no isakmp reload-wait

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was deprecated. The **crypto isakmp reload-wait** command replaced it.

Examples

The following example, entered in global configuration mode, tells the ASA to wait until all active sessions have terminated before rebooting:

```
hostname(config)# isakmp reload-wait
```

Related Commands

Command	Description
clear configure isakmp	Clears all the ISAKMP configuration.
clear configure isakmp policy	Clears all ISAKMP policy configuration.
clear isakmp sa	Clears the IKE runtime SA database.
show running-config isakmp	Displays all the active configuration.

issuer

To specify the security device that is sending assertions to a SAML-type SSO server, use the **issuer** command in webvpn-sso-saml configuration mode for that specific SAML type. To remove the issuer name, use the **no** form of this command.

issuer *identifier*

no issuer [*identifier*]

Syntax Description

identifier	Specifies a security device name, usually the hostname of the device. An identifier must be less than 65 alphanumeric characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn-sso-saml configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

SSO support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SAML POST-type SSO server and the SiteMinder-type of SSO server.

This command applies only to SAML-type SSO Servers.

Examples

The following example specifies the issuer name for a security device named asa1.example.com:

```
hostname(config-webvpn)# sso server myhostname type saml-v1.1-post
hostname(config-webvpn-sso-saml# issuer asa1.example.com
hostname(config-webvpn-sso-saml#
```

Related Commands

Command	Description
assertion-consumer-url	Specifies the URL that the security device uses to contact the SAML-type SSO server assertion consumer service.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
trustpoint	Specifies a trustpoint name that contains the certificate to use to sign the SAML-type browser assertion.

issuer-name

To specify the issuer name DN of all issued certificates, use the **issuer-name** command in local certificate authority (CA) server configuration mode. To remove the subject DN from the certificate authority certificate, use the **no** form of this command.

issuer-name *DN-string*

no issuer-name *DN-string*

Syntax Description

DN-string	Specifies the distinguished name of the certificate, which is also the subject name DN of the self-signed CA certificate. Use commas to separate attribute-value pairs. Insert quotation marks around any value that contains a comma. An issuer name must be less than 500 alphanumeric characters.

Defaults

The default issuer name is cn=*hostame.domain-name*, for example cn=asa.example.com.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
7.3(1)	This command was introduced.
8.0(2)	Support for quotation marks was added to retain commas in *DN-string* values.

Usage Guidelines

This command specifies the issuer name that appears on any certificate created by the local CA server. Use this optional command if you want the issuer name to be different from the default CA name.

Note This issuer name configuration cannot be changed after you have enabled the CA server and generated the certificate by issuing the **no shutdown** command.

Examples

The following example configures certificate authentication:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# issuer-name cn=asa-ca.example.com,ou=Eng,o=Example,c="cisco
systems, inc."
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to ca server configuration mode commands, which allow you to configure and manage the local CA.
keysize	Specifies the size of the public and private keys generated at certificate enrollment.
lifetime	Specifies the lifetime of the CA certificate and issued certificates.
show crypto ca server	Displays the characteristics of the local CA.
show crypto ca server cert-db	Displays local CA server certificates.

CHAPTER 29

java-trustpoint through kill Commands

java-trustpoint

To configure the WebVPN Java object signing facility to use a PKCS12 certificate and keying material from a specified trustpoint location, use the **java-trustpoint** command in webvpn configuration mode.To remove a trustpoint for Java object signing, use the **no** form of this command.

java-trustpoint *trustpoint*

no java-trustpoint

Syntax Description

trustpoint	Specifies the trustpoint location configured by the **crypto ca import** command.

Defaults

By default, a trustpoint for Java object signing is set to none.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(2)	This command was introduced.

Usage Guidelines

A trustpoint is a representation of a certificate authority (CA) or identity key pair. For the **java-trustpoint** command, the given trustpoint must contain the X.509 certificate of the application signing entity, the RSA private key corresponding to that certificate, and a certificate authority chain extending up to a root CA. This is typically achieved by using the **crypto ca import** command to import a PKCS12 formatted bundle. You can obtain a PKCS12 bundle from a trusted CA authority or you can manually create one from an existing X.509 certificate and an RSA private key using open source tools such as openssl.

Note An uploaded certificate cannot be used to sign Java objects that are embedded with packages (for example, the CSD package).

Examples

The following example first configures a new trustpoint, then configures it for WebVPN Java object signing:

```
hostname(config)# crypto ca import mytrustpoint pkcs12 mypassphrase
Enter the base 64 encoded PKCS12.
End with the word "quit" on a line by itself.
[ PKCS12 data omitted ]
```

```
quit
INFO: Import PKCS12 operation completed successfully.
hostname(config)#
```

The following example configures the new trustpoint for signing WebVPN Java objects:

```
hostname(config)# webvpn
hostname(config)# java-trustpoint mytrustpoint
hostname(config)#
```

Related Commands

Command	Description
crypto ca import	Imports the certificate and key pair for a trustpoint using PKCS12 data.

join-failover-group

To assign a context to a failover group, use the **join-failover-group** command in context configuration mode. To restore the default setting, use the **no** form of this command.

join-failover-group *group_num*

no join-failover-group *group_num*

Syntax Description

group_num	Specifies the failover group number.

Defaults

Failover group 1.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Context configuration	•	•	—	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The admin context is always assigned to failover group 1. You can use the **show context detail** command to display the failover group and context association.

Before you can assign a context to a failover group, you must create the failover group with the **failover group** command in the system context. Enter this command on the unit where the context is in the active state. By default, unassigned contexts are members of failover group 1, so if the context had not been previously assigned to a failover group, you should enter this command on the unit that has failover group 1 in the active state.

You must remove all contexts from a failover group, using the **no join-failover-group** command, before you can remove a failover group from the system.

Examples

The following example assigns a context named ctx1 to failover group 2:

```
hostname(config)# context ctx1
hostname(config-context)# join-failover-group 2
hostname(config-context)# exit
```

Related Commands

Command	Description
context	Enters context configuration mode for the specified context.
failover group	Defines a failover group for Active/Active failover.
show context detail	Displays context detail information, including name, class, interfaces, failover group association, and configuration file URL.

jumbo-frame reservation

To enable jumbo frames for supported models, use the **jumbo-frame reservation** command in global configuration mode. To disable jumbo frames, use the **no** form of this command.

Note Changes in this setting require you to reboot the ASA.

jumbo-frame reservation

no jumbo-frame reservation

Syntax Description

This command has no arguments or keywords.

Defaults

Jumbo frame reservation is disabled by default.

Jumbo frames are supported by default on the ASASM; you do not need to use this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.1(1)	This command was introduced for the ASA 5580.
8.2(5)/8.4(1)	We added support for the ASA 5585-X.
8.6(1)	We added support for the ASA 5512-X through ASA 5555-X.

Usage Guidelines

A jumbo frame is an Ethernet packet larger than the standard maximum of 1518 bytes (including Layer 2 header and FCS), up to 9216 bytes. Jumbo frame support requires extra memory, which might limit the maximum use of other features, such as access lists.

Jumbo frames are not supported on the Management *n*/*n* interface.

Be sure to set the MTU for each interface that needs to transmit jumbo frames to a higher value than the default 1500; for example, set the value to 9000 using the **mtu** command. For the ASASM, you do not need to set the **jumbo-frame** reservation command; it supports jumbo frames by default. Just set the MTU to the desired value.

Also, be sure to configure the MSS (maximum segment size) value for TCP when using jumbo frames. The MSS should be 120 bytes less than the MTU. For example, if you configure the MTU to be 9000, then the MSS should be configured to 8880. You can configure the MSS with the **sysopt connection tcpmss** command.

Both the primary and the secondary units require a reboot so that the failover pair supports jumbo frames. To avoid downtime, do the following:

- Issue the command on the active unit.
- Save the running configuration on the active unit.
- Reboot the primary and secondary units, one at a time.

Examples

The following example enables jumbo frame reservation, saves the configuration, and reloads the ASA:

```
hostname(config)# jumbo-frame reservation
WARNING: this command will take effect after the running-config is saved
and the system has been rebooted. Command accepted.

hostname(config)# write memory
Building configuration...
Cryptochecksum: 718e3706 4edb11ea 69af58d0 0a6b7cb5

70291 bytes copied in 3.710 secs (23430 bytes/sec)
[OK]
hostname(config)# reload
Proceed with reload? [confirm] Y
```

Related Commands

Command	Description
mtu	Specifies the maximum transmission unit for an interface.
show jumbo-frame reservation	Shows the current configuration of the **jumbo-frame reservation** command.

kcd-server

To allow the ASA to join an Active Directory domain, use the **kcd-server** command in webvpn configuration mode. To remove the specified behavior for the ASA, use the **no** form of this command.

kcd-server *aaa-server-group_name* **user** *username* **password** *password*

no kcd-server

Syntax Description

user	Specifies the Active Directory user with service level privileges.
password	Specifies the password for the specified user.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Use the **kcd-server** command in webvpn configuration mode to allow the ASA to join an Active Directory domain. The domain controller name and realm are specified in the **aaa-server-groupname** command. The AAA server group has to be a Kerberos server type. The **username** and **password** options do not correspond to a user with Administrator privileges, but they should correspond to a user with service-level privileges on the domain controller. The success or failure status is displayed as the result of this command. The result can also be viewed using the **show webvpn kcd** command.

Kerberos Constrained Delegation, or KCD, in the ASA environment provides WebVPN users Single Sign-on (SSO) access to all web services that are protected by Kerberos. The ASA maintains a credential on behalf of the user (a service ticket) and uses this ticket to authenticate the user to the services.

In order for the **kcd-server** command to function, the ASA must establish a trust relationship between the *source* domain (the domain where the ASA resides) and the *target* or *resource* domain (the domain where the web services reside). The ASA, using its unique format, crosses the certification path from the source to the destination domain and acquires the necessary tickets on behalf of the remote access user to access the services.

This path is called cross-realm authentication. During each phase of cross-realm authentication, the ASA relies on the credentials at a particular domain and the trust relationship with the subsequent domain.

To configure the ASA for cross-realm authentication, you must use the following commands to join the Active Directory domain: **ntp**, **hostname**, **dns domain-lookup, dns server-group**.

Examples

The following example shows the usage of the **kcd-server** command:

```
hostname(config)# aaa-server kcd-grp protocol kerberos
hostname(config-aaa-server-group)# aaa-server kcd-grp host DC
hostname(config-aaa-server-group)# kerberos-realm EXAMPLE.COM
hostname(config)# webvpn
hostname(config-webvpn)# kcd-server kcd-grp user Administrator password Cisco123
hostname(config-aaa-server-group)# exit
hostname(config)#
```

The following is a configuration example of cross-realm authentication, where the Domain Controller is 10.1.1.10 (reachable via inside interface) and the domain name is PRIVATE.NET. Additionally, the Service Account username and password on the domain controller is dcuser and dcuser123! .

```
hostname(config)# config t

-----Create an alias for the Domain Controller-------------

hostname(config)# name 10.1.1.10 DC

----Configure the Name server-----------------------------

hostname(config)# ntp server DC

----Enable a DNS lookup by configuring the DNS server and Domain name --------------

hostname(config)# dns domain-lookup inside
hostname(config)# dns server-group DefaultDNS
hostname(config-dns-server-group)# name-server DC
hostname(config-dns-server-group)# domain-name private.net

----Configure the AAA server group with Server and Realm-------------------------------

hostname(config)# aaa-server KerberosGroup protocol Kerberos
hostname(config-asa-server-group)# aaa-server KerberosGroup (inside) host DC
hostname(config-asa-server-group)# Kerberos-realm PRIVATE.NET

----Configure the Domain Join-----------------------------

hostname(config)# webvpn
hostname(config-webvpn)# kcd-server KerberosGroup username dcuser password dcuser123!
hostname(config)#
```

Related Commands

Command	Description
aaa-server	Enters aaa-server configuration mode, so you can configure AAA server parameters.
aaa-server host	Enters aaa-server host configuration mode, so you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
dns	Specifies the Domain Name Server.
domain-name	Specifies the domain name of the server.

hostname	Specifies the hostname.
ntp	Specifies the transfer protocol.
show aaa-kerberos	Displays server statistics for all AAA Kerberos servers.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

keepout

To present an administrator-defined message rather than a login page for new user sessions (when the ASA undergoes a maintenance or troubleshooting period), use the **keepout** command in webvpn configuration mode. To remove a previously set keepout page, use the **no** version of the command.

keepout

no keepout *string*

Syntax Description

string	An alphanumeric string in double quotation marks.

Defaults

No keepout page.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

When this command is enabled, the clientless WebVPN portal page becomes unavailable. You receive an administrator-defined message stating the unavailability of the portal rather than a login page for the portal. Use the **keepout** command to disable clientless access, but still allow AnyConnect access. You can also use this command to indicate portal unavailability when maintenance is occurring.

Examples

The following example shows how to configure a keepout page:

```
hostname(config)# webvpn
hostname(config-webvpn)# keepout "The system is unavailable until 7:00 a.m. EST."
hostname(config-webvpn)#
```

Related Commands

Command	Description
webvpn	Enters webvpn configuration mode, which lets you configure attributes for clientless SSL VPN connections.

kerberos-realm

To specify the realm name for this Kerberos server, use the **kerberos-realm** command in aaa-server host configuration mode. To remove the realm name, use the **no** form of this command:

kerberos-realm *string*

no kerberos-realm

Syntax Description

string	A case-sensitive, alphanumeric string, up to 64 characters long. Spaces are not permitted in the string. **Note** Kerberos realm names use numbers and upper case letters only. Although the ASA accepts lower case letters in the *string* argument, it does not translate lower case letters to upper case letters. Be sure to use upper case letters only.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for Kerberos servers.

The value of the *string* argument should match the output of the Microsoft Windows **set USERDNSDOMAIN** command when it is run on the Windows 2000 Active Directory server for the Kerberos realm. In the following example, EXAMPLE.COM is the Kerberos realm name:

```
C:\>set USERDNSDOMAIN
USERDNSDOMAIN=EXAMPLE.COM
```

The *string* argument must use numbers and upper case letters only. The **kerberos-realm** command is case sensitive, and the ASA does not translate lower case letters to upper case letters.

Examples

The following sequence shows the **kerberos-realm** command to set the kerberos realm to "EXAMPLE.COM" in the context of configuring a AAA server host:

```
hostname(config)# aaa-server svrgrp1 protocol kerberos
```

```
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# kerberos-realm EXAMPLE.COM
hostname(config-aaa-server-host)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa-server host	Enter AAA server host configuration submode so you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Remove all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

key (aaa-server host)

To specify the server secret value used to authenticate the NAS to the AAA server, use the **key** command in aaa-server host configuration mode. The aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove the key, use the **no** form of this command.

key *key*

no key

Syntax Description

key	An alphanumeric keyword, which can be up to 127 characters long.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configurationj	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The *key* value is a case-sensitive, alphanumeric keyword of up to 127 characters, which is the same value as the key on the TACACS+ server. Any characters over 127 are ignored. The key is used between the client and the server for encrypting data between them. The key must be the same on both the client and server systems.The key cannot contain spaces, but other special characters are allowed. The key (server secret) value authenticates the ASA to the AAA server.

This command is valid only for RADIUS and TACACS+ servers.

Examples

The following example configures a TACACS+ AAA server named “srvgrp1” on host “1.2.3.4,” sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the key as “myexclusivemumblekey.”

```
hostname(config)# aaa-server svrgrp1 protocol tacacs+
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry-interval 7
hostname(config-aaa-server-host)# key myexclusivemumblekey
```

Related Commands

Command	Description
aaa-server host	Enters aaa-server host configuration mode, so that you can configure host-specific AAA server parameters.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays the AAA server configuration.

key (cluster group)

To set an authentication key for control traffic on the cluster control link, use the **key** command in ckuster group configuration mode. To remove the key, use the **no** form of this command.

key *shared_secret*

no key [*shared_secret*]

Syntax Description

shared_secret	Sets the shared secret to an ASCII string from 1 to 63 characters. The shared secret is used to generate the key.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

This command does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

Examples

The following example sets a shared secret:

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# key chuntheunavoidable
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.

Command	Description
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

key config-key password-encryption

To set the passphrase used for generation the encryption key, use the **key config-key password-encryption** command in global configuration mode. To decrypt passwords encrypted with the pass phrase, use the **no** form of this command.

key config-key password-encryption [*new pass phrase* [*old pass phrase*]]

no key config-key password-encryption [*current pass phrase*]

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

When this command is enabled it sets the passphrase used for generation the encryption key. If the pass phrase is configured for the first time, then you will not need to enter the current password. Otherwise, you must enter the current password. The new passphrase must be between 8 and 128 character long. All characters except the back space and double quote will be accepted for the passphrase.

The **write erase** command when followed by the **reload** command will remove the master passphrase if it is lost.

Examples

The following example sets the passphrase used for generating the encryption key:

```
hostname(config)# key config-key password-encryption
```

Related Commands

Command	Description
password encryption aes	Enables password encryption.
write erase	Removes the master passphrase if it is lost when followed by the **reload** command.

keypair

To specify the key pair whose public key is to be certified, use the **keypair** command in crypto ca trustpoint configuration mode. To restore the default setting, use the **no** form of the command.

keypair *name*

no keypair

Syntax Description

name	Specify the name of the key pair.

Defaults

The default setting is not to include the key pair.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca trustpoint configuration mode for the trustpoint central, and specifies a key pair to be certified for the trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# keypair exchange
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode.
crypto key generate dsa	Generates DSA keys.
crypto key generate rsa	Generates RSA keys.
default enrollment	Returns enrollment parameters to their defaults.

keysize

To specify the size of the public and private keys generated by the local Certificate Authority (CA) server at user certificate enrollment, use the **keysize** command in ca-server configuration mode. To reset the keysize to the default length of 1024 bits, use the **no** form of this command.

keysize {**512** | **768** | **1024** | **2048**}

no keysize

Syntax Description

512	Specifies a size of 512 bits for the public and private keys generated at certificate enrollment.
768	Specifies a size of 768 bits for the public and private keys generated at certificate enrollment.
1024	Specifies a size of 1024 bits for the public and private keys generated at certificate enrollment.
2048	Specifies a size of 2048 bits for the public and private keys generated at certificate enrollment.

Defaults

By default, each key in the key pair is 1024 bits long.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca-server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example specifies a key size of 2048 bits for all public and private key pairs generated for users by the local CA server:

```
hostname(config)# crypto ca server
hostname(config-ca-server))# keysize 2048
hostname(config-ca-server)#
```

The following example resets the key size to the default length of 1024 bits for all public and private key pairs generated for users by the local CA server:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no keysize
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca-server configuration mode command set, which allows you to configure and manage the local CA.
issuer-name	Specifies the subject name DN of the certificate authority certificate.
subject-name-default	Specifies a generic subject name DN to be used along with the username in all user certificates issued by a CA server.

keysize server

To specify the size of the public and private keys generated by the local Certificate Authority (CA) server for configuring the size of the CA keypair, use the **keysize server** command in ca-server configuration mode. To reset the keysize to the default length of 1024 bits, use the **no** form of this command.

keysize server{**512** | **768** | **1024** | **2048**}

no keysize server

Syntax Description

512	Specifies a size of 512 bits for the public and private keys generated at certificate enrollment.
768	Specifies a size of 768 bits for the public and private keys generated at certificate enrollment.
1024	Specifies a size of 1024 bits for the public and private keys generated at certificate enrollment.
2048	Specifies a size of 2048 bits for the public and private keys generated at certificate enrollment.

Defaults

By default, each key in the key pair is 1024 bits long.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example specifies a key size of 2048 bits for the CA certificate:

```
hostname(config)# crypto ca server
hostname(config-ca-server))# keysize server 2048
hostname(config-ca-server)#
```

The following example resets the key size to the default length of 1024 bits for the CA certificate:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no keysize server
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca-server configuration mode command set, which allows you to configure and manage the local CA.
issuer-name	Specifies the subject name DN of the certificate authority certificate.
keysize	Specifies the key pair size for the user certificate.
subject-name-default	Specifies a generic subject name DN to be used along with the username in all user certificates issued by a CA server.

kill

To terminate a Telnet session, use the **kill** command in privileged EXEC mode.

kill *telnet_id*

Syntax Description

telnet_id	Specifies the Telnet session ID.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **kill** command lets you terminate a Telnet session. Use the **who** command to see the Telnet session ID. When you kill a Telnet session, the ASA lets any active commands terminate and then drops the connection without warning.

Examples

The following example shows how to terminate a Telnet session with the ID "2". First, the **who** command is entered to display the list of active Telnet sessions. Then the **kill 2** command is entered to terminate the Telnet session with the ID "2".

```
hostname# who
2: From 10.10.54.0

hostname# kill 2
```

Related Commands

Command	Description
telnet	Configures Telnet access to the ASA.
who	Displays a list of active Telnet sessions.

CHAPTER 30

l2tp tunnel hello through log-adjacency-changes Commands

l2tp tunnel hello

To specify the interval between hello messages on L2TP over IPsec connections, use the **l2tp tunnel hello** command in global configuration mode. To reset the interval to the default, use the **no** form of the command:

l2tp tunnel hello *interval*

no l2tp tunnel hello *interval*

Syntax Description

interval	Interval between hello messages in seconds. The Default is 60 seconds. The range is 10 to 300 seconds.

Defaults

The default is 60 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **l2tp tunnel hello** command enables the ASA to detect problems with the physical layer of the L2TP connection. The default is 60 secs. If you configure it to a lower value, connections that are experiencing problems are disconnected earlier.

Examples

The following example configures the interval between hello messages to 30 seconds:

```
hostname(config)# l2tp tunnel hello 30
```

Related Commands

Command	Description
show vpn-sessiondbdetail remote filter protocol L2TPOverIPsec	Displays the details of L2TP connections.
vpn-tunnel-protocol l2tp-ipsec	Enables L2TP as a tunneling protocol for a specific tunnel group.

lacp max-bundle

To specify the maximum number of active interfaces allowed in the EtherChannel channel group, use the **lacp max-bundle** command in interface configuration mode. To set the value to the default, use the **no** form of this command.

lacp max-bundle *number*

no lacp max-bundle

Syntax Description

number	Sets the maximum number of active interfaces allowed in the EtherChannel channel group, between 1 and 8.

Command Default

The default is 8.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

Enter this command for a port-channel interface. The maximum number of active interfaces per channel group is eight; to decrease the number, use this command.

Examples

The following example sets the maximum number of interfaces in the EtherChannel to four:

```
hostname(config)# interface port-channel 1
hostname(config-if)# lacp max-bundle 4
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.

Command	Description
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

lacp port-priority

To set the priority for a physical interface in an EtherChannel, use the **lacp port-priority** command in interface configuration mode. To set the priority to the default, use the **no** form of this command.

lacp port-priority *number*

no lacp port-priority

Syntax Description

number	Sets the priority between 1 and 65535. The higher the number, the lower the priority.

Command Default

The default is 32768.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

Enter this command for a physical interface. The ASA uses this setting to decide which interfaces are active and which are standby if you assign more interfaces than can be used. If the port priority setting is the same for all interfaces, then the priority is determined by the interface ID (slot/port). The lowest interface ID is the highest priority. For example, GigabitEthernet 0/0 is a higher priority than GigabitEthernet 0/1.

If you want to prioritize an interface to be active even though it has a higher interface ID, then set this command to have a lower value. For example, to make GigabitEthernet 1/3 active before GigabitEthernet 0/7, then make the **lacp port-priority** value be 12345 on the 1/3 interface vs. the default 32768 on the 0/7 interface.

If the device at the other end of the EtherChannel has conflicting port priorities, the system priority is used to determine which port priorities to use. See the **lacp system-priority** command.

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group.

Examples

The following example sets a lower port priority for GigabitEthernet 0/2 so it will be used as part of the EtherChannel ahead of GigabitEthernet 0/0 and 0/1:

```
hostname(config)# interface GigabitEthernet0/0
hostname(config-if)# channel-group 1 mode active
hostname(config-if)# interface GigabitEthernet0/1
hostname(config-if)# channel-group 1 mode active
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# lacp port-priority 1234
hostname(config-if)# channel-group 1 mode active
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

lacp system-priority

For EtherChannels, to set the LACP system priority globally for the ASA, use the **lacp system-priority** command in global configuration mode. To set the value to the default, use the **no** form of this command.

lacp system-priority *number*

no lacp system-priority

Syntax Description

number	Sets the LACP system priority, from 1 to 65535. The default is 32768. The higher the number, the lower the priority. This command is global for the ASA.

Command Default

The default is 32768.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

If the device at the other end of the EtherChannel has conflicting port priorities, the system priority is used to determine which port priorities to use. For interface priorities within an EtherChannel, see the **lacp port-priority** command.

Examples

The following example sets the system priority to be higher than the default (a lower number):

```
hostname(config)# lacp system-priority 12345
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.

Command	Description
port-channel load-balance	Configures the load-balancing algorithm.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

ldap attribute-map

To create and name an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names, use the **ldap attribute-map** command in global configuration mode. To remove the map, use the **no** form of this command.

ldap attribute-map *map-name*

no ldap attribute-map *map-name*

Syntax Description

map-name	Specifies a user-defined name for an LDAP attribute map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

With the **ldap attribute-map** command, you can map your own attribute names and values to Cisco attribute names. You can then bind the resulting attribute map to an LDAP server. Your typical steps would be as follows:

1. Use the **ldap attribute-map** command in global configuration mode to create an unpopulated attribute map. This commands enters ldap-attribute-map configuration mode.
2. Use the **map-name** and **map-value** commands in ldap-attribute-map configuration mode to populate the attribute map.
3. Use the **ldap-attribute-map** command in aaa-server host mode to bind the attribute map to an LDAP server. Note the hyphen after ldap in this command.

Note To use the attribute mapping features correctly, you need to understand both the Cisco LDAP attribute names and values as well as the user-defined attribute names and values.

Examples

The following example command, entered in global configuration mode, creates an LDAP attribute map named myldapmap prior to populating it or binding it to an LDAP server:

```
hostname(config)# ldap attribute-map myldapmap
```

```
hostname(config-ldap-attribute-map)#
```

Related Commands

Command	Description
ldap-attribute-map (aaa-server host mode)	Binds an LDAP attribute map to an LDAP server.
map-name	Maps a user-defined LDAP attribute name to a Cisco LDAP attribute name.
map-value	Maps a user-defined attribute value to the Cisco attribute name.
show running-config ldap attribute-map	Displays a specific running LDAP attribute map or all running attribute maps.
clear configure ldap attribute-map	Removes all LDAP attribute maps.

ldap-attribute-map

To bind an existing mapping configuration to an LDAP host, use the **ldap-attribute-map** command in aaa-server host configuration mode. To remove the binding, use the **no** form of this command.

ldap-attribute-map *map-name*

no ldap-attribute-map *map-name*

Syntax Description

map-name	Specifies an LDAP attribute mapping configuration.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

If the Cisco-defined LDAP attribute names do not meet your ease-of-use or other requirements, you can create your own attribute names, map them to Cisco attributes, and then bind the resulting attribute configuration to an LDAP server. Your typical steps would include:

1. Use the **ldap attribute-map** command in global configuration mode to create an unpopulated attribute map. This command enters ldap-attribute-map configuration mode. Note that there is no hyphen after "ldap" in this command.
2. Use the **map-name** and **map-value** commands in ldap-attribute-map configuration mode to populate the attribute mapping configuration.
3. Use the **ldap-attribute-map** command in aaa-server host mode to bind the attribute map configuration to an LDAP server.

Examples

The following example commands, entered in aaa-server host configuration mode, bind an existing attribute map named myldapmap to an LDAP server named ldapsvr1:

```
hostname(config)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# ldap-attribute-map myldapmap
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.
map-name	Maps a user-defined LDAP attribute name with a Cisco LDAP attribute name.
map-value	Maps a user-defined attribute value to a Cisco attribute.
show running-config ldap attribute-map	Displays a specific running ldap attribute mapping configuration or all running attribute mapping configurations.
clear configure ldap attribute-map	Removes all LDAP attribute maps.

ldap-base-dn

To specify the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request, use the **ldap-base-dn** command in aaa-server host configuration mode. Aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove this specification, thus resetting the search to start at the top of the list, use the **no** form of this command.

ldap-base-dn *string*

no ldap-base-dn

Syntax Description

string	A case-sensitive string of up to 128 characters that specifies the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request; for example, OU=Cisco. Spaces are not permitted in the string, but other special characters are allowed.

Defaults

Start the search at the top of the list.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for LDAP servers.

Examples

The following example configures an LDAP AAA server named srvgrp1 on host 1.2.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the LDAP base DN as starthere.

```
hostname(config)# aaa-server svrgrp1 protocol ldap
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# ldap-base-dn starthere
hostname(config-aaa-server-host)# exit
```

Related Commands

Command	Description
aaa-server host	Enters AAA server host configuration mode so you can configure AAA server parameters that are host-specific.
ldap-scope	Specifies the extent of the search in the LDAP hierarchy that the server should make when it receives an authorization request.
ldap-naming-attribute	Specifies the Relative Distinguished Name attribute (or attributes) that uniquely identifies an entry on the LDAP server.
ldap-login-dn	Specifies the name of the directory object that the system should bind as.
ldap-login-password	Specifies the password for the login DN.

ldap-defaults

To define LDAP default values, use the **ldap-defaults** command in crl configure configuration mode. Crl configure configuration mode is accessible from crypto ca trustpoint configuration mode. These default values are used only when the LDAP server requires them. To specify no LDAP defaults, use the **no** form of this command.

ldap-defaults *server* [*port*]

no ldap-defaults

Syntax Description

port	(Optional) Specifies the LDAP server port. If this parameter is not specified, the ASA uses the standard LDAP port (389).
server	Specifies the IP address or domain name of the LDAP server. If one exists within the CRL distribution point, it overrides this value.

Defaults

The default setting is not set.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crl configure configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example defines LDAP default values on the default port (389):

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# ldap-defaults ldapdomain4 8389
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
protocol ldap	Specifies LDAP as a retrieval method for CRLs

ldap-dn

To pass a X.500 distinguished name and password to an LDAP server that requires authentication for CRL retrieval, use the **ldap-dn** command in crl configure configuration mode. Crl configure configuration mode is accessible from crypto ca trustpoint configuration mode. These parameters are used only when the LDAP server requires them. To specify no LDAP DN, use the **no** form of this command.

ldap-dn *x.500-name password*

no ldap-dn

Syntax Description

password	Defines a password for this distinguished name. The maximum field length is 128 characters.
x.500-name	Defines the directory path to access this CRL database, for example: cn=crl,ou=certs,o=CAName,c=US. The maximum field length is 128 characters.

Defaults

The default setting is not on.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crl configure configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example specifies an X.500 name CN=admin,OU=devtest,O=engineering and a password xxzzyy for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# ldap-dn cn=admin,ou=devtest,o=engineering xxzzyy
```

Related Commands

Command	Description
crl configure	Enters crl configure configuration mode.
crypto ca trustpoint	Enters ca trustpoint configuration mode.
protocol ldap	Specifies LDAP as a retrieval method for CRLs.

ldap-group-base-dn

To specify the base group in the Active Directory hierarchy used by dynamic access policies for group searches, use the **ldap-group-base-dn** command in aaa-server host configuration mode. To remove the command from the running configuration, use the **no** form of the command:

ldap-group-base-dn [*string*]

no ldap-group-base-dn [*string*]

Syntax Description

string	A case-sensitive string of up to 128 characters that specifies the location in the Active Directory hierarchy where the server should begin searching. For example, ou=Employees. Spaces are not permitted in the string, but other special characters are allowed.

Defaults

No default behavior or values. If you do not specify a group search DN, the search begins at the base DN.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
aaa-server host configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

The **ldap-group-base-dn** command applies only to Active Directory servers using LDAP, and specifies an Active Directory heirarchy level that the **show ad-groups** command uses to begin its group search. The groups retrieved from the search are used by dynamic group policies as selection criteria for a specific policy.

Examples

The following example sets the group base DN to begin the search at the organization unit (ou) level Employees:

```
hostname(config-aaa-server-host)# ldap-group-base-dn ou=Employees
```

Related Commands

Command	Description
group-search-timeout	Adjusts the time the ASA waits for a response from an Active Directory server for a list of groups.
show ad-groups	Displays groups that are listed on an Active Directory server**.**

ldap-login-dn

To specify the name of the directory object that the system should bind this as, use the **ldap-login-dn** command in aaa-server host configuration mode. Aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove this specification, use the **no** form of this command.

ldap-login-dn *string*

no ldap-login-dn

Syntax Description

string	A case-sensitive string of up to 128 characters that specifies the name of the directory object in the LDAP hierarchy. Spaces are not permitted in the string, but other special characters are allowed.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for LDAP servers. The maximum supported string length is 128 characters.

Some LDAP servers, including the Microsoft Active Directory server, require that the ASAestablish a handshake via authenticated binding before they will accept requests for any other LDAP operations. The ASA identifies itself for authenticated binding by attaching a Login DN field to the user authentication request. The Login DN field describes the authentication characteristics of the ASA. These characteristics should correspond to those of a user with administrator privileges.

For the *string* variable, enter the name of the directory object for VPN Concentrator authenticated binding, for example: cn=Administrator, cn=users, ou=people, dc=XYZ Corporation, dc=com. For anonymous access, leave this field blank.

Examples

The following example configures an LDAP AAA server named svrgrp1 on host 1.2.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the LDAP login DN as myobjectname.

```
hostname(config)# aaa-server svrgrp1 protocol ldap
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
```

```
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# ldap-login-dn myobjectname
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa-server host	Enters AAA server host configuration mode so you can configure AAA server parameters that are host-specific.
ldap-base-dn	Specifies the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request.
ldap-login-password	Specifies the password for the login DN. This command is valid only for LDAP servers.
ldap-naming-attribute	Specifies the Relative Distinguished Name attribute (or attributes) that uniquely identifies an entry on the LDAP server.
ldap-scope	Specifies the extent of the search in the LDAP hierarchy that the server should make when it receives an authorization request.

ldap-login-password

To specify the login password for the LDAP server, use the **ldap-login-password** command in aaa-server host configuration mode. Aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove this password specification, use the **no** form of this command:

ldap-login-password *string*

no ldap-login-password

Syntax Description

string	A case-sensitive, alphanumeric password, up to 64 characters long. The password cannot contain space characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for LDAP servers. The maximum password string length is 64 characters.

Examples

The following example configures an LDAP AAA server named srvgrp1 on host 1.2.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the LDAP login password as obscurepassword.

```
hostname(config)# aaa-server svrgrp1 protocol ldap
hostname(config)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server)# timeout 9
hostname(config-aaa-server)# retry 7
hostname(config-aaa-server)# ldap-login-password obscurepassword
hostname(config-aaa-server)#
```

Related Commands

Command	Description
aaa-server host	Enters AAA server host configuration mode so you can configure AAA server parameters that are host-specific.
ldap-base-dn	Specifies the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request.
ldap-login-dn	Specifies the name of the directory object that the system should bind as.
ldap-naming-attribute	Specifies the Relative Distinguished Name attribute (or attributes) that uniquely identifies an entry on the LDAP server.
ldap-scope	Specifies the extent of the search in the LDAP hierarchy that the server should make when it receives an authorization request.

ldap-naming-attribute

To specify the Relative Distinguished Name attribute, use the **ldap-naming-attribute** command in aaa-server host configuration mode. Aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove this specification, use the **no** form of this command:

ldap-naming-attribute *string*

no ldap-naming-attribute

Syntax Description

string	The case-sensitive, alphanumeric Relative Distinguished Name attribute, consisting of up to 128 characters, that uniquely identifies an entry on the LDAP server. Spaces are not permitted in the string, but other special characters are allowed.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Enter the Relative Distinguished Name attribute that uniquely identifies an entry on the LDAP server. Common naming attributes are Common Name (cn) and User ID (uid).

This command is valid only for LDAP servers. The maximum supported string length is 128 characters.

Examples

The following example configures an LDAP AAA server named srvgrp1 on host 1.2.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the LDAP naming attribute as cn.

```
hostname(config)# aaa-server svrgrp1 protocol ldap
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# ldap-naming-attribute cn
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa-server host	Enters AAA server host configuration mode so you can configure AAA server parameters that are host-specific.
ldap-base-dn	Specifies the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request.
ldap-login-dn	Specifies the name of the directory object that the system should bind as.
ldap-login-password	Specifies the password for the login DN. This command is valid only for LDAP servers.
ldap-scope	Specifies the extent of the search in the LDAP hierarchy that the server should make when it receives an authorization request.

ldap-over-ssl

To establish a secure SSL connection between the ASA and the LDAP server, use the **ldap-over-ssl** command in aaa-server host configuration mode. To disable SSL for the connection, use the **no** form of this command.

ldap-over-ssl enable

no ldap-over-ssl enable

Syntax Description

enable	Specifies that SSL secures a connection to an LDAP server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use this command to specify that SSL secures a connection between the ASA and an LDAP server.

Note We recommend enabling this feature if you are using plain text authentication. See the **sasl-mechanism** command.

Examples

The following commands, entered in aaa-server host configuration mode, enable SSL for a connection between the ASA and the LDAP server named ldapsvr1 at IP address 10.10.0.1. They also configure the plain SASL authentication mechanism.

```
hostname(config)# aaa-server ldapsvr1 protocol ldap
hostname(config-aaa-server-host)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# ldap-over-ssl enable
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
sasl-mechanism	Specifies SASL authentication between the LDAP client and server.
server-type	Specifies the LDAP server vendor as either Microsoft or Sun.
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.

ldap-scope

To specify the extent of the search in the LDAP hierarchy that the server should make when it receives an authorization request, use the **ldap-scope** command in aaa-server host configuration mode. Aaa-server host configuration mode is accessibile from aaa-server protocol configuration mode. To remove this specification, use the **no** form of this command.

ldap-scope *scope*

no ldap-scope

Syntax Description

scope	The number of levels in the LDAP hierarchy for the server to search when it receives an authorization request. Valid values are: • **onelevel**—Search only one level beneath the Base DN • **subtree**—Search all levels beneath the Base DN

Defaults

The default value is **onelevel**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	Pre-existing command, modified for this release

Usage Guidelines

Specifying the scope as **onelevel** results in a faster search, because only one level beneath the Base DN is searched. Specifying **subtree** is slower, because all levels beneath the Base DN are searched.

This command is valid only for LDAP servers.

Examples

The following example configures an LDAP AAA server named svrgrp1 on host 1.2.3.4, sets a timeout of 9 seconds, sets a retry-interval of 7 seconds, and configures the LDAP scope to include the subtree levels.

```
hostname(config)# aaa-server svrgrp1 protocol ldap
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# ldap-scope subtree
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa-server host	Enters AAA server host configuration mode so you can configure AAA server parameters that are host-specific.
ldap-base-dn	Specifies the location in the LDAP hierarchy where the server should begin searching when it receives an authorization request.
ldap-login-dn	Specifies the name of the directory object that the system should bind as.
ldap-login-password	Specifies the password for the login DN. This command is valid only for LDAP servers.
ldap-naming-attribute	Specifies the Relative Distinguished Name attribute (or attributes) that uniquely identifies an entry on the LDAP server.

leap-bypass

To enable LEAP Bypass, use the **leap-bypass enable** command in group-policy configuration mode. To disable LEAP Bypass, use the **leap-bypass disable** command. To remove the LEAP Bypass attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a value for LEAP Bypass from another group policy.

leap-bypass {**enable** | **disable**}

no leap-bypass

Syntax Description

disable	Disables LEAP Bypass.
enable	Enables LEAP Bypass.

Defaults

LEAP Bypass is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When enabled, LEAP Bypass allows LEAP packets from wireless devices behind a VPN hardware client to travel across a VPN tunnel prior to user authentication. This lets workstations using Cisco wireless access point devices establish LEAP authentication. Devices are then able to authenticate again, per user authentication.

This feature does not work as intended if you enable interactive hardware client authentication.

For further information, see the CLI configuration guide.

Note There may be security risks in allowing any unauthenticated traffic to traverse the tunnel.

Examples

The following example shows how to set LEAP Bypass for the group policy named "FirstGroup":

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# leap-bypass enable
```

Related Commands

Command	Description
secure-unit-authentication	Requires VPN hardware clients to authenticate with a username and password each time the client initiates a tunnel.
user-authentication	Requires users behind VPN hardware clients to identify themselves to the ASA before connecting.

license

To configure the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes, use the **license** command in scansafe general-options configuration mode. To remove the license, use the **no** form of this command.

license *hex_key*

no license [*hex_key*]

Syntax Description

hex_key	Specifies the authentication key as a 16-byte hexidecimal number.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Each ASA must use an authentication key that you obtain from Cloud Web Security. The authentication key lets Cloud Web Security identify the company associated with web requests and ensures that the ASA is associated with valid customer.

You can use one of two types of authentication keys for your ASA: the company key or the group key.

Company Authentication Key

A Company authentication key can be used on multiple ASAs within the same company. This key simply enables the Cloud Web Security service for your ASAs. The administrator generates this key in ScanCenter (https://scancenter.scansafe.com/portal/admin/login.jsp); you have the opportunity to e-mail the key for later use. You cannot look up this key later in ScanCenter; only the last 4 digits are shown in ScanCenter. For more information, see the Cloud Web Security documentation: http://www.cisco.com/en/US/products/ps11720/products_installation_and_configuration_guides_list.html.

Group Authentication Key

A Group authentication key is a special key unique to each ASA that performs two functions:

- Enables the Cloud Web Security service for one ASA.

- Identifies all traffic from the ASA so you can create ScanCenter policy per ASA.

The administrator generates this key in ScanCenter (https://scancenter.scansafe.com/portal/admin/login.jsp); you have the opportunity to e-mail the key for later use. You cannot look up this key later in ScanCenter; only the last 4 digits are shown in ScanCenter. For more information, see the Cloud Web Security documentation: http://www.cisco.com/en/US/products/ps11720/products_installation_and_configuration_guides_list.html.

Examples

The following example configures a primary server only:

```
scansafe general-options
 server primary ip 180.24.0.62 port 8080
 retry-count 5
 license 366C1D3F5CE67D33D3E9ACEC265261E5
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

license-server address

To identify the shared licensing server IP address and shared secret for use by a participant, use the **license-server address** command in global configuration mode. To disable participation in shared licensing, use the **no** form of this command. A shared license lets you purchase a large number of SSL VPN sessions and share the sessions as needed amongst a group of ASAs by configuring one of the ASAs as a shared licensing server, and the rest as shared licensing participants.

license-server address *address* **secret** *secret* [**port** *port*]

no license-server address [*address* **secret** *secret* [**port** *port*]]

Syntax Description

address	Identifies the shared licensing server IP address.
port *port*	(Optional) If you changed the default port in the server configuration using the **license-server port** command, set the port for the backup server to match, between 1 and 65535. The default port is 50554.
secret *secret*	Identifies the shared secret. The secret muct match the secret set on the server using the **license-server secret** command.

Command Default

The default port is 50554.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The shared licensing participant must have a shared licensing participant key. Use the **show activation-key** command to check your installed licenses.

You can only specify one shared license server for each participant.

The following steps describe how shared licenses operate:

1. Decide which ASA should be the shared licensing server, and purchase the shared licensing server license using that device serial number.
2. Decide which ASAs should be shared licensing participants, including the shared licensing backup server, and obtain a shared licensing participant license for each device, using each device serial number.

3. (Optional) Designate a second ASA as a shared licensing backup server. You can only specify one backup server.

Note The shared licensing backup server only needs a participant license.

4. Configure a shared secret on the shared licensing server; any participants with the shared secret can use the shared license.
5. When you configure the ASA as a participant, it registers with the shared licensing server by sending information about itself, including the local license and model information.

Note The participant needs to be able to communicate with the server over the IP network; it does not have to be on the same subnet.

6. The shared licensing server responds with information about how often the participant should poll the server.
7. When a participant uses up the sessions of the local license, it sends a request to the shared licensing server for additional sessions in 50-session increments.
8. The shared licensing server responds with a shared license. The total sessions used by a participant cannot exceed the maximum sessions for the platform model.

Note The shared licensing server can also participate in the shared license pool if it runs out of local sessions. It does not need a participant license as well as the server license to participate.

   a. If there are not enough sessions left in the shared license pool for the participant, then the server responds with as many sessions as available.
   b. The participant continues to send refresh messages requesting more sessions until the server can adequately fulfill the request.

9. When the load is reduced on a participant, it sends a message to the server to release the shared sessions.

Note The ASA uses SSL between the server and participant to encrypt all communications.

Communication Issues Between Participant and Server

See the following guidelines for communication issues between the participant and server:

- If a participant fails to send a refresh after 3 times the refresh interval, then the server releases the sessions back into the shared license pool.
- If the participant cannot reach the license server to send the refresh, then the participant can continue to use the shared license it received from the server for up to 24 hours.
- If the participant is still not able to communicate with a license server after 24 hours, then the participant releases the shared license, even if it still needs the sessions. The participant leaves existing connections established, but cannot accept new connections beyond the license limit.

- If a participant reconnects with the server before 24 hours expires, but after the server expired the participant sessions, then the participant needs to send a new request for the sessions; the server responds with as many sessions as can be reassigned to that participant.

Examples

The following example sets the license server IP address and shared secret, as well as the backup license server IP address:

```
hostname(config)# license-server address 10.1.1.1 secret farscape
hostname(config)# license-server backup address 10.1.1.2
```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
clear shared license	Clears shared license statistics.
license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server backup address

To identify the shared licensing backup server IP address for use by a participant, use the **license-server backup address** command in global configuration mode. To disable use of the backup server, use the **no** form of this command.

license-server backup address *address*

no license-server address [*address*]

Syntax Description

address	Identifies the shared licensing backup server IP address.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The shared licensing backup server must have the **license-server backup enable** command configured.

Examples

The following example sets the license server IP address and shared secret, as well as the backup license server IP address:

```
hostname(config)# license-server address 10.1.1.1 secret farscape
hostname(config)# license-server backup address 10.1.1.2
```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
clear shared license	Clears shared license statistics.
license-server address	Identifies the shared licensing server IP address and shared secret for a participant.

Command	Description
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server backup backup-id

To identify the shared licensing backup server in the main shared licensing server configuration, use the **license-server backup backup-id** command in global configuration mode. To remove the backup server configuration, use the **no** form of this command.

license-server backup *address* **backup-id** *serial_number* [**ha-backup-id** *ha_serial_number*]

no license-server backup *address* [**backup-id** *serial_number* [**ha-backup-id** *ha_serial_number*]]

Syntax Description

address	Identifies the shared licensing backup server IP address.
backup-id *serial_number*	Identifies the shared licensing backup server serial number.
ha-backup-id *ha_serial_number*	If you use failover for the backup server, identifies the secondary shared licensing backup server serial number.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

You can only identify 1 backup server and its optional standby unit.

To view the backup server serial number, enter the **show activation-key** command.

To enable a participant to be the backup server, use the **license-server backup enable** command.

The shared licensing backup server must register successfully with the main shared licensing server before it can take on the backup role. When it registers, the main shared licensing server syncs server settings as well as the shared license information with the backup, including a list of registered participants and the current license usage. The main server and backup server sync the data at 10 second intervals. After the initial sync, the backup server can successfully perform backup duties, even after a reload.

When the main server goes down, the backup server takes over server operation. The backup server can operate for up to 30 continuous days, after which the backup server stops issuing sessions to participants, and existing sessions time out. Be sure to reinstate the main server within that 30-day period. Critical-level syslog messages are sent at 15 days, and again at 30 days.

When the main server comes back up, it syncs with the backup server, and then takes over server operation.

When the backup server is not active, it acts as a regular participant of the main shared licensing server.

Note When you first launch the main shared licensing server, the backup server can only operate independently for 5 days. The operational limit increases day-by-day, until 30 days is reached. Also, if the main server later goes down for any length of time, the backup server operational limit decrements day-by-day. When the main server comes back up, the backup server starts to increment again day-by-day. For example, if the main server is down for 20 days, with the backup server active during that time, then the backup server will only have a 10-day limit left over. The backup server "recharges" up to the maximum 30 days after 20 more days as an inactive backup. This recharging function is implemented to discourage misuse of the shared license.

Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and dmz interface:

```
hostname(config)# license-server secret farscape
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

Related Commands

Command	Description

show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server backup enable

To enable this unit to be the shared licensing backup server, use the **license-server backup enable** command in global configuration mode. To disable the backup server, use the **no** form of this command.

license-server backup enable *interface_name*

no license-server enable *interface_name*

Syntax Description

interface_name	Specifies the interface on which participants contact the backup server. You can repeat this command for as many interfaces as desired.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The backup server must have a shared licensing participant key.

The shared licensing backup server must register successfully with the main shared licensing server before it can take on the backup role. When it registers, the main shared licensing server syncs server settings as well as the shared license information with the backup, including a list of registered participants and the current license usage. The main server and backup server sync the data at 10 second intervals. After the initial sync, the backup server can successfully perform backup duties, even after a reload.

When the main server goes down, the backup server takes over server operation. The backup server can operate for up to 30 continuous days, after which the backup server stops issuing sessions to participants, and existing sessions time out. Be sure to reinstate the main server within that 30-day period. Critical-level syslog messages are sent at 15 days, and again at 30 days.

When the main server comes back up, it syncs with the backup server, and then takes over server operation.

When the backup server is not active, it acts as a regular participant of the main shared licensing server.

Note When you first launch the main shared licensing server, the backup server can only operate independently for 5 days. The operational limit increases day-by-day, until 30 days is reached. Also, if the main server later goes down for any length of time, the backup server operational limit decrements day-by-day. When the main server comes back up, the backup server starts to increment again day-by-day. For example, if the main server is down for 20 days, with the backup server active during that time, then the backup server will only have a 10-day limit left over. The backup server "recharges" up to the maximum 30 days after 20 more days as an inactive backup. This recharging function is implemented to discourage misuse of the shared license.

Examples

The following example identifies the license server and shared secret, and enables this unit as the backup shared license server on the inside interface and dmz interface.

```
hostname(config)# license-server address 10.1.1.1 secret farscape
hostname(config)# license-server backup enable inside
hostname(config)# license-server backup enable dmz
```

Related Commands

Command	Description

show vpn-sessiondb	Shows license information about VPN sessions.

license-server enable

To identify this unit as a shared licensing server, use the **license-server enable** command in global configuration mode. To disable the shared licensing server, use the **no** form of this command. A shared license lets you purchase a large number of SSL VPN sessions and share the sessions as needed amongst a group of ASAs by configuring one of the ASAs as a shared licensing server, and the rest as shared licensing participants.

license-server enable *interface_name*

no license-server enable *interface_name*

Syntax Description

interface_name	Specifies the interface on which participants contact the server. You can repeat this command for as many interfaces as desired.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

The shared licensing server must have a shared licensing server key. Use the **show activation-key** command to check your installed licenses.

The following steps describe how shared licenses operate:

1. Decide which ASA should be the shared licensing server, and purchase the shared licensing server license using that device serial number.
2. Decide which ASAs should be shared licensing participants, including the shared licensing backup server, and obtain a shared licensing participant license for each device, using each device serial number.
3. (Optional) Designate a second ASA as a shared licensing backup server. You can only specify one backup server.

Note The shared licensing backup server only needs a participant license.

4. Configure a shared secret on the shared licensing server; any participants with the shared secret can use the shared license.
5. When you configure the ASA as a participant, it registers with the shared licensing server by sending information about itself, including the local license and model information.

Note The participant needs to be able to communicate with the server over the IP network; it does not have to be on the same subnet.

6. The shared licensing server responds with information about how often the participant should poll the server.
7. When a participant uses up the sessions of the local license, it sends a request to the shared licensing server for additional sessions in 50-session increments.
8. The shared licensing server responds with a shared license. The total sessions used by a participant cannot exceed the maximum sessions for the platform model.

Note The shared licensing server can also participate in the shared license pool if it runs out of local sessions. It does not need a participant license as well as the server license to participate.

   a. If there are not enough sessions left in the shared license pool for the participant, then the server responds with as many sessions as available.
   b. The participant continues to send refresh messages requesting more sessions until the server can adequately fulfill the request.
9. When the load is reduced on a participant, it sends a message to the server to release the shared sessions.

Note The ASA uses SSL between the server and participant to encrypt all communications.

Communication Issues Between Participant and Server

See the following guidelines for communication issues between the participant and server:

- If a participant fails to send a refresh after 3 times the refresh interval, then the server releases the sessions back into the shared license pool.
- If the participant cannot reach the license server to send the refresh, then the participant can continue to use the shared license it received from the server for up to 24 hours.
- If the participant is still not able to communicate with a license server after 24 hours, then the participant releases the shared license, even if it still needs the sessions. The participant leaves existing connections established, but cannot accept new connections beyond the license limit.
- If a participant reconnects with the server before 24 hours expires, but after the server expired the participant sessions, then the participant needs to send a new request for the sessions; the server responds with as many sessions as can be reassigned to that participant.

Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and DMZ interface:

```
hostname(config)# license-server secret farscape
```

```
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

Related Commands

Command	Description
activation-key	Enters a license activation key.
clear configure license-server	Clears the shared licensing server configuration.
clear shared license	Clears shared license statistics.

license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server port	Sets the port on which the server listens for SSL connections from participants.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server port

To set the port on which the shared licensing server listens for SSL connections from participants, use the **license-server port** command in global configuration mode. To restore the default port, use the **no** form of this command.

license-server port *port*

no license-server port [*port*]

Syntax Description

seconds	Sets the port on which the server listens for SSL connections from participants, between 1 and 65535. The default is TCP port 50554.

Command Default

The default port is 50554.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

If you change the port from the default, be sure to set the same port for each participant using the **license-server address** command.

Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and DMZ interface:

```
hostname(config)# license-server secret farscape
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

Related Commands

Command	Description
activation-key	Enters a license activation key.

clear shared license	Clears shared license statistics.
license-server address	Identifies the shared licensing server IP address and shared secret for a participant.
license-server backup address	Identifies the shared licensing backup server for a participant.
license-server backup backup-id	Identifies the backup server IP address and serial number for the main shared licensing server.
license-server backup enable	Enables a unit to be the shared licensing backup server.
license-server enable	Enables a unit to be the shared licensing server.
license-server refresh-interval	Sets the refresh interval provided to participants to set how often they should communicate with the server.
license-server secret	Sets the shared secret on the shared licensing server.
show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server refresh-interval

To set the refresh interval provided to participants to set how often they should communicate with the shared licensing server, use the **license-server refresh-interval** command in global configuration mode. To restore the default refresh interval, use the **no** form of this command.

license-server refresh-interval *seconds*

no license-server refresh-interval [*seconds*]

Syntax Description

seconds	Sets the refresh interval between 10 and 300 seconds. The default is 30 seconds.

Command Default

The default is 30 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Each participant regularly communicates with the shared licensing server using SSL so the shared licensing server can keep track of current license usage and receive and respond to license requests.

Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and dmz interface:

```
hostname(config)# license-server secret farscape
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

Related Commands

Command	Description

show activation-key	Shows the current licenses installed.
show running-config license-server	Shows the shared licensing server configuration.
show shared license	Shows shared license statistics.
show vpn-sessiondb	Shows license information about VPN sessions.

license-server secret

To set the shared secret on the shared licensing server, use the **license-server secret** command in global configuration mode. To remove the secret, use the **no** form of this command.

license-server secret *secret*

no license-server secret *secret*

Syntax Description

secret	Sets the shared secret, a string between 4 and 128 ASCII characters.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Any participant with this secret identified in the **license-server address** command can use the licensing server.

Examples

The following example sets the shared secret, changes the refresh interval and port, configures a backup server, and enables this unit as the shared licensing server on the inside interface and dmz interface:

```
hostname(config)# license-server secret farscape
hostname(config)# license-server refresh-interval 100
hostname(config)# license-server port 40000
hostname(config)# license-server backup 10.1.1.2 backup-id JMX0916L0Z4 ha-backup-id
JMX1378N0W3
hostname(config)# license-server enable inside
hostname(config)# license-server enable dmz
```

show vpn-sessiondb	Shows license information about VPN sessions.

lifetime (ca server mode)

To specify the length of time that the Local Certificate Authority (CA) certificate, each issued user certificates, or the Certificate Revocation List (CRL) is valid, use the **lifetime** command in ca server configuration mode. To reset the lifetime to the default setting, use the **no** form of this command.

lifetime {**ca-certificate | certificate | crl**} *time*

no lifetime {**ca-certificate | certificate | crl**}

Syntax Description

ca-certificate	Specifies the lifetime of the local CA server certificate.
certificate	Specifies the lifetime of all user certificates issued by the CA server.
crl	Specifies the lifetime of the CRL.
time	For the CA certificate and all issued certificates, *time* specifies the number of days the certificate is valid. The valid range is from 1 to 3650 days. For the CRL, *time* specifies the number of hours the CRL is valid. The valid range for the CRL is from 1 to 720 hours.

Defaults

The default lifetimes are:

- CA certificate—Three years
- Issued certificates—One year
- CRL—Six hours

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

By specifying the number of days or hours that a certificate or CRL is valid, this command determines the expiration date included in the certificate or the CRL.

The **lifetime ca-certificate** command takes effect when the local CA server certificate is first generated (that is, when you initially configure the local CA server and issue the **no shutdown** command). When the CA certificate expires, the configured lifetime value is used to generate the new CA certificate. You cannot change the lifetime value for existing CA certificates.

Examples

The following example configures the CA to issue certificates that are valid for three months:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# lifetime certificate 90
hostname(config-ca-server))#
```

The following example configures the CA to issue a CRL that is valid for two days:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# lifetime crl 48
hostname(config-ca-server)#
```

Related Commands

Command	Description
cdp-url	Specifies the certificate revocation list distribution point (CDP) to be included in the certificates issued by the CA.
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage the local CA.
crypto ca server crl issue	Forces the issuance of a CRL.
show crypto ca server	Displays the local CA configuration details in ASCII text.
show crypto ca server cert-db	Displays local CA server certificates.
show crypto ca server crl	Displays the current CRL of the local CA.

lifetime (ikev2 policy mode)

To specify the encryption algorithm in an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **encryption** command in IKEv2 policy configuration mode. To remove the command and use the default setting, use the **no** form of this command:

lifetime {{ **seconds** *seconds*} | **none** }

Syntax Description

seconds	The lifetime in seconds, from 120 to 2,147,483,647 seconds. The default is 86,400 seconds (24 hours).

Defaults

The default is 86,400 seconds (24 hours).

Usage Guidelines

An IKEv2 SA is a key used in phase 1 to enable IKEv2 peers to communicate securely in phase 2. After entering the **crypto ikev2 policy** command, use the **lifetime** command to set the SA lifetime.

The lifetime sets the interval for IKEv2 SA rekeys. Using the none keyword disables rekeying the SA. However, the AnyConnect client can still rekey the SA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was added.

Examples

The following example enters IKEv2 policy configuration mode and sets the lifetime to 43,200 seconds (12 hours):

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)# lifetime 43200
```

Related Commands

Command	Description
encryption	Specifies the encryption algorithm in an IKEv2 SA for AnyConnect IPsec connections.
group	Specifies the Diffie-Hellman group in an IKEv2 SA for AnyConnect IPsec connections.

Command	Description
integrity	Specifies the ESP integrity algorithm in an IKEv2 SA for AnyConnect IPsec connections.
prf	Specifies the pseudo-random function in an IKEv2 SA for AnyConnect IPsec connections.

limit-resource

To specify a resource limit for a class in multiple context mode, use the **limit-resource** command in class configuration mode. To restore the limit to the default, use the **no** form of this command. The ASA manages resources by assigning contexts to resource classes. Each context uses the resource limits set by the class.

limit-resource [**rate**] {**all** | *resource_name*} *number*[**%**]}

no limit-resource {**all** | [**rate**] *resource_name*}

Syntax Description

all	Sets the limit for all resources.
number[**%**]	Specifies the resource limit as a fixed number greater than or equal to 1, or as a percentage of the system limit between 1 and 100 (when used with the percent sign (%)). Set the limit to **0** to indicate an unlimited resource, or for VPN resource types, to set the limit to none. For resources that do not have a system limit, you cannot set the percentage (%); you can only set an absolute value.
rate	Specifies that you want to set the rate per second for a resource. See Table 30-1 for resources for which you can set the rate per second.
resource_name	Specifies the resource name for which you want to set a limit. This limit overrides the limit set for **all**.

Defaults

All contexts belong to the default class if they are not assigned to another class; you do not have to actively assign a context to the default class.

For most resources, the default class provides unlimited access to resources for all contexts, except for the following limits:

- Telnet sessions—5 sessions. (The maximum per context.)
- SSH sessions—5 sessions. (The maximum per context.)
- IPsec sessions—5 sessions. (The maximum per context.)
- MAC addresses—65,535 entries. (The maximum per context.)
- VPN site-to-site tunnels—0 sessions. (You must manually configure the class to allow any VPN sessions.)

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	A new resource type, routes, was created to set the maximum number of routing table entries in each context. New resource types, vpn other and vpn burst other, were created to set the maximum number of site-to-site VPN tunnels in each context.

Usage Guidelines

By default, all security contexts have unlimited access to the resources of the ASA, except where maximum limits per context are enforced; the only exception is VPN resources, which are disabled by default. If you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context. For VPN resources, you must configure resource management to allow any VPN tunnels.

Table 30-1 lists the resource types and the limits. See also the **show resource types** command.

Table 30-1 Resource Names and Limits

Resource Name	Rate or Concurrent	Minimum and Maximum Number per Context	System Limit[1]	Description
asdm	Concurrent	1 minimum 5 maximum	32	ASDM management sessions. **Note** ASDM sessions use two HTTPS connections: one for monitoring that is always present, and one for making configuration changes that is present only when you make changes. For example, the system limit of 32 ASDM sessions represents a limit of 64 HTTPS sessions.
conns	Concurrent or Rate	N/A	Concurrent connections: See the CLI configuration guide for the connection limit for your platform. Rate: N/A	TCP or UDP connections between any two hosts, including connections between one host and multiple other hosts.
hosts	Concurrent	N/A	N/A	Hosts that can connect through the ASA.
inspects	Rate	N/A	N/A	Application inspections.
mac-addresses	Concurrent	N/A	65,535	For transparent firewall mode, the number of MAC addresses allowed in the MAC address table.
routes	Concurrent	N/A	N/A	Dynamic routes.
ssh	Concurrent	1 minimum 5 maximum	100	SSH sessions.
syslogs	Rate	N/A	N/A	System log messages.

Table 30-1 Resource Names and Limits (continued)

Resource Name	Rate or Concurrent	Minimum and Maximum Number per Context	System Limit[1]	Description
telnet	Concurrent	1 minimum 5 maximum	100	Telnet sessions.
vpn burst other	Concurrent	N/A	The Other VPN session amount for your model minus the sum of the sessions assigned to all contexts for **vpn other**.	The number of site-to-site VPN sessions allowed beyond the amount assigned to a context with **vpn other**. For example, if your model supports 5000 sessions, and you assign 4000 sessions across all contexts with **vpn other**, then the remaining 1000 sessions are available for **vpn burst other**. Unlike **vpn other**, which guarantees the sessions to the context, **vpn burst other** can be oversubscribed; the burst pool is available to all contexts on a first-come, first-served basis.
vpn other	Concurrent	N/A	See the "Supported Feature Licenses Per Model" section in the CLI configuration guide for the Other VPN sessions available for your model.	Site-to-site VPN sessions. You cannot oversubscribe this resource; all context assignments combined cannot exceed the model limit. The sessions you assign for this resource are guaranteed to the context.
xlates	Concurrent	N/A	N/A	Address translations.

1. If this column value is N/A, then you cannot set a percentage of the resource because there is no hard system limit for the resource.

Examples

The following example sets the default class limit for conns to 10 percent instead of unlimited:

```
hostname(config)# class default
hostname(config-class)# limit-resource conns 10%
```

All other resources remain at unlimited.

To add a class called gold, enter the following commands:

```
hostname(config)# class gold
hostname(config-class)# limit-resource mac-addresses 10000
hostname(config-class)# limit-resource conns 15%
hostname(config-class)# limit-resource rate conns 1000
hostname(config-class)# limit-resource rate inspects 500
hostname(config-class)# limit-resource hosts 9000
hostname(config-class)# limit-resource asdm 5
hostname(config-class)# limit-resource ssh 5
hostname(config-class)# limit-resource rate syslogs 5000
hostname(config-class)# limit-resource telnet 5
hostname(config-class)# limit-resource xlates 36000
hostname(config-class)# limit-resource routes 700
```

Related Commands

Command	Description
class	Creates a resource class.
context	Configures a security context.
member	Assigns a context to a resource class.
show resource allocation	Shows how you allocated resources across classes.
show resource types	Shows the resource types for which you can set limits.

lmfactor

To set a revalidation policy for caching objects that have only the last-modified timestamp, and no other server-set expiration values, use the **lmfactor** command in cache configuration mode. To set a new policy for revalidating such objects, use the command again. To reset the attribute to the default value of 20, enter the **no** version of the command.

lmfactor *value*

no lmfactor

Syntax Description

value	An integer in the range of 0 to 100.

Defaults

The default value is 20.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cache configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The ASA uses the value of the lmfactor to estimate the length of time for which it considers a cached object to be unchanged. This is known as the expiration time. The ASA estimates th expiration time by the time elapsed since the last modification multiplied by the lmfactor.

Setting the lmfactor to zero is equivalent to forcing an immediate revalidation, while setting it to 100 results in the longest allowable time until revalidation.

Examples

The following example shows how to set an lmfactor of 30:

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)# lmfactor 30
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache	Enters WebVPN Cache mode.
cache-compressed	Configures WebVPN cache compression.
disable	Disables caching.
expiry-time	Configures the expiration time for caching objects without revalidating them.
max-object-size	Defines the maximum size of an object to cache.
min-object-size	Defines the minimum sizze of an object to cache.

local-unit

To provide a name for this cluster member, use the **local-unit** command in cluster group configuration mode. To remove the name, use the **no** form of this command.

local-unit *unit_name*

no local-unit [*unit_name*]

Syntax Description

unit_name	Names this member of the cluster with a unique ASCII string from 1 to 38 characters.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Each unit must have a unique name. A unit with a duplicated name will be not be allowed in the cluster.

Examples

The following example names this unit as unit1:

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# local-unit unit1
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.

Command	Description
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.
priority (cluster group)	Sets the priority of this unit for master unit elections.

log

When using the Modular Policy Framework, log packets that match a **match** command or class map by using the **log** command in match or class configuration mode. This log action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic. To disable this action, use the **no** form of this command.

log

no log

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **log** command to log all packets that match the **match** command or **class** command.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action, for example, enter the **inspect http http_policy_map** command where http_policy_map is the name of the inspection policy map.

Examples

The following example sends a log when packets match the http-traffic class map.

```
hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# log
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

log-adj-changes (OSPFv2)

To configure the router to send a syslog message when an OSPF neighbor goes up or down, use the **log-adj-changes** command in router configuration mode. To turn off this function, use the **no** form of this command.

log-adj-changes [**detail**]

no log-adj-changes [**detail**]

Syntax Description

detail	(Optional) Sends a syslog message for each state change, not just when a neighbor goes up or down.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.01)	Multiple context mode is supported.

Usage Guidelines

The **log-adj-changes** command is enabled by default; it appears in the running configuration unless removed with the **no** form of the command.

Examples

The following example disables the sending of a syslog message when an OSPF neighbor goes up or down:

```
hostname(config)# router ospf 5
hostname(config-router)# no log-adj-changes
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show ospf	Displays general information about the OSPF routing processes.

log-adjacency-changes (OSPFv3)

To configure the router to send a syslog message when an OSPFv3 neighbor goes up or down, use the **log-adjacency-changes** command in IPv6 router configuration mode. To turn off this function, use the **no** form of this command.

log-adjacency-changes [**detail**]

no log-adjacency-changes [**detail**]

Syntax Description

detail	(Optional) Sends a syslog message for each state change, not just when a neighbor goes up or down.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
9.01)	We introduced this command.

Usage Guidelines

The **log-adjacency-changes** command is enabled by default; it appears in the running configuration unless removed with the **no** form of the command.

Examples

The following example disables the sending of a syslog message when an OSPFv3 neighbor goes up or down:

```
hostname(config)# ipv6 router ospf 5
hostname(config-router)# no log-adjacency-changes
```

Related Commands

Command	Description
ipv6 router ospf	Enters router configuration mode.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.

logging asdm through logout message Commands

logging asdm

To send syslog messages to the ASDM log buffer, use the **logging asdm** command in global configuration mode. To disable logging to the ASDM log buffer, use the **no** form of this command.

logging asdm [*logging_list* | *level*]

no logging asdm [*logging_list* | *level*]

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the ASDM log buffer. For information about creating lists, see the **logging list** command.

Defaults

ASDM logging is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Before any messages are sent to the ASDM log buffer, you must enable logging using the **logging enable** command.

When the ASDM log buffer is full, the ASA deletes the oldest message to make room in the buffer for new messages. To control the number of syslog messages retained in the ASDM log buffer, use the **logging asdm-buffer-size** command.

The ASDM log buffer is a different buffer than the log buffer enabled by the **logging buffered** command.

Examples

The following example shows how to enable logging, send log buffer messages of severity levels 0, 1, and 2 to the ASDM, and how to set the ASDM log buffer size to 200 messages:

```
hostname(config)# logging enable
hostname(config)# logging asdm 2
hostname(config)# logging asdm-buffer-size 200
hostname(config)# show logging
Syslog logging: enabled
    Facility: 20
    Timestamp logging: disabled
    Standby logging: disabled
    Deny Conn when Queue Full: disabled
    Console logging: disabled
    Monitor logging: disabled
    Buffer logging: disabled
    Trap logging: disabled
    History logging: disabled
    Device ID: disabled
    Mail logging: disabled
    ASDM logging: level critical, 48 messages logged
```

Related Commands

Command	Description
clear logging asdm	Clears the ASDM log buffer of all messages that it contains.
logging asdm-buffer-size	Specifies the number of ASDM messages retained in the ASDM log buffer
logging enable	Enables logging.
logging list	Creates a reusable list of message selection criteria.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging configuration.

logging asdm-buffer-size

To specify the number of syslog messages retained in the ASDM log buffer, use the **logging asdm-buffer-size** command in global configuration mode. To reset the ASDM log buffer to its default size of 100 messages, use the **no** form of this command.

logging asdm-buffer-size *num_of_msgs*

no logging asdm-buffer-size *num_of_msgs*

Syntax Description

num_of_msgs	Specifies the number of syslog messages that the ASA retains in the ASDM log buffer.

Defaults

The default ASDM syslog buffer size is 100 messages.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When the ASDM log buffer is full, the ASA deletes the oldest message to make room in the buffer for new messages. To control whether logging to the ASDM log buffer is enabled or to control the kind of syslog messages retained in the ASDM log buffer, use the **logging asdm** command.

The ASDM log buffer is a different buffer than the log buffer enabled by the **logging buffered** command.

Examples

The following example shows how to enable logging, sendmessages of severity levels 0, 1, and 2 to the ASDM log buffer, and how to set the ASDM log buffer size to 200 messages:

```
hostname(config)# logging enable
hostname(config)# logging asdm 2
hostname(config)# logging asdm-buffer-size 200
hostname(config)# show logging
Syslog logging: enabled
    Facility: 20
    Timestamp logging: disabled
    Standby logging: disabled
    Deny Conn when Queue Full: disabled
    Console logging: disabled
    Monitor logging: disabled
```

```
Buffer logging: disabled
Trap logging: disabled
History logging: disabled
Device ID: disabled
Mail logging: disabled
ASDM logging: level critical, 48 messages logged
```

Related Commands

Command	Description
clear logging asdm	Clears the ASDM log buffer of all messages that it contains.
logging asdm	Enables logging to the ASDM log buffer.
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the currently running logging configuration.

logging buffered

To enable the ASA to send syslog messages to the log buffer, use the **logging buffered** command in global configuration mode. To disable logging to the log buffer, use the **no** form of this command.

logging buffered [*logging_list* | *level*]

no logging buffered [*logging_list* | *level*]

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the log buffer. For information about creating lists, see the **logging list** command.

Defaults

The defaults are as follows:

- Logging to the buffer is disabled.
- The buffer size is 4 KB.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Before any messages are sent to the log buffer, you must enable logging using the **logging enable** command.

New messages append to the end of the buffer. When the buffer fills up, the ASA clears the buffer and continues adding messages to it. When the log buffer is full, the ASA deletes the oldest message to make room in the buffer for new messages. You can have buffer contents automatically saved each time the contents of the buffer have "wrapped," which means that all the messages since the last save have been replaced by new messages. For more information, see the **logging flash-bufferwrap** and **logging ftp-bufferwrap** commands.

At any time, you can save the contents of the buffer to flash memory. For more information, see the **logging savelog** command.

You can view syslog messages that have been sent to the buffer with the **show logging** command.

Examples

The following example configures logging to the buffer for severity level 0 and level 1 events:

```
hostname(config)# logging buffered alerts
hostname(config)#
```

The following example creates a list named" notif-list" with a maximum severity level of 7 and configures logging to the buffer for syslog messages identified by the "notif-list" list:

```
hostname(config)# logging list notif-list level 7
hostname(config)# logging buffered notif-list
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
logging buffer-size	Specifies log buffer size.
logging enable	Enables logging.
logging list	Creates a reusable list of message selection criteria.
logging savelog	Saves the contents of the log buffer to flash memory.

logging buffer-size

To specify the size of the log buffer, use the **logging buffer-size** command in global configuration mode. To reset the log buffer to its default size of 4 KB of memory, use the **no** form of this command.

logging buffer-size *bytes*

no logging buffer-size *bytes*

Syntax Description

bytes	Sets the amount of memory used for the log buffer, in bytes. For example, if you specify 8192, the ASA uses 8 KB of memory for the log buffer.

Defaults

The default log buffer size is 4 KB of memory.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To see whether the ASA is using a log buffer of a size other than the default buffer size, use the **show running-config logging** command. If the **logging buffer-size** command is not shown, then the ASA uses a log buffer of 4 KB.

For more information about how the ASA uses the buffer, see the **logging buffered** command.

Examples

The following example enables logging, enables the logging buffer, and specifies that the ASA uses 16 KB of memory for the log buffer:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging buffer-size 16384
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
logging buffered	Enables logging to the log buffer.
logging enable	Enables logging.
logging flash-bufferwrap	Writes the log buffer to flash memory when the log buffer is full.
logging savelog	Saves the contents of the log buffer to flash memory.

logging class

To configure the maximum severity level per logging destination for a message class, use the **logging class** command in global configuration mode. To remove a message class severity level configuration, use the **no** form of this command.

logging class *class destination level* [*destination level . . .*]

no logging class *class*

Syntax Description

class	Specifies the message class whose maximum severity levels are configured per destination. For valid values of *class*, see the "Usage Guidelines" section.
destination	Specifies a logging destination for *class*. For the destination, the *level* determines the maximum severity level sent to *destination*. For valid values of *destination*, see the "Usage Guidelines" section that follows.
level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action is needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.

Defaults

By default, the ASA does not apply severity levels on a logging destination and message class basis. Instead, each enabled logging destination receives messages for all classes at the severity level determined by the logging list or severity level specified when you enabled the logging destination.

Command Modes

The following table shows the modes in which you may enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Added **eigrp** to valid class values.
8.2(1)	Added **dap** to valid class values.

Usage Guidelines

Valid values for *class* include the following:

- **auth**—User authentication.
- **bridge**—Transparent firewall.
- **ca**—PKI certificate authority.
- **config**—Command interface.
- **dap—**Dynamic Access Policies.
- **eap**—Extensible Authentication Protocol (EAP). Logs the following types of events to support Network Admission Control: EAP session state changes, EAP status query events, and a hexadecimal dump of EAP header and packet contents.
- **eapoudp**—Extensible Authentication Protocol (EAP) over UDP. Logs EAPoUDP events to support Network Admission Control, and generates a complete record of EAPoUDP header and packet contents.
- **eigrp**—EIGRP routing.
- **email**—Email proxy.
- **ha**—Failover.
- **ids**—Intrusion detection system.
- **ip**—IP stack.
- **ipaa—**IP address assignment
- **nac**—Network Admission Control. Logs the following types of events: initializations, exception list matches, ACS transactions, clientless authentications, default ACL applications, and revalidations.
- **np**—Network processor.
- **ospf**—OSPF routing.
- **rip**—RIP routing.
- **rm**—Resource Manager.
- **session**—User session.
- **snmp**—SNMP.
- **sys**—System.
- **vpn**—IKE and IPSec.
- **vpnc**—VPN client.
- **vpnfo**—VPN failover.
- **vpnlb**—VPN load balancing.

Valid logging destinations are as follows:

- **asdm**—To learn about this destination, see the **logging asdm** command.

- **buffered**—To learn about this destination, see the **logging buffered** command.
- **console**—To learn about this destination, see the **logging console** command.
- **history**—To learn about this destination, see the **logging history** command.
- **mail**—To learn about this destination, see the **logging mail** command.
- **monitor**—To learn about this destination, see the **logging monitor** command.
- **trap**—To learn about this destination, see the **logging trap** command.

Examples

The following example specifies that, for failover-related messages, the maximum severity level for the ASDM log buffer is 2 and the maximum severity level for the syslog buffer is 7:

```
hostname(config)# logging class ha asdm 2 buffered 7
```

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging console

To enable the ASA to display syslog messages in console sessions, use the **logging console** command in global configuration mode. To disable the display of syslog messages in console sessions, use the **no** form of this command.

logging console [*logging_list* | *level*]

no logging console

Note We recommend that you do not use this command, because it may cause many syslog messages to be dropped due to buffer overflow. For more information, see the "Usage Guidelines" section.

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the console session. For information about creating lists, see the **logging list** command.

Defaults

The ASA does not display syslog messages in console sessions by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Before any messages are sent to the console, you must enable logging using the **logging enable** command.

Caution Using the **logging console** command could significantly degrade system performance. Instead, use the **logging buffered** command to start logging and the **show logging** command to view the messages. To make viewing the most current messages easier, use the **clear logging buffer** command to clear the buffer.

Examples

The following example shows how to enable syslog messages of severity levels 0, 1, 2, and 3 to appear in console sessions:

```
hostname(config)# logging enable
hostname(config)# logging console errors
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging list	Creates a reusable list of message selection criteria.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging debug-trace

To redirect debugging messages to logs as syslog message 711001 issued at severity level 7, use the **logging debug-trace** command in global configuration mode. To stop sending debugging messages to logs, use the **no** form of this command.

logging debug-trace

no logging debug-trace

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA does not include debugging output in syslog messages.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Debugging messages are generated as severity level 7 messages. They appear in logs with the syslog message number 711001, but do not appear in any monitoring session.

Examples

The following example shows how to enable logging, send log messages to the system log buffer, redirect debugging output to logs, and turn on debugging of disk activity.

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging debug-trace
hostname(config)# debug disk filesystem
```

The following is sample output of a debugging message that could appear in the logs:

```
%ASA-7-711001: IFS: Read: fd 3, bytes 4096
```

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging device-id

To configure the ASA to include a device ID in non-EMBLEM-format syslog messages, use the **logging device-id** command in global configuration mode. To disable the use of a device ID, use the **no** form of this command.

logging device-id {**cluster-id** | **context-name** | **hostname** | **ipaddress** *interface_name* [**system**] | **string** *text*}

no logging device-id {**cluster-id** | **context-name** | **hostname** | **ipaddress** *interface_name* [**system**] | **string** *text*}

Syntax Description

cluster-id	Specifies the unique name of an individual ASA unit in the cluster as the device ID.
hostname	Specifies the hostname of the ASA as the device ID.
ipaddress *interface_name*	Specifies the device ID or the IP address of the interface in *interface_name*. If you use the **ipaddress** keyword, syslog messages sent to an external server include the IP address of the interface specified, regardless of which interface the ASA uses to send the log data to the external server.
string *text*	Specifies the characters included in *text* as the device ID, which can be up to 16 characters long. You cannot use white space characters or any of the following characters: • &—ampersand • '—single quote • "—double quote • <—less than • >—greater than • ?—question mark
system	(Optional) In the cluster environment, dictates that the device ID becomes the system IP address on the interface.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The **cluster-id** and **system** keywords have been added.

Usage Guidelines

If you use the **ipaddress** keyword, the device ID becomes the specified ASA interface IP address, regardless of the interface from which the message is sent. This keyword provides a single, consistent device ID for all messages that are sent from the device. If you use the **system** keyword, the specified ASA uses the system IP address instead of the local IP address of the unit in a cluster. The **cluster-id** and **system** keywords apply to the ASA 5580 and 5585-X only.

Examples

The following example shows how to configure a host named “secappl-1”:

```
hostname(config)# logging device-id hostname
hostname(config)# show logging
Syslog logging: disabled
Facility: 20
Timestamp logging: disabled
Standby logging: disabled
Console logging: disabled
Monitor logging: disabled
Buffer logging: level informational, 991 messages logged
Trap logging: disabled
History logging: disabled
Device ID: hostname "secappl-1"
```

The hostname appears at the beginning of syslog messages, as shown in the following message:

```
secappl-1 %ASA-5-111008: User 'enable_15' executed the 'logging buffer-size 4096' command.
```

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging emblem

To use the EMBLEM format for syslog messages sent to destinations other than a syslog server, use the **logging emblem** command in global configuration mode. To disable the use of EMBLEM format, use the **no** form of this command.

logging emblem

no logging emblem

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA does not use EMBLEM format for syslog messages.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed to be independent of the **logging host** command.

Usage Guidelines

The **logging emblem** command lets you to enable EMBLEM-format logging for all logging destinations other than syslog servers. If you also enable the **logging timestamp** keyword, the messages with a time stamp are sent.

To enable EMBLEM-format logging for syslog servers, use the **format emblem** option with the **logging host** command.

Examples

The following example shows how to enable logging and enable the use of EMBLEM-format for logging to all logging destinations except syslog servers:

```
hostname(config)# logging enable
hostname(config)# logging emblem
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.

Command	Description
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging enable

To enable logging for all configured output locations, use the **logging enable** command in global configuration mode. To disable logging, use the **no** form of this command.

logging enable

no logging enable

Syntax Description

This command has no arguments or keywords.

Defaults

Logging is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **logging on** command.

Usage Guidelines

The **logging enable** command allows you to enable or disable sending syslog messages to any of the supported logging destinations. You can stop all logging with the **no logging enable** command.

You can enable logging to individual logging destinations with the following commands:

- **logging asdm**
- **logging buffered**
- **logging console**
- **logging history**
- **logging mail**
- **logging monitor**
- **logging trap**

Examples

The following example shows how to enable logging. The output of the **show logging** command illustrates how each possible logging destination must be enabled separately:

```
hostname(config)# logging enable
hostname(config)# show logging
Syslog logging: enabled
```

```
Facility: 20
Timestamp logging: disabled
Standby logging: disabled
Deny Conn when Queue Full: disabled
Console logging: disabled
Monitor logging: disabled
Buffer logging: disabled
Trap logging: disabled
History logging: disabled
Device ID: disabled
Mail logging: disabled
ASDM logging: disabled
```

Related Commands

Command	Description
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging facility

To specify the logging facility used for messages sent to syslog servers, use the **logging facility** command in global configuration mode. To reset the logging facility to its default of 20, use the **no** form of this command.

logging facility *facility*

no logging facility

Syntax Description

facility	Specifies the logging facility; valid values are 16 through 23.

Defaults

The default facility is 20 (LOCAL4).

Command Modes

The following table shows the modes in which you can enter the command, with the exceptions noted in the Syntax Description section.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Syslog servers file messages based on the *facility* number in the message. There are eight possible facilities: 16 (LOCAL0) through 23 (LOCAL7).

Examples

The following example shows how to specify that the ASA indicate the logging facility as 16 in syslog messages. The output of the **show logging** command includes the facility being used by the ASA:

```
hostname(config)# logging facility 16
hostname(config)# show logging
Syslog logging: enabled
    Facility: 16
    Timestamp logging: disabled
    Standby logging: disabled
    Deny Conn when Queue Full: disabled
    Console logging: disabled
    Monitor logging: disabled
    Buffer logging: disabled
    Trap logging: level errors, facility 16, 3607 messages logged
        Logging to infrastructure 10.1.2.3
    History logging: disabled
    Device ID: 'inside' interface IP address "10.1.1.1"
```

```
Mail logging: disabled
ASDM logging: disabled
```

Related Commands

Command	Description
logging enable	Enables logging.
logging host	Defines a syslog server.
logging trap	Enables logging to syslog servers.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging flash-bufferwrap

To enable the ASA to write the log buffer to flash memory every time the buffer is full of messages that have never been saved, use the **logging flash-bufferwrap** command in global configuration mode. To disable writing of the log buffer to flash memory, use the **no** form of this command.

logging flash-bufferwrap

no logging flash-bufferwrap

Syntax Description

This command has no arguments or keywords.

Defaults

The defaults are as follows:

- Logging to the buffer is disabled.
- Writing the log buffer to flash memory is disabled.
- The buffer size is 4 KB.
- Minimum free flash memory is 3 MB.
- Maximum flash memory allocation for buffer logging is 1 MB.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

For the ASA to write the log buffer to flash memory, you must enable logging to the buffer; otherwise, the log buffer never has data to be written to flash memory. To enable logging to the buffer, use the **logging buffered** command.

While the ASA writes log buffer contents to flash memory, it continues storing any new event messages to the log buffer.

The ASA creates log files with names that use a default time-stamp format, as follows:

`LOG-`*`YYYY-MM-DD-HHMMSS`*`.TXT`

where *YYYY* is the year, *MM* is the month, *DD* is the day of the month, and *HHMMSS* is the time in hours, minutes, and seconds.

The availability of flash memory affects how the ASA saves syslog messages using the **logging flash-bufferwrap** command. For more information, see the **logging flash-maximum-allocation** and the **logging flash-minimum-free** commands.

Examples

The following example shows how to enable logging, enable the log buffer, and enable the ASA to write the log buffer to flash memory:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging flash-bufferwrap
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
copy	Copies a file from one location to another, including to a TFTP or FTP server.
delete	Deletes a file from the disk partition, such as saved log files.
logging buffered	Enables logging to the log buffer.
logging buffer-size	Specifies log buffer size.

logging flash-maximum-allocation

To specify the maximum amount of flash memory that the ASA uses to store log data, use the **logging flash-maximum-allocation** command in global configuration mode. To reset the maximum amount of flash memory used for this purpose to its default size of 1 MB of flash memory, use the **no** form of this command.

logging flash-maximum-allocation *kbytes*

no logging flash-maximum-allocation *kbytes*

Syntax Description

kbytes	The largest amount of flash memory, in kilobytes, that the ASA can use to save log buffer data.

Defaults

The default maximum flash memory allocation for log data is 1 MB.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command determines how much flash memory is available for the **logging savelog** and **logging flash-bufferwrap** commands.

If a log file to be saved by **logging savelog** or **logging flash-bufferwrap** causes flash memory use for log files to exceed the maximum amount specified by the **logging flash-maximum-allocation** command, the ASA deletes the oldest log files to free sufficient memory for the new log file. If there are no files to delete or if, after all old files are deleted, free memory is too small for the new log file, the ASA fails to save the new log file.

To see whether the ASA has a maximum flash memory allocation of a size different than the default size, use the **show running-config logging** command. If the **logging flash-maximum-allocation** command is not shown, then the ASA uses a maximum of 1 MB for saved log buffer data. The memory allocated is used for both the **logging savelog** and **logging flash-bufferwrap** commands.

For more information about how the ASA uses the log buffer, see the **logging buffered** command.

Examples

The following example shows how to enable logging, enable the log buffer, enable the ASA to write the log buffer to flash memory, with the maximum amount of flash memory used for writing log files set to approximately 1.2 MB of memory:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging flash-bufferwrap
hostname(config)# logging flash-maximum-allocation 1200
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages it contains.
logging buffered	Enables logging to the log buffer.
logging enable	Enables logging.
logging flash-bufferwrap	Writes the log buffer to flash memory when the log buffer is full.
logging flash-minimum-free	Specifies the minimum amount of flash memory that must be available for the ASA to permit writing of the log buffer to flash memory.

logging flash-minimum-free

To specify the minimum amount of free flash memory that must exist before the ASA saves a new log file, use the **logging flash-minimum-free** command in global configuration mode. To reset the minimum required amount of free flash memory to its default size of 3 MB, use the **no** form of this command.

logging flash-minimum-free *kbytes*

no logging flash-minimum-free *kbytes*

Syntax Description

kbytes	The minimum amount of flash memory, in kilobytes, that must be available before the ASA saves a new log file.

Defaults

The default minimum free flash memory is 3 MB.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The logging flash-minimum-free command specifies how much flash memory the **logging savelog** and **logging flash-bufferwrap** commands must preserve at all times.

If a log file to be saved by **logging savelog** or **logging flash-bufferwrap** would cause the amount of free flash memory to fall below the limit specified by the **logging flash-minimum-free** command, the ASA deletes the oldest log files to ensure that the minimum amount of memory remains free after saving the new log file. If there are no files to delete or if, after all old files are deleted, free memory would still be below the limit, the ASA fails to save the new log file.

Examples

The following example shows how to enable logging, enable the log buffer, enable the ASA to write the log buffer to flash memory, and specifies that the minimum amount of free flash memory must be 4000 KB:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging flash-bufferwrap
hostname(config)# logging flash-minimum-free 4000
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
logging buffered	Enables logging to the log buffer.
logging enable	Enables logging.
logging flash-bufferwrap	Writes the log buffer to flash memory when the log buffer is full.
logging flash-maximum-allocation	Specifies the maximum amount of flash memory that can be used for writing log buffer contents.

logging flow-export-syslogs enable | disable

To enable all of the syslog messages that NetFlow captures, use the **logging flow-export-syslogs enable** command in global configuration mode. To disable all of the syslog messages that NetFlow captures, use the **logging flow-export-syslogs disable** command in global configuration mode.

logging flow-export-syslogs {enable | disable}

Syntax Description

This command has no arguments or keywords.

Defaults

By default, all syslogs that are captured by NetFlow are enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.1(1)	This command was introduced.

Usage Guidelines

If the security appliance is configured to export NetFlow data, to improve performance, we recommend that you disable redundant syslog messages (those also captured by NetFlow) by entering the **logging flow-export-syslogs disable** command. The syslog messages that will be disabled are as follows:

Syslog Message	Description
106015	A TCP flow was denied because the first packet was not a SYN packet.
106023	A flow that is denied by an ingress ACL or an egress ACL that is attached to an interface through the **access-group** command.
106100	A flow that is permitted or denied by an ACL.
302013 and 302014	A TCP connection and deletion.
302015 and 302016	A UDP connection and deletion.
302017 and 302018	A GRE connection and deletion.
302020 and 302021	An ICMP connection and deletion.
313001	An ICMP packet to the security appliance was denied.
313008	An ICMPv6 packet to the security appliance was denied.
710003	An attempt to connect to the security appliance was denied.

Note Although this is a configuration mode command, it is not stored in the configuration. Only the **no logging message xxxxxx** commands are stored in the configuration.

Examples

The following example shows how to disable redundant syslog messages that NetFlow captures and the sample output that appears:

```
hostname(config)# logging flow-export-syslogs disable

hostname(config)# show running-config logging

no logging message xxxxx1
no logging message xxxxx2
```

where the *xxxxx1* and *xxxxx2* are syslog messages that are redundant because the same information has been captured through NetFlow. This command is like a command alias, and will convert to a batch of **no logging message xxxxxx** commands. After you have disabled the syslog messages, you can enable them individually with the **logging message xxxxxx** command, where *xxxxxx* is the specific syslog message number.

Related Commands

Commands	Description
flow-export destination *interface-name ipv4-address* | *hostname udp-port*	Specifies the IP address or hostname of the NetFlow collector, and the UDP port on which the NetFlow collector is listening.
flow-export template timeout-rate *minutes*	Controls the interval at which the template information is sent to the NetFlow collector.
show flow-export counters	Displays a set of runtime counters for NetFlow.

logging from-address

To specify the sender e-mail address for syslog messages sent by the ASA, use the **logging from-address** command in global configuration mode. All sent syslog messages appear to come from the address you specify. To remove the sender e-mail address, use the **no** form of this command.

logging from-address *from-email-address*

no logging from-address *from-email-address*

Syntax Description

from-email-address	Source e-mail address, that is, the e-mail address that syslog messages appear to come from (for example, cdb@example.com).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Sending syslog messages by e-mail is enabled by the **logging mail** command.

The address specified with this command need not correspond to an existing e-mail account.

Examples

To enable logging and set up the ASA to send syslog messages by e-mail, use the following criteria:

- Send messages that are critical, alerts, or emergencies.
- Send messages using ciscosecurityappliance@example.com as the sender address.
- Send messages to admin@example.com.
- Send messages using SMTP, the primary servers pri-smtp-host, and secondary server sec-smtp-host.

Enter the following commands:

```
hostname(config)# logging enable
hostname(config)# logging mail critical
hostname(config)# logging from-address ciscosecurityappliance@example.com
hostname(config)# logging recipient-address admin@example.com
hostname(config)# smtp-server pri-smtp-host sec-smtp-host
```

Related Commands

Command	Description
logging enable	Enables logging.
logging mail	Enables the ASA to send syslog messages by e-mail and determines which messages are sent by e-mail.
logging recipient-address	Specifies the e-mail address to which syslog messages are sent.
smtp-server	Configures an SMTP server.
show logging	Displays the enabled logging options.

logging ftp-bufferwrap

To enable the ASA to send the log buffer to an FTP server every time the buffer is full of messages that have never been saved, use the **logging ftp-bufferwrap** command in global configuration mode. To disable sending the log buffer to an FTP server, use the **no** form of this command.

logging ftp-bufferwrap

no logging ftp-bufferwrap

Syntax Description

This command has no arguments or keywords.

Defaults

The defaults are as follows:

- Logging to the buffer is disabled.
- Sending the log buffer to an FTP server is disabled.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When you enable **logging ftp-bufferwrap**, the ASA sends log buffer data to the FTP server that you specify with the **logging ftp-server** command. While the ASA sends log data to the FTP server, it continues storing any new event messages to the log buffer.

For the ASA to send log buffer contents to an FTP server, you must enable logging to the buffer; otherwise, the log buffer never has data to be written to flash memory. To enable logging to the buffer, use the **logging buffered** command.

The ASA creates log files with names that use a default time-stamp format, as follows:

`LOG-`*`YYYY-MM-DD-HHMMSS`*`.TXT`

where *YYYY* is the year, *MM* is the month, *DD* is the day of the month, and *HHMMSS* is the time in hours, minutes, and seconds.

Examples

The following example shows how to enable logging, enable the log buffer, specify an FTP server, and enable the ASA to write the log buffer to an FTP server. The example specifies an FTP server whose hostname is logserver-352. The server can be accessed with the username, logsupervisor and password, 1luvMy10gs. Log files are to be stored in the /syslogs directory:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging ftp-server logserver-352 /syslogs logsupervisor 1luvMy10gs
hostname(config)# logging ftp-bufferwrap
hostname(config)#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
logging buffered	Enables logging to the log buffer.
logging buffer-size	Specifies log buffer size.
logging enable	Enables logging.
logging ftp-server	Specifies FTP server parameters for use with the **logging ftp-bufferwrap** command.

logging ftp-server

To specify details about the FTP server that the ASA sends log buffer data to when **logging ftp-bufferwrap** is enabled, use the **logging ftp-server** command in global configuration mode. To remove all details about an FTP server, use the **no** form of this command.

logging ftp-server *ftp_server path username* [*0* | *8*] *password*

no logging ftp-server *ftp_server path username* [*0* | *8*] *password*

Syntax Description

0	(Optional) Specifies that an unencrypted (clear text) user password will follow.
8	(Optional) Specifies that an encrypted user password will follow.
ftp-server	External FTP server IP address or hostname. **Note** If you specify a hostname, be sure that DNS is operating correctly on your network.
password	The password for the username specified, which can be up to 64 characters long.
path	Directory path on the FTP server where the log buffer data is to be saved. This path is relative to the FTP root directory. For example: `/security_appliances/syslogs/appliance107`
username	A username that is valid for logging in to the FTP server.

Defaults

No FTP server is specified by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.3(1)	Support for password encryption has been added.

Usage Guidelines

You can only specify one FTP server. If a logging FTP server is already specified, using the **logging ftp-server** command replaces this FTP server configuration with the new one that you enter.

The ASA does not verify the FTP server information that you specify. If you misconfigure any of the details, the ASA fails to send log buffer data to the FTP server.

During bootup or upgrade of the ASA, single-digit passwords and passwords startingwith a digit followed by a whitespace are not supported. For example, 0 pass and 1 are invalid passwords.

Examples

The following example shows how to enable logging, enable the log buffer, specify an FTP server, and enable the ASA to write the log buffer to an FTP server. This example specifies an FTP server whose hostname is logserver. The server can be accessed with the username, user1 and password, pass1. Log files are to be stored in the /path1 directory:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# logging ftp-server logserver /path1 user1 pass1
hostname(config)# logging ftp-bufferwrap
```

The following example shows how to enter an encrypted password:

```
hostname(config)# logging ftp-server logserver /path1 user1 8 JPAGWzIIFVlheXv2I9nglfytOzHU
```

The following example shows how to enter an unencrypted (clear text) password:

```
hostname(config)# logging ftp-server logserver /path1 user1 0 pass1
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
logging buffered	Enables logging to the log buffer.
logging buffer-size	Specifies log buffer size.
logging enable	Enables logging.
logging ftp-bufferwrap	Sends the log buffer to an FTP server when the log buffer is full.

logging history

To enable SNMP logging and specify which messages are to be sent to SNMP servers, use the **logging history** command in global configuration mode. To disable SNMP logging, use the **no** form of this command.

logging history [*logging_list* | *level*]

no logging history

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the SNMP server. For information about creating lists, see the **logging list** command.

Defaults

The ASA does not log to SNMP servers by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **logging history** command allows you to enable logging to an SNMP server and to set the SNMP message level or event list.

Examples

The following example shows how to enable SNMP logging and specify that messages of severity levels 0, 1, 2, and 3 are sent to the SNMP server configured:

```
hostname(config)# logging enable
hostname(config)# snmp-server host infrastructure 10.2.3.7 trap community gam327
hostname(config)# snmp-server enable traps syslog
hostname(config)# logging history errors
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging list	Creates a reusable list of message selection criteria.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.
snmp-server	Specifies SNMP server details.

logging host

To define a syslog server, use the **logging host** command in global configuration mode. To remove a syslog server definition, use the **no** form of this command.

logging host *interface_name syslog_ip* [**tcp/***port* | **udp/***port*] [**format emblem**] [**secure**]

no logging host *interface_name syslog_ip* [**tcp/***port* | **udp/***port*] [**format emblem**] [**secure**]

Syntax Description

format emblem	(Optional) Enables EMBLEM format logging for the syslog server.
interface_name	Specifies the interface on which the syslog server resides.
port	Indicates the port that the syslog server listens to for messages. Valid port values are 1025 through 65535 for either protocol. If you enter zero as a port number, or use an invalid character or symbol, an error occurs.
secure	(Optional) Specifies that the connection to the remote logging host should use SSL/TLS. This option is valid only if the protocol selected is TCP. **Note** A secure logging connection can only be established with an SSL/TLS-capable syslog server. If an SSL/TLS connection cannot be established, all new connections will be denied. You may change this default behavior by entering the **logging permit-hostdown** command.
syslog_ip	Specifies the IP address of the syslog server.
tcp	Specifies that the ASA should use TCP to send messages to the syslog server.
udp	Specifies that the ASA should use UDP to send messages to the syslog server.

Defaults

The default protocol is UDP.

The default setting for the **format emblem** option is false.

The default setting for the **secure** option is false.

The default port numbers are as follows:

- UDP—514
- TCP —1470

Command Modes

The following table shows the modes in which you can enter the command.

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0	This command was introduced.
8.0(2)	The **secure** keyword was added.
8.4(1)	Connection blocking can be enabled and disabled.

Usage Guidelines

The **logging host** *syslog_ip* **format emblem** command allows you to enable EMBLEM-format logging for each syslog server. EMBLEM-format logging is available for UDP syslog messages only. If you enable EMBLEM-format logging for a particular syslog server, then the messages are sent to that server. If you use the **logging timestamp** command, the messages with a time stamp are also sent.

You can use multiple **logging host** commands to specify additional servers that would all receive the syslog messages. However, you can only specify a server to receive either UDP or TCP syslog messages, not both.

The default setting for connection blocking is on when the **logging host** command has been configured to use TCP to send messages to a syslog server. If a TCP-based syslog server is configured, you can disable connection blocking with the **logging permit-hostdown** command.

Note When the **tcp** option is used in the **logging host** command, the ASA will drop connections across the firewall if the syslog server is unreachable.

You can display only the *port* and *protocol* values that you previously entered by using the **show running-config logging** command and finding the command in the listing—TCP is listed as 6, and UDP is listed as 17. TCP ports work only with the syslog server. The *port* must be the same port on which the syslog server listens.

Note An error message occurs if you try to use the **logging host** command and the **secure** keyword with UDP.

Sending syslogs over TCP is not supported on a standby ASA.

Examples

The following example shows how to send syslog messages of severity levels 0, 1, 2, and 3 to a syslog server on the inside interface that uses the default protocol and port number:

```
hostname(config)# logging enable
hostname(config)# logging host inside 10.2.2.3
hostname(config)# logging trap errors
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging trap	Enables logging to syslog servers.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging list

To create a logging list to use in other commands to specify messages by various criteria (logging level, event class, and message IDs), use the **logging list** command in global configuration mode. To remove the list, use the **no** form of this command.

logging list *name* {**level** *level* [**class** *event_class*] | **message** *start_id*[**-***end_id*]}

no logging list *name*

Syntax Description

class *event_class*	(Optional) Sets the class of events for syslog messages. For the level specified, only syslog messages of the class specified are identified by the command. See the "Usage Guidelines" section for a list of classes.
level *level*	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
message *start_id*[**-***end_id*]	Specified a message ID or range of IDs. To look up the default level of a message, use the **show logging** command or see the syslog messages guide.
name	Sets the logging list name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Logging commands that can use lists are the following:

- **logging asdm**
- **logging buffered**
- **logging console**
- **logging history**
- **logging mail**
- **logging monitor**
- **logging trap**

Possible values for the *event_class* include the following:

- **auth**—User authentication.
- **bridge**—Transparent firewall.
- **ca**—PKI certificate authority.
- **config**—Command interface.
- **eap**—Extensible Authentication Protocol (EAP). Logs the following types of events to support Network Admission Control: EAP session state changes, EAP status query events, and a hexadecimal dump of EAP header and packet contents.
- **eapoudp**—Extensible Authentication Protocol (EAP) over UDP. Logs EAPoUDP events to support Network Admission Control, and generates a complete record of EAPoUDP header and packet contents.
- **email**—Email proxy.
- **ha**—Failover.
- **ids**—Intrusion detection system.
- **ip**—IP stack.
- **nac**—Network Admission Control. Logs the following types of events: initializations, exception list matches, ACS transactions, clientless authentications, default ACL applications, and revalidations.
- **np**—Network processor.
- **ospf**—OSPF routing.
- **rip**—RIP routing.
- **session**—User session.
- **snmp**—SNMP.
- **sys**—System.
- **vpn**—IKE and IPSec.
- **vpnc**—VPN client.
- **vpnfo**—VPN failover.
- **vpnlb**—VPN load balancing.

Examples

The following example shows how to use the logging list command:

```
hostname(config)# logging list my-list 100100-100110
hostname(config)# logging list my-list level critical
```

```
hostname(config)# logging list my-list level warning class vpn
hostname(config)# logging buffered my-list
```

The preceding example states that syslog messages that match the criteria specified will be sent to the logging buffer. The criteria specified in this example are:

- Syslog message IDs that fall in the range of 100100 to 100110
- All syslog messages with critical level or higher (emergency, alert, or critical)
- All VPN class syslog messages with warning level or higher (emergency, alert, critical, error, or warning)

If a syslog message satisfies any one of these conditions, it is logged to the buffer.

Note When you design list criteria, the criteria can specify overlapping sets of messages. Syslog messages matching more than one set of criteria are logged normally.

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging mail

To enable the ASA to send syslog messages by e-mail and to determine which messages are sent by e-mail, use the **logging mail** command in global configuration mode. To disable e-mailing of syslog messages, use the **no** form of this command.

logging mail [*logging_list* | *level*]

no logging mail [*logging_list* | *level*]

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the e-mail recipient. For information about creating lists, see the **logging list** command.

Defaults

Logging to e-mail is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

E-mailed syslog messages appear in the subject line of the e-mails sent.

Examples

To set up the ASA to send syslog messages by e-mail, use the following criteria:

- Send messages that are critical, alerts, or emergencies.
- Send messages using ciscosecurityappliance@example.com as the sender address.
- Send messages to admin@example.com.
- Send messages using SMTP, the primary servers pri-smtp-host, and secondary server sec-smtp-host.

Enter the following commands:

```
hostname(config)# logging mail critical
hostname(config)# logging from-address ciscosecurityappliance@example.com
hostname(config)# logging recipient-address admin@example.com
hostname(config)# smtp-server pri-smtp-host sec-smtp-host
```

Related Commands

Command	Description
logging enable	Enables logging.
logging from-address	Specifies the e-mail address from which e-mailed syslog messages appear to come.
logging list	Creates a reusable list of message selection criteria.
logging recipient-address	Specifies the e-mail address to which e-mailed syslog messages are sent.
smtp-server	Configures an SMTP server.

logging message

To specify the logging level of a syslog message, use the **logging message** command with the **level** keyword in global configuration mode. To reset the logging level of a message to its default level, use the **no** form of this command.

logging message *syslog_id* **level** *level*

no logging message *syslog_id* **level** *level*

logging message *syslog_id*

no logging message *syslog_id*

Syntax Description

level *level*	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
syslog_id	The ID of the syslog message that you want to enable or disable or whose severity level you want to modify. To look up the default level of a message, use the **show logging** command or see the syslog messages guide.

Defaults

By default, all syslog messages are enabled and the severity levels of all messages are set to their default levels.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can use the **logging message** command for two purposes:

- To control whether a message is enabled or disabled.
- To control the severity level of a message.

You can use the **show logging** command to determine the level currently assigned to a message and whether the message is enabled.

To prevent the ASA from generating a particular syslog message, use the **no** form of the **logging message** command (without the **level** keyword) in global configuration mode. To let the ASA generate a particular syslog message, use the **logging message** command (without the **level** keyword). These two versions of the **logging message** command can be used in parallel.

Examples

The series of commands in the following example show the use of the **logging message** command to control both whether a message is enabled and the severity level of the message:

```
hostname(config)# show logging message 403503
syslog 403503: default-level errors (enabled)

hostname(config)# logging message 403503 level 1
hostname(config)# show logging message 403503
syslog 403503: default-level errors, current-level alerts (enabled)

hostname(config)# no logging message 403503
hostname(config)# show logging message 403503
syslog 403503: default-level errors, current-level alerts (disabled)

hostname(config)# logging message 403503
hostname(config)# show logging message 403503
syslog 403503: default-level errors, current-level alerts (enabled)

hostname(config)# no logging message 403503 level 3
hostname(config)# show logging message 403503
syslog 403503: default-level errors (enabled)
```

Related Commands

Command	Description
clear configure logging	Clears all logging configuration or message configuration only.
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging monitor

To enable the ASA to display syslog messages in SSH and Telnet sessions, use the **logging monitor** command in global configuration mode. To disable the display of syslog messages in SSH and Telnet sessions, use the **no** form of this command.

logging monitor [*logging_list* | *level*]

no logging monitor

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the SSH or Telnet session. For information about creating lists, see the **logging list** command.

Defaults

The ASA does not display syslog messages in SSH and Telnet sessions by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **logging monitor** command enables syslog messages for all sessions in the current context; however, in each session, the **terminal** command controls whether syslog messages appear in that session.

Examples

The following example shows how to enable the display of syslog messages in console sessions. The use of the **errors** keyword indicates that messages of severity levels 0, 1, 2, and 3 should display in SSH and Telnet sessions. The **terminal** command enables the messages to appear in the current session:

```
hostname(config)# logging enable
hostname(config)# logging monitor errors
hostname(config)# terminal monitor
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging list	Creates a reusable list of message selection criteria.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.
terminal	Sets terminal line parameters.

logging permit-hostdown

To make the status of a TCP-based syslog server irrelevant to new user sessions, use the **logging permit-hostdown** command in global configuration mode. To cause the ASA to deny new user sessions when a TCP-based syslog server is unavailable, use the **no** form of this command.

logging permit-hostdown

no logging permit-hostdown

Syntax Description

This command has no arguments or keywords.

Defaults

By default, if you have enabled logging to a syslog server that uses a TCP connection, the ASA does not allow new network access sessions when the syslog server is unavailable for any reason. The default setting is false for the **logging permit-hostdown** command.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you are using TCP as the logging transport protocol for sending messages to a syslog server, the ASA denies new network access sessions as a security measure if the ASA is unable to reach the syslog server. You can use the **logging permit-hostdown** command to remove this restriction.

Examples

The following example makes the status of TCP-based syslog servers irrelevant to whether the ASA permits new sessions. When the **logging permit-hostdown** command includes in its output the **show running-config logging** command, the status of TCP-based syslog servers is irrelevant to new network access sessions.

```
hostname(config)# logging permit-hostdown
hostname(config)# show running-config logging
logging enable
logging trap errors
logging host infrastructure 10.1.2.3 6/1470
logging permit-hostdown
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging host	Defines a syslog server.
logging trap	Enables logging to syslog servers.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging queue

To specify how many syslog messages the ASA may hold in its queue before processing them according to the logging configuration, use the **logging queue** command in global configuration mode. To reset the logging queue size to the default of 512 messages, use the **no** form of this command.

logging queue *queue_size*

no logging queue *queue_size*

Syntax Description

queue_size	The number of syslog messages permitted in the queue used for storing syslog messages before processing them. Valid values are from 0 to 8192 messages, depending on the platform type. If the logging queue is set to zero, the queue will be the maximum configurable size (8192 messages), depending on the platform. On the ASA-5505, the maximum queue size is 1024. On the ASA-5510, it is 2048, and on all other platforms, it is 8192 .

Defaults

The default queue size is 512 messages.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

When traffic is so heavy that the queue fills up, the ASA may discard messages. On the ASA-5505, the maximum queue size is 1024. On the ASA-5510, it is 2048. On all other platforms, it is 8192 .

Examples

The following example shows how to display the output of the **logging queue** and **show logging queue** commands:

```
hostname(config)# logging queue 0
hostname(config)# show logging queue
Logging Queue length limit : Unlimited
Current 5 msg on queue, 3513 msgs most on queue, 1 msg discard.
```

In this example, the **logging queue** command is set to 0, which means that the queue is set to the maximum of 8192. The syslog messages in the queue are processed by the ASA in the manner dictated by the logging configuration, such as sending syslog messages to mail recipients, saving them to flash memory, and so forth.

The output of this example **show logging queue** command shows that 5 messages are queued, 3513 messages was the largest number of messages in the queue at one time since the ASA was last booted, and that 1 message was discarded. Even though the queue was set for unlimited messages, the message was discarded because no block memory was available to add the message to the queue.

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging rate-limit

To limit the rate at which syslog messages are generated, use the **logging rate-limit** command in privileged EXEC mode. To disable rate limiting, use the **no** form of this command in privileged EXEC mode.

logging rate-limit {**unlimited** | {*num* [*interval*]}} **message** *syslog_id* | **level** *severity_level*

[no] logging rate-limit [**unlimited** | {*num* [*interval*]}} **message** *syslog_id*] **level** *severity_level*

Syntax Description

interval	(Optional) Time interval (in seconds) to use for measuring the rate at which messages are generated. The valid range of values for *interval* is 0 through 2147483647.
level *severity_level*	Applies the set rate limits on all syslog messages that belong to a certain severity level. All syslog messages at a specified severity level are rate-limited individually. The valid range for *severity_level* is 1 through 7.
message	Suppresses reporting of this syslog message.
num	Number of syslog messages that can be generated during the specified time interval. The valid range of values for *num* is 0 through 2147483647.
syslog_id	ID of the syslog message to be suppressed. The valid range of values is 100000-999999.
unlimited	Disables rate limiting, which means that there is no limit on the logging rate.

Defaults

The default setting for *interval* is 1.

Command Modes

The following table shows the modes in which you can enter the command.

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

The syslog message severity levels are as follows:

- 0—System is unusable
- 1—Immediate action needed
- 2—Critical Conditions
- 3—Error Conditions

- 4—Warning Conditions
- 5—Normal but significant conditions
- 6—Informational Messages
- 7—Debugging Messages

Examples

To limit the rate of syslog message generation, you can enter a specific message ID. The following example shows how to limit the rate of syslog message generation using a specific message ID and time interval:

```
hostname(config)# logging rate-limit 100 600 message 302020
```

This example suppresses syslog message 302020 from being sent to the host after the rate limit of 100 is reached in the specified interval of 600 seconds.

To limit the rate of syslog message generation, you can enter a specific severity level. The following example shows how to limit the rate of syslog message generation using a specific severity level and time interval.

```
hostname(config)# logging rate-limit 1000 600 level 6
```

This example suppresses all syslog messages under severity level 6 to the specified rate limit of 1000 in the specified time interval of 600 seconds. Each syslog message in severity level 6 has a rate limit of 1000.

Related Commands

Command	Description
clear running-config logging rate-limit	Resets the logging rate limit setting to its default.
show logging	Shows the messages currently in the internal buffer or logging configuration settings.
show running-config logging rate-limit	Shows the current logging rate limit setting.

logging recipient-address

To specify the receiving e-mail address for syslog messages sent by the ASA, use the **logging recipient-address** command in global configuration mode. To remove the receiving e-mail address, use the **no** form of this command.

logging recipient-address *address* [**level** *level*]

no logging recipient-address *address* [**level** *level*]

Syntax Description

address	Specifies recipient e-mail address when sending syslog messages by e-mail.
level	Indicates that a severity level follows.
level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages. **Note** We do not recommend using a severity level greater than 3 with the **logging recipient-address** command. Higher severity levels are likely to cause dropped syslog messages because of buffer overflow. The message severity level specified by a **logging recipient-address** command overrides the message severity level specified by the **logging mail** command. For example, if a **logging recipient-address** command specifies a severity level of 7 but the **logging mail** command specifies a severity level of 3, the ASA sends all messages to the recipient, including those of severity levels 4, 5, 6, and 7.

Defaults

The default value is set to the errors logging level.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can configure up to 5 recipient addresses. If you want, each recipient address can have a different message level than that specified by the **logging mail** command. Sending syslog messages by e-mail is enabled by the **logging mail** command.

Use this command to have more urgent messages sent to a larger number of recipients.

Examples

To set up the ASA to send syslog messages by e-mail, use the following criteria:

- Send messages that are critical, alerts, or emergencies.
- Send messages using ciscosecurityappliance@example.com as the sender address.
- Send messages to admin@example.com.
- Send messages using SMTP, the primary servers pri-smtp-host, and secondary server sec-smtp-host.

Enter the following commands:

```
hostname(config)# logging mail critical
hostname(config)# logging from-address ciscosecurityappliance@example.com
hostname(config)# logging recipient-address admin@example.com
hostname(config)# smtp-server pri-smtp-host sec-smtp-host
```

Related Commands

Command	Description
logging enable	Enables logging.
logging from-address	Specifies the e-mail address from which syslog messages appear to come.
logging mail	Enables the ASA to send syslog messages by e-mail and determines which messages are sent by e-mail.
smtp-server	Configures an SMTP server.
show logging	Displays the enabled logging options.

logging savelog

To save the log buffer to flash memory, use the **logging savelog** command in privileged EXEC mode.

logging savelog [*savefile*]

Syntax Description

savefile	(Optional) Saved flash memory file name. If you do not specify the file name, the ASA saves the log file using a default time-stamp format, as follows: `LOG-YYYY-MM-DD-HHMMSS.TXT` where *YYYY* is the year, *MM* is the month, *DD* is the day of the month, and *HHMMSS* is the time in hours, minutes, and seconds.

Defaults

The defaults are as follows:

- Buffer size is 4 KB.
- Minimum free flash memory is 3 MB.
- Maximum flash memory allocation for buffer logging is 1 MB.
- The default log file name is described in the "Syntax Description" section.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Before you can save the log buffer to flash memory, you must enable logging to the buffer; otherwise, the log buffer never has data to be saved to flash memory. To enable logging to the buffer, use the **logging buffered** command.

Note The **logging savelog** command does not clear the buffer. To clear the buffer, use the **clear logging buffer** command.

Examples

The following example enables logging and the log buffer, exits global configuration mode, and saves the log buffer to flash memory using the file name, latest-logfile.txt:

```
hostname(config)# logging enable
hostname(config)# logging buffered
hostname(config)# exit
hostname# logging savelog latest-logfile.txt
hostname#
```

Related Commands

Command	Description
clear logging buffer	Clears the log buffer of all syslog messages that it contains.
copy	Copies a file from one location to another, including to a TFTP or FTP server.
delete	Deletes a file from the disk partition, such as saved log files.
logging buffered	Enables logging to the log buffer.
logging enable	Enables logging.

logging standby

To enable the failover standby ASA to send the syslog messages of this ASA to logging destinations, use the **logging standby** command in global configuration mode. To disable syslog messaging and SNMP logging, use the **no** form of this command.

logging standby

no logging standby

Syntax Description

This command has no arguments or keywords.

Defaults

The **logging standby** command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can enable **logging standby** to ensure that the syslog messages of the failover standby ASA stay synchronized if failover occurs.

Note Using the **logging standby** command causes twice as much traffic on shared logging destinations, such as syslog servers, SNMP servers, and FTP servers.

Examples

The following example enables the ASA to send syslog messages to the failover standby ASA. The output of the **show logging** command reveals that this feature is enabled:

```
hostname(config)# logging standby
hostname(config)# show logging
Syslog logging: enabled
    Facility: 20
    Timestamp logging: disabled
    Standby logging: enabled
    Deny Conn when Queue Full: disabled
    Console logging: disabled
    Monitor logging: disabled
    Buffer logging: disabled
```

```
Trap logging: disabled
History logging: disabled
Device ID: 'inside' interface IP address "10.1.1.1"
Mail logging: disabled
ASDM logging: disabled
```

Related Commands

Command	Description
failover	Enables the failover feature.
logging enable	Enables logging.
logging host	Defines a syslog server.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging timestamp

To specify that syslog messages should include the date and time that the messages was generated, use the **logging timestamp** command in global configuration mode. To remove the date and time from syslog messages, use the **no** form of this command.

logging timestamp

no logging timestamp

Syntax Description

This command has no arguments or keywords.

Defaults

The ASA does not include the date and time in syslog messages by default.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **logging timestamp** command makes the ASA include a timestamp in all syslog messages.

Examples

The following example enables the inclusion of timestamp information in all syslog messages:

```
hostname(config)# logging enable
hostname(config)# logging timestamp
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

logging trap

To specify which syslog messages the ASA sends to a syslog server, use the **logging trap** command in global configuration mode. To remove this command from the configuration, use the **no** form of this command.

logging trap [*logging_list* | *level*]

no logging trap

Syntax Description

level	Sets the maximum severity level for syslog messages. For example, if you set the severity level to 3, then the ASA generates syslog messages for severity levels 3, 2, 1, and 0. You can specify either the number or the name, as follows: • **0** or **emergencies**—System is unusable. • **1** or **alerts**—Immediate action needed. • **2** or **critical**—Critical conditions. • **3** or **errors**—Error conditions. • **4** or **warnings**—Warning conditions. • **5** or **notifications**—Normal but significant conditions. • **6** or **informational**—Informational messages. • **7** or **debugging**—Debugging messages.
logging_list	Specifies the list that identifies the messages to send to the syslog server. For information about creating lists, see the **logging list** command.

Defaults

No default syslog message trap is defined.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you are using TCP as the logging transport protocol, the ASA denies new network access sessions as a security measure if the ASA is unable to reach the syslog server, if the syslog server is misconfigured, or if the disk is full.

UDP-based logging does not prevent the ASA from passing traffic if the syslog server fails.

Examples

The following example shows how to send syslog messages of severity levels 0, 1, 2, and 3 to a syslog server that resides on the inside interface and uses the default protocol and port number.

```
hostname(config)# logging enable
hostname(config)# logging host inside 10.2.2.3
hostname(config)# logging trap errors
hostname(config)#
```

Related Commands

Command	Description
logging enable	Enables logging.
logging host	Defines a syslog server.
logging list	Creates a reusable list of message selection criteria.
show logging	Displays the enabled logging options.
show running-config logging	Displays the logging-related portion of the running configuration.

login

To log into privileged EXEC mode using the local user database (see the username command) or to change user names, use the **login** command in user EXEC mode.

login

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

From user EXEC mode, you can log in to privileged EXEC mode as any username in the local database using the **login** command. The **login** command is similar to the **enable** command when you have enable authentication turned on (see the **aaa authentication console** command). Unlike enable authentication, the **login** command can only use the local username database, and authentication is always required with this command. You can also change users using the **login** command from any CLI mode.

To allow users to access privileged EXEC mode (and all commands) when they log in, set the user privilege level to 2 (the default) through 15. If you configure local command authorization, then the user can only enter commands assigned to that privilege level or lower. See the **aaa authorization command** for more information.

Caution If you add users to the local database who can gain access to the CLI and whom you do not want to enter privileged EXEC mode, you should configure command authorization. Without command authorization, users can access privileged EXEC mode (and all commands) at the CLI using their own password if their privilege level is 2 or greater (2 is the default). Alternatively, you can use RADIUS or TACACS+ authentication, or you can set all local users to level 1 so you can control who can use the system enable password to access privileged EXEC mode.

Examples

The following example shows the prompt after you enter the **login** command:

```
hostname> login
```

```
Username:
```

Related Commands

Command	Description
aaa authorization command	Enables command authorization for CLI access.
aaa authentication console	Requires authentication for console, Telnet, HTTP, SSH, or **enable** command access.
logout	Logs out of the CLI.
username	Adds a user to the local database.

login-button

To customize the Login button of the WebVPN page login box that is displayed to WebVPN users when they connect to the security appliance, use the **login-button** command from webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

login-button {**text** | **style**} *value*

[**no**] **login-button** {**text** | **style**} *value*

Syntax Description

style	Specifies you are changing the style.
text	Specifies you are changing the text.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default login button text is “Login”.

The default login button style is:

border: 1px solid black;background-color:white;font-weight:bold; font-size:80%

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.

- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the Login button with the text "OK":

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# login-button text OK
```

Related Commands

Command	Description
login-title	Customizes the title of the WebVPN page login box.
group-prompt	Customizes the group prompt of the WebVPN page login box.
password-prompt	Customizes the password prompt of the WebVPN page login box.
username-prompt	Customizes the username prompt of the WebVPN page login box.

login-message

To customize the login message of the WebVPN page displayed to WebVPN users when they connect to the security appliance, use the **login-message** command from webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

login-message {**text** | **style**} *value*

[**no**] **login-message** {**text** | **style**} *value*

Syntax Description

text	Specifies you are changing the text.
style	Specifies you are changing the style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default login message is “Please enter your username and password”.

The default login message style is background-color:#CCCCCC;color:black.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
WebVPN customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

In the following example, the login message text is set to "username and password":

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# login-message text username and password
```

Related Commands

Command	Description
login-title	Customizes the title of the login box on the WebVPN page.
username-prompt	Customizes the username prompt of the WebVPN page login.
password-prompt	Customizes the password prompt of the WebVPN page login.
group-prompt	Customizes the group prompt of the WebVPN page login.

login-title

To customize the title of the login box on the WebVPN page displayed to WebVPN users, use the **login-title** command from webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

login-title {**text** | **style**} *value*

[**no**] **login-title** {**text** | **style**} *value*

Syntax Description

text	Specifies you are changing the text.
style	Specifies you are changing the HTML style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default login text is “Login”.

The default HTML style of the login title is background-color: #666666; color: white.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. - HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example configures the login title style:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# login-title style background-color: rgb(51,51,255);color:
rgb(51,51,255); font-family: Algerian; font-size: 12pt; font-style: italic; font-weight:
bold
```

Related Commands

Command	Description
login-message	Customizes the login message of the WebVPN login page.
username-prompt	Customizes the username prompt of the WebVPN login page.
password-prompt	Customizes the password prompt of the WebVPN login page.
group-prompt	Customizes the group prompt of the WebVPN login page.

logo

To customize the logo on the WebVPN page displayed to WebVPN users when they connect to the security appliance, use the **logo** command from webvpn customization mode. To remove a logo from the configuration and reset the default (the Cisco logo), use the **no** form of this command.

logo {**none** | **file** {*path value*}}

[**no**] **logo** {**none** | **file** {*path value*}}

Syntax Description

file	Indicates you are supplying a file containing a logo.
none	Indicates that there is no logo. Sets a null value, thereby disallowing a logo. Prevents inheriting a logo.
path	The path of the filename. The possible paths are disk0:, disk1:, or flash:
value	Specifies the filename of the logo. Maximum length is 255 characters, with no spaces. File type must be JPG, PNG, or GIF, and must be less than 100 KB.

Defaults

The default logo is the Cisco logo.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

If the filename you specify does not exist, an error message displays. If you remove a logo file but the configuration still points to it, no logo displays.

The filename cannot contain spaces.

Examples

In the following example, the file cisco_logo.gif contains a custom logo:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)#logo file disk0:cisco_logo.gif
```

Related Commands

Command	Description
title	Customizes the title of the WebVPN page.
page style	Customizes the WebVPN page using Cascading Style Sheet (CSS) parameters.

logout

To exit from the CLI, use the **logout** command in user EXEC mode.

logout

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **logout** command lets you log out of the ASA. You can use the **exit** or **quit** commands to go back to unprivileged mode.

Examples

The following example shows how to log out of the ASA:

```
hostname> logout
```

Related Commands

Command	Description
login	Initiates the log-in prompt.
exit	Exits an access mode.
quit	Exits configuration or privileged mode.

logout-message

To customize the logout message of the WebVPN logout screen that is displayed to WebVPN users when they logout from WebVPN service, use the **logout-message** command from webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

logout-message {**text** | **style**} *value*

[**no**] **logout-message** {**text** | **style**} *value*

Syntax Description

style	Specifies you are changing the style.
text	Specifies you are changing the text.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default logout message text is “Goodbye”.

The default logout message style is background-color:#999999;color:black.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
WebVPN customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.

- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example configures the logout message style:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# logout-message style background-color:
rgb(51,51,255);color: rgb(51,51,255); font-family: Algerian; font-size: 12pt; font-style:
italic; font-weight: bold
```

Related Commands

Command	Description
logout-title	Customizes the logout title of the WebVPN page.
group-prompt	Customizes the group prompt of the WebVPN page login box.
password-prompt	Customizes the password prompt of the WebVPN page login box.
username-prompt	Customizes the username prompt of the WebVPN page login box.

CHAPTER 32

mac address through match dscp Commands

mac address

To specify the virtual MAC addresses for the active and standby units, use the **mac address** command in failover group configuration mode. To restore the default virtual MAC addresses, use the **no** form of this command.

mac address *phy_if* [*active_mac*] [*standby_mac*]

no mac address *phy_if* [*active_mac*] [*standby_mac*]

Syntax Description

phy_if	The physical name of the interface to set the MAC address.
active_mac	The virtual MAC address for the active unit. The MAC address must be entered in h.h.h format, where h is a 16-bit hexadecimal number.
standby_mac	The virtual MAC address for the standby unit. The MAC address must be entered in h.h.h format, where h is a 16-bit hexadecimal number.

Defaults

The defaults are as follows:

- Active unit default MAC address: 00a0.c9*physical_port_number.failover_group_id*01.
- Standby unit default MAC address: 00a0.c9*physical_port_number.failover_group_id*02.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the virtual MAC addresses are not defined for the failover group, the default values are used.

If you have more than one Active/Active failover pair on the same network, it is possible to have the same default virtual MAC addresses assigned to the interfaces on one pair as are assigned to the interfaces of the other pairs because of the way the default virtual MAC addresses are determined. To avoid having duplicate MAC addresses on your network, make sure you assign each physical interface a virtual active and standby MAC address.

You can also set the MAC address using other commands or methods, but we recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

Examples

The following partial example shows a possible configuration for a failover group:

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)# failover group 2
hostname(config-fover-group)# secondary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# mac address e1 0000.a000.a011 0000.a000.a012
hostname(config-fover-group)# exit
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
failover mac address	Specifies a virtual MAC address for a physical interface.

mac-address

To manually assign a private MAC address to an interface or subinterface, use the **mac-address** command in interface configuration mode. In multiple context mode, this command can assign a different MAC address to the interface in each context. For an individual interface in a cluster, you can assign a cluster pool of MAC addresses. To revert the MAC address to the default, use the **no** form of this command.

mac-address {*mac_address* [**standby** *mac_address*] | **cluster-pool** *pool_name*}

no mac-address [*mac_address* [**standby** *mac_address*] | **cluster-pool** *pool_name*]

Syntax Description

cluster-pool *pool_name*	For a cluster in individual interface mode (see the **cluster interface-mode** command), or for a management interface in any cluster interface mode, sets a pool of MAC addresses to be used for a given interface on each cluster member. Define the pool using the **mac-address pool** command.
mac_address	Sets the MAC address for this interface in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. If you use failover, this MAC address is the active MAC address. **Note** Because auto-generated addresses (the **mac-address auto** command) start with A2, you cannot start manual MAC addresses with A2 if you also want to use auto-generation.
standby *mac_address*	(Optional) Sets the standby MAC address for failover. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Defaults

The default MAC address is the burned-in MAC address of the physical interface. Subinterfaces inherit the physical interface MAC address. Some commands set the physical interface MAC address (including this command in single mode), so the inherited address depends on that configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Release	Modification
8.0(5)/8.2(2)	The use of A2 to start the MAC address was restricted when also used with the **mac-address auto** command.
9.0(1)	We added the **cluster-pool** keyword t support clustering.

Usage Guidelines

In multiple context mode, if you share an interface between contexts, you can assign a unique MAC address to the interface in each context. This feature lets the ASA easily classify packets into the appropriate context. Using a shared interface without unique MAC addresses is possible, but has some limitations. See the CLI configuration guide for more information.

You can assign each MAC address manually with this command, or you can automatically generate MAC addresses for shared interfaces in contexts using the **mac-address auto** command. If you automatically generate MAC addresses, you can use the **mac-address** command to override the generated address.

For single context mode, or for interfaces that are not shared in multiple context mode, you might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address.

You can also set the MAC address using other commands or methods, but we recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

Examples

The following example configures the MAC address for GigabitEthernet 0/1.1:

```
hostname/contextA(config)# interface gigabitethernet0/1.1
hostname/contextA(config-if)# nameif inside
hostname/contextA(config-if)# security-level 100
hostname/contextA(config-if)# ip address 10.1.2.1 255.255.255.0
hostname/contextA(config-if)# mac-address 030C.F142.4CDE standby 040C.F142.4CDE
hostname/contextA(config-if)# no shutdown
```

Related Commands

Command	Description
failover mac address	Sets the active and standby MAC address of a physical interface for Active/Standby failover.
mac address	Sets the active and standby MAC address of a physical interface for Active/Active failover.
mac-address auto	Auto-generates MAC addresses (active and standby) for shared interfaces in multiple context mode.
mode	Sets the security context mode to multiple or single.
show interface	Shows the interface characteristics, including the MAC address.

mac-address auto

To automatically assign private MAC addresses to each shared context interface, use the **mac-address auto** command in global configuration mode. To disable automatic MAC addresses, use the **no** form of this command.

mac-address auto [**prefix** *prefix*]

no mac-address auto

Syntax Description

prefix *prefix*	(Optional) Sets a user-defined prefix as part of the MAC address. The *prefix* is a decimal value between 0 and 65535. If you do not enter a prefix, then the ASA generates a default prefix. This prefix is converted to a 4-digit hexadecimal number. The prefix ensures that each ASA uses unique MAC addresses (using different prefix values), so you can have multiple ASAs on a network segment, for example.

Defaults

Automatic MAC address generation is enabled—Uses an autogenerated prefix. The ASA autogenerates the prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address. You cannot use the legacy auto-generation method (without a prefix).

If you disable MAC address generation, see the following default MAC addresses:

- For the ASA 5500 series appliances—The physical interface uses the burned-in MAC address, and all subinterfaces of a physical interface use the same burned-in MAC address.
- For the ASASM—All VLAN interfaces use the same MAC address, derived from the backplane MAC address.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(5)/8.2(2)	The **prefix** keyword was added. The MAC address format was changed to use the prefix, to use a fixed starting value (A2), and to use a different scheme for the primary and secondary unit MAC addresses in a failover pair. The MAC addresess are also now persistent accross reloads. The command parser now checks if auto-generation is enabled; if you want to also manually assign a MAC address, you cannot start the manual MAC address with A2.

Release	Modification
8.5(1)	Autogeneration is now enabled by default (**mac-address auto**).
8.6(1)	The ASA now converts the automatic MAC address generation configuration to use a default prefix. The ASA auto-generates the prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address. This conversion happens automatically when you reload, or if you reenable MAC address generation. The legacy method of MAC address generation is no longer available. **Note** To maintain hitless upgrade for failover pairs, the ASA does *not* convert the MAC address method in an existing configuration upon a reload if failover is enabled.

Usage Guidelines

To allow contexts to share interfaces, we suggest that you assign unique MAC addresses to each shared context interface. The MAC address is used to classify packets within a context. If you share an interface, but do not have unique MAC addresses for the interface in each context, then the destination IP address is used to classify packets. The destination address is matched with the context NAT configuration, and this method has some limitations compared to the MAC address method. See the CLI configuration guide for information about classifying packets.

In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, you can manually set the MAC address for the interface within the context. See the **mac-address** command to manually set the MAC address.

Interaction with Manual MAC Addresses

If you manually assign a MAC address and also enable auto-generation, then the manually assigned MAC address is used. If you later remove the manual MAC address, the auto-generated address is used.

Because auto-generated addresses start with A2, you cannot start manual MAC addresses with A2 if you also want to use auto-generation.

Failover MAC Addresses

For use with failover, the ASA generates both an active and standby MAC address for each interface. If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption. See the "MAC Address Format Using a Prefix" section for more information.

For upgrading failover units with the legacy version of the **mac-address auto** command before the **prefix** keyword was introduced, see the "MAC Address Format Without a Prefix (Legacy Method)" section.

MAC Address Format Using a Prefix

The ASA generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or an autogenerated prefix based on the last two bytes of the interface (ASA 5500) or backplane (ASASM) MAC address, and *zz.zzzz* is an internal counter generated by the ASA. For the standby MAC address, the address is identical except that the internal counter is increased by 1.

For an example of how the prefix is used, if you set a prefix of 77, then the ASA converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the ASA native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

MAC Address Format Without a Prefix (Legacy Method)

This method may be used if you use failover and you upgraded to Version 8.6 or later; in this case, you have to manually enable the prefix method.

Without a prefix, the MAC address is generated using the following format:

- Active unit MAC address: 12*_slot.port_subid.contextid*.
- Standby unit MAC address: 02*_slot.port_subid.contextid*.

For platforms with no interface slots, the slot is always 0. The *port* is the interface port. The *subid* is an internal ID for the subinterface, which is not viewable. The *contextid* is an internal ID for the context, viewable with the **show context detail** command. For example, the interface GigabitEthernet 0/1.200 in the context with the ID 1 has the following generated MAC addresses, where the internal ID for subinterface 200 is 31:

- Active: 1200.0131.0001
- Standby: 0200.0131.0001

This MAC address generation method does not allow for persistent MAC addresses across reloads, does not allow for multiple ASAs on the same network segment (because unique MAC addresses are not guaranteed), and does not prevent overlapping MAC addresses with manually assigned MAC addresses. We recommend using a prefix with the MAC address generation to avoid these issues.

When the MAC Address is Generated

When you configure a **nameif** command for the interface in a context, the new MAC address is generated immediately. If you enable this command after you configure context interfaces, then MAC addresses are generated for all interfaces immediately after you enter the command. If you use the **no mac-address auto** command, the MAC address for each interface reverts to the default MAC address. For example, subinterfaces of GigabitEthernet 0/1 revert to using the MAC address of GigabitEthernet 0/1.

Setting the MAC Address Uisng Other Methods

You can also set the MAC address using other commands or methods, but we recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

Viewing MAC Addresses in the System Configuration

To view the assigned MAC addresses from the system execution space, enter the **show running-config all context** command.

The **all** option is required to view the assigned MAC addresses. Although this command is user-configurable in global configuration mode only, the **mac-address auto** command appears as a read-only entry in the configuration for each context along with the assigned MAC address. Only allocated interfaces that are configured with a **nameif** command within the context have a MAC address assigned.

Note If you manually assign a MAC address to an interface, but also have auto-generation enabled, the auto-generated address continues to show in the configuration even though the manual MAC address is the one that is in use. If you later remove the manual MAC address, the auto-generated one shown will be used.

Viewing MAC Addresses Within a Context

To view the MAC address in use by each interface within the context, enter the **show interface | include (Interface)|(MAC)** command.

Note The **show interface** command shows the MAC address in use; if you manually assign a MAC address and also have auto-generation enabled, then you can only view the unused auto-generated address from within the system configuration.

Examples

The following example enables automatic MAC address generation with a prefix of 78:

```
hostname(config)# mac-address auto prefix 78
```

The following output from the **show running-config all context admin** command shows the primary and standby MAC address assigned to the Management0/0 interface:

```
hostname# show running-config all context admin

context admin
  allocate-interface Management0/0
  mac-address auto Management0/0 a24d.0000.1440 a24d.0000.1441
  config-url disk0:/admin.cfg
```

The following output from the **show running-config all context** command shows all the MAC addresses (primary and standby) for all context interfaces. Note that because the GigabitEthernet0/0 and GigabitEthernet0/1 main interfaces are not configured with a **nameif** command inside the contexts, no MAC addresses have been generated for them.

```
hostname# show running-config all context

admin-context admin
context admin

Related Commands

Command	Description
failover mac address	Sets the active and standby MAC address of a physical interface for Active/Standby failover.
mac address	Sets the active and standby MAC address of a physical interface for Active/Active failover.
mac-address	Manually sets the MAC address (active and standby) for a physical interface or subinterface. In multiple context mode, you can set different MAC addresses in each context for the same interface.
mode	Sets the security context mode to multiple or single.
show interface	Shows the interface characteristics, including the MAC address.

mac-address pool

To add a MAC address pool for use on an individual interface in an ASA cluster, use the **mac-address pool** command in global configuration mode. To remove an unused pool, use the **no** form of this command.

mac-address pool *name start_mac_address* **-** *end_mac_address*

no mac-address pool *name* [*start_mac_address* **-** *end_mac_address*]

Syntax Description

name	Names the pool up to 63 characters in length.
start_mac_address **-** *end_mac_address*	Specifies the first MAC address and the last MAC address. Note to add a space around the dash (-).

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You can use the pool in the **mac-address cluster-pool** command in interface configuration mode. It is not common to manually configure MAC addresses for an interface, but if you have special needs to do so, then this pool is used to assign a unique MAC address to each interface.

Examples

The following example adds a MAC address pool with 8 MAC addresses, and assigns it to the gigabitethernet 0/0 interface:

```
hostname(config)# mac-address pool pool1 000C.F142.4CD1 - 000C.F142.4CD7
hostname(config)# interface gigabitethernet 0/0
hostname(config-ifc)# mac-address cluster-pool pool1
```

Related Commands

Command	Description
interface	Configures an interface.
mac-address	Configures a MAC address for an interface.

mac-address-table aging-time

To set the timeout for MAC address table entries, use the **mac-address-table aging-time** command in global configuration mode. To restore the default value of 5 minutes, use the **no** form of this command.

mac-address-table aging-time *timeout_value*

no mac-address-table aging-time

Syntax Description

timeout_value	The time a MAC address entry stays in the MAC address table before timing out, between 5 and 720 minutes (12 hours). 5 minutes is the default.

Defaults

The default timeout is 5 minutes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

No usage guidelines.

Examples

The following example sets the MAC address timeout to 10 minutes:

```
hostname(config)# mac-address-timeout aging time 10
```

Related Commands

Command	Description
arp-inspection	Enables ARP inspection, which compares ARP packets to static ARP entries.
firewall transparent	Sets the firewall mode to transparent.
mac-address-table static	Adds static MAC address entries to the MAC address table.
mac-learn	Disables MAC address learning.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.

mac-address-table static

To add a static entry to the MAC address table, use the **mac-address-table static** command in global configuration mode. To remove a static entry, use the **no** form of this command. Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can add static MAC addresses to the MAC address table if desired. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the ASA drops the traffic and generates a system message.

mac-address-table static *interface_name mac_address*

no mac-address-table static *interface_name mac_address*

Syntax Description

interface_name	The source interface.
mac_address	The MAC address you want to add to the table.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example adds a static MAC address entry to the MAC address table:

```
hostname(config)# mac-address-table static inside 0010.7cbe.6101
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
firewall transparent	Sets the firewall mode to transparent.
mac-address-table aging-time	Sets the timeout for dynamic MAC address entries.

Command	Description
mac-learn	Disables MAC address learning.
show mac-address-table	Shows MAC address table entries.

mac-learn

To disable MAC address learning for an interface, use the **mac-learn** command in global configuration mode. To reenable MAC address learning, use the **no** form of this command. By default, each interface automatically learns the MAC addresses of entering traffic, and the ASA adds corresponding entries to the MAC address table. You can disable MAC address learning if desired.

mac-learn *interface_name* **disable**

no mac-learn *interface_name* **disable**

Syntax Description

interface_name	The interface on which you want to disable MAC learning.
disable	Disables MAC learning.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example disables MAC learning on the outside interface:

```
hostname(config)# mac-learn outside disable
```

Related Commands

Command	Description
clear configure mac-learn	Sets the **mac-learn** configuration to the default.
firewall transparent	Sets the firewall mode to transparent.
mac-address-table static	Adds static MAC address entries to the MAC address table.
show mac-address-table	Shows the MAC address table, including dynamic and static entries.
show running-config mac-learn	Shows the **mac-learn** configuration.

mac-list

To specify a list of MAC addresses to be used to exempt MAC addresses from authentication and/or authorization, use the **mac-list** command in global configuration mode. To remove a MAC list entry, use the **no** form of this command.

mac-list *id* {**deny | permit**} *mac macmask*

no mac-list *id* {**deny | permit**} *mac macmask*

Syntax Description

deny	Indicates that traffic matching this MAC address does not match the MAC list and is subject to both authentication and authorization when specified in the **aaa mac-exempt** command. You might need to add a deny entry to the MAC list if you permit a range of MAC addresses using a MAC address mask such as ffff.ffff.0000, and you want to force a MAC address in that range to be authenticated and authorized.
id	Specifies a hexadecimal MAC access list number. To group a set of MAC addresses, enter the **mac-list** command as many times as needed with the same ID value. The order of entries matters, because the packet uses the first entry it matches, as opposed to a best match scenario. If you have a permit entry, and you want to deny an address that is allowed by the permit entry, be sure to enter the deny entry before the permit entry.
mac	Specifies the source MAC address in 12-digit hexadecimal form; that is, nnnn.nnnn.nnnn
macmask	Specifies the portion of the MAC address that should be used for matching. For example, ffff.ffff.ffff matches the MAC address exactly. ffff.ffff.0000 matches only the first 8 digits.
permit	Indicates that traffic matching this MAC address matches the MAC list and is exempt from both authentication and authorization when specified in the **aaa mac-exempt** command.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To enable MAC address exemption from authentication and authorization, use the **aaa mac-exempt** command. You can only add one instance of the **aaa mac-exempt** command, so be sure that your MAC list includes all the MAC addresses you want to exempt. You can create multiple MAC lists, but you can only use one at a time.

Examples

The following example bypasses authentication for a single MAC address:

```
hostname(config)# mac-list abc permit 00a0.c95d.0282 ffff.ffff.ffff
hostname(config)# aaa mac-exempt match abc
```

The following entry bypasses authentication for all Cisco IP Phones, which have the hardware ID 0003.E3:

```
hostname(config)# mac-list acd permit 0003.E300.0000 FFFF.FF00.0000
hostname(config)# aaa mac-exempt match acd
```

The following example bypasses authentication for a a group of MAC addresses except for 00a0.c95d.02b2. Enter the deny statement before the permit statement, because 00a0.c95d.02b2 matches the permit statement as well, and if it is first, the deny statement will never be matched.

```
hostname(config)# mac-list 1 deny 00a0.c95d.0282 ffff.ffff.ffff
hostname(config)# mac-list 1 permit 00a0.c95d.0000 ffff.ffff.0000
hostname(config)# aaa mac-exempt match 1
```

Related Commands

Command	Description
aaa authentication	Enables user authentication.
aaa authorization	Enables user authorization services.
aaa mac-exempt	Exempts a list of MAC addresses from authentication and authorization.
clear configure mac-list	Removes a list of MAC addresses previously specified by the **mac-list** command.
show running-config mac-list	Displays a list of MAC addresses previously specified in the **mac-list** command.

mail-relay

To configure a local domain name, use the **mail-relay** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

mail-relay *domain_name* **action** {**drop-connection** | **log**}

no mail-relay *domain_name* **action** {**drop-connection** | **log**}

Syntax Description

domain_name	Specifies the domain name.
drop-connection	Closes the connection.
log	Generates a system log message.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a mail relay for a specific domain:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# mail-relay mail action drop-connection
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

management-access

To allow management access to an interface other than the one from which you entered the ASA when using VPN, use the **management-access** command in global configuration mode. To disable management access, use the **no** form of this command.

management-access *mgmt_if*

no management-access *mgmt_if*

Syntax Description

mgmt_if	Specifies the name of the management interface you want to access when entering the ASA from another interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•		—

Command History

Release	Modification
7.0(1)	This command was itnroduced.

Usage Guidelines

This command allows you to connect to an interface other than the one you entered the ASA from when using a full tunnel IPsec VPN or SSL VPN client (AnyConnect 2.x client, SVC 1.x) or across a site-to-site IPsec tunnel. You can use Telnet, SSH, Ping, or ASDM to connect to an ASA interface.

You can define only one management-access interface.

Note When using identity NAT between the management-access interface network and VPN networks (a common NAT configuration for VPN traffic), you must specify the **nat** command **route-lookup** keyword. Without route lookup, the ASA sends traffic out the interface specified in the **nat** command, regardless of what the routing table says. For example, you configure **management-access inside**, so a VPN user entering on the outside can manage the inside interface. If the identity **nat** command specifies **(inside,outside)**, then you do not want the ASA to send the management traffic out to the inside network; it will never return to the inside interface IP address. The route lookup option lets the ASA send the traffic directly to the inside interface IP address instead of to the inside network. For traffic from the VPN client to a host on the inside network, the route lookup option will still result in the correct egress interface (inside), so normal traffic flow is not affected.

Examples

The following example shows how to configure a firewall interface named “inside” as the management access interface:

```
hostname(config)# management-access inside
hostname(config)# show running-config management-access
management-access inside
```

Related Commands

Command	Description
clear configure management-access	Removes the configuration of an internal interface for management access of the ASA.
show management-access	Displays the name of the internal interface configured for management access.

management-only

To set an interface to accept management traffic only, use the **management-only** command in interface configuration mode. To allow through traffic, use the **no** form of this command.

management-only

no management-only

Syntax Description

This command has no arguments or keywords.

Defaults

The Management *n*/*n* interface, if available for your model, is set to management-only mode by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	The placement of this command in the running configuration has been moved to the top of the interface section to support ASA clustering, which has special exemptions for management interfaces.

Usage Guidelines

Some models include a dedicated management interface called Management *n*/*n*, which is meant to support traffic to the ASA. However, you can configure any interface to be a management-only interface using the **management-only** command. Also, for Management *n*/*n*, you can disable management-only mode so the interface can pass through traffic just like any other interface.

Note For the ASA 5512-X through ASA 5555-X, you cannot disable management-only mode for the Management interface. By default, this command is always enabled.

In transparent firewall mode, in addition to the maximum allowed through-traffic interfaces, you can also use the Management interface (either the physical interface, a subinterface (if supported for your model), or an EtherChannel interface comprised of Management interfaces (if you have multiple Management interfaces)) as a separate management interface. You cannot use any other interface types as management interfaces.

If your model does not include a Management interface, you must manage the transparent firewall from a data interface.

In multiple context mode, you cannot share any interfaces, including the Management interface, across contexts. To provide management per context, you can create subinterfaces of the Management interface and allocate a Management subinterface to each context. Note that the ASA 5512-X through ASA 5555-X do not allow subinterfaces on the Management interface, so for per-context management, you must connect to a data interface.

The management interface is not part of a normal bridge group. Note that for operational purposes, it is part of a non-configurable bridge group.

Examples

The following example disables management-only mode on the Management interface:

```
hostname(config)# interface management0/0
hostname(config-if)# no management-only
```

The following example enables management-only mode on a subinterface:

```
hostname(config)# interface gigabitethernet0/2.1
hostname(config-subif)# management-only
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.

map-name

To map a user-defined attribute name to a Cisco attribute name, use the **map-name** command in ldap-attribute-map configuration mode.

To remove this mapping, use the **no** form of this command.

map-name *user-attribute-name Cisco-attribute-name*

no map-name *user-attribute-name Cisco-attribute-name*

Syntax Description

user-attribute-name	Specifies the user-defined attribute name that you are mapping to the Cisco attribute.
Cisco-attribute-name	Specifies the Cisco attribute name that you are mapping to the user-defined name.

Defaults

By default, no name mappings exist.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
ldap-attribute-map configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

With the **map-name** command, you can map your own attribute names to Cisco attribute names. You can then bind the resulting attribute map to an LDAP server. Your typical steps would include:

1. Use the **ldap attribute-map** command in global configuration mode to create an unpopulated attribute map. This commands enters ldap-attribute-map configuration mode.
2. Use the **map-name** and **map-value** commands in ldap-attribute-map configuration mode to populate the attribute map.
3. Use the **ldap-attribute-map** command in aaa-server host mode to bind the attribute map to an LDAP server. Note the hyphen after “ldap” in this command.

Note To use the attribute mapping features correctly, you need to understand both the Cisco LDAP attribute names and values as well as the user-defined attribute names and values.

Examples

The following example commands map a user-defined attribute name Hours to the Cisco attribute name cVPN3000-Access-Hours in the LDAP attribute map myldapmap:

```
hostname(config)# ldap attribute-map myldapmap
hostname(config-ldap-attribute-map)# map-name Hours cVPN3000-Access-Hours
hostname(config-ldap-attribute-map)#
```

Within ldap-attribute-map configuration mode, you can enter "?" to display the complete list of Cisco LDAP attribute names:

```
hostname(config-ldap-attribute-map)# map-name <name>
ldap mode commands/options:
cisco-attribute-names:
  cVPN3000-Access-Hours
  cVPN3000-Allow-Network-Extension-Mode
  cVPN3000-Auth-Service-Type
  cVPN3000-Authenticated-User-Idle-Timeout
  cVPN3000-Authorization-Required
  cVPN3000-Authorization-Type
    :
    :
  cVPN3000-X509-Cert-Data
hostname(config-ldap-attribute-map)#
```

Related Commands

Command	Description
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.
ldap-attribute-map (aaa-server host mode)	Binds an LDAP attribute map to an LDAP server.
map-value	Maps a user-defined attribute value to a Cisco attribute.
show running-config ldap attribute-map	Displays a specific running LDAP attribute map or all running attribute maps.
clear configure ldap attribute-map	Removes all LDAP attribute maps.

map-value

To map a user-defined value to a Cisco LDAP value, use the **map-value** command in ldap-attribute-map configuration mode. To delete an entry within a map, use the **no** form of this command.

map-value *user-attribute-name user-value-string Cisco-value-string*

no map-value *user-attribute-name user-value-string Cisco-value-string*

Syntax Description

Cisco-value-string	Specifies the Cisco value string for the Cisco attribute.
user-attribute-name	Specifies the user-defined attribute name that you are mapping to the Cisco attribute name.
user-value-string	Specifies the user-defined value string that you are mapping to the Cisco attribute value.

Defaults

By default, there are no user-defined values mapped to Cisco attributes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
ldap-attribute-map configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

With the **map-value** command, you can map your own attribute values to Cisco attribute names and values. You can then bind the resulting attribute map to an LDAP server. Your typical steps would include:

1. Use the **ldap attribute-map** command in global configuration mode to create an unpopulated attribute map. This commands enters ldap-attribute-map configuration mode.
2. Use the **map-name** and **map-value** commands in ldap-attribute-map configuration mode to populate the attribute map.
3. Use the **ldap-attribute-map** command in aaa-server host mode to bind the attribute map to an LDAP server. Note the hyphen after “ldap” in this command.

Note To use the attribute mapping features correctly, you need to understand both the Cisco LDAP attribute names and values as well as the user-defined attribute names and values.

Examples

The following example, entered in ldap-attribute-map configuration mode, sets the user-defined value of the user attribute Hours to a user-defined time policy named workDay and a Cisco-defined time policy named Daytime:

```
hostname(config)# ldap attribute-map myldapmap
hostname(config-ldap-attribute-map)# map-value Hours workDay Daytime
hostname(config-ldap-attribute-map)#
```

Related Commands

Command	Description
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.
ldap-attribute-map (aaa-server host mode)	Binds an LDAP attribute map to an LDAP server.
map-name	Maps a user-defined LDAP attribute name with a Cisco LDAP attribute name.
show running-config ldap attribute-map	Displays a specific running LDAP attribute map or all running attribute maps.
clear configure ldap attribute-map	Removes all LDAP maps.

mapping-service

To configure a mapping service for the Cisco Intercompany Media Engine proxy, use the **mapping-service** command in UC-IME configuration mode. To remove the mapping service from the proxy, use the **no** form of this command.

mapping-service listening-interface *interface* [**listening-port** *port*] **uc-ime-interface** *interface*

no mapping-service listening-interface *interface* [**listening-port** *port*] **uc-ime-interface** *interface*

Syntax Description

interface	Specifies the name of the interface to be used for the listening interface or uc-ime interface.
listening-interface	Configures the interface on which the ASA listens for the mapping requests.
listening-port	(Optional) Configures the listening port for the mapping service.
port	(Optional) Specifies the TCP port number on which the ASA listens for the mapping requests. The port number must be 1024 or higher to avoid conflicts with other services on the device, such as Telnet or SSH. By default, the port number is TCP 8060.
uc-ime-interface	Configures the interface that connects to the remote Cisco UCM.

Defaults

By default the mapping-service for off-path deployments of the Cisco Intercompany Media Engine proxy listens on TCP port 8060.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
UC-IME configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

For an off-path deployment of the Cisco Intercompany Media Engine proxy on the ASA, adds the mapping service to the proxy configuration. To configure the mapping service, you must specify the outside interface (remote enterprise side) on which to listen for mapping requests and the interface that connects to the remote Cisco UCM.

Note You can only configure one mapping server for the Cisco Intercompany Media Engine proxy.

You configure the mapping service when the Cisco Intercompany Media Engine proxy is configured for an off-path deployment.

In an off path deployment, inbound and outbound Cisco Intercompany Media Engine calls pass through an adaptive security appliance enabled with the Cisco Intercompany Media Engine proxy. The adaptive security appliance is located in the DMZ and configured to support primarily Cisco Intercompany Media Engine. Normal Internet-facing traffic does not flow through this ASA.

For all inbound calls, the signaling is directed to the ASA because destined Cisco UCMs are configured with the global IP address on the ASA. For outbound calls, the called party could be any IP address on the Internet; therefore, the ASA is configured with a mapping service that dynamically provides an internal IP address on the ASA for each global IP address of the called party on the Internet.

Cisco UCM sends all outbound calls directly to the mapped internal IP address on the adaptive security appliance instead of the global IP address of the called party on the Internet. The ASA then forwards the calls to the global IP address of the called party.

Examples

The following example shows ...:

```
hostname(config)# uc-ime offpath_uc-ime_proxy
hostname(config-uc-ime)# media-termination ime-media-term
hostname(config-uc-ime)# ucm address 192.168.10.30 trunk-security-mode non-secure
hostname(config-uc-ime)# ticket epoch 1 password password1234
hostname(config-uc-ime)# fallback monitoring timer 120
hostname(config-uc-ime)# fallback hold-down timer 30
hostname(config-uc-ime)# mapping-service listening-interface inside listening-port 8060
uc-ime-interface outside
```

Related Commands

Command	Description
show running-config uc-ime	Shows the running configuration of the Cisco Intercompany Media Engine proxy.
show uc-ime	Displays statistical or detailed information about fallback-notifications, mapping-service-sessions, and signaling-sessions.
uc-ime	Creates the Cisco Intercompany Media Engine proxy instance on the ASA.

mask

When using the Modular Policy Framework, mask out part of the packet that matches a **match** command or class map by using the **mask** command in match or class configuration mode. This mask action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic; however, not all applications allow this action. For example, you can you use **mask** command for the DNS application inspection to mask a header flag before allowing the traffic through the ASA. To disable this action, use the **no** form of this command.

mask [**log**]

no mask [**log**]

Syntax Description

log	Logs the match. The system log message number depends on the application.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **mask** command to mask part of the packet that matches the **match** command or **class** command.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action, for example, enter the **inspect dns dns_policy_map** command where dns_policy_map is the name of the inspection policy map.

Examples

The following example masks the RD and RA flags in the DNS header before allowing the traffic through the ASA:

```
hostname(config-cmap)# policy-map type inspect dns dns-map1
```

```
hostname(config-pmap-c)# match header-flag RD
hostname(config-pmap-c)# mask log
hostname(config-pmap-c)# match header-flag RA
hostname(config-pmap-c)# mask log
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

mask-banner

To obfuscate the server banner, use the **mask-banner** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

mask-banner

no mask-banner

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to mask the server banner:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# mask-banner
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

mask-syst-reply

To hide the FTP server response from clients, use the **mask-syst-reply** command in FTP map configuration mode, which is accessible by using the **ftp-map** command. To remove the configuration, use the **no** form of this command.

mask-syst-reply

no mask-syst-reply

Syntax Description

This command has no arguments or keywords.

Defaults

This command is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
FTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the mask-syst-reply command with strict FTP inspection to protect the FTP server system from clients. After enabling this command, the servers replies to the **syst** command are replaced by a series of Xs.

Examples

The following example causes the ASA to replace the FTP server replies to the syst command with Xs:

```
hostname(config)# ftp-map inbound_ftp
hostname(config-ftp-map)# mask-syst-reply
hostname(config-ftp-map)#
```

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
ftp-map	Defines an FTP map and enables FTP map configuration mode.
inspect ftp	Applies a specific FTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.
request-command deny	Specifies FTP commands to disallow.

match access-list

When using the Modular Policy Framework, use an access list to identify traffic to which you want to apply actions by using the **match access-list** command in class-map configuration mode. To remove the **match access-list** command, use the **no** form of this command.

match access-list *access_list_name*

no match access-list *access_list_name*

Syntax Description

access_list_name	Specifies the name of an access list to be used as match criteria.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** command.

   After you enter the **class-map** command, you can enter the **match access-list** command to identify the traffic. Alternatively, you can enter a different type of **match** command, such as the **match port** command. You can only include one **match access-list** command in the class map, and you cannot combine it with other types of **match** commands. The exception is if you define the **match default-inspection-traffic** command which matches the default TCP and UDP ports used by all applications that the ASA can inspect, then you can narrow the traffic to match using a **match access-list** command. Because the **match default-inspection-traffic** command specifies the ports to match, any ports in the access list are ignored.

2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

Examples

The following example creates three Layer 3/4 class maps that match three access lists:

```
hostname(config)# access-list udp permit udp any any
hostname(config)# access-list tcp permit tcp any any
hostname(config)# access-list host_foo permit ip any 10.1.1.1 255.255.255.255

hostname(config)# class-map all_udp
hostname(config-cmap)# description "This class-map matches all UDP traffic"
hostname(config-cmap)# match access-list udp

hostname(config-cmap)# class-map all_tcp
hostname(config-cmap)# description "This class-map matches all TCP traffic"
hostname(config-cmap)# match access-list tcp

hostname(config-cmap)# class-map to_server
hostname(config-cmap)# description "This class-map matches all traffic to server 10.1.1.1"
hostname(config-cmap)# match access-list host_foo
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match any

When using the Modular Policy Framework, match all traffic to which you want to apply actions by using the **match any** command in class-map configuration mode. To remove the **match any** command, use the **no** form of this command.

match any

no match any

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** command.

   After you enter the **class-map** command, you can enter the **match any** command to identify all traffic. Alternatively, you can enter a different type of **match** command, such as the **match port** command. You cannot combine the **match any** command with other types of **match** commands.
2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

Examples

This example shows how to define a traffic class using a class map and the **match any** command:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match any
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match access-list	Matches traffic according to an access list.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match apn

To configure a match condition for an access point name in GTP messages, use the **match apn** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **apn regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **apn regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a GTP class map or policy map. Only one entry can be entered in a GTP class map.

Examples

The following example shows how to configure a match condition for an access point name in an GTP inspection class map:

```
hostname(config-cmap)# match apn class gtp_regex_apn
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match body

To configure a match condition on the length or length of a line of an ESMTP body message, use the **match body** command in class-map or policy-map configuration mode. To remove a configured section, use the **no** form of this command.

match [**not**] **body [length | line length] gt** *bytes*

no match [**not**] **body [length | line length] gt** *bytes*

Syntax Description

length	Specifies the length of an ESMTP body message.
line length	Specifies the length of a line of an ESMTP body message.
bytes	Specifies the number to match in bytes.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for a body line length in an ESMTP inspection policy map:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# match body line length gt 1000
```

Related Commands

match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match called-party

To configure a match condition on the H.323 called party, use the **match called-party** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **called-party [regex** *regex***]**

no match [**not**] **match** [**not**] **called-party [regex** *regex***]**

Syntax Description

regex *regex*	Specifies to match on the regular expression.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for the called party in an H.323 inspection class map:

```
hostname(config-cmap)# match called-party regex caller1
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match calling-party

To configure a match condition on the H.323 calling party, use the **match calling-party** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **calling-party [regex** *regex***]**

no match [**not**] **match** [**not**] **calling-party [regex** *regex***]**

Syntax Description

regex *regex*	Specifies to match on the regular expression.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for the calling party in an H.323 inspection class map:

```
hostname(config-cmap)# match calling-party regex caller1
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.

show running-config class-map	Displays the information about the class map configuration.

match certificate

To configure a certificate match rule, use the **match certificate** command in crypto ca trustpoint configuration mode. To remove the rule from the configuration, use the **no** form of this command.

match certificate *map-name* **override ocsp [trustpoint** *trustpoint-name***]** *seq-num* **url** *URL*

no match certificate *map-name* **override ocsp**

Syntax Description

map-name	Specifies the name of the certificate map to match to this rule. You must configure the certificate map before configuring a match rule. The maximum length is 65 characters.
override ocsp	Specifies that the purpose of the rule is to override an OCSP URL in a certificate.
seq-num	Sets the priority for this match rule. The valid range is from 1 to 10000. The ASA evaluates the match rule with the lowest sequence number first, followed by higher numbers until it finds a match.
trustpoint	(Optional) Specifies using a trustpoint for verifying the OCSP responder certificate.
trustpoint-name	(Optional) Identifies the trustpoint to use with the override to validate responder certificates.
url	Specifies accessing a URL for OCSP revocation status.
URL	Identifies the URL to access for OCSP revocation status.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

During the PKI certificate validation process, the ASA checks certificate revocation status to maintain security by using either CRL checking or Online Certificate Status Protocol (OCSP). With CRL checking, the ASA retrieves, parses, and caches CRLs, which provide a complete list of revoked certificates. OCSP offers a more scalable method of checking revocation status bdecause OCSP localizes certificate status on a validation authority, which it queries for the status of a specific certificate.

Certificate match rules let you configure OCSP URL overrides, which specify a URL to check for revocation status, rather than the URL in the AIA field of the remote user certificate. Match rules also let you configure trustpoints to use to validate OCSP responder certificates, which let the ASA validate responder certificates from any CA, including self-signed certificates and certificates external to the validation path of the client certificate.

When configuring OCSP, be aware of the following requirements:

- You can configure multiple match rules within a trustpoint configuration, but you can have only one match rule for each crypto ca certificate map. You can, however, configure multiple crypto ca certificate maps and associate them with the same trustpoint.
- You must configure the certificate map before configuring a match rule.
- To configure a trustpoint to validate a self-signed OCSP responder certificates, you import the self-signed responder certificate into its own trustpoint as a trusted CA certificate. Then you configure the **match certificate** command in the client certificate validating trustpoint to use the trustpoint that contains the self-signed OCSP responder certificate to validate the responder certificate. The same applies for validating responder certificates external to the validation path of the client certificate.
- A trustpoint can validate both the client certificate and the responder certificate if the same CA issues both of them. But if different CAs issue the client and responder certificates, you need to configure two trustpoints, one trustpoint for each certificate.
- The OCSP server (responder) certificate typically signs the OCSP response. After receiving the response, the ASA tries to verify the responder certificate. The CA normally sets the lifetime of its OCSP responder certificate to a relatively short period to minimize the chance of it being compromised.The CA typically also includes an ocsp-no-check extension in the responder certificate indicating that this certificate does not need revocation status checking. But if this extension is not present, the ASA tries to check its revocation status using the same method specified in the trustpoint. If the responder certificate is not verifiable, revocation checks fails. To avoid this possibility, use the **revocation-check none** command when configuring the responder certificate validating trustpoint, and use the **revocation-check ocsp** command when configuring the client certificate.
- If the ASA does not find a match, it uses the URL specified in the **ocsp url** command. If you have not configured the **ocsp url** command, the ASA uses the AIA field of the remote user certificate. If the certificate does not have an AIA extension, revocation status checking fails.

Examples

The following example shows how to create a certificate match rule for a trustpoint called newtrust. The rule has a map name called mymap, a sequence number of 4, a trustpoint called mytrust, and specifies a URL of 10.22.184.22.

```
hostname(config)# crypto ca trustpoint newtrust
hostname(config-ca-trustpoint)# match certificate mymap override ocsp trustpoint mytrust 4
url 10.22.184.22
hostname(config-ca-trustpoint)#
```

The following example shows how to configure a crypto ca certificate map, and then a match certificate rule to identify a trustpoint that contains a CA certificate to validate the responder certificate. This certificate is necessary if the CA identified in the newtrust trustpoint does not issue an OCSP responder certificate.

Step 1 Configure the certificate map that identifies the client certificates to which the map rule applies. In this example, the name of the certificate map is mymap and the sequence number is 1. Any client certificate with a subject-name that contains a CN attribute equal to mycert matches the mymap entry.

```
hostname(config)# crypto ca certificate map mymap 1 subject-name attr cn eq mycert
hostname(config-ca-cert-map)# subject-name attr cn eq mycert
hostname(config-ca-cert-map)#
```

Step 2 Configure a trustpoint that contains the CA certificate to use to validate the OCSP responder certificate. In the case of self-signed certificates, this is the self-signed certificate itself, which is imported and locally trusted. You can also obtain a certificate for this purpose through external CA enrollment. When prompted to do so, paste in the CA certificate.

```
hostname(config-ca-cert-map)# exit
hostname(config)# crypto ca trustpoint mytrust
hostname(config-ca-trustpoint)# enroll terminal
hostname(config-ca-trustpoint)# crypto ca authenticate mytrust
Enter the base 64 encoded CA certificate.
End with the word "quit" on a line by itself

INFO: Certificate has the following attributes:
Fingerprint:     9508g897 82914638 435f9f0fc x9y2p42
Do you accept this certificate? [yes/no]: y
Trustpoint CA certificate accepted.
```

```
% Certificate successfully imported
hostname(config)# crypto ca trustpoint newtrust
hostname(config-ca-trustpoint)# revocation-check ocsp
hostname(config-ca-trustpoint)# match certificate mymap override ocsp trustpoint mytrust 4
url 10.22.184.22
```

Any connection that uses the newtrust trustpoint for client certificate authentication checks to see if the client certificate matches the attribute rules specified in the mymap certificate map. If so, the ASA accesses the OCSP responder at 10.22.184.22 for certificate revocation status, then then uses the mytrust trustpoint to validate the responder certificate.

Note The newtrust trustpoint is configured to perform revocation checking via OCSP for the client certificates. However, the mytrust trustpoint is configured for the default revocation-check method, which is none. As a result, no revocation checking is performed on the OCSP responder certificate.

Related Commands

Command	Description
crypto ca certificate map	Creates crypto ca certificate maps. Use this command in global configuration mode.
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode. Use this command in global configuration mode.
ocsp disable-nonce	Disables the nonce extension of the OCSP request.
ocsp url	Specifies the OCSP server to use to check all certificates associated with a trustpoint.
revocation-check	Specifies the method(s) to use for revocation checking and the order in which to try them.

match certificate allow expired-certificate

To allow an administrator to exempt certain certificates from expiration checking, use the **match certificate allow expired-certificate** command in ca-trustpool configuration mode. To disable the exemption of certain certificates, use the **no** form of this command.

match certificate <map> allow expired-certificate

no match certificate <map> allow expired-certificate

Syntax Description

allow	Allows expired certificate to be accepted.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-trustpool configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The trustpool match commands leverage the certificate map objects to configure certificate specific exceptions or overrides to the global trustpool policy. The match rules are written relative to the certificate that is being validated.

Related Commands

Command	Description
match certificate skip revocation check	Exempts certain certificates from revocation checking.

match certificate skip revocation-check

To allow an administrator to exempt certain certificates from revocation checking, use the **match certificate skip revocation-check** command in ca-trustpool configuration mode. To disable the exemption from revocation checking, use the **no** form of this command.

match certificate map skip revocation-check

no match certificate map skip revocation-check

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-trustpool configuration	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The trustpool match commands leverage the certificate map objects to configure certificate specific exceptions or overrides to the global trustpool policy. The match rules are written relative to the certificate that is being validated.

Examples

The following example shows skipping the validity check for the certificate with the Subject DN common name of “mycompany123.”

```
crypto ca certificate map mycompany 1
subject-name attr cn eq mycompany123
crypto ca trustpool policy
match certificate mycompany skip revocation-check
```

Related Commands

Command	Description
match certificate allow expired-certificate	Exempts certain certificates from expiration checking.

match cmd

To configure a match condition on the ESMTP command verb, use the **match cmd** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **cmd** [**verb** *verb* | **line length gt** *bytes* | **RCPT count gt** *recipients_number*]

no match [**not**] **cmd** [**verb** *verb* | **line length gt** *bytes* | **RCPT count gt** *recipients_number*]

Syntax Description

verb *verb*	Specifies the ESMTP command verb.
line length gt *bytes*	Specifies the length of a line.
RCPT count gt *recipients_number*	Specifies the number of recipient email addresses.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition in an ESMTP inspection policy map for the verb (method) NOOP exchanged in the ESMTP transaction:

```
hostname(config-pmap)# match cmd verb NOOP
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match default-inspection-traffic

To specify default traffic for the inspect commands in a class map, use the **match default-inspection-traffic** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match default-inspection-traffic

no match default-inspection-traffic

Syntax Description

This command has no arguments or keywords.

Defaults

See the Usage Guidelines section for the default traffic of each inspection.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

Using the **match default-inspection-traffic** command, you can match default traffic for the individual **inspect** commands. The **match default-inspection-traffic** command can be used in conjunction with one other match command, which is typically an access-list in the form of **permit ip** *src-ip dst-ip*.

The rule for combining a second **match** command with the **match default-inspection-traffic** command is to specify the protocol and port information using the **match default-inspection-traffic** command and specify all other information (such as IP addresses) using the second **match** command. Any protocol or port information specified in the second **match** command is ignored with respect to the **inspect** commands.

For instance, port 65535 specified in the example below is ignored:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match default-inspection-traffic
hostname(config-cmap)# match port 65535
```

Default traffic for inspections are as follows:

Inspection Type	Protocol Type	Source Port	Destination Port
ctiqbe	tcp	N/A	1748
dcerpc	tcp	N/A	135
dns	udp	53	53
ftp	tcp	N/A	21
gtp	udp	2123,3386	2123,3386
h323 h225	tcp	N/A	1720
h323 ras	udp	N/A	1718-1719
http	tcp	N/A	80
icmp	icmp	N/A	N/A
ils	tcp	N/A	389
im	tcp	N/A	1-65539
ipsec-pass-thru	udp	N/A	500
mgcp	udp	2427,2727	2427,2727
netbios	udp	137-138	N/A
rpc	udp	111	111
rsh	tcp	N/A	514
rtsp	tcp	N/A	554
sip	tcp,udp	N/A	5060
skinny	tcp	N/A	2000
smtp	tcp	N/A	25
sqlnet	tcp	N/A	1521
tftp	udp	N/A	69
xdmcp	udp	177	177

Examples

The following example shows how to define a traffic class using a class map and the **match default-inspection-traffic** command:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match default-inspection-traffic
hostname(config-cmap)#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.

Command	Description
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match dns-class

To configure a match condition for the Domain System Class in a DNS Resource Record or Question section, use the **match dns-class** command in class-map or policy-map configuration mode. To remove a configured class, use the **no** form of this command.

match [**not**] **dns-class** {**eq** *c_well_known* | *c_val*} {**range** *c_val1 c_val2*}

no match [**not**] **dns-class** {**eq** *c_well_known* | *c_val*} {**range** *c_val1 c_val2*}

Syntax Description

eq	Specifies an exact match.
c_well_known	Specifies DNS class by well-known name, IN.
c_val	Specifies an arbitrary value in the DNS class field (0-65535).
range	Specifies a range.
c_val1 c_val2	Specifies values in a range match. Each value between 0 and 65535.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

By default, this command inspects all fields (questions and RRs) of a DNS message and matches the specified class. Both DNS query and response are examined.

The match can be narrowed down to the question portion of a DNS query by the following two commands: **match not header-flag QR** and **match question**.

This command can be configured within a DNS class map or policy map. Only one entry can be entered within a DNS class-map.

Examples

The following example shows how to configure a match condition for a DNS class in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# match dns-class eq IN
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match dns-type

To configure a match condition for a DNS type, including Query type and RR type, use the **match dns-type** command in class-map or policy-map configuration mode. To remove a configured dns type, use the **no** form of this command.

match [**not**] **dns-type** {**eq** *t_well_known* | *t_val*} {**range** *t_val1 t_val2*}

no match [**not**] **dns-type** {**eq** *t_well_known* | *t_val*} {**range** *t_val1 t_val2*}

Syntax Description

eq	Specifies an exact match.
t_well_known	Specifies DNS type by well-known name: A, NS, CNAME, SOA, TSIG, IXFR, or AXFR.
t_val	Specifies an arbitrary value in the DNS type field (0-65535).
range	Specifies a range.
t_val1 t_val2	Specifies values in a range match. Each value between 0 and 65535.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

By default, this command inspects all sections of a DNS message (questions and RRs) and matches the specified type. Both DNS query and response are examined.

The match can be narrowed down to the question portion of a DNS query by the following two commands: **match not header-flag QR** and **match question**.

This command can be configured within a DNS class map or policy map. Only one entry can be entered within a DNS class-map.

Examples

The following example shows how to configure a match condition for a DNS type in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
```

```
hostname(config-pmap)# match dns-type eq a
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match domain-name

To configure a match condition for a DNS message domain name list, use the **match domain-name** command in class-map or policy-map configuration mode. To remove a configured section, use the **no** form of this command.

match [**not**] **domain-name regex** *regex_id*

match [**not**] **domain-name regex class** *class_id*

no match [**not**] **domain-name regex** *regex_id*

no match [**not**] **domain-name regex class** *class_id*

Syntax Description

regex	Specifies a regular expression.
regex_id	Specifies the regular expression ID.
class	Specifies the class map that contains multiple regular expression entries.
class_id	Specifies the regular expression class map ID.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command matches domain names in the DNS message against predefined list. Compressed domain names will be expanded before matching. The match condition can be narrowed down to a particular field in conjunction with other DNS **match** commands.

This command can be configured within a DNS class map or policy map. Only one entry can be entered within a DNS class-map.

Examples

The following example shows how to match the DNS domain name in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# match domain-name regex
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match dscp

To identify the IETF-defined DSCP value (in an IP header) in a class map, use the **match dscp** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match dscp {*values*}

no match dscp {*values*}

Syntax Description

values	Specifies up to eight different the IETF-defined DSCP values in the IP header. Range is 0 to 63.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

Using the **match dscp** command, you can match the IETF-defined DSCP values in the IP header.

Examples

The following example shows how to define a traffic class using a class map and the **match dscp** command:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match dscp af43 cs1 ef
hostname(config-cmap)#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.
match port	Specifies the TCP/UDP ports as the comparison criteria for packets received on that interface.
show running-config class-map	Displays the information about the class map configuration.

CHAPTER 33

match ehlo-reply-parameter through match question Commands

match ehlo-reply-parameter

To configure a match condition on the ESMTP ehlo reply parameter, use the **match ehlo-reply-parameter** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **ehlo-reply-parameter** *parameter*

no match [**not**] **ehlo-reply-parameter** *parameter*

Syntax Description

parameter	Specifies the ehlo reply parameter.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for an ehlo reply parameter in an ESMTP inspection policy map:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# match ehlo-reply-parameter auth
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match filename

To configure a match condition for a filename for FTP transfer, use the **match filename** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **filename regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **filename regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an FTP class map or policy map. Only one entry can be entered in a FTP class map.

Examples

The following example shows how to configure a match condition for an FTP transfer filename in an FTP inspection class map:

```
hostname(config)# class-map type inspect ftp match-all ftp_class1
hostname(config-cmap)# description Restrict FTP users ftp1, ftp2, and ftp3 from accessing
/root
hostname(config-cmap)# match username regex class ftp_regex_user
hostname(config-cmap)# match filename regex ftp-file
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match filetype

To configure a match condition for a filetype for FTP transfer, use the **match filetype** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **filetype regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **filetype regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an FTP class map or policy map. Only one entry can be entered in a FTP class map.

Examples

The following example shows how to configure a match condition for an FTP transfer filetype in an FTP inspection policy map:

```
hostname(config-pmap)# match filetype class regex ftp-regex-filetype
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match flow ip destination-address

To specify the flow IP destination address in a class map, use the **match flow ip destination-address** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match flow ip destination-address

no match flow ip destination-address

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

To enable flow-based policy actions on a tunnel group, use the **match flow ip destination-address** and **match tunnel-group** commands with the **class-map**, **policy-map**, and **service-policy** commands. The criteria to define flow is the destination IP address. All traffic going to a unique IP destination address is considered a flow. Policy action is applied to each flow instead of the entire class of traffic. QoS action police is applied using the **match flow ip destination-address** command. Use **match tunnel-group** to police every tunnel within a tunnel group to a specified rate.

Examples

The following example shows how to enable flow-based policing within a tunnel group and limit each tunnel to a specified rate:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match tunnel-group
hostname(config-cmap)# match flow ip destination-address
hostname(config-cmap)# exit
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# police 56000
hostname(config-pmap)# exit
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.
show running-config class-map	Displays the information about the class map configuration.
tunnel-group	Creates and manages the database of connection-specific records for VPN.

match header (policy-map type inspect esmtp)

To configure a match condition on the ESMTP header, use the **match header** command in policy-map type inspect esmtp configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **header [[length | line length] gt** *bytes* **| to-fields count gt** *to_fields_number*]

no match [**not**] **header [[length | line length] gt** *bytes* **| to-fields count gt** *to_fields_number*]

Syntax Description

length gt *bytes*	Specifies to match on the length of the ESMTP header message.
line length gt bytes	Specifies to match on the length of a line of an ESMTP header message.
to-fields count gt *to_fields_number*	Specifies to match on the number of To: fields.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy-map type inspect esmtp configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for a header in an ESMTP inspection policy map:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# match header length gt 512
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match header (policy-map type inspect ipv6)

To configure a match condition on the IPv6 header, use the **match header** command in policy-map type inspect ipv6 configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **header** {**ah** | **count gt** *number* | **destination-option** | **esp** | **fragment** | **hop-by-hop** | **routing-address count gt** *number* | **routing-type** {**eq** | **range**} *number*}

no match [**not**] **header** {**ah** | **count gt** *number* | **destination-option** | **esp** | **fragment** | **hop-by-hop** | **routing-address count gt** *number* | **routing-type** {**eq** | **range**} *number*}

Syntax Description

ah	Matches the IPv6 Authentication extension header
count gt *number*	Specifies the maximum number of IPv6 extension headers, from 0 to 255.
destination-option	Matches the IPv6 destination-option extension header.
esp	Matches the IPv6 Encapsulation Security Payload (ESP) extension header.
fragment	Matches the IPv6 fragment extension header.
hop-by-hop	Matches the IPv6 hop-by-hop extension header.
not	(Optional) Does not match the specified parameter.
routing-address count gt *number*	Sets the maximum number of IPv6 routing header type 0 addresses, greater than a number between 0 and 255.
routing-type {**eq** | **range**} *number*	Matches the IPv6 routing header type, from 0 to 255. For a range, separate values by a space, for example, **30 40**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy-map type inspect ipv6 configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

Specifies the headers you want to match. By default, the packet is logged (**log**); if you want to drop (and optionally also log) the packet, enter the **drop** and optional **log** commands in match configuration mode.

Re-enter the **match** command and optional **drop** action for each extension you want to match:

Examples

The following example creates an inspection policy map that will drop and log all IPv6 packets with the hop-by-hop, destination-option, routing-address, and routing type 0 headers:

```
policy-map type inspect ipv6 ipv6-pm
 parameters
 match header hop-by-hop
  drop log
 match header destination-option
  drop log
 match header routing-address count gt 0
  drop log
 match header routing-type eq 0
  drop log
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match header-flag

To configure a match condition for a DNS header flag, use the **match header-flag** command in class-map or policy-map configuration mode. To remove a configured header flag, use the **no** form of this command.

match [**not**] **header-flag** [**eq**] {*f_well_known* | *f_value*}

no match [**not**] **header-flag** [**eq**] {*f_well_known* | *f_value*}

Syntax Description

eq	Specifies an exact match. If not configured, specifies a **match-all** bit mask match.
f_well_known	Specifies DNS header flag bits by well-known name. Multiple flag bits may be entered and logically OR'd. QR (Query, note: QR=1, indicating a DNS response) AA (Authoritative Answer) TC (TrunCation) RD (Recursion Desired) RA (Recursion Available)
f_value	Specifies an arbitrary 16-bit value in hexidecimal form.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a DNS class map or policy map. Only one entry can be entered in a DNS class map.

Examples

The following example shows how to configure a match condition for a DNS header flag in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# match header-flag AA
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match im-subscriber

To configure a match condition for a SIP IM subscriber, use the **match im-subscriber** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **im-subscriber regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **im-subscriber regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a SIP class map or policy map. Only one entry can be entered in a SIP class map.

Examples

The following example shows how to configure a match condition for a SIP IM subscriber in a SIP inspection class map:

```
hostname(config-cmap)# match im-subscriber regex class im_sender
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match interface

To distribute any routes that have their next hop out one of the interfaces specified, use the **match interface** command in route-map configuration mode. To remove the match interface entry, use the **no** form of this command.

match interface *interface-name*

no match interface *interface-name*

Syntax Description

interface-name	Name of the interface (not the physical interface). Multiple interface names can be specified.

Defaults

No match interfaces are defined.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

An ellipsis (...) in the command syntax indicates that your command input can include multiple values for the interface-type interface-number arguments.

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match** route-map configuration command has multiple formats. You can give the **match** commands in any order. All **match** commands must “pass” to cause the route to be redistributed according to the set actions that are given with the **set** commands. The **no** forms of the **match** commands remove the specified match criteria. If there is more than one interface specified in the **match** command. then the **no match interface** *interface-name* can be used to remove a single interface.

A route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored. If you want to modify only some data, you must configure a second route map section and specify an explicit match.

Examples

The following example shows that the routes with their next hop outside is distributed:

```
hostname(config)# route-map name
hostname(config-route-map)# match interface outside
```

Related Commands

Command	Description
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
match ip route-source	Redistributes routes that have been advertised by routers and access servers at the address that is specified by the access lists.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match invalid-recipients

To configure a match condition on the ESMTP invalid recipient address, use the **match invalid-recipients** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **invalid-recipients count gt** *number*

no match [**not**] **invalid-recipients count gt** *number*

Syntax Description

count gt *number*	Specifies to match on the invalid recipient number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for invalid recipients count in an ESMTP inspection policy map:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# match invalid-recipients count gt 1000
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match ip address

To redistribute any routes that have a route address or match packet that is passed by one of the access lists specified, use the **match ip address** command in route-map configuration mode. To restore the default settings, use the **no** form of this command.

match ip address {*acl...*} **prefix-list**

no match ip address {*acl...*} **prefix-list**

Syntax Description

acl	Specifies the name of an access list. Multiple access lists can be specified.
prefix-list	Specifies the name of a match prefix list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

Examples

The following example shows how to redistribute internal routes:

```
hostname(config)# route-map name
hostname(config-route-map)# match ip address acl_dmz1 acl_dmz2
```

Related Commands

Command	Description
match interface	Distributes any routes that have their next hop out one of the interfaces specified,
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
match ipv6 address	Distributes any routes that have an IPv6 route address or match packet that is passed by one of the access lists specified.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match ipv6 address

To redistribute any routes that have an IPv6 route address or match packet that is passed by one of the access lists specified, use the **match ipv6 address** command in route-map configuration mode. To restore the default settings, use the **no** form of this command.

match ipv6 address {*acl...*} **prefix-list**

no match ipv6 address {*acl...*} **prefix-list**

Syntax Description

acl	Specifies the name of an access list. Multiple access lists can be specified.
prefix-list	Specifies the name of a match prefix list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

Examples

The following example shows how to redistribute internal routes: access-list acl_dmz1 extended permit ipv6 any <net> <mask>

```
hostname(config)# access-list acl_dmz1 extended permit ipv6 any <net> <mask>
hostname(config)# route-map name
hostname(config-route-map)# match ipv6 address acl_dmz1 acl_dmz2
```

Related Commands

Command	Description
match interface	Distributes any routes that have their next hop out one of the interfaces specified,
match ip address	Distributes any routes that have a route address or match packet that is passed by one of the access lists specified.
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match ip next-hop

To redistribute any routes that have a next-hop router address that is passed by one of the access lists specified, use the **match ip next-hop** command in route-map configuration mode. To remove the next-hop entry, use the **no** form of this command.

match ip next-hop {*acl...*} | **prefix-list** *prefix_list*

no match ip next-hop {*acl...*} | **prefix-list** *prefix_list*

Syntax Description

acl	Name of an ACL. Multiple ACLs can be specified.
prefix-list *prefix_list*	Name of prefix list.

Defaults

Routes are distributed freely, without being required to match a next-hop address.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

An ellipsis (...) in the command syntax indicates that your command input can include multiple values for the *acl* argument.

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match** route-map configuration command has multiple formats. You can enter the **match** commands in any order. All **match** commands must "pass" to cause the route to be redistributed according to the set actions given with the **set** commands. The **no** forms of the **match** commands remove the specified match criteria.

When you are passing routes through a route map, a route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored. To modify only some data, you must configure a second route map section and specify an explicit match.

Examples

The following example shows how to distribute routes that have a next-hop router address passed by access list acl_dmz1 or acl_dmz2:

```
hostname(config)# route-map name
hostname(config-route-map)# match ip next-hop acl_dmz1 acl_dmz2
```

Related Commands

Command	Description
match interface	Distributes distribute any routes that have their next hop out one of the interfaces specified.
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match ip route-source

To redistribute routes that have been advertised by routers and access servers at the address that is specified by the ACLs, use the **match ip route-source** command in the route-map configuration mode. To remove the next-hop entry, use the **no** form of this command.

match ip route-source {*acl...*} | **prefix-list** *prefix_list*

no match ip route-source {*acl...*}

Syntax Description

acl	Name of an ACL. Multiple ACLs can be specified.
prefix_list	Name of prefix list.

Defaults

No filtering on a route source.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

An ellipsis (...) in the command syntax indicates that your command input can include multiple values for the access-list-name argument.

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match** route-map configuration command has multiple formats. You can enter the **match** commands in any order. All **match** commands must "pass" to cause the route to be redistributed according to the set actions given with the **set** commands. The **no** forms of the **match** commands remove the specified match criteria.

A route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored. To modify only some data, you must configure a second route map section and specify an explicit match. The next-hop and source-router address of the route are not the same in some situations.

Examples

The following example shows how to distribute routes that have been advertised by routers and access servers at the addresses specified by ACLs acl_dmz1 and acl_dmz2:

```
hostname(config)# route-map name
hostname(config-route-map)# match ip route-source acl_dmz1 acl_dmz2
```

Related Commands

Command	Description
match interface	Distributes distribute any routes that have their next hop out one of the interfaces specified.
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the ACLs specified.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match login-name

To configure a match condition for a client login name for instant messaging, use the **match login-name** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **login-name regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **login-name regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an IM class map or policy map. Only one entry can be entered in a IM class map.

Examples

The following example shows how to configure a match condition for a client login name in an instant messaging class map:

```
hostname(config)# class-map type inspect im im_class
hostname(config-cmap)# match login-name regex login
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match media-type

To configure a match condition on the H.323 media type, use the **match media-type** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **media-type [audio | data | video]**

no match [**not**] **media-type [audio | data | video]**

Syntax Description

audio	Specifies to match audio media type.
data	Specifies to match data media type.
video	Specifies to match video media type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for audio media type in an H.323 inspection class map:

```
hostname(config-cmap)# match media-type audio
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match message id

To configure a match condition for a GTP message ID, use the **match message id** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **message id** [*message_id* | **range** *lower_range upper_range*]

no match [**not**] **message id** [*message_id* | **range** *lower_range upper_range*]

Syntax Description

message_id	Specifies an alphanumeric identifier between 1 and 255.
range *lower_range upper_range*	Specifies a lower and upper range of IDs.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a GTP class map or policy map. Only one entry can be entered in a GTP class map.

Examples

The following example shows how to configure a match condition for a message ID in a GTP inspection class map:

```
hostname(config-cmap)# match message id 33
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match message length

To configure a match condition for a GTP message ID, use the **match message length** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **message length min** *min_length* **max** *max_length*

no match [**not**] **message length min** *min_length* **max** *max_length*

Syntax Description

min *min_length*	Specifies a minimum message ID length. Value is between 1 and 65536.
max *max_length*	Specifies a maximum message ID length. Value is between 1 and 65536.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a GTP class map or policy map. Only one entry can be entered in a GTP class map.

Examples

The following example shows how to configure a match condition for a message length in a GTP inspection class map:

```
hostname(config-cmap)# match message length min 8 max 200
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.

match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match message-path

To configure a match condition for the path taken by a SIP message as specified in the Via header field, use the **match message-path** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **message-path regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **message-path regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a SIP class map or policy map. Only one entry can be entered in a SIP class map.

Examples

The following example shows how to configure a match condition for the path taken by a SIP message in a SIP inspection class map:

```
hostname(config-cmap)# match message-path regex class sip_message
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match metric

To redistribute routes with the metric specified, use the **match metric** command in route-map configuration mode. To remove the entry, use the **no** form of this command.

match metric *number*

no match metric *number*

Syntax Description

number	Route metric, which can be an IGRP five-part metric; valid values are from 0 to 4294967295.

Defaults

No filtering on a metric value.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **route-map global** configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match** route-map configuration command has multiple formats. The **match** commands can be given in any order, and all **match** commands must "pass" to cause the route to be redistributed according to the set actions given with the **set** commands. The **no** forms of the **match** commands remove the specified match criteria.

A route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored. To modify only some data, you must configure a second route map section and specify an explicit match.

Examples

The following example shows how to redistribute routes with the metric 5:

```
hostname(config)# route-map name
hostname(config-route-map)# match metric 5
```

Related Commands

Command	Description
match interface	Distributes distribute any routes that have their next hop out one of the interfaces specified,
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match mime

To configure a match condition on the ESMTP mime encoding type, mime filename length, or mime file type, use the **match mime** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **mime [encoding** *type* **| filename length gt** *bytes* **| filetype** *regex***]**

no match [**not**] **mime [encoding** *type* **| filename length gt** *bytes* **| filetype** *regex***]**

Syntax Description

encoding *type*	Specifies to match on the encoding type.
filename length gt *bytes*	Specifies to match on the filename length.
filetype *regex*	Specifies to match on the file type.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for a mime filename length in an ESMTP inspection policy map:

```
hostname(config)# policy-map type inspect esmtp esmtp_map
hostname(config-pmap)# match mime filename length gt 255
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match peer-ip-address

To configure a match condition for the peer IP address for instant messaging, use the **match peer-ip-address** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **peer-ip-address** *ip_address ip_address_mask*

no match [**not**] **peer-ip-address** *ip_address ip_address_mask*

Syntax Description

ip_address	Specifies a hostname or IP address of the client or server.
ip_address_mask	Specifies the netmask for the client or server IP address.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an IM class map or policy map. Only one entry can be entered in a IM class map.

Examples

The following example shows how to configure a match condition for the peer IP address in an instant messaging class map:

```
hostname(config)# class-map type inspect im im_class
hostname(config-cmap)# match peer-ip-address 10.1.1.0 255.255.255.0
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match peer-login-name

To configure a match condition for the peer login name for instant messaging, use the **match peer-login-name** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **peer-login-name regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **peer-login-name regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an IM class map or policy map. Only one entry can be entered in a IM class map.

Examples

The following example shows how to configure a match condition for the peer login name in an instant messaging class map:

```
hostname(config)# class-map type inspect im im_class
hostname(config-cmap)# match peer-login-name regex peerlogin
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match port

When using the Modular Policy Framework, match the TCP or UDP ports to which you want to apply actions by using the **match port** command in class-map configuration mode. To remove the **match port** command, use the **no** form of this command.

match port {**tcp** | **udp**} {**eq** *port* | **range** *beg_port end_port*}

no match port {**tcp** | **udp**} {**eq** *port* | **range** *beg_port end_port*}

Syntax Description

eq *port*	Specifies a single port name or number.
range *beg_port end_port*	Specifies beginning and ending port range values between 1 and 65535.
tcp	Specifies a TCP port.
udp	Specifies a UDP port.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** or **class-map type management** command.

   After you enter the **class-map** command, you can enter the **matchport** command to identify the traffic. Alternatively, you can enter a different type of **match** command, such as the **match access-list** command (the **class-map type management** command only allows the match port command). You can only include one **match port** command in the class map, and you cannot combine it with other types of **match** commands.

2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

Examples

The following example shows how to define a traffic class using a class map and the **match port** command:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match port tcp eq 8080
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match access-list	Matches traffic according to an access list.
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match precedence

To specify a precedence value in a class map, use the **match precedence** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match precedence *value*

no match precedence *value*

Syntax Description

value	Specifies up to four precedence values separated by a space. Range is 0 to 7.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

Use the **match precedence** command to specify the value represented by the TOS byte in the IP header.

Examples

The following example shows how to define a traffic class using a class map and the **match precedence** command:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match precedence 1
hostname(config-cmap)#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match protocol

To configure a match condition for a specific instant messaging protocol, such as MSN or Yahoo, use the **match protocol** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **protocol** {**msn-im** | **yahoo-im**}

no match [**not**] **protocol** {**msn-im** | **yahoo-im**}

Syntax Description

msn-im	Specifies to match the MSN instant messaging protocol.
yahoo-im	Specifies to match the Yahoo instant messaging protocol.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an IM class map or policy map. Only one entry can be entered in a IM class map.

Examples

The following example shows how to configure a match condition for the Yahoo instant messaging protocol in an instant messaging class map:

```
hostname(config)# class-map type inspect im im_class
hostname(config-cmap)# match protocol yahoo-im
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match question

To configure a match condition for a DNS question or resource record, use the **match question** command in class-map or policy-map configuration mode. To remove a configured section, use the **no** form of this command.

match {**question** | {**resource-record answer** | **authority** | **additional**}}

no match {**question** | {**resource-record answer** | **authority** | **additional**}}

Syntax Description

question	Specifies the question portion of a DNS message.
resource-record	Specifies the resource record portion of a DNS message.
answer	Specifies the Answer RR section.
authority	Specifies the Authority RR section.
additional	Specifies the Additional RR section.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

By default, this command inspects the DNS header and matches the specified field. It can be used in conjunction with other DNS **match** commands to define inspection of a particular question or RR type..

This command can be configured within a DNS class map or policy map. Only one entry can be entered within a DNS class-map.

Examples

The following example shows how to configure a match condition for a DNS question in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# match question
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

CHAPTER 34

match regex through message-length Commands

match regex

To identify a regular expression in a regular expression class map, use the **match regex** command in class-map type regex configuration mode. To remove the regular expression from the class map, use the **no** form of this command.

match regex *name*

no match regex *name*

Syntax Description

name	The name of the regular expression you added with the **regex** command.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map type regex configuration	•	•	•	—	•

Command History

Release	Modification
7.0(2)	We introduced this command.

Usage Guidelines

The **regex** command can be used for various features that require text matching. You can group regular expressions in a regular expression class map using the **class-map type regex** command and then multiple **match regex** commands.

For example, you can configure special actions for application inspection using an inspection policy map (see the **policy map type inspect** command). In the inspection policy map, you can identify the traffic you want to act upon by creating an inspection class map containing one or more **match** commands or you can use **match** commands directly in the inspection policy map. Some **match** commands let you identify text in a packet using a regular expression; for example, you can match URL strings inside HTTP packets.

Examples

The following is an example of an HTTP inspection policy map and the related class maps. This policy map is activated by the Layer 3/4 policy map, which is enabled by the service policy.

```
hostname(config)# regex url_example example\.com
hostname(config)# regex url_example2 example2\.com
hostname(config)# class-map type regex match-any URLs
hostname(config-cmap)# match regex url_example
hostname(config-cmap)# match regex url_example2
```

```
hostname(config-cmap)# class-map type inspect http match-all http-traffic
hostname(config-cmap)# match req-resp content-type mismatch
hostname(config-cmap)# match request body length gt 1000
hostname(config-cmap)# match not request uri regex class URLs

hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# drop-connection log
hostname(config-pmap-c)# match req-resp content-type mismatch
hostname(config-pmap-c)# reset log
hostname(config-pmap-c)# parameters
hostname(config-pmap-p)# protocol-violation action log
hostname(config-pmap-p)# policy-map test
hostname(config-pmap)# class test [a Layer 3/4 class map not shown]
hostname(config-pmap-c)# inspect http http-map1
hostname(config-pmap-c)# service-policy test interface outside
```

Related Commands

Command	Description
class-map type regex	Creates a regular expression class map.
regex	Adds a regular expression.
test regex	Tests a regular expression.

match req-resp

To configure a match condition for both HTTP requests and responses, use the **match req-resp** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **req-resp content-type mismatch**

no match [**not**] **req-resp content-type mismatch**

Syntax Description

content-type	Specifies to match the content type in the response to the accept types in the request.
mismatch	Specifies that the content type field in the response must match one of the mime types in the accept field of the request.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command enables the following checks:

- Verifies that the value of the header content-type is in the internal list of supported content types,
- Verifies that the header content-type matches the actual content in the data or entity body portion of the message.
- Verifies the content type field in the HTTP response matches the **accept** field in the corresponding HTTP request message.

If the message fails any of the above checks, the ASA takes the configured action.

The following is the list of supported content types.

audio/* |	audio/basic |	video/x-msvideo
audio/mpeg |	audio/x-adpcm |	audio/midi
audio/x-ogg |	audio/x-wav |	audio/x-aiff |
application/octet-stream	application/pdf	application/msword
application/vnd.ms-excel	application/vnd.ms-powerpoint	application/postscript
application/x-java-arching	application/x-msn-messenger	application/x-gzip
image |	application/x-java-xm	application/zip
image/jpeg |	image/cgf |	image/gif |
image/x-3ds |	image/png |	image/tiff |
image/x-portable-bitmap |	image/x-bitmap |	image/x-niff |
text/* |	image/x-portable-greymap |	image/x-xpm |
text/plain |	text/css	text/html |
text/xmcd	text/richtext |	text/sgml
video/-flc	text/xml	video/*
video/sgi	video/mpeg	video/quicktime
video/x-mng	video/x-avi	video/x-fli

Some content-types in this list may not have a corresponding regular expression (magic number) so they cannot be verified in the body portion of the message. When this case occurs, the HTTP message will be allowed.

Examples

The following example shows how to restrict HTTP traffic based on the content type of the HTTP message in an HTTP policy map:

```
hostname(config)# policy-map type inspect http http_map
hostname(config-pmap)# match req-resp content-type mismatch
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
show running-config class-map	Displays the information about the class map configuration.

match request-command

To restrict specific FTP commands, use the **match request-command** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **request-command** *ftp_command* [*ftp_command...*]

no match [**not**] **request-command** *ftp_command* [*ftp_command...*]

Syntax Description

ftp_command	Specifies one or more FTP commands to restrict.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an FTP class map or policy map. Only one entry can be entered in a FTP class map.

Examples

The following example shows how to configure a match condition for a specific FTP command in an FTP inspection policy map:

```
hostname(config)# policy-map type inspect ftp ftp_map1
hostname(config-pmap)# match request-command stou
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match request-method

To configure a match condition for the SIP method type, use the **match request-method** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **request-method** *method_type*

no match [**not**] **request-method** *method_type*

Syntax Description

method_type	Specifies a method type according to RFC 3261 and supported extensions. Supported method types include: ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, unknown, update.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a SIP class map or policy map. Only one entry can be entered in a SIP class map.

Examples

The following example shows how to configure a match condition for the path taken by a SIP message in a SIP inspection class map:

```
hostname(config-cmap)# match request-method ack
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match request method

To configure a match condition for HTTP requests, use the **match request method** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **request** {*built-in-regex* | **regex** {*regex_name* | **class** *class_map_name*}}

no match [**not**] **request** {*built-in-regex* | **regex** {*regex_name* | **class** *class_map_name*}}

Syntax Description

built-in-regex	Specifies the built-in regex for content type, method, or transfer encoding.
class *class_map name*	Specifies the name of the class map of regex type.
regex *regex_name*	Specifies the name of the regular expression configured using the **regex** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Table 34-1 Built-in Regex Values

bcopy	bdelete	bmove	bpropfind
bproppatch	connect	copy	delete
edit	get	getattribute	getattributenames
getproperties	head	index	lock
mkcol	mkdir	move	notify
options	poll	post	propfind
proppatch	put	revadd	revlabel
revlog	revnum	save	search
setattribute	startrev	stoprev	subscribe
trace	unedit	unlock	unsubscribe

Examples

The following example shows how to define an HTTP inspection policy map that will allow and log any HTTP connection that attempts to access "www\.example.com/.*\.asp" or "www\example[0-9][0-9]\.com" with methods "GET" or "PUT." All other URL/Method combinations will be silently allowed:

```
hostname(config)# regex url1 "www\.example.com/.*\.asp
hostname(config)# regex url2 "www\.example[0-9][0-9]\.com"
hostname(config)# regex get "GET"
hostname(config)# regex put "PUT"
hostname(config)# class-map type regex match-any url_to_log
hostname(config-cmap)# match regex url1
hostname(config-cmap)# match regex url2
hostname(config-cmap)# exit
hostname(config)# class-map type regex match-any methods_to_log
hostname(config-cmap)# match regex get
hostname(config-cmap)# match regex put
hostname(config-cmap)# exit
hostname(config)# class-map type inspect http http_url_policy
hostname(config-cmap)# match request uri regex class url_to_log
hostname(config-cmap)# match request method regex class methods_to_log
hostname(config-cmap)# exit
hostname(config)# policy-map type inspect http http_policy
hostname(config-pmap)# class http_url_policy
hostname(config-pmap-c)# log
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
show running-config class-map	Displays the information about the class map configuration.

match route-type

To redistribute routes of the specified type, use the **match route-type** command in route-map configuration mode. To remove the route type entry, use the **no** form of this command.

match route-type {**local** | **internal** | {**external** [**type-1** | **type-2**]} | {**nssa-external** [**type-1** | **type-2**]}}

no match route-type {**local** | **internal** | {**external** [**type-1** | **type-2**]} | {**nssa-external** [**type-1** | **type-2**]}}

Syntax Description

external	OSPF external routes or EIGRP external routes.
internal	OSPF intra-area and interarea routes or EIGRP internal routes.
local	Locally generated BGP routes.
nssa-external	Specifies the external NSSA.
type-1	(Optional) Specifies the route type 1.
type-2	(Optional) Specifies the route type 2.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **route-map** global configuration command and the **match** and **set** configuration commands allow you to define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria—the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions—the particular redistribution actions to perform if the criteria that is enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match** route-map configuration command has multiple formats. You can enter the **match** commands in any order. All **match** commands must "pass" to cause the route to be redistributed according to the set actions given with the **set** commands. The **no** forms of the **match** commands remove the specified match criteria.

A route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored. To modify only some data, you must configure a second route map section and specify an explicit match.

For OSPF, the **external type-1** keywords match only type 1 external routes and the **external type-2** keywords match only type 2 external routes.

Examples

The following example shows how to redistribute internal routes:

```
hostname(config)# route-map name
hostname(config-route-map)# match route-type internal
```

Related Commands

Command	Description
match interface	Distributes distribute any routes that have their next hop out one of the interfaces specified,
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
match metric	Redistributes routes with the metric specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

match rtp

To specify a UDP port range of even-number ports in a class map, use the **match rtp** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match rtp *starting_port range*

no match rtp *starting_port range*

Syntax Description

starting_port	Specifies lower bound of even-number UDP destination port. Range is 2000-65535
range	Specifies range of RTP ports. Range is 0-16383.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

Use the **match rtp** command to match RTP ports (even UDP port numbers between the *starting_port* and the *starting_port* plus the *range*).

Examples

The following example shows how to define a traffic class using a class map and the **match rtp** command:

```
hostname(config)# class-map cmap
```

```
hostname(config-cmap)# match rtp 20000 100
hostname(config-cmap)#
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match sender-address

To configure a match condition on the ESMTP sender e-mail address, use the **match sender-address** command in policy-map configuration mode. To disable this feature, use the **no** form of this command.

match [**not**] **sender-address [length gt** *bytes* **| regex** *regex***]**

no match [**not**] **sender-address [length gt** *bytes* **| regex** *regex***]**

Syntax Description

length gt *bytes*	Specifies to match on the sender e-mail address length.
regex *regex*	Specifies to match on the regular expression.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to configure a match condition for the sender email address of length greater than 320 characters in an ESMTP inspection policy map:

```
hostname(config-pmap)# match sender-address length gt 320
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match server

To configure a match condition for an FTP server, use the **match server** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **server regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **server regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an FTP class map or policy map. Only one entry can be entered in a FTP class map.

The ASA matches the server name based using the initial 220 server message that is displayed above the login prompt when connecting to an FTP server. The 220 server message might contain multiple lines. The server match is not based on the FQDN of the server name resolved through DNS.

Examples

The following example shows how to configure a match condition for an FTP server in an FTP inspection policy map:

```
hostname(config-pmap)# match server class regex ftp-server
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match service

To configure a match condition for a specific instant messaging service, use the **match service** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **service** {**chat** | **file-transfer** | **games** | **voice-chat** | **webcam** | **conference**}

no match [**not**] **service** {**chat** | **file-transfer** | **games** | **voice-chat** | **webcam** | **conference**}

Syntax Description

chat	Specifies to match the instant messaging chat service.
file-transfer	Specifies to match the instant messaging file transfer service.
games	Specifies to match the instant messaging games service.
voice-chat	Specifies to match the instant messaging voice chat service.
webcam	Specifies to match the instant messaging webcam service.
conference	Specifies to match the instant messaging conference service.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an IM class map or policy map. Only one entry can be entered in a IM class map.

Examples

The following example shows how to configure a match condition for the chat service in an instant messaging class map:

```
hostname(config)# class-map type inspect im im_class
hostname(config-cmap)# match service chat
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
show running-config class-map	Displays the information about the class map configuration.

match third-party-registration

To configure a match condition for the requester of a third-party registration, use the **match third-party-registration** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **third-party-registration regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **third-party-registration regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a SIP class map or policy map. Only one entry can be entered in a SIP class map.

The third-party registration match command is used to identify the user who can register others with a SIP registar or SIP proxy. It is identified by the From header field in the REGISTER message in the case of mismatching From and To values.

Examples

The following example shows how to configure a match condition for third-party registration in a SIP inspection class map:

```
hostname(config-cmap)# match third-party-registration regex class sip_regist
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match tunnel-group

To match traffic in a class map that belongs to a previously defined tunnel-group, use the **match tunnel-group** command in class-map configuration mode. To remove this specification, use the **no** form of this command.

match tunnel-group *name*

no match tunnel-group *name*

Syntax Description

name	Text for the tunnel group name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **match** commands are used to identify the traffic included in the traffic class for a class map. They include different criteria to define the traffic included in a class-map. Define a traffic class using the **class-map** global configuration command as part of configuring a security feature using Modular Policy Framework. From class-map configuration mode, you can define the traffic to include in the class using the **match** command.

After a traffic class is applied to an interface, packets received on that interface are compared to the criteria defined by the **match** statements in the class map. If the packet matches the specified criteria, it is included in the traffic class and is subjected to any actions associated with that traffic class. Packets that do not match any of the criteria in any traffic class are assigned to the default traffic class.

To enable flow-based policy actions, use the **match flow ip destination-address** and **match tunnel-group** commands with the **class-map**, **policy-map**, and **service-policy** commands. The criteria to define flow is the destination IP address. All traffic going to a unique IP destination address is considered a flow. Policy action is applied to each flow instead of the entire class of traffic. QoS action police is applied using the **police** command. Use **match tunnel-group** along with **match flow ip destination-address** to police every tunnel within a tunnel group to a specified rate.

Examples

The following example shows how to enable flow-based policing within a tunnel group and limit each tunnel to a specified rate:

```
hostname(config)# class-map cmap
hostname(config-cmap)# match tunnel-group
hostname(config-cmap)# match flow ip destination-address
hostname(config-cmap)# exit
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# police 56000
hostname(config-pmap)# exit
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class-map	Applies a traffic class to an interface.
clear configure class-map	Removes all of the traffic map definitions.
match access-list	Identifies access list traffic within a class map.
show running-config class-map	Displays the information about the class map configuration.
tunnel-group	Creates and manages the database of connection-specific records for IPsec and L2TP,

match uri

To configure a match condition for the URI in the SIP headers, use the **match uri** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **uri** {**sip** | **tel**} **length gt** *gt_bytes*

no match [**not**] **uri** {**sip** | **tel**} **length gt** *gt_bytes*

Syntax Description

sip	Specifies a SIP URI.
tel	Specifies a TEL URI.
length gt *gt_bytes*	Specifies the maximum length of the URI. Value is between 0 and 65536.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a SIP class map or policy map. Only one entry can be entered in a SIP class map.

Examples

The following example shows how to configure a match condition for the URI in the SIP message:

```
hostname(config-cmap)# match uri sip length gt
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match url-filter

To configure a match condition for URL filtering in an RTSP message, use the **match url-filter** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **url-filter regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **url-filter regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

This command can be configured in an RTSP class map or policy map.

Examples

The following example shows how to configure a match condition for URL filtering in an RTSP inspection policy map:

```
hostname(config)# regex badurl www.example.com/rtsp.avi
hostname(config)# policy-map type inspect rtsp rtsp-map
hostname(config-pmap)# match url-filter regex badurl
hostname(config-pmap-p)# drop-connection
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match user group

To specifie a user or group to whitelist for Cloud Web Security, use the **match user group** command in parameters configuration mode. You can access the parameters onfiguration mode by first entering the **class-map type inspect scansafe** command. To remove the match, use the **no** form of this command.

match [**not**] {[**user** *username*] [**group** *groupname*]}

no match [**not**] {[**user** *username*] [**group** *groupname*]}

Syntax Description

not	(Optional) Specifies that the user and/or group should be filtered using Web Cloud Security. For example, if you whitelist the group "cisco," but you want to scan traffic from users "johncrichton" and "aerynsun," you can specify **match not** for those users.
user *username*	Specifies a user to whitelist.
group *groupname*	Specifies a group to whitelist.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

If you use AAA rules or IDFW, you can configure the ASA so that web traffic from specific users or groups that otherwise match the service policy rule is not redirected to the Cloud Web Security proxy server for scanning. When you bypass Cloud Web Security scanning, the ASA retrieves the content directly from the originally requested web server without contacting the proxy server. When it receives the response from the web server, it sends the data to the client. This process is called "whitelisting" traffic.

Although you can achieve the same results of exempting traffic based on user or group when you configure the class of traffic using ACLs to send to Cloud Web Security, you might find it more straightforward to use a whitelist instead. Note that the whitelist feature is only based on user and group, not on IP address.

After creating the whitelist as part of the inspection policy map (**policy-map type inspect scansafe**), you can use this map when you specify the Cloud Web Security action using the **inspect scansafe** command.

Examples

The following example whitelists the same users and groups for the HTTP and HTTPS inspection policy maps:

```
hostname(config)# class-map type inspect scansafe match-any whitelist1
hostname(config-cmap)# match user user1 group cisco
hostname(config-cmap)# match user user2
hostname(config-cmap)# match group group1
hostname(config-cmap)# match user user3 group group3

hostname(config)# policy-map type inspect scansafe cws_inspect_pmap1
hostname(config-pmap)# parameters
hostname(config-pmap-p)# http
hostname(config-pmap-p)# default group default_group
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist

hostname(config)# policy-map type inspect scansafe cws_inspect_pmap2
hostname(config-pmap)# parameters
hostname(config-pmap-p)# https
hostname(config-pmap-p)# default group2 default_group2
hostname(config-pmap-p)# class whitelist1
hostname(config-pmap-c)# whitelist
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.

Command	Description
whitelist	Performs the whitelist action on the class of traffic.

match username

To configure a match condition for an FTP username, use the **match username** command in class-map or policy-map configuration mode. To remove the match condtion, use the **no** form of this command.

match [**not**] **username regex** [*regex_name* | **class** *regex_class_name*]

no match [**not**] **username regex** [*regex_name* | **class** *regex_class_name*]

Syntax Description

regex_name	Specifies a regular expression.
class *regex_class_name*	Specifies a regular expression class map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an FTP class map or policy map. Only one entry can be entered in a FTP class map.

Examples

The following example shows how to configure a match condition for an FTP username in an FTP inspection class map:

```
hostname(config)# class-map type inspect ftp match-all ftp_class1
hostname(config-cmap)# match username regex class ftp_regex_user
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.
match any	Includes all traffic in the class map.

Command	Description
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

match version

To configure a match condition for a GTP message ID, use the **match message length** command in class-map or policy-map configuration mode. To remove the match condition, use the **no** form of this command.

match [**not**] **version** [*version_id* | **range** *lower_range upper_range*]

no match [**not**] **version** [*version_id* | **range** *lower_range upper_range*]

Syntax Description

vresion_id	Specifies a version between 0 and 255.
range *lower_range upper_range*	Specifies a lower and upper range of versions.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map or policy map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in a GTP class map or policy map. Only one entry can be entered in a GTP class map.

Examples

The following example shows how to configure a match condition for a message version in a GTP inspection class map:

```
hostname(config-cmap)# match version 1
```

Related Commands

Command	Description
class-map	Creates a Layer 3/4 class map.
clear configure class-map	Removes all class maps.

Command	Description
match any	Includes all traffic in the class map.
match port	Identifies a specific port number in a class map.
show running-config class-map	Displays the information about the class map configuration.

max-failed-attempts

To specify the number of failed attempts allowed for any given server in the server group before that server is deactivated, use the **max-failed-attempts** command in aaa-server group configuration mode. To remove this specification and revert to the default value, use the **no** form of this command.

max-failed-attempts *number*

no max-failed-attempts

Syntax Description

number	An integer in the range of 1-5, specifying the number of failed connection attempts allowed for any given server in the server group specified in a previous **aaa-server** command.

Defaults

The default value of *number* is 3.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
aaa-server group configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must have configured the AAA server or group before issuing this command.

Examples

```
hostname(config)# aaa-server svrgrp1 protocol tacacs+
hostname(config-aaa-server-group)# max-failed-attempts 4
hostname(config-aaa-server-group)#
```

Related Commands

Command	Description
aaa-server *server-tag* **protocol** *protocol*	Enters aaa-server group configuration mode so that you can configure AAA server parameters that are group-specific and common to all hosts in the group.

clear configure aaa-server	Removes all AAA server configurations.
show running-config aaa	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

max-forwards-validation

To enable check on Max-forwards header field of 0, use the **max-forwards-validation** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

max-forwards-validation action {**drop** | **drop-connection** | **reset** | **log**} [**log**}

no max-forwards-validation action {**drop** | **drop-connection** | **reset** | **log**} [**log**}

Syntax Description

drop	Drops the packet if validation occurs.
drop-connection	Drops the connection of a violation occurs.
reset	Resets the connection of a violation occurs.
log	Specifies standalone or additional log in case of violation. It can be associated to any of the actions.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command counts the number of hops to destination, which cannot be 0 before reaching the destination.

Examples

The following example shows how to enable max forwards validation in a SIP inspection policy map:

```
hostname(config)# policy-map type inspect sip sip_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# max-forwards-validation action log
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

max-header-length

To restrict HTTP traffic based on the HTTP header length, use the **max-header-length** command in HTTP map configuration mode, which is accessible using the **http-map** command. To remove this command, use the **no** form of this command.

max-header-length {**request** *bytes* [**response** *bytes*] | **response** *bytes*} **action** {**allow** | **reset** | **drop**} [**log**]

no max-header-length {**request** *bytes* [**response** *bytes*] | **response** *bytes*} **action** {**allow** | **reset** | **drop**} [**log**]

Syntax Description

action	The action taken when a message fails this command inspection.
allow	Allow the message.
drop	Closes the connection.
bytes	Number of bytes, range is 1 to 65535.
log	(Optional) Generate a syslog.
request	Request message.
reset	Send a TCP reset message to client and server.
response	(Optional) Response message.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
HTTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After enabling the **max-header-length** command, the ASA only allows messages having an HTTP header within the configured limit and otherwise takes the specified action. Use the **action** keyword to cause the ASA to reset the TCP connection and optionally create a syslog entry.

Examples

The following example restricts HTTP requests to those with HTTP headers that do not exceed 100 bytes. If a header is too large, the ASA resets the TCP connection and creates a syslog entry.

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# max-header-length request bytes 100 action log reset
hostname(config-http-map)#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug appfw	Displays detailed information about traffic associated with enhanced HTTP inspection.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

max-object-size

To set a maximum size for objects that the ASA can cache for WebVPN sessions, use the max-object-size command in cache mode. To change the size, use the command again.

max-object-size *integer range*

Syntax Description

integer range	0 - 10000 KB

Defaults

1000 KB

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cache mode	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The Maximum object size must be larger than the minimum object size. The ASA calculates the size after compressing the object, if cache compression is enabled.

Examples

The following example shows how to set a maximum object size of 4000 KB:

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)# max-object-size 4000
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache	Enters WebVPN Cache mode.
cache-compressed	Configures WebVPN cache compression.
disable	Disables caching.
expiry-time	Configures the expiration time for caching objects without revalidating them.
lmfactor	Sets a revalidation policy for caching objects that have only the last-modified timestamp.
min-object-size	Defines the minimum sizze of an object to cache.

max-retry-attempts

To configure the number of times the ASA retries a failed SSO authentication attempt before letting the request time out, use the **max-retry-attempts** command in the webvpn configuration mode for the specific SSO server type.

To return to the default value, use the **no** form of this command.

max-retry-attempts *retries*

no max-retry-attempts

Syntax Description

retries	The number of times the ASA retries a failed SSO authentication attempt. The range is 1 to 5 retries.

Defaults

The default value for this command is 3.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
config-webvpn-sso-saml	•	—	•	—	—
config-webvpn-sso-siteminder	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports the SiteMinder-type of SSO server and the SAML POST-type SSO server.

This command applies to both types of SSO Servers.

Once you have configured the ASA to support SSO authentication, optionally you can adjust two timeout parameters:

- The number of times the ASA retries a failed SSO authentication attempt using the **max-retry-attempts** command.
- The number of seconds before a failed SSO authentication attempt times out (see the **request-timeout** command).

Examples

The following example, entered in webvpn-sso-siteminder configuration mode, configures four authentication retries for the SiteMinder SSO server named my-sso-server:

```
hostname(config-webvpn)# sso-server my-sso-server type siteminder
hostname(config-webvpn-sso-siteminder)# max-retry-attempts 4
hostname(config-webvpn-sso-siteminder)#
```

Related Commands

Command	Description
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

max-uri-length

To restrict HTTP traffic based on the length of the URI in the HTTP request message, use the **max-uri-length** command in HTTP map configuration mode, which is accessible using the **http-map** command. To remove this command, use the **no** form of this command.

max-uri-length *bytes* **action** {**allow** | **reset** | **drop**} [**log**]

no max-uri-length *bytes* **action** {**allow** | **reset** | **drop**} [**log**]

Syntax Description

action	The action taken when a message fails this command inspection.
allow	Allow the message.
drop	Closes the connection.
bytes	Number of bytes, range is 1 to 65535.
log	(Optional) Generate a syslog.
reset	Send a TCP reset message to client and server.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
HTTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

After enabling the **max-uri-length** command, the ASA only allows messages having a URI within the configured limit and otherwise takes the specified action. Use the **action** keyword to cause the ASA to reset the TCP connection and create a syslog entry.

URIs with a length less than or equal to the configured value will be allowed. Otherwise, the specified action will be taken.

Examples

The following example restricts HTTP requests to those with URIs that do not exceed 100 bytes. If a URI is too large, the ASA resets the TCP connection and creates a syslog entry.

```
hostname(config)# http-map inbound_http
hostname(config-http-map)# max-uri-length 100 action reset log
hostname(config-http-map)#
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
debug appfw	Displays detailed information about traffic associated with enhanced HTTP inspection.
http-map	Defines an HTTP map for configuring enhanced HTTP inspection.
inspect http	Applies a specific HTTP map to use for application inspection.
policy-map	Associates a class map with specific security actions.

mcc

To identify the mobile country code and the mobile network code for IMSI prefix filtering, use the **mcc** command in GTP map configuration mode. To remove the configuration, use the **no** form of this command.

mcc *country_code* **mnc** *network_code*

no mcc *country_code* **mnc** *network_code*

Syntax Description

country_code	A non-zero, three-digit value identifying the mobile country code. One or two-digit entries will be prepended by 0 to create a three-digit value.
network_code	A two or three-digit value identifying the network code.

Defaults

By default, the ASA does not check for valid MCC/MNC combinations.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is used for IMSI Prefix filtering. The MCC and MNC in the IMSI of the received packet is compared with the MCC/MNC configured with this command and is dropped if it does not match.

This command must be used to enable IMSI Prefix filtering. You can configure multiple instances to specify permitted MCC and MNC combinations. By default, the ASA does not check the validity of MNC and MCC combinations, so you must verify the validity of the combinations configured. To find more information about MCC and MNC codes, see the ITU E.212 recommendation, *Identification Plan for Land Mobile Stations*.

Examples

The following example identifies traffic for IMSI Prefix filtering with an MCC of 111 and an MNC of 222:

```
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# mcc 111 mnc 222
hostname(config-gtpmap)#
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.

media-termination

To specify the media termination instance to use for media connections to the Phone Proxy feature, use the **media-termination** command in global configuration mode.

To remove the media-termination address from the Phone Proxy configuration, use the **no** form of this command.

media-termination *instance_name*

no media-termination *instance_name*

Syntax Description

instance_name	Specifies the name of the interface for which the media termination address is used. Only one media-termination address can be configured per interface.

Defaults

There are no default settings for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.
8.2(1)	This command was updated to allow for using NAT with the media-termination address. The **rtp-min-port** and **rtp-max-ports** keywords were removed from the command syntax and included as a separate command

Usage Guidelines

The ASA must have IP addresses for media termination that meet the following criteria:

For the media termination instance, you can configure a global media-termination address for all interfaces or configure a media-termination address for different interfaces. However, you cannot use a global media-termination address and media-termination addresses configured for each interface at the same time.

If you configure a media termination address for multiple interfaces, you must configure an address on each interface that the ASA uses when communicating with IP phones.

The IP addresses are publicly routable addresses that are unused IP addresses within the address range on that interface.

See CLI configuration guide for the complete list of prerequisites that you must follow when creating the media termination instance and configuring the media termination addresses.

Examples

The following example shows the use of the media-termination address command to specify the IP address to use for media connections:

```
hostname(config-phone-proxy)# media-termination mta_instance1
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

media-type

To set the media type to copper or fiber Gigabit Ethernet, use the **media-type** command in interface configuration mode. The fiber SFP connector is available on the 4GE SSM for the ASA 5500 series adaptive security appliance. To restore the media type setting to the default, use the **no** form of this command.

media-type {**rj45** | **sfp**}

no media-type [**rj45** | **sfp**]

Syntax Description

rj45	(Default) Sets the media type to the copper RJ-45 connector.
sfp	Sets the media type to the fiber SFP connector.

Defaults

The default is **rj45**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

The **sfp** setting uses a fixed speed (1000 Mbps), so the **speed** command allows you to set whether the interface negotiates link parameters or not. The **duplex** command is not supported for **sfp**.

Examples

The following example sets the media type to SFP:

```
hostname(config)# interface gigabitethernet1/1
hostname(config-if)# media-type sfp
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show interface	Displays the runtime status and statistics of interfaces.
show running-config interface	Shows the interface configuration.
speed	Sets the interface speed.

member

To assign a context to a resource class, use the **member** command in context configuration mode. To remove the context from the class, use the **no** form of this command.

member *class_name*

no member *class_name*

Syntax Description

class_name	Specifies the class name you created with the **class** command.

Defaults

By default, the context is assigned to the default class.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Context configuration	•	•	—	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

By default, all security contexts have unlimited access to the resources of the ASA, except where maximum limits per context are enforced. However, if you find that one or more contexts use too many resources, and they cause other contexts to be denied connections, for example, then you can configure resource management to limit the use of resources per context. The ASA manages resources by assigning contexts to resource classes. Each context uses the resource limits set by the class.

Examples

The following example assigns the context test to the gold class:

```
hostname(config-ctx)# context test
hostname(config-ctx)# allocate-interface gigabitethernet0/0.100 int1
hostname(config-ctx)# allocate-interface gigabitethernet0/0.102 int2
hostname(config-ctx)# allocate-interface gigabitethernet0/0.110-gigabitethernet0/0.115
int3-int8
hostname(config-ctx)# config-url ftp://user1:passw0rd@10.1.1.1/configlets/test.cfg
hostname(config-ctx)# member gold
```

Related Commands

Command	Description
class	Creates a resource class.
context	Configures a security context.
limit-resource	Sets the limit for a resource.
show resource allocation	Shows how you allocated resources across classes.
show resource types	Shows the resource types for which you can set limits.

member-interface

To assign a physical interface to a redundant interface, use the **member-interface** command in interface configuration mode. This command is available only for the redundant interface type. You can assign two member interfaces to a redundant interface. To remove a member interface, use the **no** form of this command. You cannot remove both member interfaces from the redundant interface; the redundant interface requires at least one member interface.

member-interface *physical_interface*

no member-interface *physical_interface*

Syntax Description

physical_interface	Identifies the interface ID, such as **gigabitethernet 0/1**. See the **interface** command for accepted values. Both member interfaces must be the same physical type.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Both member interfaces must be of the same physical type. For example, both must be Ethernet.

You cannot add a physical interface to the redundant interface if you configured a name for it. You must first remove the name using the **no nameif** command.

Caution If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

The only configuration available to physical interfaces that are part of a redundant interface pair are physical parameters such as **speed** and **duplex** commands, the **description** command, and the **shutdown** command. You can also enter run-time commands like **default** and **help**.

If you shut down the active interface, then the standby interface becomes active.

To change the active interface, enter the **redundant-interface** command.

The redundant interface uses the MAC address of the first physical interface that you add. If you change the order of the member interfaces in the configuration, then the MAC address changes to match the MAC address of the interface that is now listed first. Alternatively, you can assign a MAC address to the redundant interface, which is used regardless of the member interface MAC addresses (see the **mac-address** command or the **mac-address auto** command). When the active interface fails over to the standby, the same MAC address is maintained so traffic is not disrupted.

Examples

The following example creates two redundant interfaces:

```
hostname(config)# interface redundant 1
hostname(config-if)# member-interface gigabitethernet 0/0
hostname(config-if)# member-interface gigabitethernet 0/1
hostname(config-if)# interface redundant 2
hostname(config-if)# member-interface gigabitethernet 0/2
hostname(config-if)# member-interface gigabitethernet 0/3
```

Related Commands

Command	Description
clear interface	Clears counters for the **show interface** command.
debug redundant-interface	Displays debug messages related to redundant interface events or errors.
interface redundant	Creates a redundant interface.
redundant-interface	Changes the active member interface.
show interface	Displays the runtime status and statistics of interfaces.

memberof

To specify a list of group-names that this user is a member of, use the **memberof** command in username attributes configuration mode. To remove this attribute from the configuration, use the **no** form of this command.

memberof *group_1*[,*group_2,...group_n*]

no memberof *group_1*[,*group_2,...group_n*]

Syntax Description

group_1 through group_n	Specifies the groups to which this user belongs.

Defaults

No default behavior or value.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Username attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Enter a comma-separated list of group names to which this user belongs.

Examples

The following example entered in global configuration mode, creates a username called newuser, then specifies that newuser is a member of the DevTest and management groups:

```
hostname(config)# username newuser nopassword
hostname(config)# username newuser attributes
hostname(config-username)# memberof DevTest,management
hostname(config-username)#
```

Related Commands

Command	Description
clear configure username	Clears the entire username database or just the specified username.
show running-config username	Displays the currently running username configuration for a specified user or for all users.
username	Creates and manages the database of user names.

memory delayed-free-poisoner enable

To enable the delayed free-memory poisoner tool, use the **memory delayed-free-poisoner enable** command in privileged EXEC mode. To disable the delayed free-memory poisoner tool, use the **no** form of this command. The delayed free-memory poisoner tool lets you monitor freed memory for changes after it has been released by an application.

memory delayed-free-poisoner enable

no memory delayed-free-poisoner enable

Syntax Description

This command has no arguments or keywords.

Defaults

The **memory delayed-free-poisoner enable** command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Enabling the delayed free-memory poisoner tool has a significant impact on memory usage and system performance. The command should only be used under the supervision of the Cisco TAC. It should not be run in a production environment during heavy system usage.

When you enable this tool, requests to free memory by the applications running on the ASA are written to a FIFO queue. As each request is written to the queue, each associated byte of memory that is not required by lower-level memory management is “poisoned” by being written with the value 0xcc.

The freed memory requests remain in the queue until more memory is required by an application than is in the free memory pool. When memory is needed, the first freed memory request is pulled from the queue and the poisoned memory is validated.

If the memory is unmodified, it is returned to the lower-level memory pool and the tool reissues the memory request from the application that made the initial request. The process continues until enough memory for the requesting application is freed.

If the poisoned memory has been modified, then the system forces a crash and produces diagnostic output to determine the cause of the crash.

The delayed free-memory poisoner tool periodically performs validation on all of the elements of the queue automatically. Validation can also be started manually using the **memory delayed-free-poisoner validate** command.

The **no** form of the command causes all of the memory referenced by the requests in the queue to be returned to the free memory pool without validation and any statistical counters to be cleared.

Examples

The following example enables the delayed free-memory poisoner tool:

```
hostname# memory delayed-free-poisoner enable
```

The following is sample output when the delayed free-memory poisoner tool detects illegal memory reuse:

```
delayed-free-poisoner validate failed because a
        data signature is invalid at delayfree.c:328.

    heap region:    0x025b1cac-0x025b1d63 (184 bytes)
    memory address: 0x025b1cb4
    byte offset:    8
    allocated by:   0x0060b812
    freed by:       0x0060ae15

Dumping 80 bytes of memory from 0x025b1c88 to 0x025b1cd7
025b1c80:                         ef cd 1c a1 e1 00 00 00  |           ........
025b1c90: 23 01 1c a1 b8 00 00 00 15 ae 60 00 68 ba 5e 02  |  #.........`.h.^.
025b1ca0: 88 1f 5b 02 12 b8 60 00 00 00 00 00 6c 26 5b 02  |  ..[...`.....l&[.
025b1cb0: 8e a5 ea 10 ff ff ff ff cc cc cc cc cc cc cc cc  |  ................
025b1cc0: cc cc cc cc cc cc cc cc cc cc cc cc cc cc cc cc  |  ................
025b1cd0: cc cc cc cc cc cc cc cc                         |  ........

An internal error occurred.  Specifically, a programming assertion was
violated.  Copy the error message exactly as it appears, and get the
output of the show version command and the contents of the configuration
file.  Then call your technical support representative.

assertion "0" failed: file "delayfree.c", line 191
```

Table 34-2 describes the significant portion of the output.

Table 34-2 Illegal Memory Usage Output Description

Field	Description
heap region	The address region and size of the region of memory available for use by the requesting application. This is not the same as the requested size, which may be smaller given the manner in which the system may parcel out memory at the time the memory request was made.
memory address	The location in memory where the fault was detected.
byte offset	The byte offset is relative to the beginning of the heap region and can be used to find the field that was modified if the result was used to hold a data structure starting at this address. A value of 0 or that is larger than the heap region byte count may indicate that the problem is an unexpected value in the lower level heap package.

Table 34-2 Illegal Memory Usage Output Description

Field	Description
allocated by/freed by	Instruction addresses where the last malloc/calloc/realloc and free calls where made involving this particular region of memory.
Dumping...	A dump of one or two regions of memory, depending upon how close the detected fault was to the beginning of the region of heap memory. The next eight bytes after any system heap header is the memory used by this tool to hold a hash of various system header values plus the queue linkage. All other bytes in the region until any system heap trailer is encountered should be set to 0xcc.

Related Commands

Command	Description
clear memory delayed-free-poisoner	Clears the delayed free-memory poisoner tool queue and statistics.
memory delayed-free-poisoner validate	Forces validation of the elements in the delayed free-memory poisoner tool queue.
show memory delayed-free-poisoner	Displays a summary of the delayed free-memory poisoner tool queue usage.

memory delayed-free-poisoner validate

To force validation of all elements in the **memory delayed-free-poisoner** queue, use the **memory delayed-free-poisoner validate** command in privileged EXEC mode.

memory delayed-free-poisoner validate

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must enable the delayed free-memory poisoner tool using the **memory delayed-free-poisoner enable** command before issuing the **memory delayed-free-poisoner validate** command.

The **memory delayed-free-poisoner validate** command causes each element of the **memory delayed-free-poisoner** queue to be validated. If an element contains unexpected values, then the system forces a crash and produces diagnostic output to determine the cause of the crash. If no unexpected values are encountered, the elements remain in the queue and are processed normally by the tool; the **memory delayed-free-poisoner validate** command does not cause the memory in the queue to be returned to the system memory pool.

Note The delayed free-memory poisoner tool periodically performs validation on all of the elements of the queue automatically.

Examples

The following example causes all elements in the **memory delayed-free-poisoner** queue to be validated:

```
hostname# memory delayed-free-poisoner validate
```

Related Commands

Command	Description
clear memory delayed-free-poisoner	Clears the delayed free-memory poisoner tool queue and statistics.
memory delayed-free-poisoner enable	Enables the delayed free-memory poisoner tool.
show memory delayed-free-poisoner	Displays a summary of the delayed free-memory poisoner tool queue usage.

memory caller-address

To configure a specific range of program memory for the call tracing, or caller PC, to help isolate memory problems, use the **memory caller-address** command in privileged EXEC mode. The caller PC is the address of the program that called a memory allocation primitive. To remove an address range, use the **no** form of this command.

memory caller-address *startPC endPC*

no memory caller-address

Syntax Description

endPC	Specifies the end address range of the memory block.
startPC	Specifies the start address range of the memory block.

Defaults

The actual caller PC is recorded for memory tracing.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0	This command was introduced.

Usage Guidelines

Use the **memory caller-address** command to isolate memory problems to a specific block of memory.

In certain cases the actual caller PC of the memory allocation primitive is a known library function that is used at many places in the program. To isolate individual places in the program, configure the start and end program address of the library function, thereby recording the program address of the caller of the library function.

Note The ASA might experience a temporary reduction in performance when caller-address tracing is enabled.

Examples

The following examples show the address ranges configured with the **memory caller-address** commands, and the resulting display of the **show memory-caller address** command:

```
hostname# memory caller-address 0x00109d5c 0x00109e08
hostname# memory caller-address 0x009b0ef0 0x009b0f14
hostname# memory caller-address 0x00cf211c 0x00cf4464
```

```
hostname# show memory-caller address
Move down stack frame for the addresses:
pc = 0x00109d5c-0x00109e08
pc = 0x009b0ef0-0x009b0f14
pc = 0x00cf211c-0x00cf4464
```

Related Commands

Command	Description
memory profile enable	Enables the monitoring of memory usage (memory profiling).
memory profile text	Configures a text range of memory to profile.
show memory	Displays a summary of the maximum physical memory and current free memory available to the operating system.
show memory binsize	Displays summary information about the chunks allocated for a specific bin size.
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory-caller address	Displays the address ranges configured on the ASA.

memory profile enable

To enable the monitoring of memory usage (memory profiling), use the **memory profile enable** command in privileged EXEC mode. To disable memory profiling, use the **no** form of this command.

memory profile enable peak *peak_value*

no memory profile enable peak *peak_value*

Syntax Description

peak_value	Specifies the memory usage threshold at which a snapshot of the memory usage is saved to the peak usage buffer. The contents of this buffer could be analyzed at a later time to determine the peak memory needs of the system.

Defaults

Memory profiling is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0	This command was introduced.

Usage Guidelines

Before enabling memory profiling, you must first configure a memory text range to profile with the **memory profile text** command.

Some memory is held by the profiling system until you enter the **clear memory profile** command. See the output of the **show memory status** command.

Note The ASA might experience a temporary reduction in performance when memory profiling is enabled.

The following example enables memory profiling:

```
hostname# memory profile enable
```

Related Commands

Command	Description
memory profile text	Configures a text range of memory to profile.
show memory profile	Displays information about the memory usage (profiling) of the ASA.

memory profile text

To configure a program text range of memory to profile, use the **memory profile text** command in privileged EXEC mode. To disable, use the **no** form of this command.

memory profile text {*startPC endPC* | **all** *resolution*}

no memory profile text {*startPC endPC* | **all** *resolution*}

Syntax Description

all	Specifies the entire text range of the memory block.
endPC	Specifies the end text range of the memory block.
resolution	Specifies the resolution of tracing for the source text region.
startPC	Specifies the start text range of the memory block.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0	This command was introduced.

Usage Guidelines

For a small text range, a resolution of "4" normally traces the call to an instruction. For a larger text range, a coarse resolution is probably enough for the first pass and the range could be narrowed down to a set of smaller regions in the next pass.

After entering the text range with the **memory profile text** command, you must then enter the **memory profile enable** command to begin memory profiling. Memory profiling is disabled by default.

Note The ASA might experience a temporary reduction in performance when memory profiling is enabled.

Examples

The following example shows how to configure a text range of memory to profile, with a resolution of 4:

```
hostname# memory profile text 0x004018b4 0x004169d0 4
```

The following example displays the configuration of the text range and the status of memory profiling (OFF):

```
hostname# show memory profile
InUse profiling: OFF
Peak profiling: OFF
Profile:
0x004018b4-0x004169d0(00000004)
```

Note To begin memory profiling, you must enter the **memory profile enable** command. Memory profiling is disabled by default.

Related Commands

Command	Description
clear memory profile	Clears the buffers held by the memory profiling function.
memory profile enable	Enables the monitoring of memory usage (memory profiling).
show memory profile	Displays information about the memory usage (profiling) of the ASA.
show memory-caller address	Displays the address ranges configured on the ASA.

memory-size

To configure the amount of memory on the ASA which the various components of WebVPN can access, use the **memory-size** command in webvpn mode. You can configure the amount of memory either as a as a set amount of memory in KB or as a percentage of total memory. To remove a configured memory size, use the **no** form of this command.

Note A reboot is required for the new memory size setting to take effect.

memory-size {percent | kb} *size*

no memory-size [{percent | kb} *size***]**

Syntax Description

kb	Specifies the amount of memory in Kilobytes.
percent	Specifies the amount of memory as a percentage of total memory on the ASA.
size	Specifies the amount of memory, either in KB or as a percentage of total memory.

Defaults

No default behavior or value.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn mode	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The configured amount of memory will be allocated immediately. Before configuring this command, check the amount of available memory by using show memory. If a percentage of total memory is used for configuration, ensure that the configured value is below the available percentage. If a Kilobyte value is used for configuration, ensure that the configured value is below the available amount of memory in Kilobytes.

Examples

The following example shows how to configure a WebVPN memory size of 30 per cent:

```
hostname(config)# webvpn
hostname(config-webvpn)# memory-size percent 30
```

```
hostname(config-webvpn)#
hostname(config-webvpn)# reload
```

Related Commands

Command	Description
show memory webvpn	Displays WebVPN memory usage statistics.

memory tracking enable

To enable the tracking of heap memory request, use the **memory tracking enable** command in privileged EXEC mode. To disable memory tracking, use the **no** form of this command.

memory tracking enable

no memory tracking enable

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	•	•

Command History

Release	Modification
7.0(8)	This command was introduced.

Usage Guidelines

Use the **memory tracking enable** command to track heap memory requests. To disable memory tracking, use the **no** form of this command.

Examples

The following example enables tracking heap memory requests:

```
hostname# memory tracking enable
```

Related Commands

Command	Description
clear memory tracking	Clears all currently gathered information.
show memory tracking	Shows currently allocated memory.
show memory tracking address	Lists the size, location, and topmost caller function of each currently allocated piece memory tracked by the tool.
show memory tracking dump	This command shows the size, location, partial callstack, and a memory dump of the given memory address.
show memory tracking detail	Shows various internal details to be used in gaining insight into the tool's internal behavior.

merge-dacl

To merge a downloadable ACL with the ACL received in the Cisco AV pair from a RADIUS packet, use the **merge-dacl** command in aaa-server group configuration mode. To disable the merging of a downloadable ACL with the ACL received in the Cisco AV pair from a RADIUS packet, use the **no** form of this command.

merge dacl {**before_avpair** | **after_avpair**}

no merge dacl

Syntax Description

after_avpair	Specifies that the downloadable ACL entries should be placed after the Cisco AV pair entries. This option applies only to VPN connections. For VPN users, ACLs can be in the form of Cisco AV pair ACLs, downloadable ACLs, and an ACL that is configured on the ASA. This option determines whether or not the downloadable ACL and the AV pair ACL are merged, and does not apply to any ACLs configured on the ASA.
before_avpair	Specifies that the downloadable ACL entries should be placed before the Cisco AV pair entries.

Defaults

The default setting is **no merge dacl**, which specifies that downloadable ACLs will not be merged with Cisco AV pair ACLs.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
AAA-server group configuration	•	•	•	•	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

If both an AV pair and a downloadable ACL are received, the AV pair has priority and is used.

Examples

The following example specifies that the downloadable ACL entries should be placed before the Cisco AV pair entries:

```
hostname(config)# aaa-server servergroup1 protocol radius
hostname(config-aaa-server-group)# merge-dacl before-avpair
```

Related Commands

Command	Description
aaa-server host	Identifies the server and the AAA server group to which it belongs.
aaa-server protocol	Identifies the server group name and the protocol.
max-failed-attempts	Specifies the maximum number of requests sent to a AAA server in the group before trying the next server..

message-length

To filter GTP packets that do not meet the configured maximum and minimum length, use the **message-length** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. Use the **no** form to remove the command.

message-length min *min_bytes* **max** *max_bytes*

no message-length min *min_bytes* **max** *max_bytes*

Syntax Description

max	Specifies the maximum number of bytes allowed in the UDP payload.
max_bytes	The maximum number of bytes in the UDP payload. The range is from 1 to 65536
min	Specifies the minimum number of bytes allowed in the UDP payload
min_bytes	The minimum number of bytes in the UDP payload. The range is from 1 to 65536

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The length specified by this command is the sum of the GTP header and the rest of the message, which is the payload of the UDP packet.

Examples

The following example allows messages between 20 bytes and 300 bytes in length:

```
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# permit message-length min 20 max 300
hostname(config-gtpmap)#
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.

CHAPTER 35

mfib forwarding through mus server Commands

mfib forwarding

To reenable MFIB forwarding on an interface, use the **mfib forwarding** command in interface configuration mode. To disable MFIB forwarding on an interface, use the **no** form of this command.

mfib forwarding

no mfib forwarding

Syntax Description

This command has no arguments or keywords.

Defaults

The **multicast-routing** command enables MFIB forwarding on all interfaces by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

When you enable multicast routing, MFIB forwarding is enabled on all interfaces by default. Use the **no** form of the command to disable MFIB forwarding on a specific interface. Only the **no** form of the command appears in the running configuration.

When MFIB forwarding is disabled on an interface, the interface does not accept any multicast packets unless specifically configured through other methods. IGMP packets are also prevented when MFIB forwarding is disabled.

Examples

The following example disables MFIB forwarding on the specified interface:

```
hostname(config)# interface GigabitEthernet 0/0
hostname(config-if)# no mfib forwarding
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing.
pim	Enables PIM on an interface.

migrate

To migrate a LAN-to-LAN (IKEv1) or remote access configuration (SSL or IKEv1) to IKEv2, use the **migrate** command from global configuration mode:

migrate {**l2l** | **remote-access** {**ikev2** | **ssl**} | **overwrite**}

Syntax Description

l2l	Migrates the IKEv1 LAN-to-LAN configuration to IKEv2.
remote-access	Specifies remote access configuration.
ikev2	Migrates the remote access IKEv1 configuration to IKEv2.
ssl	Migrates the remote access SSL configuration to IKEv2.
overwrite	Overwrites existing IKEv2 configuration.

Defaults

- There is no default value or behavior.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
global configuration	•	—	•	•	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Support for multiple context mode was added.

Usage Guidelines

The **migrate l2l** command migrates all LAN-to-LAN IKEv1 configuration to IKEv2.

If you use the **overwrite** keyword, the ASA overwrites any existing IKEv2 configuration with migrated commands instead of merging them.

The **migrate remote-access** command migrates the IKEv1 or SSL settings to IKEv2, but you must still perform these configuration tasks:

- Load the AnyConnect client package file(s) in webvpn configuration mode.
- Configure AnyConnect client profiles and specify them for group policies.
- Associate any customization objects you used for IKEv1 connections with the tunnel group(s) used for IKEv2 connections.
- Specify server authentication identity certificates (trustpoints) using the **crypto ikev2 remote-access trust-point** command. The ASA uses the trustpoint to authenticate itself to remote AnyConnect clients connecting with IKEv2.

- Specify IKEv2 and/or SSL for any tunnel groups or group policies you may have configured in addition to the default ones (the DefaultWEBVPNGroup tunnel-group and default group-policy are configured to allow IKEv2 or SSL).
- Configure group aliases or group URLs in the tunnel-groups to enable the clients to connect to groups other than the default group.
- Update any external group policies and/or user records.
- Any other global, tunnel group, group policy settings to change client behavior.
- Configure the port to be used by the client to download files and/or perform software upgrades for IKEv2 using the **crypto ikev2 enable** <*interface*> [**client-services** [*port*]] command.

Related Commands

Command	Description
crypto ikev2 enable	Enables IKEv2 negotiation on the interface on which the IPsec peers communicate.
show run crypto ikev2	Displays IKEv2 configuration information.

min-object-size

To set a minimum size for objects that the ASA can cache for WebVPN sessions, use the min-object-size command in cache mode. To change the size, use the command again. To set no minimum object size, enter a value of zero (0).

min-object-size *integer range*

Syntax Description

integer range	0 - 10000 KB.

Defaults

The default size is 0 KB.

Command Modes

The following table shows the modes in which you enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cache mode	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The minimum object size must be smaller than the maximum object size. The ASA calculates the size after compressing the object, if cache compression is enabled.

Examples

The following example shows how to set a maximum object size of 40 KB:

```
hostname(config)# webvpn
hostname(config-webvpn)# cache
hostname(config-webvpn-cache)# min-object-size 40
hostname(config-webvpn-cache)#
```

Related Commands

Command	Description
cache	Enters WebVPN Cache mode.
cache-compressed	Configures WebVPN cache compression.
disable	Disables caching.
expiry-time	Configures the expiration time for caching objects without revalidating them.

Command	Description
lmfactor	Sets a revalidation policy for caching objects that have only the last-modified timestamp.
max-object-size	Defines the maximum size of an object to cache.

mkdir

To create a new directory, use the **mkdir** command in privileged EXEC mode.

mkdir [**/noconfirm**] [**disk0: | disk1: | flash:**]*path*

Syntax Description

noconfirm	(Optional) Suppresses the confirmation prompt.
disk0*:*	(Optional) Specifies the internal Flash memory, followed by a colon.
disk1:	(Optional) Specifies the external Flash memory card, followed by a colon.
flash:	(Optional) Specifies the internal Flash memory, followed by a colon. In the ASA 5500 series adaptive security appliances, the **flash** keyword is aliased to **disk0**.
path	The name and path of the directory to create.

Defaults

If you do not specify a path, the directory is created in the current working directory.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If a directory with the same name already exists, then the new directory is not created.

Examples

The following example shows how to make a new directory called “backup”:

```
hostname# mkdir backup
```

Related Commands

Command	Description
cd	Changes the current working directory to the one specified.
dir	Displays the directory contents.
rmdir	Removes the specified directory.
pwd	Display the current working directory.

mobile-device portal

To change the clientless vpn access web portal from the mini-portal to the full-browser portal, for all mobile devices, use the **mobile-device portal** command from webvpn configuration mode. You will only need to make this configuration for smart phones running older operating systems such as Windows CE. You will not need to configure this option using modern smart phones as they use the full-browser portal by default.

mobile-device portal {full}

no mobile-device portal {full}

Syntax Description

mobile-device portal {full}	Changes the clientless vpn access portal from the mini-portal to the full-browser portal for all mobile devices.

Command Default

Before you run the command, the default behavior is that some mobile devices will get clientless vpn access through the mini-portal and some will use the full portal.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.2(5)	We introduced this command simultaneouslyin 8.2(5) and 8.4(2).
8.4(2)	We introduced this command simultaneously in 8.2(5) and 8.4(2).

Usage Guidelines

Use this command only if you are recommended to do so by Cisco Technical Assistance Center (TAC).

Examples

Changes the clientless vpn access portal to a full-browser portal for all mobile devices.

```
hostname# config t
hostname(config)# webvpn
hostname(config-webvpn)# mobile-device portal full
```

Related Commands

Command	Description
show running-config webvpn	Displays the running configuration for webvpn.

mode

To set the security context mode to single or multiple, use the **mode** command in global configuration mode. You can partition a single ASA into multiple virtual devices, known as security contexts. Each context behaves like an independent device, with its own security policy, interfaces, and administrators. Multiple contexts are similar to having multiple standalone appliances. In single mode, the ASA has a single configuration and behaves as a single device. In multiple mode, you can create multiple contexts, each with its own configuration. The number of contexts allowed depends on your license.

mode {**single** | **multiple**} [**noconfirm**]

Syntax Description

multiple	Sets multiple context mode.
noconfirm	(Optional) Sets the mode without prompting you for confirmation. This option is useful for automated scripts.
single	Sets the context mode to single.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

In multiple context mode, the ASA includes a configuration for each context that identifies the security policy, interfaces, and almost all the options you can configure on a stand-alone device (see the **config-url** command to identify the context configuration location). The system administrator adds and manages contexts by configuring them in the system configuration, which, like a single mode configuration, is the startup configuration. The system configuration identifies basic settings for the ASA. The system configuration does not include any network interfaces or network settings for itself; rather, when the system needs to access network resources (such as downloading the contexts from the server), it uses one of the contexts that is designated as the admin context.

When you change the context mode using the **mode** command, you are prompted to reboot.

The context mode (single or multiple) is not stored in the configuration file, even though it does endure reboots. If you need to copy your configuration to another device, set the mode on the new device to match using the **mode** command.

When you convert from single mode to multiple mode, the ASA converts the running configuration into two files: a new startup configuration that comprises the system configuration, and admin.cfg that comprises the admin context (in the root directory of the internal Flash memory). The original running configuration is saved as old_running.cfg (in the root directory of the internal Flash memory). The original startup configuration is not saved. The ASA automatically adds an entry for the admin context to the system configuration with the name "admin."

If you convert from multiple mode to single mode, you might want to first copy a full startup configuration (if available) to the ASA; the system configuration inherited from multiple mode is not a complete functioning configuration for a single mode device.

Not all features are supported in multiple context mode. See the CLI configuration guide for more information.

Examples

The following example sets the mode to multiple:

```
hostname(config)# mode multiple
WARNING: This command will change the behavior of the device
WARNING: This command will initiate a Reboot
Proceed with change mode? [confirm] y
Convert the system configuration? [confirm] y
Flash Firewall mode: multiple

***
*** --- SHUTDOWN NOW ---
***
*** Message to all terminals:
***
***   change mode

Rebooting....

Booting system, please wait...
```

The following example sets the mode to single:

```
hostname(config)# mode single
WARNING: This command will change the behavior of the device
WARNING: This command will initiate a Reboot
Proceed with change mode? [confirm] y
Flash Firewall mode: single

***
*** --- SHUTDOWN NOW ---
***
*** Message to all terminals:
***
***   change mode

Rebooting....

Booting system, please wait...
```

Related Commands

Command	Description
context	Configures a context in the system configuration and enters context configuration mode.
show mode	Shows the current context mode, either single or multiple.

monitor-interface

To enable health monitoring on a specific interface, use the **monitor-interface** command in global configuration mode. To disable interface monitoring, use the **no** form of this command.

monitor-interface *if_name*

no monitor-interface *if_name*

Syntax Description

if_name	Specifies the name of the interface being monitored.

Defaults

Monitoring of physical interfaces is enabled by default; monitoring of logical interfaces is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The number of interfaces that can be monitored for the ASA is platform dependent and can be determined by viewing the **show failover** command output.

Hello messages are exchanged during every interface poll frequency time period between the ASA failover pair. The failover interface poll time is 3 to 15 seconds. For example, if the poll time is set to 5 seconds, testing begins on an interface if 5 consecutive hellos are not heard on that interface (25 seconds).

Monitored failover interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface or VLAN is administratively down.
- No Link—The physical link for the interface is down.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

In Active/Active failover, this command is only valid within a context.

Examples

The following example enables monitoring on an interface named “inside”:

```
hostname(config)# monitor-interface inside
hostname(config)#
```

Related Commands

Command	Description
clear configure monitor-interface	Restores the default interface health monitoring for all interfaces.
failover interface-policy	Specifies the number or percentage of monitored interface that must fail for failover to occur.
failover polltime	Specifies the interval between hello messages on an interface (Active/Standby failover).
polltime interface	Specifies the interval between hello messages on an interface (Active/Active failover).
show running-config monitor-interface	Displays the **monitor-interface** commands in the running configuration.

more

To display the contents of a file, use the **more** command in privileged EXEC mode.

more {**/ascii** | **/binary**| **/ebcdic** | **disk0**: | **disk1**: | **flash**: | **ftp**: | **http**: | **https**: | **system**: | **tftp**:}*filename*

Syntax Description

/ascii	(Optional) Displays a binary file in binary mode and an ASCII file in binary mode.
/binary	(Optional) Displays any file in binary mode.
/ebcdic	(Optional) Displays binary files in EBCDIC.
disk0*:*	(Optional) Displays a file on the internal Flash memory.
disk1:	(Optional) Displays a file on the external Flash memory card.
filename	Specifies the name of the file to display.
flash:	(Optional) Specifies the internal Flash memory, followed by a colon. In the ASA 5500 series adaptive security appliance, the **flash** keyword is aliased to **disk0**.
ftp:	(Optional) Displays a file on an FTP server.
http:	(Optional) Displays a file on a website.
https:	(Optional) Displays a file on a secure website.
system:	(Optional) Displays the file system.
tftp:	(Optional) Displays a file on a TFTP server.

Defaults

ASCII mode

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **more filesystem:** command prompts you to enter the alias of the local directory or file systems.

Note When you view a configuration file that you have saved using the **more** command, tunnel-group passwords in the configuration file appear in clear text.

Examples

The following example shows how to display the contents of a local file named “test.cfg”:

```
hostname# more test.cfg
: Saved
: Written by enable_15 at 10:04:01 Apr 14 2005

Related Commands

Command	Description
cd	Changes to the specified directory.
pwd	Displays the current working directory.

mount (CIFS)

To make a Common Internet File System (CIFS) accessible to the security appliance, use the **mount** command in global configuration mode. This command lets you enter mount cifs configuration mode. To un-mount the CIFS network file system, use the **no** form of this command.

mount *name* **type cifs server** *server-name* **share** *share* **status enable | status disable [domain** *domain-name* **] username** *username* **password** *password*

[**no**] **mount** *name* **type cifs server** *server-name* **share** *share* **status enable | status disable [domain** *domain-name* **] username** *username* **password** *password*

Syntax Description

domain *domain-name*	(Optional) For CIFS file systems only, this argument specifies the Windows NT domain name. A maximum of 63 characters is permitted.
name	Specifies the name of an existing file system to be assigned to the Local CA.
no	Removes an already mounted CIFS file system and renders it inaccessible.
password *password*	Identifies the authorized password for file-system mounting.
server *server-name*	Specifies the predefined name (or the IP address in dotted decimal notation) of the CIFS file-system server.
share *sharename*	Explicitly identifies a specific server share (a folder) by name to access file data within a server.
status enable/disable	Identifies the state of the file system as mounted or un-mounted (available or unavailable).
type	Specifies the CIFS type of file system to mount. For alternative **type** keywords, refer to the **mount (FTP)** command.
type cifs	Specifies that the file system being mounted is CIFS, a file system that provides volume-mounting capabilities for CIFS-shared directories.
user *username*	The authorized username for file-system mounting.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Mount cifs configuration	•	•	•	—	•
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **mount** command uses the Installable File System (IFS) to mount the CIFS file system. IFS, a filesystem API, enables the security appliance to recognize and load drivers for file systems.

The **mount** command attaches the CIFS file system on the security appliance to the UNIX file tree. Conversely, the **no mount** command detaches it.

The *mount-name* specified in the **mount** command is used by other CLI commands to refer to the filesystem already mounted on the security appliance. For example, the **database** command, which sets up file storage for the Local Certificate Authority, needs the mount name of an existing mounted file system to save database files to non-flash storage.

The CIFS remote file-access protocol is compatible with the way applications share data on local disks and network file servers. Running over TCP/IP and using the Internet's global DNS, CIFS is an enhanced version of Microsoft's open, cross-platform Server Message Block (SMB) protocol, the native file-sharing protocol in the Windows operating systems.

Always exit from the root shell after using the **mount** command. The **exit** keyword in mount-cifs-config mode returns the user to global configuration mode.

In order to reconnect, remap your connections to storage.

Note Mounting of CIFS and FTP file systems are supported. (See the **mount** *name* **type ftp** command.) Mounting Network File System (NFS) volumes is not supported for this release.

Examples

The following example mounts *cifs://amer;chief:big-boy@myfiler02/my_share* as the label, *cifs_share:*

```
hostname(config)# mount cifs_share type CIFS
hostname (config-mount-cifs)# server myfiler02a
```

Related Commands

Command	Description
debug cifs	Logs CIFS debug messages.
debug ntdomain	Logs Web VPN NT Domain debug messages
debug webvpn cifs	Logs WebVPN CIFS debug messages.
dir all-filesystems	Displays the files of all filesystems mounted on the ASA.

mount (FTP)

To make a File Transfer Protocol (FTP) file system accessible to the security appliance, use the **mount** *name* **type ftp** command in global configuration mode to enter mount FTP configuration mode. The **no mount** *name* **type ftp** command is used to unmount the FTP network file system.

[**no**] **mount** *name* **type ftp server** *server-name* **path** *pathname* **status enable | status disable mode active | mode passive username** *username* **password** *password*

Syntax Description

exit	Exits from mount-ftp configuration mode and returns to global configuration mode.
ftp	Specifies that the file system being mounted is FTP, a Linux kernel module, enhancing the Virtual File System (VFS) with FTP volume-mounting capabilities that allow you to mount FTP-shared directories.
mode	Identifies the FTP transfer mode as either active or passive.
no	Removes an already mounted FTP file system, rendering it inaccessible.
password *password*	Identifies the authorized password for file-system mounting.
path *pathname*	Specifies the directory pathname to the specified FTP file-system server. The pathname cannot contain spaces.
server *server-name*	Specifies the predefined name (or the IP address in dotted decimal notation) of the FTPFS file-system server.
status enable/disable	Identifies the state of the file system as mounted or unmounted (available or unavailable).
username *username*	Specifies the authorized username for file-system mounting.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Mount-ftp-configuration	•	•	•	—	•
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **mount** *name* **type ftp** command uses the Installable File System (IFS) to mount the specified network file system. IFS, a filesystem API, enables the security appliance to recognize and load drivers for file systems.

To confirm that the FTP file system actually is mounted, use the **dir all-filesystems** instruction

The mount-name specified in the **mount** command is used when other CLI commands refer to the filesystem already mounted on the security appliance. For example, the **database** command, which sets up file storage for the local certificate authority, needs the mount name of a mounted file system to save database files to non-flash storage.

Note Using the **mount** command when you create an FTP-type mount requires that the FTP server must have a UNIX directory listing style. Microsoft FTP servers have the MS-DOS directory listing style as their default.

Note Mounting of CIFS and FTP file systems are supported. (See the **mount** *name* **type ftp** command.) Mounting Network File System (NFS) volumes is not supported for this release.

Examples

This example mounts *ftp://amor;chief:big-kid@myfiler02* as the label, *my ftp:*

```
hostname(config)# mount myftp type ftp server myfiler02a path status enable username chief
password big-kid
```

Related Commands

Command	Description
debug webvpn	Logs WebVPN debugging messages.
ftp mode passive	Controls interaction between the FTP client on the security appliance and the FTP server.

mroute

To configure a static multicast route, use the **mroute** command in global configuration mode. To remove a static multicast route, use the **no** form of this command.

mroute *src smask* {*in_if_name* [**dense** *output_if_name*] | *rpf_addr*} [*distance*]

no mroute *src smask* {*in_if_name* [**dense** *output_if_name*] | *rpf_addr*} [*distance*]

Syntax Description

dense *output_if_name*	(Optional) The interface name for dense mode output. The **dense** *output_if_name* keyword and argument pair is only supported for SMR stub multicast routing (igmp forwarding).
distance	(Optional) The administrative distance of the route. Routes with lower distances have preference. The default is 0.
in_if_name	Specifies the incoming interface name for the mroute.
rpf_addr	Specifies the incoming interface for the mroute. If the RPF address PIM neighbor, PIM join, graft, and prune messages are sent to it. The *rpf-addr* argument can be a host IP address of a directly connected system or a network/subnet number. When it is a route, a recursive lookup is done from the unicast routing table to find a directly connected system.
smask	Specifies the multicast source network address mask.
src	Specifies the IP address of the multicast source.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command lets you statically configure where multicast sources are located. The ASA expects to receive multicast packets on the same interface as it would use to send unicast packets to a specific source. In some cases, such as bypassing a route that does not support multicast routing, multicast packets may take a different path than the unicast packets.

Static multicast routes are not advertised or redistributed.

Use the **show mroute** command displays the contents of the multicast route table. Use the **show running-config mroute** command to display the mroute commands in the running configuration.

Examples

The following example shows how configure a static multicast route using the **mroute** command:

```
hostname(config)# mroute 172.16.0.0 255.255.0.0 inside
```

Related Commands

Command	Description
clear configure mroute	Removes the **mroute** commands from the configuration.
show mroute	Displays the IPv4 multicast routing table.
show running-config mroute	Displays the **mroute** commands in the configuration.

mschapv2-capable

To enable MS-CHAPv2 authentication requests to the RADIUS server, use the **mschapv2-capable** command in aaa-server host configuration mode. To disable MS-CHAPv2, use the **no** form of this command.

mschapv2-capable

no mschapv2-capable

Syntax Description

This command has no arguments or keywords.

Defaults

MS-CHAPv2 is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

To enable MS-CHAPv2 as the protocol used between the ASA and the RADIUS server for a VPN connection, password management must be enabled in the tunnel-group general-attributes. Enabling password management generates an MS-CHAPv2 authentication request from the ASA to the RADIUS server. See the description of the **password-management** command for details.

If you use double authentication and enable password management in the tunnel group, then the primary and secondary authentication requests include MS-CHAPv2 request attributes. If a RADIUS server does not support MS-CHAPv2, then you can configure that server to send a non-MS-CHAPv2 authentication request by using the **no mschapv2-capable** command.

Examples

The following example disables MS-CHAPv2 for the RADIUS server authsrv1.cisco.com:

```
hostname(config)# aaa-server rsaradius protocol radius
hostname(config-aaa-server-group)# aaa-server rsaradius (management) host
authsrv1.cisco.com
hostname(config-aaa-server-host)# key secretpassword
hostname(config-aaa-server-host)# authentication-port 21812
hostname(config-aaa-server-host)# accounting-port 21813
hostname(config-aaa-server-host)# no mschapv2-capable
```

Related Commands

Command	Description
aaa-server host	Identifies a AAA server for a AAA server group.
password-management	When you configure the password-management command, the ASA notifies the remote user at login that the user's current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password.
secondary-authentication-server-group	Specifies the secondary AAA server group, which cannot be an SDI server group.

msie-proxy except-list

To configure browser proxy exception list settings for a local bypass on the client device, enter the **msie-proxy except-list** command in group-policy configuration mode. To remove the attribute from the configuration, use the **no** form of the command.

msie-proxy except-list {value *server*[*:port*] **| none}**

no msie-proxy except-list

Syntax Description

none	Indicates that there is no IP address/hostname or port and prevents inheriting an exception list.
value *server:port*	Specifies the IP address or name of an MSIE server and port that is applied for this client device. The port num ber is optional.

Defaults

By default, msie-proxy except-list is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The line containing the proxy server IP address or hostname and the port number must be less than 100 characters long.

Note These settings are applied to IE for client connections only.

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Examples

The following example shows how to set a Microsoft Internet Explorer proxy exception list, consisting of the server at IP address 192.168.20.1, using port 880, for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy except-list value 192.168.20.1:880
hostname(config-group-policy)#
```

Related Commands

Command	Description
show running-configuration group-policy	Shows the value of the configured group-policy attributes.
clear configure group-policy	Removes all configured group-policy attributes.

msie-proxy local-bypass

To configure browser proxy local-bypass settings for a client device, enter the **msie-proxy local-bypass** command in group-policy configuration mode. To remove the attribute from the configuration, use the **no** form of the command.

msie-proxy local-bypass {enable | disable}

no msie-proxy local-bypass {enable | disable}

Syntax Description

disable	Disables browser proxy local-bypass settings for a client device.
enable	Enables browser proxy local-bypass settings for a client device.

Defaults

By default, msie-proxy local-bypass is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Note These settings are applied to IE for client connections only.

Examples

The following example shows how to enable Microsoft Internet Explorer proxy local-bypass for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy local-bypass enable
hostname(config-group-policy)#
```

Related Commands

Command	Description
show running-configuration group-policy	Shows the value of the configured group-policy attributes.
clear configure group-policy	Removes all configured group-policy attributes.

msie-proxy lockdown

Enabling this feature hides the Connections tab in the browser for the duration of an AnyConnect VPN session. Disabling the feature leaves the display of the Connections tab unchanged

To hide the Connections tab for the duration of an AnyConnect VPN session or to leave it unchanged, use the **msie-proxy lockdown** command in group-policy configuration mode.

msie-proxy lockdown [enable | disable]

SyntaxDescription

disable	Leaves the Connections tab in browser unchanged.
enable	Hides the Connections tab in browser for the duration of an AnyConnect VPN session.

Defaults

The default value of this command in the default group policy is enable. Each group policy inherits its default values from the default group policy.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	•	•	—	—

Command History

Release	Modification
8.2(3)	This command was introduced.

Usage Guidelines

This command makes a temporary change to the user registry for the duration of the AnyConnect VPN session. When AnyConnect closes the VPN session, it returns the registry to the state it was in before the session.

You might enable this feature to prevent users from specifying a proxy service and changing LAN settings. Preventing user access to these settings enhances endpoint security during the AnyConnect session.

Note These settings are applied to IE for client connections only.

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Examples

The following example hides the Connections tab for the duration of the AnyConnect session:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy lockdown enable
```

The following example leaves the Connections tab unchanged:

```
hostname(config-group-policy)# msie-proxy lockdown disable
```

Related Commands

Command	Description
msie-proxy except-list	Specifies an exception list of proxy servers for browser on the client device.
msie-proxy local-bypass	Bypasses the local browser proxy settings configured on the client device.
msie-proxy method	Specifies the browser proxy actions for a client device.
msie-proxy pac-url	Specifies a URL from which to retrieve a proxy auto-configuration file that defines the proxy servers.
msie-proxy server	Configures proxy server for browser on the client device.
show running-config group-policy	Shows the group policy settings in the running configuration.

msie-proxy method

To configure the browser proxy actions (“methods”) for a client device, enter the **msie-proxy method** command in group-policy configuration mode. To remove the attribute from the configuration, use the **no** form of the command.

msie-proxy method [**auto-detect** | **no-modify** | **no-proxy** | **use-server** | **use-pac-url**]

no msie-proxy method [**auto-detect** | **no-modify** | **no-proxy** | **use-server** | **use-pac-url**]

Note See the Usage Guidelines section for qualifications that apply to this syntax.

Syntax Description

auto-detect	Enables the use of automatic proxy server detection in the browser for the client device.
no-modify	Leaves the HTTP browser proxy server setting in the browser unchanged for this client device.
no-proxy	Disables the HTTP proxy setting in the browser for the client device.
use-pac-url	Directs the browser to retrieve the HTTP proxy server setting from the proxy auto-configuration file URL specified in the **msie-proxy pac-url** command.
use-server	Sets the HTTP proxy server setting in the browser to use the value configured in the **msie-proxy server** command.

Defaults

The default method is use-server.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Added the use-pac-url option.

Usage Guidelines

The line containing the proxy server IP address or hostname and the port number can contain up to 100 characters.

This command supports the following combinations of options:

- **[no] msie-proxy method no-proxy**
- **[no] msie-proxy method no-modify**
- **[no] msie-proxy method [auto-detect] [use-server] [use-pac-url]**

You can use a text editor to create a proxy auto-configuration (.pac) file for your browser. A .pac file is a JavaScript file that contains logic that specifies one or more proxy servers to be used, depending on the contents of the URL. The .pac file resides on a web server. When you specify **use-pac-url**, the browser uses the .pac file to determine the proxy settings. Use the **msie-proxy pac-url** command to specify the URL from which to retrieve the .pac file.

Note These settings are applied to IE for client connections only.

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Examples

The following example shows how to configure auto-detect as the Microsoft Internet Explorer proxy setting for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy method auto-detect
hostname(config-group-policy)#
```

The following example configures the Microsoft Internet Explorer proxy setting for the group policy named FirstGroup to use the server QAserver, port 1001 as the server for the client PC:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy server QAserver:port 1001
hostname(config-group-policy)# msie-proxy method use-server
hostname(config-group-policy)#
```

Related Commands

Command	Description
msie-proxy pac-url	Specifies a URL from which to retrieve a proxy auto-configuration file.
msie-proxy server	Configures a browser proxy server and port for a client device.
show running-configuration group-policy	Shows the value of the configured group-policy attributes.
clear configure group-policy	Removes all configured group-policy attributes.

msie-proxy pac-url

To tell a browser where to look for proxy information, enter the **msie-proxy pac-url** command in group-policy configuration mode. To remove the attribute from the configuration, use the **no** form of the command.

msie-proxy pac-url {**none** | **value** *url*}

no msie-proxy pac-url

Syntax Description

none	Specifies that there is no URL value.
value *url*	Specifies the URL of the website at which the browser can get the proxy auto-configuration file that defines the proxy server or servers to use.

Defaults

The default value is none.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Requirements

To use the proxy auto-configuration feature, the remote user must use the Cisco AnyConnect VPN Client. To enable the use of the proxy auto-configuration URL, you must also configure the **msie-proxy method** command with the **use-pac-url** option.

Why Use This Command

Many network environments define HTTP proxies that connect a web browser to a particular network resource. The HTTP traffic can reach the network resource only if the proxy is specified in the browser and the client routes the HTTP traffic to the proxy. SSLVPN tunnels complicate the definition of HTTP proxies because the proxy required when tunneled to an enterprise network can differ from that required when connected to the Internet via a broadband connection or when on a third-party network.

In addition, companies with large networks might need to configure more than one proxy server and let users choose between them, based on transient conditions. By using .pac files, an administrator can author a single script file that determines which of numerous proxies to use for all client computers throughout the enterprise.

The following are some examples of how you might use a PAC file:

- Choosing a proxy at random from a list for load balancing.
- Rotating proxies by time of day or day of the week to accommodate a server maintenance schedule.
- Specifying a backup proxy server to use in case the primary proxy fails.
- Specifying the nearest proxy for roaming users, based on the local subnet.

How to Use the Proxy Auto-Configuration Feature

You can use a text editor to create a proxy auto-configuration (.pac) file for your browser. A .pac file is a JavaScript file that contains logic that specifies one or more proxy servers to be used, depending on the contents of the URL. Use the **msie-proxy pac-url** command to specify the URL from which to retrieve the .pac file. Then, when you specify **use-pac-url** in the **msie-proxy method** command, the browser uses the .pac file to determine the proxy settings.

Note These settings are applied to IE for client connections only.

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Examples

The following example shows how to configure a browser to get its proxy setting from the URL www.example.com for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy pac-url value http://www.example.com
hostname(config-group-policy)#
```

The following example disables the proxy auto-configuration feature for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy pac-url none
hostname(config-group-policy)#
```

Related Commands

Command	Description
msie-proxy method	Configures the browser proxy actions (“methods”) for a client device.
msie-proxy server	Configures a browser proxy server and port for a client device.
show running-configuration group-policy	Shows the value of the configured group-policy attributes.
clear configure group-policy	Removes all configured group-policy attributes.

msie-proxy server

To configure a browser proxy server and port for a client device, enter the **msie-proxy server** command in group-policy configuration mode. To remove the attribute from the configuration, use the **no** form of the command.

msie-proxy server {value *server*[*:port*] **| none}**

no msie-proxy server

Syntax Description

none	Indicates that there is no IP address/hostname or port specified for the proxy server and prevents inheriting a server.
value *server:port*	Specifies the IP address or name of an MSIE server and port that is applied for this client device. The port number is optional.

Defaults

By default, no msie-proxy server is specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The line containing the proxy server IP address or hostname and the port number must be less than 100 characters long.

Note These settings are applied to IE for client connections only.

Refer to the *Cisco AnyConnect Secure Mobility Client Administrator Guide*, *Release 3.1* for further information about proxy settings.

Examples

The following example shows how to configure the IP address 192.168.10.1 as a Microsoft Internet Explorer proxy server, using port 880, for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy server value 192.168.21.1:880
hostname(config-group-policy)#
```

Related Commands

Command	Description
show running-configuration group-policy	Shows the value of the configured group-policy attributes.
clear configure group-policy	Removes all configured group-policy attributes.

mtu

To specify the maximum transmission unit for an interface, use the **mtu** command in global configuration mode. To reset the MTU block size to 1500 for Ethernet interfaces, use the **no** form of this command. This command supports IPv4 and IPv6 traffic.

mtu *interface_name bytes*

no mtu *interface_name bytes*

Syntax Description

bytes	Number of bytes in the MTU; valid values are from 64 to 65,535 bytes.
interface_name	Internal or external network interface name.

Defaults

The default *bytes* is 1500 for Ethernet interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **mtu** command lets you to set the data size that is sent on a connection. Data that is larger than the MTU value is fragmented before being sent.

The ASA supports IP path MTU discovery (as defined in RFC 1191), which allows a host to dynamically discover and cope with the differences in the maximum allowable MTU size of the various links along the path. Sometimes, the ASA cannot forward a datagram because the packet is larger than the MTU that you set for the interface, but the "don't fragment" (DF) bit is set. The network software sends a message to the sending host, alerting it to the problem. The host has to fragment packets for the destination so that they fit the smallest packet size of all the links along the path.

The default MTU is 1500 bytes in a block for Ethernet interfaces (which is also the maximum). This value is sufficient for most applications, but you can pick a lower number if network conditions require it.

When using the Layer 2 Tunneling Protocol (L2TP), we recommend that you set the MTU size to 1380 to account for the L2TP header and IPsec header length.

The minimum MTU allowed on an IPv6 enabled interface is 1280 bytes; however, if IPsec is enabled on the interface, the MTU value should not be set below 1380 because of the overhead of IPsec encryption. Setting the interface below 1380 bytes may result in dropped packets.

Examples

This example shows how to specify the MTU for an interface:

```
hostname(config)# show running-config mtu
mtu outside 1500
mtu inside 1500
hostname(config)# mtu inside 8192
hostname(config)# show running-config mtu
mtu outside 1500
mtu inside 8192
```

Related Commands

Command	Description
clear configure mtu	Clears the configured maximum transmission unit values on all interfaces.
show running-config mtu	Displays the current maximum transmission unit block size.

mtu cluster

To set the maximum transmission unit of the cluster control link, use the **mtu cluster** command in global configuration mode. To restore the default setting, use the **no** form of this command.

mtu cluster *bytes*

no mtu cluster [*bytes*]

Syntax Description

bytes	Specifies the maximum transmission unit for the cluster control link interface, between 64 and 65,535 bytes. The default MTU is 1500 bytes.

Command Default

The default MTU is 1500 bytes.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

We suggest setting the MTU to 1600 bytes or greater, which requires you to enable jumbo frame reservation using the **jumbo-frame reservation** command.

This command is a global configuration command, but is also part of the bootstrap configuration, which is not replicated between units.

Examples

The following example sets the cluster control link MTU to 9000 bytes:

```
hostname(config)# mtu cluster 9000
```

Related Commands

Command	Description
cluster-interface	Identifies the cluster control link interface.
jumbo frame-reservation	Enables use of jumbo Ethernet frames.

multicast boundary

To configure a multicast boundary for administratively-scoped multicast addresses, use the **multicast boundary** command in interface configuration mode. To remove the boundary, use the **no** form of this command. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains.

multicast boundary *acl* [**filter-autorp**]

no multicast boundary *acl* [**filter-autorp**]

Syntax Description

acl	Specifies an access list name or number. The access list defines the range of addresses affected by the boundary. Use only standard ACLs with this command; extended ACLs are not supported.
filter-autorp	Filters Auto-RP messages denied by the boundary ACL. If not specified, all Auto-RP messages are passed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Use this command to configure an administratively scoped boundary on an interface to filter multicast group addresses in the range defined by the *acl* argument. A standard access list defines the range of addresses affected. When this command is configured, no multicast data packets are allowed to flow across the boundary in either direction. Restricting multicast data packet flow enables reuse of the same multicast group address in different administrative domains.

If you configure the **filter-autorp** keyword, the administratively scoped boundary also examines Auto-RP discovery and announcement messages and removes any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

Examples

The following example sets up a boundary for all administratively scoped addresses and filters the Auto-RP messages:

```
hostname(config)# access-list boundary_test deny 239.0.0.0 0.255.255.255
hostname(config)# access-list boundary_test permit 224.0.0.0 15.255.255.255
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# multicast boundary boundary_test filter-autorp
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

multicast-routing

To enable IP multicast routing on the ASA, use the **multicast routing** command in global configuration mode. To disable IP multicast routing, use the **no** form of this command.

multicast-routing

no multicast-routing

Syntax Description

This command has no arguments or keywords.

Defaults

The **multicast-routing** command enables PIM and IGMP on all interfaces by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **multicast-routing** command enables PIM and IGMP on all interfaces.

Note PIM is not supported with PAT. The PIM protocol does not use ports and PAT only works with protocols that use ports.

If the security appliance is the PIM RP, use the untranslated outside address of the security appliance as the RP address.

The number of entries in the multicast routing tables are limited by the amount of RAM on the system. Table 35-1 lists the maximum number of entries for specific multicast tables based on the amount of RAM on the security appliance. Once these limits are reached, any new entries are discarded.

Table 35-1 Entry Limits for Multicast Tables

Table	16 MB	128 MB	128+ MB
MFIB	1000	3000	5000
IGMP Groups	1000	3000	5000
PIM Routes	3000	7000	12000

Examples

The following example enables IP multicast routing on the ASA:

```
hostname(config)# multicast-routing
```

Related Commands

Command	Description
igmp	Enables IGMP on an interface.
pim	Enables PIM on an interface.

mus

To specify the IP range and interface on which the ASA identifies the WSA, use the **mus** command in global configuration mode. To turn the service off, use the **no** form of this command. This command supports IPv4 and IPv6 traffic. Only WSAs found on the specified subnet and interface are registered.

mus *IPv4 address IPv4 mask interface_name*

no mus *IPv4 address IPv4 mask interface_name*

Note To function as expected, this command requires a release of the AsyncOS for Web version 7.0 that provides AnyConnect Secure Mobility licensing support for the AnyConnect secure mobility client. It also requires an AnyConnect release that supports AnyConnect Secure Mobility, ASA 8.3, and ASDM 6.3.

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

The following commands are possible:

- A.B.C.D—The IP address of WSA authorized to access ASA.
- host—The client periodically checks connectivity to the Web Security appliance by sending a request to a fictitious host. By default, the fictitious host URL is mus.cisco.com. When AnyConnect Security Mobility is enabled, the Web Security appliance intercepts requests destined for the fictitious host and replies to the client.
- password—Configure WSA password.
- server—Configure WSA server

Examples

The following example allows WSA servers on the 1.2.3.x subnet to access secure mobility solutions on the *inside* interface:

```
hostname(config)# mus 1.2.3.0 255.255.255.0 inside
```

Related Commands

Command	Description
mus password	Sets up shared secret for AnyConnect Secure Mobility communications.
mus server	Specifies the port on which the ASA listens for WSA communication.
show webvpn mus	Displays information about the active WSA connection security appliance.

mus host

To specify the MUS hostname on the ASA, enter the **mus host** command in global configuration mode. This is the telemetry URL sent from the ASA to the AnyConnect Client. The AnyConnect clients use this URL to contact the WSA in the private network for MUS-related services. To remove any commands entered with this command, use the **no mus host** command.

mus host *host name*

no mus host

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You can enable AnyConnect Secure Mobility for a given port. The WSA port values are 1 through 21000. If a port is not specified in the command, port 11999 is used.

You must configure AnyConnect Secure Mobility shared secret before executing this command.

Note To function as expected, this command requires a release of the AsyncOS for Web version 7.0 that provides AnyConnect Secure Mobility licensing support for the AnyConnect Secure Mobility client. It also requires an AnyConnect release that supports AnyConnect Secure Mobility, ASA 8.3, and ASDM 6.3.

Examples

The following example shows how to enter the AnyConnect Secure Mobility host and WebVPN command submode:

```
hostname(config)# webvpn
hostname(config-webvpn)# mus 0.0.0.0 0.0.0.0 inside
hostname(config-webvpn)# mus password abcdefgh123
hostname(config-webvpn)# mus server enable 960 # non-default port
hostname(config-webvpn)# mus host mus.cisco.com
```

Related Commands

Command	Description
mus	Specifies the IP range and interface on which the ASA identifies the WSA.
mus password	Sets up shared secret for AnyConnect Secure Mobility communications.
show webvpn mus	Displays information about the active WSA connection security appliance.

mus password

To set up shared secred for AnyConnect Secure Mobility communications, enter the **mus password** command in global configuration mode. To remove the shared secred, use the **no mus password** command.

mus password

no mus password

Note To function as expected, this command requires a release of the AsyncOS for Web version 7.0 that provides AnyConnect Secure Mobility licensing support for the AnyConnect secure mobility client. It also requires an AnyConnect release that supports AnyConnect Secure Mobility, ASA 8.3, and ASDM 6.3.

Syntax Description

This command has no arguments or keywords.

Defaults

.The valid password is defined by the regular expression [0-9, a-z, A-Z,:;_/-]{8,20}. The overall length of the shared secret password is a minimum of 8 characters and maximum of 20 characters.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

This WebVPN submode lets you configure global settings for WebVPN. You can set up the shared secret for AnyConnect Secure Mobility communications.

Examples

The following example shows how to enter an AnyConnect Secure Mobility password and WebVPN command submode:

```
hostname(config)# mus password <password_string>
hostname(config-webvpn)#
```

Related Commands

Command	Description
mus	Specifies the IP range and interface on which the ASA identifies the WSA.
mus server	Specifies the port on which the ASA listens for WSA communication.
show webvpn mus	Displays information about the active WSA connection security appliance.

mus server

To specify the port on which the ASA listens for WSA communication, enter the **mus server** command in global configuration mode. To remove any commands entered with this command, use the **no mus server** command.

mus server enable

no mus server enable

Note To function as expected, this command requires a release of the AsyncOS for Web version 7.0 that provides AnyConnect Secure Mobility licensing support for the AnyConnect secure mobility client. It also requires an AnyConnect release that supports AnyConnect Secure Mobility, ASA 8.3, and ASDM 6.3.

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You must specify a port the AnyConnect Secure Mobility service uses. The communication between the ASA and the WSA is by a secure SSL connection on a port specified by the administrator with values of 1 through 21000.

You must configure AnyConnect Secure Mobility shared secret before executing this command.

Examples

The following example shows how to enter the AnyConnect Secure Mobility password and WebVPN command submode:

```
hostname(config-webvpn)# mus server enable?
webvpn mode commands/options
    port Configure WSA port
hostname(config-webvpn)# mus server enable port 12000
```

Related Commands

Command	Description
mus	Specifies the IP range and interface on which the ASA identifies the WSA.
mus password	Sets up shared secret for AnyConnect Secure Mobility communications.
show webvpn mus	Displays information about the active WSA connection security appliance.

CHAPTER 36

nac-authentication-server-group through num-packets Commands

nac-authentication-server-group (deprecated)

To identify the group of authentication servers to be used for Network Admission Control posture validation, use the **nac-authentication-server-group** command in tunnel-group general-attributes configuration mode. To inherit the authentication server group from the default remote access group, access the alternative group policy from which to inherit it, then use the **no** form of this command.

nac-authentication-server-group *server-group*

no nac-authentication-server-group

Syntax Description

server-group	Name of the posture validation server group, as configured on the ASA using the **aaa-server host** command. The name must match the server-tag variable specified in that command.

Defaults

This command has no arguments or keywords.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.3(0)	This command was deprecated. The **authentication-server-group** command in nac-policy-nac-framework configuration mode replaced it.
7.2(1)	This command was introduced.

Usage Guidelines

Configure at least one Access Control Server to support NAC. Use the **aaa-server** command to name the ACS group. Then use the **nac-authentication-server-group** command, using the same name for the server group.

Examples

The following example identifies acs-group1 as the authentication server group to be used for NAC posture validation:

```
hostname(config-group-policy)# nac-authentication-server-group acs-group1
hostname(config-group-policy)
```

The following example inherits the authentication server group from the default remote access group.

```
hostname(config-group-policy)# no nac-authentication-server-group
```

```
hostname(config-group-policy)
```

Related Commands

Command	Description
aaa-server	Creates a record of the AAA server or group and sets the host-specific AAA server attributes.
debug eap	Enables logging of EAP events to debug NAC messaging.
debug eou	Enables logging of EAP over UDP (EAPoUDP) events to debug NAC messaging.
debug nac	Enables logging of NAC events.
nac	Enables Network Admission Control on a group policy.

nac-policy

To create or access a Cisco Network Admission Control (NAC) policy, and specify its type, use the **nac-policy** command in global configuration mode. To remove the NAC policy from the configuration, use the **no** form of this command.

nac-policy *nac-policy-name* **nac-framework**

[**no**] **nac-policy** *nac-policy-name* **nac-framework**

Syntax Description

nac-policy-name	Name of the NAC policy. Enter a string of up to 64 characters to name the NAC policy. The **show running-config nac-policy** command displays the name and configuration of each NAC policy already present on the security appliance.
nac-framework	Specifies the use of a NAC framework to provide a network access policy for remote hosts. A Cisco Access Control Server must be present on the network to provide NAC Framework services for the ASA. If you specify this type, the prompt indicates you are in config--nac-policy-nac-framework configuration mode. This mode lets you configure the NAC Framework policy.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use this command once for each NAC Appliance to be assigned to a group policy. Then use the **nac-settings** command to assign the NAC policy to each applicable group policy. Upon the setup of an IPsec or Cisco AnyConnect VPN tunnel, the ASA applies the NAC policy associated with the group policy in use.

You cannot use the **no nac-policy** *name* command to remove a NAC policy if it is already assigned to one or more group policies.

Examples

The following command creates and accesses a NAC Framework policy named nac-framework1:

```
hostname(config)# nac-policy nac-framework1 nac-framework
hostname(config-nac-policy-nac-framework)
```

The following command removes the NAC Framework policy named nac-framework1:

```
hostname(config)# no nac-policy nac-framework1
hostname(config-nac-policy-nac-framework)
```

Related Commands

Command	Description
show running-config nac-policy	Displays the configuration of each NAC policy on the ASA.
show nac-policy	Displays NAC policy usage statistics on the ASA.
clear nac-policy	Resets the NAC policy usage statistics.
nac-settings	Assigns a NAC policy to a group policy.
clear configure nac-policy	Removes all NAC policies from the running configuration except for those that are assigned to group policies.

nac-settings

To assign a NAC policy to a group policy, use the **nac-settings** command in group-policy configuration mode, as follows:

nac-settings {**value** *nac-policy-name* | **none**}

[**no**] **nac-settings** {**value** *nac-policy-name* | **none**}

Syntax Description

nac-policy-name	NAC policy to be assigned to the group policy. The NAC policy you name must be present in the configuration of the ASA. The **show running-config nac-policy** command displays the name and configuration of each NAC policy.
none	Removes the *nac-policy-name* from the group policy and disables the use of a NAC policy for this group policy. The group policy does not inherit the nac-settings value from the default group policy.
value	Assigns the NAC policy to be named to the group policy.

Defaults

This command has no arguments or keywords.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **nac-policy** command to specify the name and type of the NAC policy, then use this command to assign it to a group policy.

The **show running-config nac-policy** command displays the name and configuration of each NAC policy.

The ASA automatically enables NAC for a group policy when you assign a NAC policy to it.

Examples

The following command removes the *nac-policy-name* from the group policy. The group policy inherits the *nac-settings* value from the default group policy:

```
hostname(config-group-policy)# no nac-settings
hostname(config-group-policy)
```

The following command removes the *nac-policy-name* from the group policy and disables the use of a NAC policy for this group policy. The group policy does not inherit the nac-settings value from the default group policy.

```
hostname(config-group-policy)# nac-settings none
hostname(config-group-policy)
```

Related Commands

Command	Description
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
show running-config nac-policy	Displays the configuration of each NAC policy on the ASA.
show nac-policy	Displays NAC policy usage statistics on the ASA.
show vpn-session_summary.db	Displays the number IPsec, WebVPN, and NAC sessions.
show vpn-session.db	Displays information about VPN sessions, including NAC results.

name

To associate a name with an IP address, use the **name** command in global configuration mode. To disable the use of the text names but not remove them from the configuration, use the **no** form of this command.

name *ip_address name* [**description** *text*]]

no name *ip_address* [*name* [**description** *text*]]

Syntax Description

description	(Optional) Specifies a description for the ip address name.
ip_address	Specifies an IP address of the host that is named.
name	Specifies the name assigned to the IP address. Use characters a to z, A to Z, 0 to 9, a dash, and an underscore. The *name* must be 63 characters or less. Also, the *name* cannot start with a number.
text	Specifies the text for the description.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.0(4)	This command was enhanced to include an optional description.
8.3(1)	You can no longer use a named IP address in a **nat** command or an **access-list** command; you must use **object network** names instead. Although **network-object** commands in an object group accept **object network** names, you can still also use a named IP address identified by the **name** command.

Usage Guidelines

To enable the association of a name with an IP address, use the **names** command. You can associate only one name with an IP address.

You must first use the **names** command before you use the **name** command. Use the **name** command immediately after you use the **names** command and before you use the **write memory** command.

The **name** command lets you identify a host by a text name and map text strings to IP addresses. The **no name** command allows you to disable the use of the text names but does not remove them from the configuration. Use the **clear configure name** command to clear the list of names from the configuration.

To disable displaying **name** values, use the **no names** command.

Both the **name** and **names** commands are saved in the configuration.

The **name** command does not support assigning a name to a network mask. For example, this command would be rejected:

```
hostname(config)# name 255.255.255.0 class-C-mask
```

Note None of the commands in which a mask is required can process a name as an accepted network mask.

Examples

This example shows that the **names** command allows you to enable use of the **name** command. The **name** command substitutes **sa_inside** for references to 192.168.42.3 and **sa_outside** for 209.165.201.3. You can use these names with the **ip address** commands when assigning IP addresses to the network interfaces. The **no names** command disables the **name** command values from displaying. Subsequent use of the **names** command again restores the **name** command value display.

```
hostname(config)# names
hostname(config)# name 192.168.42.3 sa_inside
hostname(config)# name 209.165.201.3 sa_outside

hostname(config-if)# ip address inside sa_inside 255.255.255.0
hostname(config-if)# ip address outside sa_outside 255.255.255.224

hostname(config)# show ip address
System IP Addresses:
    inside ip address sa_inside mask 255.255.255.0
    outside ip address sa_outside mask 255.255.255.224

hostname(config)# no names
hostname(config)# show ip address
System IP Addresses:
    inside ip address 192.168.42.3 mask 255.255.255.0
    outside ip address 209.165.201.3 mask 255.255.255.224

hostname(config)# names
hostname(config)# show ip address
System IP Addresses:
    inside ip address sa_inside mask 255.255.255.0
    outside ip address sa_outside mask 255.255.255.224
```

Related Commands

Command	Description
clear configure name	Clears the list of names from the configuration.
names	Enables the association of a name with an IP address.
show running-config name	Displays the names associated with an IP address.

name (dynamic-filter blacklist or whitelist)

To add a domain name to the Botnet Traffic Filter blacklist or whitelist, use the **name** command in dynamic-filter blacklist or whitelist configuration mode. To remove the name, use the **no** form of this command. The static database lets you augment the dynamic database with domain names or IP addresses that you want to whitelist or blacklist.

name *domain_name*

no name *domain_name*

Syntax Description

domain_name	Adds a name to the blacklist. You can enter this command multiple times for multiple entries. You can add up to 1000 blacklist entries.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dynamic-filter blacklist or whitelist configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

After you enter the dynamic-filter whitelist or blacklist configuration mode, you can manually enter domain names or IP addresses (host or subnet) that you want to tag as good names in a whitelist or bad names in a blacklist using the **address** and **name** commands.

You can enter this command multiple times for multiple entries. You can add up to 1000 blacklist and 1000 whitelist entries.

When you add a domain name to the static database, the ASA waits 1 minute, and then sends a DNS request for that domain name and adds the domain name/IP address pairing to the *DNS host cache*. (This action is a background process, and does not affect your ability to continue configuring the ASA).

If you do not have a domain name server configured for the ASA, or it is unavailable, then you can alternatively enable DNS packet inspection with Botnet Traffic Filter snooping (see the **inspect dns dynamic-filter-snooping** command). With DNS snooping, when an infected host sends a DNS request for a name on the static database, the ASA looks inside the DNS packets for the domain name and associated IP address and adds the name and IP address to the DNS reverse lookup cache. See the **inspect dns dynamic-filter-snooping** command for information about the DNS reverse lookup cache.

Entries in the DNS host cache have a time to live (TTL) value provided by the DNS server. The largest TTL value allowed is 1 day (24 hours); if the DNS server provides a larger TTL, it is truncated to 1 day maximum.

For the DNS host cache, after an entry times out, the ASA periodically requests a refresh for the entry.

Examples

The following example creates entries for the blacklist and whitelist:

```
hostname(config)# dynamic-filter blacklist
hostname(config-llist)# name bad1.example.com
hostname(config-llist)# name bad2.example.com
hostname(config-llist)# address 10.1.1.1 255.255.255.0
hostname(config-llist)# dynamic-filter whitelist
hostname(config-llist)# name good.example.com
hostname(config-llist)# name great.example.com
hostname(config-llist)# name awesome.example.com
hostname(config-llist)# address 10.1.1.2 255.255.255.255
```

Related Commands

Command	Description
address	Adds an IP address to the blacklist or whitelist.
clear configure dynamic-filter	Clears the running Botnet Traffic Filter configuration.
clear dynamic-filter dns-snoop	Clears Botnet Traffic Filter DNS snooping data.
clear dynamic-filter reports	Clears Botnet Traffic filter report data.
clear dynamic-filter statistics	Clears Botnet Traffic filter statistics.
dns domain-lookup	Enables the ASA to send DNS requests to a DNS server to perform a name lookup for supported commands.
dns server-group	Identifies a DNS server for the ASA.
dynamic-filter blacklist	Edits the Botnet Traffic Filter blacklist.
dynamic-filter database fetch	Manually retrieves the Botnet Traffic Filter dynamic database.
dynamic-filter database find	Searches the dynamic database for a domain name or IP address.
dynamic-filter database purge	Manually deletes the Botnet Traffic Filter dynamic database.
dynamic-filter enable	Enables the Botnet Traffic Filter for a class of traffic or for all traffic if you do not specify an access list.
dynamic-filter updater-client enable	Enables downloading of the dynamic database.
dynamic-filter use-database	Enables use of the dynamic database.
dynamic-filter whitelist	Edits the Botnet Traffic Filter whitelist.
inspect dns dynamic-filter-snoop	Enables DNS inspection with Botnet Traffic Filter snooping.
name	Adds a name to the blacklist or whitelist.
show asp table dynamic-filter	Shows the Botnet Traffic Filter rules that are installed in the accelerated security path.
show dynamic-filter data	Shows information about the dynamic database, including when the dynamic database was last downloaded, the version of the database, how many entries the database contains, and 10 sample entries.

Command	Description
show dynamic-filter dns-snoop	Shows the Botnet Traffic Filter DNS snooping summary, or with the **detail** keyword, the actual IP addresses and names.
show dynamic-filter reports	Generates reports of the top 10 botnet sites, ports, and infected hosts.
show dynamic-filter statistics	Shows how many connections were monitored with the Botnet Traffic Filter, and how many of those connections match the whitelist, blacklist, and greylist.
show dynamic-filter updater-client	Shows information about the updater server, including the server IP address, the next time the ASA will connect with the server, and the database version last installed.
show running-config dynamic-filter	Shows the Botnet Traffic Filter running configuration.

nameif

To provide a name for an interface, use the **nameif** command in interface configuration mode. To remove the name, use the **no** form of this command. The interface name is used in all configuration commands on the ASA instead of the interface type and ID (such as gigabitethernet0/1), and is therefore required before traffic can pass through the interface.

nameif *name*

no nameif

Syntax Description

name	Sets a name up to 48 characters in length. The name is not case-sensitive.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from a global configuration command to an interface configuration mode command.

Usage Guidelines

For subinterfaces, you must assign a VLAN with the **vlan** command before you enter the **nameif** command.

You can change the name by reentering this command with a new value. Do not enter the **no** form, because that command causes all commands that refer to that name to be deleted.

Examples

The following example configures the names for two interfaces to be “inside” and “outside:”

```
hostname(config)# interface gigabitethernet0/1
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
hostname(config-if)# interface gigabitethernet0/0
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
clear xlate	Resets all translations for existing connections, causing the connections to be reset.
interface	Configures an interface and enters interface configuration mode.
security-level	Sets the security level for the interface.
vlan	Assigns a VLAN ID to a subinterface.

names

To enable the association of a name with an IP address, use the **names** command in global configuration mode. You can associate only one name with an IP address. To disable displaying **name** values, use the **no names** command.

names

no names

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To enable the association of a name with an IP address, use the **names** command. You can associate only one name with an IP address.

You must first use the **names** command before you use the **name** command. Use the **name** command immediately after you use the **names** command and before you use the **write memory** command.

To disable displaying **name** values, use the **no names** command.

Both the **name** and **names** commands are saved in the configuration.

Examples

This example shows that the **names** command allows you to enable use of the **name** command. The **name** command substitutes **sa_inside** for references to 192.168.42.3 and **sa_outside** for 209.165.201.3. You can use these names with the **ip address** commands when assigning IP addresses to the network interfaces. The **no names** command disables the **name** command values from displaying. Subsequent use of the **names** command again restores the **name** command value display.

```
hostname(config)# names
hostname(config)# name 192.168.42.3 sa_inside
hostname(config)# name 209.165.201.3 sa_outside

hostname(config-if)# ip address inside sa_inside 255.255.255.0
```

```
hostname(config-if)# ip address outside sa_outside 255.255.255.224

hostname(config)# show ip address
System IP Addresses:
    inside ip address sa_inside mask 255.255.255.0
    outside ip address sa_outside mask 255.255.255.224

hostname(config)# no names
hostname(config)# show ip address
System IP Addresses:
    inside ip address 192.168.42.3 mask 255.255.255.0
    outside ip address 209.165.201.3 mask 255.255.255.224

hostname(config)# names
hostname(config)# show ip address
System IP Addresses:
    inside ip address sa_inside mask 255.255.255.0
    outside ip address sa_outside mask 255.255.255.224
```

Related Commands

Command	Description
clear configure name	Clears the list of names from the configuration.
name	Associates a name with an IP address.
show running-config name	Displays a list of names associated with IP addresses.
show running-config names	Displays the IP address-to-name conversions.

name-separator

To specify a character as a delimiter between the e-mail and VPN username and password, use the **name-separator** command in the applicable e-mail proxy mode. To revert to the default, ":", use the **no** version of this command.

name-separator [*symbol*]

no name-separator

Syntax Description

symbol	(Optional) The character that separates the e-mail and VPN usernames and passwords. Choices are "@," (at) "|" (pipe), ":"(colon), "#" (hash), "," (comma), and ";" (semi-colon).

Defaults

The default is ":" (colon).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Pop3s	•	—	•	—	—
Imap4s	•	—	•	—	—
Smtps	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The name separator must be different from the server separator.

Examples

The following example shows how to set a hash (#) as the name separator for POP3S:

```
hostname(config)# pop3s
hostname(config-pop3s)# name-separator #
```

Related Commands

Command	Description
server-separator	Separates the e-mail and server names.

name-server

To identify one or more DNS servers, use the **name-server** command in dns server-group configuration mode. To remove a server or servers, use the **no** form of this command. The ASA uses DNS to resolve server names in your SSL VPN configuration or certificate configuration (see "Usage Guidelines" for a list of supported commands). Other features that define server names (such as AAA) do not support DNS resolution. You must enter the IP address or manually resolve the name to an IP address by using the **name** command.

name-server *ip_address* [*ip_address2*] [...] [*ip_address6*]

no name-server *ip_address* [*ip_address2*] [...] [*ip_address6*]

Syntax Description

ip_address	Specifies the DNS server IP address. You can specify up to six addresses as separate commands, or for convenience, up to six addresses in one command separated by spaces. If you enter multiple servers in one command, the ASA saves each server in a separate command in the configuration. The ASA tries each DNS server in order until it receives a response.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
dns server-group configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

To enable DNS lookup, configure the **domain-name** command in dns server-group configuration mode. If you do not enable DNS lookup, the DNS servers are not used.

SSL VPN commands that support DNS resolution include the following:

- **server (pop3s)**
- **server (imap4s)**
- **server (smtps)**
- **port-forward**
- **url-list**

Certificate commands that support DNS resolution include the following:

- **enrollment url**
- **url**

You can manually enter names and IP addresses using the **name** command.

Examples

The following example adds three DNS servers to the group "dnsgroup1":

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# name-server 10.1.1.1 10.2.3.4 192.168.5.5
```

The ASA saves the configuration as separate commands, as follows:

```
name-server 10.1.1.1
name-server 10.2.3.4
name-server 192.168.5.5
```

To add two additional servers, you can enter them as one command:

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# name-server 10.5.1.1 10.8.3.8
```

To verify the dns server group configuration, enter the **show running-config dns** command in global configuration mode:

```
hostname(config)# show running-config dns
name-server 10.1.1.1
name-server 10.2.3.4
name-server 192.168.5.5
name-server 10.5.1.1
name-server 10.8.3.8
...
```

Or you can enter them as two separate commands:

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# name-server 10.5.1.1
hostname(config)# name-server 10.8.3.8
```

To delete multiple servers you can enter them as multiple commands or as one command, as follows:

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# no name-server 10.5.1.1 10.8.3.8
```

Related Commands

Command	Description
domain-name	Sets the default domain name.
retries	Specifies the number of times to retry the list of DNS servers when the ASA does not receive a response.
timeout	Specifies the amount of time to wait before trying the next DNS server.
show running-config dns server-group	Shows one or all the existing dns-server-group configurations.

nat (global)

To configure twice NAT for IPv4, IPv6, or between IPv4 and IPv6 (NAT64), use the **nat** command in global configuration mode. To remove the twice NAT configuration, use the **no** form of this command.

For static NAT:

nat [(*real_ifc*,*mapped_ifc*)] [*line* | {**after-auto** [*line*]}]
source static {*real_obj* | **any**} {*mapped_obj* | **interface** [**ipv6**] | **any**}}
[**destination static** {*mapped_obj* | **interface** [**ipv6**]} {*real_obj* | **any**}]
[**service** {*real_src_mapped_dest_svc_obj* | **any**} *mapped_src_real_dest_svc_obj*] [**net-to-net**]
[**dns**] [**unidirectional** | [**no-proxy-arp**] [**route-lookup**]] [**inactive**] [**description** *desc*]

no nat [(*real_ifc*,*mapped_ifc*)] [*line* | {**after-auto** [*line*]}]
source static {*real_obj* | **any**} {*mapped_obj* | **interface** [**ipv6**] | **any**}}
[**destination static** {*mapped_obj* | **interface** [**ipv6**]} {*real_obj* | **any**}]
[**service** {*real_src_mapped_dest_svc_obj* | **any**} *mapped_src_real_dest_svc_obj*] [**net-to-net**]
[**dns**] [**unidirectional** | [**no-proxy-arp**] [**route-lookup**]] [**inactive**] [**description** *desc*]

For dynamic NAT:

nat [(*real_ifc*,*mapped_ifc*)] [*line* | {**after-auto** [*line*]}]
source dynamic {*real_obj* | **any**}
{[*mapped_obj*] [**pat-pool** *mapped_obj* [**round-robin**] [**extended**] [**flat** [**include-reserve**]]]
[**interface** [**ipv6**]]}
[**destination static** {*mapped_obj* | **interface** [**ipv6**]} {*real_obj* | **any**}]
[**service** {*mapped_dest_svc_obj real_dest_svc_obj*] [**dns**] [**unidirectional**] [**inactive**]
[**description** *desc*]

no nat [(*real_ifc*,*mapped_ifc*)] [*line* | {**after-auto** [*line*]}]
source dynamic {*real_obj* | **any**}
{[*mapped_obj*] [**pat-pool** *mapped_obj* [**round-robin**] [**extended**] [**flat** [**include-reserve**]]]
[**interface** [**ipv6**]]}
[**destination static** {*mapped_obj* | **interface** [**ipv6**]} {*real_obj* | **any**}]
[**service** {*mapped_dest_svc_obj real_dest_svc_obj*] [**dns**] [**unidirectional**] [**inactive**]
[**description** *desc*]

or

no nat {*line* | **after-auto** *line*}

Syntax Description

(*real_ifc*,*mapped_ifc*)	(Optional) Specifies the real and mapped interfaces. If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword **any** for one or both of the interfaces. In transparent mode, you must specify the real and mapped interfaces; you cannot use **any**. Because twice NAT can translate both the source and destination addresses, these interfaces are better understood to be the source and destination interfaces.
after-auto	Inserts the rule at the end of section 3 of the NAT table, after the network object NAT rules. By default, twice NAT rules are added to section 1. You can insert a rule anywhere in section 3 using the *line* argument.

any	(Optional) Specifies a wildcard value. The main uses for **any** are: • Interfaces—You can use **any** for one or both interfaces (**(any,outside)**, for example). If you do not specify the interfaces, then **any** is the default. **any** is not available in transparent mode. • Static NAT source real and mapped IP addresses—You can specify **source static any any** to enable identity NAT for all addresses. • Dynamic NAT or PAT source real addresses—You can translate all addresses on the source interface by specifying **source dynamic any** *mapped_obj*. For static NAT, although **any** is also available for the real source port/mapped destination port, or for the source or destination real address (without **any** as the mapped address), these uses might result in unpredictable behavior. **Note** The definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the ASA performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the ASA can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.
description *desc*	(Optional) Provides a description up to 200 characters.
destination	(Optional) Configures translation for the destination address. Although the main feature of twice NAT is the inclusion of the destination IP address, the destination address is optional. If you do specify the destination address, you can configure static translation for that address or just use identity NAT for it. You might want to configure twice NAT without a destination address to take advantage of some of the other qualities of twice NAT, including the use of network object groups for real addresses, or manually ordering of rules. For more information, see the CLI configuration guide.
dns	(Optional) Translates DNS replies. Be sure DNS inspection is enabled (**inspect dns**) (it is enabled by default). You cannot configure the **dns** keyword if you configure a **destination** address. See the CLI configuration guide for more information.
dynamic	Configures dynamic NAT or PAT for the source addresses. The destination translation is always static.
extended	(Optional) Enables extended PAT for a PAT pool. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80.

flat [**include-reserve**]	(Optional) Enables use of the entire 1024 to 65535 port range when allocating ports. When choosing the mapped port number for a translation, the ASA uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also specify the **include-reserve** keyword.
inactive	(Optional) To make this rule inactive without having to remove the command, use the **inactive** keyword. To reactivate it, reenter the whole command without the **inactive** keyword.
interface [**ipv6**]	(Optional) Uses the interface IP address as the mapped address. If you specify **ipv6**, then the IPv6 address of the interface is used. For the dynamic NAT source mapped address, if you specify a mapped object or group followed by the **interface** keyword, then the IP address of the mapped interface is only used if all other mapped addresses are already allocated. For dynamic PAT, you can specify **interface** alone for the source mapped address. For static NAT with port translation (source or destination), be sure to also configure the **service** keyword. For this option, you must configure a specific interface for the *mapped_ifc*. This option is not available in transparent mode.
line	(Optional) Inserts a rule anywhere in section 1 of the NAT table. By default, the NAT rule is added to the end of section 1 (see the CLI configuration guide for more information). If you want to add the rule into section 3 instead (after the network object NAT rules), then use the **after-auto** *line* option.
mapped_dest_svc_obj	(Optional) For dynamic NAT/PAT, specifies the mapped destination port (the destination translation is always static). See the **service** keyword for more information.

mapped_object	Identifies the mapped network object or object group (**object network** or **object-group network**). For dynamic NAT, you typically configure a larger group of addresses to be mapped to a smaller group. **Note** The mapped object or group cannot contain a subnet. You can share this mapped IP address across different dynamic NAT rules, if desired. You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address. For dynamic PAT, configure a group of addresses to be mapped to a single address. You can either translate the real addresses to a single mapped address of your choosing, or you can translate them to the mapped interface address. If you want to use the interface address, do not configure a network object for the mapped address; instead use the **interface** keyword. For static NAT, the mapping is typically one-to-one, so the real addresses have the same quantity as the mapped addresses. You can, however, have different quantities if desired. For more information, see the CLI configuration guide.
mapped_src_real_dest_svc_obj	(Optional) For static NAT, specifies the either the mapped source port, the real destination port, or both together. See the **service** keyword for more information.
net-to-net	(Optional) For static NAT 46, specify **net-to-net** to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this keyword.
no-proxy-arp	(Optional) For static NAT, disables proxy ARP for incoming packets to the mapped IP addresses.
pat-pool *mapped_obj*	(Optional) Enables a PAT pool of addresses; all addresses in the object are used as PAT addresses. You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
real_dest_svc_obj	(Optional) For dynamic NAT/PAT, specifies the real destination port (the destination translation is always static). See the **service** keyword for more information.
real_ifc	(Optional) Specifies the name of the interface where packets may originate. For source option. For the source option, the origin_ifc is the real interface. For the destination option, the real_ifc is the mapped interface.
real_object	Identifies the real network object or object group (**object network** or **object-group network**). You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
real_src_mapped_dest_svc_obj	(Optional) For static NAT, specifies the either the real source port, the mapped destination port, or both together. See the **service** keyword for more information.

round-robin	(Optional) Enables round-robin address allocation for a PAT pool. By default, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns an address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
route-lookup	(Optional) For identity NAT in routed mode, determines the egress interface using a route lookup instead of using the interface specified in the NAT command. If you do not specify interfaces in the NAT command, a route lookup is used by default.
service	(Optional) Specifies the port translation. • Dynamic NAT and PAT—Dynamic NAT and PAT do not support (additional) port translation. However, because the *destination* translation is always static, you can perform port translation for the destination port. A service object (**object service**) can contain both a source and destination port, but only the destination port is used in this case. If you specify the source port, it will be ignored. • Static NAT with port translation—You should specify *either* the source *or* the destination port for both service objects. You should only specify *both* the source and destination ports if your application uses a fixed source port (such as some DNS servers); but fixed source ports are rare. For source port translation, the objects must specify the source service. The order of the service objects in the command in this case is **service** *real_port mapped_port*. For destination port translation, the objects must specify the destination service. The order of the service objects in this case is **service** *mapped_port real_port*. In the rare case where you specify both the source and destination ports in the object, the first service object contains the real source port/mapped destination port; the second service object contains the mapped source port/real destination port. See the "Usage Guidelines" section for more information about "source" and "destination" terminology. For identity port translation, simply use the same service object for both the real and mapped ports (source and/or destination ports, depending on your configuration). The "not equal" (**neq**) operator is not supported. NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP).
source	Configures translation for the source address.
static	Configures static NAT or static NAT with port translation.
unidirectional	(Optional) For static NAT, makes the translarion unidirection from the source to the destination; the destination addresses cannot initiate traffic to the source addresses. This option might be useful for testing purposes.

Defaults

- By default, the rule is added to the end of section 1 of the NAT table.
- The default value of *real_ifc* and *mapped_ifc* is **any**, which applies the rule to all interfaces.
- (8.3(1), 8.3(2), and 8.4(1)) The default behavior for identity NAT has proxy ARP disabled. You cannot configure this setting. (8.4(2) and later) The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired.

- If you specify an optional interface, then the ASA uses the NAT configuration to determine the egress interface. (8.3(1) through 8.4(1)) The only exception is for identity NAT, which always uses a route lookup, regardless of the NAT configuration. (8.4(2) and later) For identity NAT, the default behavior is to use the NAT configuration, but you have the option to always use a route lookup instead.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.3(2)	When migrating from a pre-8.3 NAT exemption configuration, the keyword **unidirectional** is added for the resulting static identity NAT rule.
8.4(2)/8.5(1)	The **no-proxy-arp**, **route-lookup**, **pat-pool**, and **round-robin** keywords were added. The default behavior for identity NAT was changed to have proxy ARP enabled, matching other static NAT rules. For pre-8.3 configurations, the migration of NAT exempt rules (the **nat 0 access-list** command) to 8.4(2) and later now includes the following keywords to disable proxy ARP and to use a route lookup: **no-proxy-arp** and **route-lookup**. The **unidirectional** keyword that was used for migrating to 8.3(2) and 8.4(1) is no longer used for migration. When upgrading to 8.4(2) from 8.3(1), 8.3(2), and 8.4(1), all identity NAT configurations will now include the **no-proxy-arp** and **route-lookup** keywords, to maintain existing functionality. The **unidirectional** keyword is removed.
8.4(3)	The **extended**, **flat**, and **include-reserve** keywords were added. When using a PAT pool with round robin allocation, if a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. *This feature is not available in 8.5(1).*
9.0(1)	NAT now supports IPv6 traffic, as well as translating between IPv4 and IPv6. Translating between IPv4 and IPv6 is not supported in transparent mode. We added the **interface ipv6** option and the **net-to-net** option.

Usage Guidelines

Twice NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y, for example.

Note For static NAT, the rule is bidirectional, so be aware that "source" and "destination" are used in commands and descriptions throughout this guide even though a given connection might originate at the "destination" address. For example, if you configure static NAT with port translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then in the command, you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the **source** address.

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

Twice NAT also lets you use service objects for static NAT with port translation; network object NAT only accepts inline definition.

For detailed information about the differences between twice NAT and network object NAT, see the CLI configuration guide.

Twice NAT rules are added to section 1 of the NAT rules table, or if specified, section 3. For more information about NAT ordering, see the CLI configuration guide.

Mapped Address Guidelines

The mapped IP address pool cannot include:

- The mapped interface IP address. If you specify **any** interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the **interface** keyword instead of the IP address.
- (Transparent mode) The management IP address.
- (Dynamic NAT) The standby interface IP address when VPN is enabled.
- Existing VPN pool addresses.

Prerequisites

- For both the real and mapped addresses, configure network objects or network object groups (the **object network** or **object-group network** command). Network object groups are particularly useful for creating a mapped address pool with discontinuous IP address ranges or multiple hosts or subnets. You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- For static NAT with port translation, configure TCP or UDP service objects (the **object service** command).

Objects and object groups used in NAT cannot be undefined; they must include IP addresses.

Clearing Translation Sessions

If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT information is used, you can clear the translation table using **clear xlate** command. However, clearing the translation table disconnects all of the current connections.

PAT Pool Guidelines

- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A-record, and the PAT rule to use is ambiguous.

- If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used. (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you have a lot of traffic that uses the lower port ranges, you can now specify a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535.
- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT and a flat range, then the other rule must also specify extended PAT and a flat range.

Extended PAT for a PAT Pool Guidelines

- Many application inspections do not support extended PAT. See the configuration guide for a complete list of unsupported inspections.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT-with-port-translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.

Round robin for a PAT Pool Guidelines

- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. **Note**: This "stickiness" does not survive a failover. If the ASA fails over, then subsequent connections from a host may not use the initial IP address.
- (8.4(2), 8.5(1), and 8.6(1)) If a host has an existing connection, then subsequent connections from that host will likely use *different* PAT addresses for each connection because of the round robin allocation. In this case, you may have problems when accessing two websites that exchange information about the host, for example an e-commerce site and a payment site. When these sites see two different IP addresses for what is supposed to be a single host, the transaction may fail.

NAT and IPv6

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address.

- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

Examples

The following example includes a host on the 10.1.2.0/24 network that accesses two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:*port*. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:*port*.

```
hostname(config)# object network myInsideNetwork
hostname(config-network-object)# subnet 10.1.2.0 255.255.255.0

hostname(config)# object network DMZnetwork1
hostname(config-network-object)# subnet 209.165.201.0 255.255.255.224

hostname(config)# object network PATaddress1
hostname(config-network-object)# host 209.165.202.129

hostname(config)# nat (inside,dmz) source dynamic myInsideNetwork PATaddress1 destination
static DMZnetwork1 DMZnetwork1

hostname(config)# object network DMZnetwork2
hostname(config-network-object)# subnet 209.165.200.224 255.255.255.224

hostname(config)# object network PATaddress2
hostname(config-network-object)# host 209.165.202.130

hostname(config)# nat (inside,dmz) source dynamic myInsideNetwork PATaddress2 destination
static DMZnetwork2 DMZnetwork2
```

The following example shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:*port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:*port*.

```
hostname(config)# object network myInsideNetwork
hostname(config-network-object)# subnet 10.1.2.0 255.255.255.0

hostname(config)# object network TelnetWebServer
hostname(config-network-object)# host 209.165.201.11

hostname(config)# object network PATaddress1
hostname(config-network-object)# host 209.165.202.129

hostname(config)# object service TelnetObj
hostname(config-network-object)# service tcp destination eq telnet

hostname(config)# nat (inside,outside) source dynamic myInsideNetwork PATaddress1
destination static TelnetWebServer TelnetWebServer service TelnetObj TelnetObj

hostname(config)# object network PATaddress2
hostname(config-network-object)# host 209.165.202.130

hostname(config)# object service HTTPObj
hostname(config-network-object)# service tcp destination eq http

hostname(config)# nat (inside,outside) source dynamic myInsideNetwork PATaddress2
destination static TelnetWebServer TelnetWebServer service HTTPObj HTTPObj
```

The following example shows the use of static interface NAT with port translation. Hosts on the outside access an FTP server on the inside by connecting to the outside interface IP address with destination port 65000 through 65004. The traffic is untranslated to the internal FTP server at 192.168.10.100:6500 through :65004. Note that you specify the source port range in the service object (and not the destination port) because you want to translate the source address and port as identified in the command; the destination port is "any." Because static NAT is bidirectional, "source" and "destination" refers primarily to the command keywords; the actual source and destination address and port in a packet depends on which host sent the packet. In this example, connections are originated from outside to inside, so the "source" address and port of the FTP server is actually the destination address and port in the originating packet.

```
hostname(config)# object service FTP_PASV_PORT_RANGE
hostname(config-service-obvject)# service tcp source range 65000 65004

hostname(config)# object network HOST_FTP_SERVER
hostname(config-network-obvject)# host 192.168.10.100

hostname(config)# nat (inside,outside) source static HOST_FTP_SERVER interface service
FTP_PASV_PORT_RANGE FTP_PASV_PORT_RANGE
```

The following example configures dynamic NAT for an IPv6 inside network 2001:DB8:AAAA::/96 when accessing servers on the IPv4 209.165.201.1/27 network as well as servers on the 203.0.113.0/24 network:

```
hostname(config)# object network INSIDE_NW
hostname(config-network-object)# subnet 2001:DB8:AAAA::/96

hostname(config)# object network MAPPED_1
hostname(config-network-object)# range 209.165.200.225 209.165.200.254

hostname(config)# object network MAPPED_2
hostname(config-network-object)# range 209.165.202.129 209.165.200.158

hostname(config)# object network SERVERS_1
hostname(config-network-object)# subnet 209.165.201.0 255.255.255.224

hostname(config)# object network SERVERS_2
hostname(config-network-object)# subnet 203.0.113.0 255.255.255.0

hostname(config)# nat (inside,outside) source dynamic INSIDE_NW MAPPED_1 destination
static SERVERS_1 SERVERS_1
hostname(config)# nat (inside,outside) source dynamic INSIDE_NW MAPPED_2 destination
static SERVERS_2 SERVERS_2
```

The following example configures interface PAT for inside network 192.168.1.0/24 when accessing outside IPv6 Telnet server 2001:DB8::23, and Dynamic PAT using a PAT pool when accessing any server on the 2001:DB8:AAAA::/96 network.

```
hostname(config)# object network INSIDE_NW
hostname(config-network-object)# subnet 192.168.1.0 255.255.255.0

hostname(config)# object network PAT_POOL
hostname(config-network-object)# range 2001:DB8:AAAA::1 2001:DB8:AAAA::200

hostname(config)# object network TELNET_SVR
hostname(config-network-object)# host 2001:DB8::23

hostname(config)# object service TELNET
hostname(config-service-object)# service tcp destination eq 23

hostname(config)# object network SERVERS
hostname(config-network-object)# subnet 2001:DB8:AAAA::/96

hostname(config)# nat (inside,outside) source dynamic INSIDE_NW interface ipv6 destination
static TELNET_SVR TELNET_SVR service TELNET TELNET
hostname(config)# nat (inside,outside) source dynamic INSIDE_NW pat-pool PAT_POOL
destination static SERVERS SERVERS
```

Related Commands

Command	Description
clear configure nat	Removes the NAT configuration (both twice NAT and network object NAT).
show nat	Displays NAT policy statistics.
show nat pool	Displays information about NAT pools.
show running-config nat	Shows the NAT configuration.
show xlate	Displays NAT session (xlate) information.

nat (object)

To configure NAT for a network object, use the **nat** command in object network configuration mode. To remove the NAT configuration, use the **no** form of this command.

For dynamic NAT and PAT:

nat [(*real_ifc*,*mapped_ifc*)] **dynamic**
{*mapped_inline_host_ip* [**interface** [**ipv6**]] | [*mapped_obj*] [**pat-pool** *mapped_obj* [**round-robin**] [**extended**] [**flat** [**include-reserve**]]] [**interface** [**ipv6**]]} [**dns**]

no nat [(*real_ifc*,*mapped_ifc*)] **dynamic**
{*mapped_inline_host_ip* [**interface** [**ipv6**]] | [*mapped_obj*] [**pat-pool** *mapped_obj* [**round-robin**] [**extended**] [**flat** [**include-reserve**]]] [**interface** [**ipv6**]]} [**dns**]

For static NAT and static NAT with port translation:

nat [(*real_ifc*,*mapped_ifc*)] **static** {*mapped_inline_ip* | *mapped_obj* | **interface** [**ipv6**]} [**net-to-net**] [**dns** | **service** {**tcp** | **udp**} *real_port mapped_port*] [**no-proxy-arp**] [**route-lookup**]

no nat [(*real_ifc*,*mapped_ifc*)] **static** {*mapped_inline_ip* | *mapped_obj* | **interface** [**ipv6**]} [**net-to-net**] [**dns** | **service** {**tcp** | **udp**} *real_port mapped_port*] [**no-proxy-arp**] [**route-lookup**]

Syntax Description

(*real_ifc*,*mapped_ifc*)	(Optional) For static NAT, specifies the real and mapped interfaces. If you do not specify the real and mapped interfaces, all interfaces are used. You can also specify the keyword **any** for one or both of the interfaces. Be sure to include the parentheses in your command. In transparent mode, you must specify the real and mapped interfaces; you cannot use **any**.
dns	(Optional) Translates DNS replies. Be sure DNS inspection (**inspect dns**) is enabled (it is enabled by default). This option is not available if you specify the **service** keyword (for static NAT). For more information, see the CLI configuration guide.
dynamic	Configures dynamic NAT or PAT.
extended	(Optional) Enables extended PAT for a PAT pool. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80.
flat [**include-reserve**]	(Optional) Enables use of the entire 1024 to 65535 port range when allocating ports. When choosing the mapped port number for a translation, the ASA uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also specify the **include-reserve** keyword.

interface [**ipv6**]	(Optional) For dynamic NAT, if you specify a mapped IP address, object, or group followed by the **interface** keyword, then the IP address of the mapped interface is only used if all of the other mapped addresses are already allocated. For dynamic PAT, if you specify the **interface** keyword instead of a mapped IP address, object, or group, then you use the interface IP address for the mapped IP address. You must use this keyword when you want to use the interface IP address; you cannot enter it inline or as an object. If you specify **ipv6**, then the IPv6 address of the interface is used. For static NAT with port translation, you can specify the **interface** keyword if you also configure the **service** keyword. For this option, you must configure a specific interface for the *mapped_ifc*. You cannot specify **interface** in transparent mode.
mapped_inline_host_ip	Specifies the mapped address as an inline value. If you specify **dynamic**, then using a host IP address configures dynamic PAT.
mapped_inline_ip	For static NAT, specifies the mapped IP address as an inline value. The netmask or range for the mapped network is the same as that of the real network. For example, if the real network is a host, then this address will be a host address. In the case of a range, then the mapped addresses include the same number of addresses as the real range. For example, if the real address is defined as a range from 10.1.1.1 through 10.1.1.6, and you specify 172.20.1.1 as the mapped address, then the mapped range will include 172.20.1.1 through 172.20.1.6.
mapped_obj	Specifies the mapped IP address(es) as a network object (**object network**) or object group (**object-group network**). You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address. For dynamic NAT, the object or group cannot contain a subnet. You can share this mapped object across different dynamic NAT rules, if desired. See the "Mapped Address Guidelines" section on page 36-34 for information about disallowed mapped IP addresses. For static NAT, typically you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses. For more information, see the CLI configuration guide.
mapped_port	(Optional) Specifies the mapped TCP or UDP port. You can specify ports by either a literal name or a number in the range of 0 to 65535.
net-to-net	(Optional) For NAT 46, specify **net-to-net** to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this keyword.
no-proxy-arp	(Optional) For static NAT, disables proxy ARP for incoming packets to the mapped IP addresses.
pat-pool *mapped_obj*	(Optional) Enables a PAT pool of addresses; all addresses in the object are used as PAT addresses. You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.

real_port	(Optional) For static NAT, specifies the real TCP or UDP port. You can specify ports by either a literal name or a number in the range of 0 to 65535.
round-robin	(Optional) Enables round-robin address allocation for a PAT pool. By default, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns an address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
route-lookup	(Optional) For identity NAT in routed mode, determines the egress interface using a route lookup instead of using the interface specified in the NAT command. If you do not specify interfaces in the NAT command, a route lookup is used by default.
service {**tcp** | **udp**}	(Optional) For static NAT with port translation, specifies the protocol for port translation. Only TCP and UDP are supported.
static	Configures static NAT or static NAT with port translation.

Defaults

- The default value of *real_ifc* and *mapped_ifc* is **any**, which applies the rule to all interfaces.
- (8.3(1), 8.3(2), and 8.4(1)) The default behavior for identity NAT has proxy ARP disabled. You cannot configure this setting. (8.4(2) and later) The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired.
- If you specify an optional interface, then the ASA uses the NAT configuration to determine the egress interface. (8.3(1) through 8.4(1)) The only exception is for identity NAT, which always uses a route lookup, regardless of the NAT configuration. (8.4(2) and later) For identity NAT, the default behavior is to use the NAT configuration, but you have the option to always use a route lookup instead.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Object network configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(2)/8.5(1)	The **no-proxy-arp**, **route-lookup**, **pat-pool**, and **round-robin** keywords were added. The default behavior for identity NAT was changed to have proxy ARP enabled, matching other static NAT rules. When upgrading to 8.4(2) from 8.3(1), 8.3(2), and 8.4(1), all identity NAT configurations will now include the **no-proxy-arp** and **route-lookup** keywords, to maintain existing functionality.

Release	Modification
8.4(3)	The **extended**, **flat**, and **include-reserve** keywords were added. When using a PAT pool with round robin allocation, if a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. *This feature is not available in 8.5(1).*
9.0(1)	NAT now supports IPv6 traffic, as well as translating between IPv4 and IPv6. Translating between IPv4 and IPv6 is not supported in transparent mode. We added the **interface ipv6** option and the **net-to-net** option.

Usage Guidelines

When a packet enters the ASA, both the source and destination IP addresses are checked against the network object NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that a source address should be translated to A when going to destination X, but be translated to B when going to destination Y. Use twice NAT for that kind of functionality (twice NAT lets you identify the source and destination address in a single rule).

For detailed information about the differences between twice NAT and network object NAT, see the CLI configuration guide.

Network object NAT rules are added to section 2 of the NAT rules table. For more information about NAT ordering, see the CLI configuration guide.

Depending on the configuration, you can configure the mapped address inline if desired or you can create a network object or network object group for the mapped address (the **object network** or **object-group network** command). Network object groups are particularly useful for creating a mapped address pool with discontinous IP address ranges or multiple hosts or subnets. You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.

Objects and object groups used in NAT cannot be undefined; they must include IP addresses.

You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules, you need to create multiple objects that specify the same IP address, for example, **object network obj-10.10.10.1-01**, **object network obj-10.10.10.1-02**, and so on.

Mapped Address Guidelines

The mapped IP address pool cannot include:

- The mapped interface IP address. If you specify **any** interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), use the **interface** keyword instead of the IP address.
- (Transparent mode) The management IP address.
- (Dynamic NAT) The standby interface IP address when VPN is enabled.
- Existing VPN pool addresses.

Clearing Translation Sessions

If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT information is used, you can clear the translation table using **clear xlate** command. However, clearing the translation table disconnects all of the current connections.

PAT Pool Guidelines

- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A-record, and the PAT rule to use is ambiguous.
- If available, the real source port number is used for the mapped port. However, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 0 to 511, 512 to 1023, and 1024 to 65535. Therefore, ports below 1024 have only a small PAT pool that can be used. (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you have a lot of traffic that uses the lower port ranges, you can now specify a flat range of ports to be used instead of the three unequal-sized tiers: either 1024 to 65535, or 1 to 65535.
- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT and a flat range, then the other rule must also specify extended PAT and a flat range.

Extended PAT for a PAT Pool Guidelines

- Many application inspections do not support extended PAT. See the configuration guide for a complete list of unsupported inspections.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT-with-port-translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.

Round robin for a PAT Pool Guidelines

- (8.4(3) and later, not including 8.5(1) or 8.6(1)) If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. **Note**: This "stickiness" does not survive a failover. If the ASA fails over, then subsequent connections from a host may not use the initial IP address.
- (8.4(2), 8.5(1), and 8.6(1)) If a host has an existing connection, then subsequent connections from that host will likely use *different* PAT addresses for each connection because of the round robin allocation. In this case, you may have problems when accessing two websites that exchange information about the host, for example an e-commerce site and a payment site. When these sites see two different IP addresses for what is supposed to be a single host, the transaction may fail.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory.

NAT and IPv6

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (twice NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6

prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address.

- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

Examples

Dynamic NAT Examples

The following example configures dynamic NAT that hides 192.168.2.0 network behind a range of outside addresses 2.2.2.1-2.2.2.10:

```
hostname(config)# object network my-range-obj
hostname(config-network-object)# range 2.2.2.1 2.2.2.10
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic my-range-obj
```

The following example configures dynamic NAT with dynamic PAT backup. Hosts on inside network 10.76.11.0 are mapped first to the nat-range1 pool (10.10.10.10-10.10.10.20). After all addresses in the nat-range1 pool are allocated, dynamic PAT is performed using the pat-ip1 address (10.10.10.21). In the unlikely event that the PAT translations are also use up, dynamic PAT is performed using the outside interface address.

```
hostname(config)# object network nat-range1
hostname(config-network-object)# range 10.10.10.10 10.10.10.20

hostname(config-network-object)# object network pat-ip1
hostname(config-network-object)# host 10.10.10.21

hostname(config-network-object)# object-group network nat-pat-grp
hostname(config-network-object)# network-object object nat-range1
hostname(config-network-object)# network-object object pat-ip1

hostname(config-network-object)# object network my_net_obj5
hostname(config-network-object)# subnet 10.76.11.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic nat-pat-grp interface
```

The following example configures dynamic NAT with dynamic PAT backup to translate IPv6 hosts to IPv4. Hosts on inside network 2001:DB8::/96 are mapped first to the IPv4_NAT_RANGE pool (209.165.201.1 to 209.165.201.30). After all addresses in the IPv4_NAT_RANGE pool are allocated, dynamic PAT is performed using the IPv4_PAT address (209.165.201.31). In the event that the PAT translations are also used up, dynamic PAT is performed using the outside interface address.

```
hostname(config)# object network IPv4_NAT_RANGE
hostname(config-network-object)# range 209.165.201.1 209.165.201.30

hostname(config-network-object)# object network IPv4_PAT
hostname(config-network-object)# host 209.165.201.31

hostname(config-network-object)# object-group network IPv4_GROUP
hostname(config-network-object)# network-object object IPv4_NAT_RANGE
hostname(config-network-object)# network-object object IPv4_PAT

hostname(config-network-object)# object network my_net_obj5
hostname(config-network-object)# subnet 2001:DB8::/96
hostname(config-network-object)# nat (inside,outside) dynamic IPv4_GROUP interface
```

Dynamic PAT Example

The following example configures dynamic PAT that hides the 192.168.2.0 network behind address 2.2.2.2:

```
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic 2.2.2.2
```

The following example configures dynamic PAT that hides the 192.168.2.0 network behind the outside interface address:

```
hostname(config)# object network my-inside-net
hostname(config-network-object)# subnet 192.168.2.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) dynamic interface
```

The following example configures dynamic PAT with a PAT pool to translate the inside IPv6 network to an outside IPv4 network:

```
hostname(config)# object network IPv4_POOL
hostname(config-network-object)# range 203.0.113.1 203.0.113.254
hostname(config)# object network IPv6_INSIDE
hostname(config-network-object)# subnet 2001:DB8::/96
hostname(config-network-object)# nat (inside,outside) dynamic pat-pool IPv4_POOL
```

Static NAT Examples

The following example configures static NAT for the real host 1.1.1.1 on the inside to 2.2.2.2 on the outside with DNS rewrite enabled.

```
hostname(config)# object network my-host-obj1
hostname(config-network-object)# host 1.1.1.1
hostname(config-network-object)# nat (inside,outside) static 2.2.2.2 dns
```

The following example configures static NAT for the real host 1.1.1.1 on the inside to 2.2.2.2 on the outside using a mapped object.

```
hostname(config)# object network my-mapped-obj
hostname(config-network-object)# host 2.2.2.2

hostname(config-network-object)# object network my-host-obj1
hostname(config-network-object)# host 1.1.1.1
hostname(config-network-object)# nat (inside,outside) static my-mapped-obj
```

The following example configures static NAT with port translation for 1.1.1.1 at TCP port 21 to the outside interface at port 2121.

```
hostname(config)# object network my-ftp-server
hostname(config-network-object)# host 1.1.1.1
hostname(config-network-object)# nat (inside,outside) static interface service tcp 21 2121
```

The following example maps an inside IPv4 network to an outside IPv6 network.

```
hostname(config)# object network inside_v4_v6
hostname(config-network-object)# subnet 10.1.1.0 255.255.255.0
hostname(config-network-object)# nat (inside,outside) static 2001:DB8::/96
```

The following example maps an inside IPv6 network to an outside IPv6 network.

```
hostname(config)# object network inside_v6
hostname(config-network-object)# subnet 2001:DB8:AAAA::/96
hostname(config-network-object)# nat (inside,outside) static 2001:DB8:BBBB::/96
```

Identity NAT Examples

The following example maps a host address to itself using an inline mapped address:

```
hostname(config)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static 10.1.1.1
```

The following example maps a host address to itself using a network object:

```
hostname(config)# object network my-host-obj1-identity
hostname(config-network-object)# host 10.1.1.1

hostname(config-network-object)# object network my-host-obj1
hostname(config-network-object)# host 10.1.1.1
hostname(config-network-object)# nat (inside,outside) static my-host-obj1-identity
```

Related Commands

Command	Description
clear configure nat	Removes the NAT configuration (both twice NAT and network object NAT).
show nat	Displays NAT policy statistics.
show nat pool	Displays information about NAT pools.
show running-config nat	Displays the NAT configuration.
show xlate	Displays xlate information.

nat (vpn load-balancing)

To set the IP address to which NAT translates the IP address of this device, use the **nat** command in VPN load-balancing configuration mode. To disable this NAT translation, use the **no** form of this command.

nat *ip-address*

no nat [*ip-adddress*]

Syntax Description

ip-address	The IP address to which you want this NAT to translate the IP address of this device.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
VPN load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first use the **vpn load-balancing** command to enter VPN load-balancing mode.

In the **no nat** form of the command, if you specify the optional *ip-address* value, the IP address must match the existing NAT IP address in the running configuration.

Examples

The following is an example of a VPN load-balancing command sequence that includes a **nat** command that sets the NAT-translated address to 192.168.10.10:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# nat 192.168.10.10
hostname(config-load-balancing)# priority 9
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
```

```
hostname(config-load-balancing)# cluster port 9023
hostname(config-load-balancing)# participate
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
vpn load-balancing	Enter VPN load-balancing mode.

nat-assigned-to-public-ip

To automatically translate a VPN peer's local IP address back to the peer's real IP address, use the **nat-assigned-to-public-ip** command in tunnel-group general-attributes configuration mode. To disable the NAT rules, use the **no** form of this command.

nat-assigned-to-public-ip *interface*

no nat-assigned-to-public-ip *interface*

Syntax Description

interface	Specifies the interface where you want to apply NAT.

Command Default

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group general-attributes configuration	•	•	•	—	—

Command History

Release	Modification
8.4(3)	We introduced this command.

Usage Guidelines

In rare situations, you might want to use a VPN peer's real IP address on the inside network instead of an assigned local IP address. Normally with VPN, the peer is given an assigned local IP address to access the inside network. However, you might want to translate the local IP address back to the peer's real public IP address if, for example, your inside servers and network security is based on the peer's real IP address.

You can enable this feature on one interface per tunnel group. Object NAT rules are dynamically added and deleted when the VPN session is established or disconnected. You can view the rules using the **show nat** command.

Data Flow

The following steps describe the packet flow through the ASA when this feature is enabled:

1. The VPN peer sends a packet to the ASA.

   The outer source/destination consists of the peer public IP address/ASA IP address. The encrypted inner source/destination consists of the VPN-assigned IP address/inside server address.

2. The ASA decrypts the packet (removing the outer source/destination).
3. The ASA performs a route lookup for the inside server, and sends the packet to the inside interface.

4. The automatically created VPN NAT policy translates the VPN-assigned source IP address to the peer public IP address.
5. The ASA sends the translated packet to the server.
6. The server responds to the packet, and sends it to the peer's public IP address.
7. The ASA receives the response, and untranslates the destination IP address to the VPN-assigned IP address.
8. The ASA forwards the untranslated packet to the outside interface where it is encrypted, and an outer source/destination is added consisting of the ASA IP address/peer public IP address.
9. The ASA sends the packet back to the peer.
10. The peer decrypts and processes the data.

Limitations

Because of routing issues, we do not recommend using this feature unless you know you need this feature; contact Cisco TAC to confirm feature compatibility with your network. See the following limitations:

- Only supports Cisco IPsec and AnyConnect client.
- Return traffic to the public IP addresses must be routed back to the ASA so the NAT policy and VPN policy can be applied.
- If you enable reverse route injection (see the **set reverse-route** command), only the VPN-assigned IP address is advertised.
- Does not support load-balancing (because of routing issues).
- Does not support roaming (public IP changing).

Examples

The following example enables NAT to the public IP for the "vpnclient" tunnel group:

```
hostname# ip local pool client 10.1.226.4-10.1.226.254
hostname# tunnel-group vpnclient type remote-access
hostname# tunnel-group vpnclient general-attributes
hostname(config-tunnel-general)# address-pool client
hostname(config-tunnel-general)# nat-assigned-to-public-ip inside
```

The following is sample output from the **show nat detail** command showing an automatic NAT rule from peer 209.165.201.10 with assigned IP 10.1.226.174:

```
hostname# show nat detail

 Auto NAT Policies (Section 2)
 1 (outside) to (inside) source static _vpn_nat_10.1.226.174 209.165.201.10
     translate_hits = 0, untranslate_hits = 0
     Source - Origin: 10.1.226.174/32, Translated: 209.165.201.10/32
```

Related Commands

Command	Description
show nat	Shows current xlates.
tunnel-group general-attributes	Sets general attributes for a tunnel group.
debug menu webvpn 99	For AnyConnect SSL sessions, the VPN NAT interface is stored in the session.

Command	Description
debug menu ike 2 *peer_ip*	For Cisco IPsec client sessions, the VPN NAT interface is stored in the SA.
debug nat 3	Shows debug messages for NAT.

nat-rewrite

To enable NAT rewrite for IP addressess embedded in the A-record of a DNS response, use the **nat-rewrite** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

nat-rewrite

no nat-rewrite

Syntax Description

This command has no arguments or keywords.

Defaults

NAT rewrite is enabled by default. This feature can be enabled when **inspect dns** is configured even if a **policy-map type inspect dns** is not defined. To disable, **no nat-rewrite** must explicitly be stated in the policy map configuration. If **inspect dns** is not configured, NAT rewrite is not performed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This feature performs NAT translation of A-type Resource Record (RR) in a DNS response.

Examples

The following example shows how to enable NAT rewrite in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# nat-rewrite
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

Command	Description
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

nbns-server (tunnel-group webvpn attributes mode)

To configure an NBNS server, use the **nbns-server** command in tunnel-group webvpn configuration mode. To remove the NBNS server from the configuration, use the **no** form of this command.

The ASA queries NBNS servers to map NetBIOS names to IP addresses. WebVPN requires NetBIOS to access or share files on remote systems.

nbns-server {*ipaddr* | *hostname*} [**master**] [**timeout** *timeout*] [**retry** *retries*]

no nbns-server

Syntax Description

hostname	Specifies the hostname for the NBNS server.
ipaddr	Specifies the IP address for the NBNS server.
master	Indicates that this is a master browser, rather than a WINS server.
retry	Indicates that a retry value follows.
retries	Specifies the number of times to retry queries to NBNS servers. The ASA recycles through the list of servers the number of times you specify here before sending an error message. The default value is 2; the range is 1 through 10.
timeout	Indicates that a timeout value follows.
timeout	Specifies the amount of time the ASA waits before sending the query again, to the same server if there is only one, or another server if there are multiple NBNS servers. The default timeout is 2 seconds; the range is 1 to 30 seconds.

Defaults

No NBNS server is configured by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Moved from webvpn mode to tunnel-group webvpn configuration mode.

Usage Guidelines

In Release 7.1(1), if you enter this command in webvpn configuration mode, it is transformed to the same command in tunnel-group webvpn-attributes configuration mode.

Maximum of 3 server entries. The first server you configure is the primary server, and the others are backups, for redundancy.

Use the **no** option to remove the matching entry from the configuration.

Examples

The following example shows how to configure the tunnel-group "test" with an NBNS server that is a master browser with an IP address of 10.10.10.19, a timeout value of 10 seconds, and 8 retries. It also shows how to configure an NBNS WINS server with an IP address of 10.10.10.24, a timeout value of 15 seconds, and 8 retries.

```
hostname(config)# tunnel-group test type webvpn
hostname(config)# tunnel-group test webvpn-attributes
hostname(config-tunnel-webvpn)# nbns-server 10.10.10.19 master timeout 10 retry 8
hostname(config-tunnel-webvpn)# nbns-server 10.10.10.24 timeout 15 retry 8
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
clear configure group-policy	Removes the configuration for a particular group policy or for all group policies.
show running-config group-policy	Displays the running configuration for a particular group policy or for all group policies.
tunnel-group webvpn-attributes	Specifies the WebVPN attributes for the named tunnel-group.

nbns-server (webvpn mode)

To configure an NBNS server, use the **nbns-server** command in tunnel-group webvpn configuration mode. To remove the NBNS server from the configuration, use the **no** form of this command.

The ASA queries NBNS servers to map NetBIOS names to IP addresses. WebVPN requires NetBIOS to access or share files on remote systems.

nbns-server {*ipaddr* | *hostname*} [**master**] [**timeout** *timeout*] [**retry** *retries*]

no nbns-server

Syntax Description

hostname	Specifies the hostname for the NBNS server.
ipaddr	Specifies the IP address for the NBNS server.
master	Indicates that this is a master browser, rather than a WINS server.
retry	Indicates that a retry value follows.
retries	Specifies the number of times to retry queries to NBNS servers. The ASA recycles through the list of servers the number of times you specify here before sending an error message. The default value is 2; the range is 1 through 10.
timeout	Indicates that a timeout value follows.
timeout	Specifies the amount of time the ASA waits before sending the query again, to the same server if there is only one, or another server if there are multiple NBNS servers. The default timeout is 2 seconds; the range is 1 to 30 seconds.

Defaults

No NBNS server is configured by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	Moved from webvpn mode to tunnel-group webvpn configuration mode.

Usage Guidelines

This command is deprecated in webvpn configuration mode. The nbns-server command in tunnel-group webvpn-attributes configuration mode replaces it. In Release 7.1(1), if you enter this command in webvpn configuration mode, it is transformed to the same command in tunnel-group webvpn-attributes mode.

Maximum of 3 server entries. The first server you configure is the primary server, and the others are backups, for redundancy.

Use the **no** option to remove the matching entry from the configuration.

Examples

The following example shows how to configure an NBNS server that is a master browser with an IP address of 10.10.10.19, a timeout value of 10 seconds, and 8 retries. It also shows how to configure an NBNS WINS server with an IP address of 10.10.10.24, a timeout value of 15 seconds, and 8 retries.

```
hostname(config)# webvpn
hostname(config-webvpn)# nbns-server 10.10.10.19 master timeout 10 retry 8
hostname(config-webvpn)# nbns-server 10.10.10.24 timeout 15 retry 8
```

neighbor

To define a static neighbor on a point-to-point, non-broadcast network, use the **neighbor** command in router configuration mode. To remove the statically defined neighbor from the configuration, use the **no** form of this command.

neighbor *ip_address* [**interface** *name*]

no neighbor *ip_address* [**interface** *name*]

Syntax Description

interface *name*	(Optional) Specifies the interface name, as specified by the **nameif** command, through which the neighbor can be reached.
ip_address	Specifies the IP address of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **neighbor** command is used to advertise OSPF routes over VPN tunnels. One neighbor entry must be included for each known non-broadcast network neighbor. The neighbor address must be on the primary address of the interface.

The **interface** option needs to be specified when the neighbor is not on the same network as any of the directly connected interfaces of the system. Additionally, a static route must be created to reach the neighbor.

Examples

The following example defines a neighbor router with an address of 192.168.1.1:

```
hostname(config-router)# neighbor 192.168.1.1
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

neighbor (EIGRP)

To define an EIGRP neighbor router with which to exchange routing information, use the **neighbor** command in router configuration mode. To remove a neighbor entry, use the **no** form of this command.

neighbor *ip_address* **interface** *name*

no neighbor *ip_address* **interface** *name*

Syntax Description

interface *name*	The interface name, as specified by the **nameif** command, through which the neighbor can be reached.
ip_address	IP address of the neighbor router.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

You can use multiple neighbor statements to establish peering sessions with specific EIGRP neighbors. The interface through which EIGRP exchanges routing updates must be specified in the neighbor statement. The interfaces through which two EIGRP neighbors exchange routing updates must be configured with IP addresses from the same network.

Note Configuring the **passive-interface** command for an interface suppresses all incoming and outgoing routing updates and hello messages on that interface. EIGRP neighbor adjacencies cannot be established or maintained over an interface that is configured as passive.

EIGRP hello messages are sent as unicast messages to neighbors defined using the **neighbor** command.

Examples

The following example configures EIGRP peering sessions with the 192.168.1.1 and 192.168.2.2 neighbors:

```
hostname(config)# router eigrp 100
hostname(config-router)# network 192.168.0.0
```

```
hostname(config-router)# neighbor 192.168.1.1 interface outside
hostname(config-router)# neighbor 192.168.2.2 interface branch_office
```

Related Commands

Command	Description
debug eigrp neighbors	Displays debug information for EIGRP neighbor messages.
show eigrp neighbors	Displays the EIGRP neighbor table.

nem

To enable network extension mode for hardware clients, use the **nem enable** command in group-policy configuration mode. To disable NEM, use the **nem disable** command. To remove the NEM attribute from the running configuration, use the **no** form of this command. This option allows inheritance of a value from another group policy.

nem {**enable** | **disable**}

no nem

Syntax Description

disable	Disables Network Extension Mode.
enable	Enables Network Extension Mode.

Defaults

Network extension mode is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policyconfiguration	•	—	•	—	—

Usage Guidelines

Network Extension mode lets hardware clients present a single, routable network to the remote private network over the VPN tunnel. IPsec encapsulates all traffic from the private network behind the hardware client to networks behind the ASA. PAT does not apply. Therefore, devices behind the ASA have direct access to devices on the private network behind the hardware client over the tunnel, and only over the tunnel, and vice versa. The hardware client must initiate the tunnel, but after the tunnel is up, either side can initiate data exchange.

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set NEM for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# nem enable
```

network

To specify a list of networks for the RIP routing process, use the **network** command in router configuration mode. To remove a network definition, use the **no** form of this command.

network *ip_addr*

no network *ip_addr*

Syntax Description

ip_addr	The IP address of a directly connected network. The interface connected to the specified network will participate in the RIP routing process.

Defaults

No networks are specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The network number specified must not contain any subnet information. There is no limit to the number of network commands you can use on the router. RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP update.

Examples

The following example defines RIP as the routing protocol to be used on all interfaces connected to networks 10.0.0.0 and 192.168.7.0:

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# network 192.168.7.0
```

Related Commands

Command	Description
router rip	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

network (EIGRP)

To specify a list of networks for the EIGRP routing process, use the **network** command in router configuration mode. To remove a network definition, use the **no** form of this command.

network *ip_addr* [*mask*]

no network *ip_addr* [*mask*]

Syntax Description

ip_addr	The IP address of a directly connected network. The interface connected to the specified network will participate in the EIGRP routing process.
mask	(Optional) The network mask for the IP address.

Defaults

No networks are specified.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **network** command starts EIGRP on all interfaces with at least one IP address in the specified network. It inserts the connected subnet from the specified network in the EIGRP topology table.

The ASA then establishes neighbors through the matched interfaces. There is no limit to the number of **network** commands that can be configured on the ASA.

Examples

The following example defines EIGRP as the routing protocol to be used on all interfaces connected to networks 10.0.0.0 and 192.168.7.0:

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0 255.0.0.0
hostname(config-router)# network 192.168.7.0 255.255.255.0
```

Related Commands

Command	Description
show eigrp interfaces	Displays information about interfaces configured for EIGRP.
show eigrp topology	Displays the EIGRP topology table.

network-acl

To specify a firewall ACL name that you configured previously using the **access-list** command, use the **network-acl** command in dynamic-access-policy-record configuration mode. To remove an existing network ACL, use the **no** form of this command. To remove all network ACL, use the command without arguments.

network-acl *name*

no network-acl [*name*]

Syntax Description

name	Specifies the name of the network ACL. Maximum 240 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Dynamic-access-policy-record configuration	•	•	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use this command multiple time to assign multiple firewall ACLs to the DAP record.

The ASA verifies each of the ACLs you specify to make sure they contain only permit rules or only deny rules for the access-list entries. If any of the specified ACLs contain mixed permit and deny rules, then the ASA rejects the command.

The following example shows how to apply a network ACL called Finance Restrictions to the DAP record named Finance.

```
hostname(config)# dynamic-access-policy-record Finance
hostname(config-dynamic-access-policy-record)# network-acl Finance Restrictions
hostname(config-dynamic-access-policy-record)#
```

Related Commands

Command	Description
access-policy	Configures a firewall access policy.

Command	Description
dynamic-access-policy-record	Creates a DAP record.
show running-config dynamic-access-policy-record [*name*]	Displays the running configuration for all DAP records, or for the named DAP record.

network area

To define the interfaces on which OSPF runs and to define the area ID for those interfaces, use the **network area** command in router configuration mode. To disable OSPF routing for interfaces defined with the address/netmask pair, use the **no** form of this command.

network *addr mask* **area** *area_id*

no network *addr mask* **area** *area_id*

Syntax Description

addr	IP address.
area *area_id*	Specifies the area that is to be associated with the OSPF address range. The *area_id* can be specified in either IP address format or in decimal format. When specified in decimal format, valid values range from 0 to 4294967295.
mask	The network mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

For OSPF to operate on the interface, the address of the interface must be covered by the **network area** command. If the **network area** command does not cover the IP address of the interface, it will not enable OSPF over that interface.

There is no limit to the number of **network area** commands you can use on the ASA.

Examples

The following example enables OSPF on the 192.168.1.1 interface and assigns it to area 2:

```
hostname(config-router)# network 192.168.1.1 255.255.255.0 area 2
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

network-object

To add a host object, a network object, or a subnet object to a network object group, use the **network-object** command in object-group network configuration mode. To remove network objects, use the **no** form of this command.

network-object {host *ip_address* **|** *ip_address mask* **| object** *name*}

no network-object {host *ip_address* **|** *ip_address mask* **| object** *name*}

Syntax Description

host *ip_address*	Specifies a host IP address.
ip_address mask	Specifies the network address and subnet mask.
object *name*	Specifies a network object (**object network** command).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object-group network configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	The **object** argument was added to support network objects (**object network** command).

Usage Guidelines

The **network-object** command is used with the **object-group** command to define a host object, a network object, or a subnet object.

Examples

The following example shows how to use the **network-object** command to create a new host object in a network object group:

```
hostname(config)# object-group network sjj_eng_ftp_servers
hostname(config-network-object-group)# network-object host sjj.eng.ftp
hostname(config-network-object-group)# network-object host 172.16.56.195
hostname(config-network-object-group)# network-object 192.168.1.0 255.255.255.224
hostname(config-network-object-group)# group-object sjc_eng_ftp_servers
hostname(config)#
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object-group** commands from the configuration.
group-object	Adds network object groups.
object network	Adds a network object.
object-group network	Defines network object groups.
service-object	Adds a service object to a service object group.
show running-config object-group	Displays the current object groups.

nop

To define an action when the No Operation IP option occurs in a packet with IP Options inspection, use the **nop** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

nop action {allow | clear}

no nop action {allow | clear}

Syntax Description

allow	Instructs the ASA to allow a packet containing the No Operation IP option to pass.
clear	Instructs the ASA to clear the No Operation IP option from a packet and then allow the packet to pass.

Defaults

By default, IP Options inspection, drops packets containing the No Operation IP option.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

This command can be configured in an IP Options inspection policy map.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the ASA. Configuring this inspection instructs the ASA to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

The Options field in the IP header can contain zero, one, or more options, which makes the total length of the field variable. However, the IP header must be a multiple of 32 bits. If the number of bits of all options is not a multiple of 32 bits, the No Operation (NOP) or IP Option 1 is used as “internal padding” to align the options on a 32-bit boundary.

Examples

The following example shows how to set up an action for IP Options inspection in a policy map:

```
hostname(config)# policy-map type inspect ip-options ip-options_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# eool action allow
hostname(config-pmap-p)# nop action allow
```

```
hostname(config-pmap-p)# router-alert action allow
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

nt-auth-domain-controller

To specify the name of the NT Primary Domain Controller for this server, use the **nt-auth-domain-controller** command in aaa-server host configuration mode. To remove this specification, use the **no** form of this command.

nt-auth-domain-controller *string*

no nt-auth-domain-controller

Syntax Description

string	Specifies the name, up to 16 characters long, of the Primary Domain Controller for this server.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for NT Authentication AAA servers. You must have first used the **aaa-server host** command to enter host configuration mode. The name in the *string* variable must match the NT entry on the server itself.

Examples

The following example configures the name of the NT Primary Domain Controller for this server as "primary1":

```
hostname(config)# aaa-server svrgrp1 protocol nt
hostname(configaaa-sesrver-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# nt-auth-domain-controller primary1
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa server host	Enters aaa server host configuration mode so that you can configure AAA server parameters that are host-specific.

clear configure aaa-server	Remove all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

ntp authenticate

To enable authentication with an NTP server, use the **ntp authenticate** command in global configuration mode. To disable NTP authentication, use the **no** form of this command.

ntp authenticate

no ntp authenticate

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you enable authentication, the ASA only communicates with an NTP server if it uses the correct trusted key in the packets (see the **ntp trusted-key** command). The ASA also uses an authentication key to synchronize with the NTP server (see the **ntp authentication-key** command).

Examples

The following example configures the ASA to synchronize only to systems that provide authentication key 42 in their NTP packets:

```
hostname(config)# ntp authenticate
hostname(config)# ntp authentication-key 42 md5 aNiceKey
hostname(config)# ntp trusted-key 42
```

Related Commands

Command	Description
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.

Command	Description
show ntp associations	Shows the NTP servers with which the ASA is associated.
show ntp status	Shows the status of the NTP association.

ntp authentication-key

To set a key to authenticate with an NTP server, use the **ntp authentication-key** command in global configuration mode. To remove the key, use the **no** form of this command.

ntp authentication-key *key_id* **md5** *key*

no ntp authentication-key *key_id* [**md5** [0 | 8] *key*]

Syntax Description

0	(optional) Indicates <key_value> is plain text. Format is plain text if 0 or 8 is not present.
8	(optional) Indicates <key_value> is encrypted text. Format is plain text if 0 or 8 is not present.
key	Sets the key value as a string up to 32 characters in length.
key_id	Identifies a key ID between 1 and 4294967295. You must specify this ID as a trusted key using the **ntp trusted-key** command.
md5	Specifies the authentication algorithm as MD5, which is the only algorithm supported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To use NTP authentication, also configure the **ntp authenticate** command.

Examples

The following example enables authentications, identifies trusted key IDs 1 and 2, and sets authentication keys for each trusted key ID:

```
hostname(config)# ntp authenticate
hostname(config)# ntp trusted-key 1
hostname(config)# ntp trusted-key 2
hostname(config)# ntp authentication-key 1 md5 aNiceKey
hostname(config)# ntp authentication-key 2 md5 aNiceKey2
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp server	Identifies an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp associations	Shows the NTP servers with which the ASA is associated.
show ntp status	Shows the status of the NTP association.

ntp server

To identify an NTP server to set the time on the ASA, use the **ntp server** command in global configuration mode. To remove the server, use the **no** form of this command.

ntp server *ip_address* [**key** *key_id*] [**source** *interface_name*] [**prefer**]

no ntp server *ip_address* [**key** *key_id*] [**source** *interface_name*] [**prefer**]

Syntax Description

ip_address	Sets the IP address or hostname of the NTP server.
key *key_id*	If you enable authentication using the **ntp authenticate** command, sets the trusted key ID for this server. See also the **ntp trusted-key** command.
source *interface_name*	Identifies the outgoing interface for NTP packets if you do not want to use the default interface in the routing table. Because the system does not include any interfaces in multiple context mode, specify an interface name defined in the admin context.
prefer	Sets this NTP server as the preferred server if multiple servers have similar accuracy. NTP uses an algorithm to determine which server is the most accurate and synchronizes to that one. If servers are of similar accuracy, then the **prefer** keyword specifies which of those servers to use. However, if a server is significantly more accurate than the preferred one, the ASA uses the more accurate one. For example, the ASA uses a server of stratum 2 over a server of stratum 3 that is preferred.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to make the source interface optional.

Usage Guidelines

You can identify multiple servers; the ASA uses the most accurate server. In multiple context mode, set the NTP server in the system configuration only.

Examples

The following example identifies two NTP servers and enables authentication for the key IDs 1 and 2:

```
hostname(config)# ntp server 10.1.1.1 key 1 prefer
```

```
hostname(config)# ntp server 10.2.1.1 key 2
hostname(config)# ntp authenticate
hostname(config)# ntp trusted-key 1
hostname(config)# ntp trusted-key 2
hostname(config)# ntp authentication-key 1 md5 aNiceKey
hostname(config)# ntp authentication-key 2 md5 aNiceKey2
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp trusted-key	Provides a key ID for the ASA to use in packets for authentication with an NTP server.
show ntp associations	Shows the NTP servers with which the ASA is associated.
show ntp status	Shows the status of the NTP association.

ntp trusted-key

To specify an authentication key ID to be a trusted key, which is required for authentication with an NTP server, use the **ntp trusted-key** command in global configuration mode. To remove the trusted key, use the **no** form of this command. You can enter multiple trusted keys for use with multiple servers.

ntp trusted-key *key_id*

no ntp trusted-key *key_id*

Syntax Description

key_id	Sets a key ID between 1 and 4294967295.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To use NTP authentication, also configure the **ntp authenticate** command. To synchronize with a server, set the authentication key for the key ID using the **ntp authentication-key** command.

Examples

The following example enables authentications, identifies trusted key IDs 1 and 2, and sets authentication keys for each trusted key ID:

```
hostname(config)# ntp authenticate
hostname(config)# ntp trusted-key 1
hostname(config)# ntp trusted-key 2
hostname(config)# ntp authentication-key 1 md5 aNiceKey
hostname(config)# ntp authentication-key 2 md5 aNiceKey2
```

Related Commands

Command	Description
ntp authenticate	Enables NTP authentication.
ntp authentication-key	Sets an encrypted authentication key to synchronize with an NTP server.
ntp server	Identifies an NTP server.

Command	Description
show ntp associations	Shows the NTP servers with which the ASA is associated.
show ntp status	Shows the status of the NTP association.

num-packets

To specify the number of request packets sent during an SLA operation, use the **num-packets** command in sla monitor protocol configuration mode. To restore the default value, use the **no** form of this command.

num-packets *number*

no num-packets *number*

Syntax Description

number	The number of packets sent during an SLA operation. Valid values are from 1 to 100.

Defaults

The default number of packets sent for echo types is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
sla monitor protocol configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Increase the default number of packets sent to prevent incorrect reachability information due to packet loss.

Examples

The following example configures an SLA operation with an ID of 123 that uses an ICMP echo request/response time probe operation. It sets the payload size of the echo request packets to 48 bytes and the number of echo requests sent during an SLA operation to 5.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# num-packets 5
hostname(config-sla-monitor-echo)# request-data-size 48
hostname(config-sla-monitor-echo)# timeout 4000
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
request-data-size	Specifies the size of the request packet payload.
sla monitor	Defines an SLA monitoring operation.
type echo	Configures the SLA operation as an echo response time probe operation.

CHAPTER 37

object network through override-svc-download Commands

object network

To configure a named network object, use the **object network** command in global configuration mode. Use the **no** form of this command to remove the object from the configuration.

object network *name* [**rename** *new_obj_name*]

no object network *name*

Syntax Description

name	Specifies the name of the network object. The name can be from 1 to 64 characters in length, consisting of letters, numbers, and the following special characters: underscore, hyphen, comma, forward slash, and period. Objects and object groups share the same name space.
rename *new_obj_name*	(Optional) Renames the object to the new object name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
8.4(2)	Support for FQDNs was introduced. See the **fqdn** command.

Usage Guidelines

The network object can contain a host, a network, a range IP addresses (IPv4 or IPv6), or an FQDN.

You can also enable NAT rules on this network object. You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules, you need to create multiple objects that specify the same IP address, for example, **object network obj-10.10.10.1-01**, object network obj-10.10.10.1-02, and so on.

If you configure an existing network object with a different IP address, the new configuration will replace the existing configuration.

You cannot remove an object or make an object empty if it is used in a command.

Examples

The following example shows how to create a network object:

```
hostname (config)# object network OBJECT1
hostname (config-network-object)# host 10.1.1.1
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
description	Adds a description to the network object.
fqdn	Specifies a fully-qualified domain name network object.
host	Specifies a host network object.
nat	Enables NAT for the network object.
object-group network	Creates a network object group.
range	Specifies a range of addresses for the network object.
show running-config object network	Shows the network object configuration.
subnet	Specifies a subnet network object.

object service

To configure a service object that is automatically reflected in all configurations in which the object is used, use the **object service** command in global configuration mode. Use the **no** form of this command to remove the object.

object service *name* [**rename** *new_obj_name*]

no object service *object name* [**rename** *new_obj_name*]

Syntax Description

name	Specifies the name of the existing service object. The name can be from 1 to 64 characters in length, consisting of letters, numbers, and the following special characters: underscore, hyphen, comma, and period. The object name must start with a letter.
rename *new_obj_name*	(Optional) Renames the object to the new object name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

The service object can contain a protocol, ICMP, ICMPv6, TCP or UDP port or port ranges.

If you configure an existing service object with a different protocol and port (or ports), the new configuration replaces the existing protocol and port (or ports) with the new ones.

Examples

The following example shows how to create a service object:

```
hostname(config)# object service SERVOBJECT1
hostname(config-service-object)# service tcp source eq www destination eq ssh
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
service	Configures the protocol and port for the service object.

object-group

To define object groups that you can use to optimize your configuration, use the **object-group** command in global configuration mode. Use the **no** form of this command to remove object groups from the configuration. This command supports IPv4 and IPv6 addresses.

object-group {**protocol** | **network** | **icmp-type** | **security** | **service** [**tcp** | **udp** | **tcp-udp**] | **user**} *grp_name*

Syntax Description

grp_name	Identifies the object group (one to 64 characters) and can be any combination of letters, digits, and the "_", "-", "." characters.
icmp-type	Defines a group of ICMP types such as echo and echo-reply. After entering the main **object-group icmp-type** command, add ICMP objects to the ICMP type group with the **icmp-object** and the **group-object** commands.
network	Defines a group of hosts or subnet IP addresses. After entering the main **object-group network** command, add network objects to the network group with the **network-object** and the **group-object** commands. You can create a group with a mix of IPv4 and IPv6 addresses. **Note** You cannot use a mixed object group for NAT.
protocol	Defines a group of protocols such as TCP and UDP. After entering the main **object-group protocol** command, add protocol objects to the protocol group with the **protocol-object** and the **group-object** commands.
security	Creates a security group object for use with Cisco TrustSec.
service	Defines a group of ports for a protocol (TCP, UDP, or TCP-UDP), or a group of services (a mix of protocols and ports). To define a group of ports, use the **tcp**, **udp**, or **tcp-udp** keywords. After entering the main **object-group service** *protocol* command, add port objects to the service group with the **port-object** and the **group-object** commands. To define a mixed group of services, do not specify the protocol type for the object-group. After entering the main **object-group service** command, add service objects to the service group with the **service-object** and the **group-object** commands.
tcp	(Optional) Specifies that the service group is used for TCP.
tcp-udp	(Optional) Specifies that the service group is used for ports in both TCP and UDP.
udp	(Optional) Specifies that the service group is used for UDP.
user	Defines object groups that you can use to control access with the Identity Firewall.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.
8.4(2)	We added support for the **user** keyword to support Identity Firewall.
9.0(1)	You can now create network object groups that can support a mix of both IPv4 and IPv6 addresses. We added support for the **security** keyword to support Cisco TrustSec.

Usage Guidelines

Objects such as hosts, protocols, or services can be grouped, and then you can use the object group in features such as ACLs (**access-list**) and NAT (**nat**). This example shows the use of a network object group in an ACL:

```
hostname(config)# access-list access_list_name permit tcp any object-group NWgroup1
```

You can group commands hierarchically; an object group can be a member of another object group.

You cannot remove or empty an object group if it is currently being used in a command.

Examples

The following example shows how to use the **object-group icmp-type** mode to create a new icmp-type object group:

```
hostname(config)# object-group icmp-type icmp-allowed
hostname(config-icmp-object-group)# icmp-object echo
hostname(config-icmp-object-group)# icmp-object time-exceeded
hostname(config-icmp-object-group)# exit
```

The following example shows how to use the **object-group network** command to create a new network object group:

```
hostname(config)# object-group network sjc_eng_ftp_servers
hostname(config-network-object-group)# network-object host sjc.eng.ftp.servcers
hostname(config-network-object-group)# network-object host 172.23.56.194
hostname(config-network-object-group)# network-object 192.1.1.0 255.255.255.224
hostname(config-network-object-group)# exit
```

The following example shows how to use the **object-group network** command to create a new network object group and map it to an existing object-group:

```
hostname(config)# object-group network sjc_ftp_servers
hostname(config-network-object-group)# network-object host sjc.ftp.servers
hostname(config-network-object-group)# network-object host 172.23.56.195
hostname(config-network-object-group)# network-object 193.1.1.0 255.255.255.224
hostname(config-network-object-group)# group-object sjc_eng_ftp_servers
hostname(config-network-object-group)# exit
```

The following example shows how to use the **object-group protocol** mode to create a new protocol object group:

```
hostname(config)# object-group protocol proto_grp_1
hostname(config-protocol-object-group)# protocol-object udp
hostname(config-protocol-object-group)# protocol-object ipsec
hostname(config-protocol-object-group)# exit

hostname(config)# object-group protocol proto_grp_2
hostname(config-protocol-object-group)# protocol-object tcp
hostname(config-protocol-object-group)# group-object proto_grp_1
hostname(config-protocol-object-group)# exit
```

The following example shows how to use the **object-group service** mode to create a new port (service) object group:

```
hostname(config)# object-group service eng_service tcp
hostname(config-service-object-group)# group-object eng_www_service
hostname(config-service-object-group)# port-object eq ftp
hostname(config-service-object-group)# port-object range 2000 2005
hostname(config-service-object-group)# exit
```

The following example shows how to add and remove a text description to an object group:

```
hostname(config)# object-group protocol protos1
hostname(config-protocol-object-group)# description This group of protocols is for our
internal network

hostname(config-protocol-object-group)# show running-config object-group id protos1
object-group protocol protos1
description: This group of protocols is for our internal network

hostname(config-protocol-object-group)# no description
hostname(config-protocol-object-group)# show running-config object-group id protos1
object-group protocol protos1
```

The following example shows how to use the **group-object** mode to create a new object group that consists of previously defined objects:

```
hostname(config)# object-group network host_grp_1
hostname(config-network-object-group)# network-object host 192.168.1.1
hostname(config-network-object-group)# network-object host 192.168.1.2
hostname(config-network-object-group)# exit

hostname(config)# object-group network host_grp_2
hostname(config-network-object-group)# network-object host 172.23.56.1
hostname(config-network-object-group)# network-object host 172.23.56.2
hostname(config-network-object-group)# exit

hostname(config)# object-group network all_hosts
hostname(config-network-object-group)# group-object host_grp_1
hostname(config-network-object-group)# group-object host_grp_2
hostname(config-network-object-group)# exit

hostname(config)# access-list grp_1 permit tcp object-group host_grp_1 any eq ftp
hostname(config)#access-list grp_2 permit tcp object-group host_grp_2 any eq smtp
hostname(config)#access-list all permit tcp object-group all_hosts any eq www
```

Without the **group-object** command, you need to define the *all_hosts* group to include all the IP addresses that have already been defined in *host_grp_1* and *host_grp_2*. With the **group-object** command, the duplicated definitions of the hosts are eliminated.

The following examples show how to use object groups to simplify the access list configuration:

```
hostname(config)# object-group network remote
hostname(config-network-object-group)# network-object host kqk.suu.dri.ixx
hostname(config-network-object-group)# network-object host kqk.suu.pyl.gnl

hostname(config)# object-group network locals
hostname(config-network-object-group)# network-object host 209.165.200.225
hostname(config-network-object-group)# network-object host 209.165.200.230
hostname(config-network-object-group)# network-object host 209.165.200.235
hostname(config-network-object-group)# network-object host 209.165.200.240

hostname(config)# object-group service eng_svc tcp
hostname(config-service-object-group)# port-object eq www
hostname(config-service-object-group)# port-object eq smtp
hostname(config-service-object-group)# port-object range 25000 25100
```

This grouping enables the access list to be configured in 1 line instead of 24 lines, which would be needed if no grouping is used. Instead, with the grouping, the access list configuration is as follows:

```
hostname(config)# access-list acl permit tcp object-group remote object-group locals
object-group eng_svc
```

The following example shows how to use the **service-object** subcommand, which is useful for grouping TCP and UDP services:

```
hostname(config)# object-group network remote
hostname(config-network-object-group)# network-object host kqk.suu.dri.ixx
hostname(config-network-object-group)# network-object host kqk.suu.pyl.gnl

hostname(config)# object-group network locals
hostname(config-network-object-group)# network-object host 209.165.200.225
hostname(config-network-object-group)# network-object host 209.165.200.230
hostname(config-network-object-group)# network-object host 209.165.200.235
hostname(config-network-object-group)# network-object host 209.165.200.240

hostname(config)# object-group service usr_svc
hostname(config-service-object-group)# service-object tcp destination eq www
hostname(config-service-object-group)# service-object tcp destination eq https
hostname(config-service-object-group)# service-object tcp destination eq pop3
hostname(config-service-object-group)# service-object udp destination eq ntp
hostname(config-service-object-group)# service-object udp destination eq domain

hostname(config)# access-list acl permit object-group usr_svc object-group locals
object-group remote
```

Note The **show running-config object-group** and **write** commands allow you to display the access list as configured with the object group names. The **show access-list** command displays the access list entries that are expanded out into individual entries without their object groupings.

Related Commands

Command	Description
clear configure object-group	Removes all the **object group** commands from the configuration.
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.

Command	Description
port-object	Adds a port object to a service object group.
show running-config object-group	Displays the current object groups.

object-group user

To create a user group object that support the Identity Firewall feature, use the **object-group user** command in global configuration mode. Use the **no** form of this command to disable the user group object.

object-group user *user_group_name*

[no] object-group user *user_group_name*

Syntax Description

user_group_name	Specifies the name for the user group. The group name can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.]. If the group name contains a space, you must enclose the name in quotation marks.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.4(2)	This command was introduced.

Usage Guidelines

The ASA sends an LDAP query to the Active Directory server for user groups globally defined in the Active Directory domain controller. The ASA imports these groups for the Identity Firewall feature. However, the ASA might have localized network resources that are not defined globally that require local user groups with localized security policies. Local user groups can contain nested groups and user groups that are imported from Active Directory. The ASA consolidates local and Active Directory groups. A user can belong to local user groups and user groups imported from Active Directory.

The ASA supports up to 256 user groups (including imported user groups and local user groups).

You active user group objects by including them within an access group, capture, or service policy.

Within a user group object, you can define the following object types:

- **User**—Adds a single user to the object-group user.

  The user can be either a LOCAL user or imported user. The *user_name* argument that you specify with the **user** keyword contains an ASCII user name and does not specify an IP address.

The name of an imported user must be the sAMAccountName, which is unique, rather than the common name (cn), which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used for imported users defined by the user object.

- **User-group**—Adds an imported user group, which is defined by an external directory server, such as Microsoft Active Directory server, to the group-object user.

  The group name of the user-group must be the sAMAccountName, which is unique, rather than the cn, which might not be unique. However, some Active Directory server administrators might require that the sAMAccountName and the cn be identical. In this case, the cn that the ASA displays in the output of the **show user-identity ad-group-member** command can be used in the *user_group_name* argument specified with the **user-group** keyword.

  Note You can add *domain_nickname**user_group_name* or *domain_nickname**user_ name* directly within a user group object without specifying them in the object first. If the *domain_nickname* is associated with a AAA server, the ASA imports the detailed nested user groups and the users defined in the external directory server, such as the Microsoft Active Directory server, to the ASA when the user object group is activated.

- **Group-object**—Adds a group defined locally on the ASA to the object-group user.

  Note When including an object-group within a object-group user object, the ASA does not expand the object-group in access groups even when you enable ACL optimization. The output of the **show object-group** command does not display the hit count, which is available only for regular network object-group when ACL optimization is enabled.

- **Description**—Adds a description for the object-group user.

Examples

The following example shows how to use the **object-group user** command to create user group objects for use with the Identity Firewall feature:

```
hostname(config)# object-group user sampleuser1-group
hostname(config-object-group user)# description group members of sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-all
hostname(config-object-group user)# user CSCO\user2
hostname(config-object-group user)# exit
hostname(config)# object-group user sampleuser2-group
hostname(config-object-group user)# description group members of sampleuser2-group
hostname(config-object-group user)# group-object sampleuser1-group
hostname(config-object-group user)# user-group CSCO\\group.sampleusers-marketing
hostname(config-object-group user)# user CSCO\user3
```

Related Commands

Command	Description
description	Adds a description to the group created with the **object-group user** command.
group-object	Adds a locally defined object group to a user object group created with the **object-group user** command for use with the Identity Firewall feature.

Command	Description
user	Adds a user to the group created with the **object-group user** command.
user-group	Adds a user group imported from Microsoft Active Directory to the group created with the **object-group user** command.
user-identity enable	Creates the Cisco Identify Firewall instance.

object-group-search

To enable ACL optimization, use the **object-group-search** command in global configuration mode. Use the **no** form of this command to disable ACL optimization.

object-group-search access-control

no object-group-search access-control

Syntax Description

access-control	Searches for the access-control domain.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

The **object-group-search** command optimizes all ACLs in the inbound direction.

When the **object-group-search** command is enabled, all of the old NP rules are removed from the soft-NP and reinserted with object-group IDs. When the command is disabled, all of the old rules are removed from the soft-NP and reinserted by expanding the object groups.

When the **object-group-search access-control** command is enabled on an ASA, with a significant number of features enabled, a large number of active connections and loaded with a large ACL, there will be a connection drop during the operation and a performance drop while establishing new connections.

Examples

The following example shows how to use the **object-group-search** command to enable ACL optimization:

```
hostname(config)# object-group-search access-control
```

The following is sample output from the **show access-list** command when **object-group-search** is not enabled:

```
hostname# show access-list KH-BLK-Tunnel
access-list KH-BLK-Tunnel; 9 elements
```

```
access-list KH-BLK-Tunnel line 1 extended permit ip object-group KH-LAN object-group
BLK-LAN 0x724c956b
   access-list KH-BLK-Tunnel line 1 extended permit ip 192.168.97.0 255.255.255.0

Related Commands

Command	Description
clear config object-group search	Clears the object-group-search configuration.
show object-group	Shows the hit count if the object group is of the network object-group type.
show running-config object-group	Displays the current object groups.
show running-config object-group-search	Show the object-group-search configuration in the running configuration.

ocsp disable-nonce

To disable the nonce extension, use the **ocsp disable-nonce** command in crypto ca trustpoint configuration mode. To re-enable the nonce extension, use the **no** form of this command.

ocsp disable-nonce

no ocsp disable-nonce

Syntax Description

This command has no arguments or keywords.

Defaults

By default, OCSP requests include a nonce extension.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

When you use this command, the OCSP request does not include the OCSP nonce extension, and the ASA does not check it. By default, OCSP requests include a nonce extension, which cryptographically binds requests with responses to avoid replay attacks. However, some OCSP servers use pre-generated responses that do not contain this matching nonce extension. To use OCSP with these servers, you must disable the nonce extension.

Examples

The following example shows how to disable the nonce extension for a trustpoint called newtrust.

```
hostname(config)# crypto ca trustpoint newtrust
hostname(config-ca-trustpoint)# ocsp disable-nonce
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode. Use this command in global configuration mode.
match certificate	Configures an OCSP override rule.

Command	Description
ocsp url	Specifies the OCSP server to use to check all certificates associated with a trustpoint.
revocation-check	Specifies the method(s) to use for revocation checking, and the order in which to try them.

ocsp url

To configure an OCSP server for the ASA to use to check all certificates associated with a trustpoint rather than the server specified in the AIA extension of the client certificate, use the **ocsp url** command in crypto ca trustpoint configuration mode. To remove the server from the configuration, use the **no** form of this command.

ocsp url *URL*

no ocsp url

Syntax Description

URL	Specifies the HTTP URL for the OCSP server.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The ASA supports only HTTP URLs, and you can specify only one URL per trustpoint.

The ASA provides three ways to define an OCSP server URL, and it attempts to use OCSP servers according to how you define them, in the following order:

- An OCSP server you set using **match certificate** command.
- An OCSP server you set using the **ocsp url** command.
- The OCSP server in the AIA field of the client certificate.

If you do not configure an OCSP URL via the **match certificate** command or the **ocsp url** command, the ASA uses the OCSP server in the AIA extension of the client certificate. If the certificate does not have an AIA extension, revocation status checking fails.

Examples

The following example shows how to configure an OCSP server with the URL http://10.1.124.22.

```
hostname(config)# crypto ca trustpoint newtrust
hostname(config-ca-trustpoint)# ocsp url http://10.1.124.22
hostname(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpoint	Enters crypto ca trustpoint configuration mode. Use this command in global configuration mode.
match certificate	Configures an OCSP override rule,
ocsp disable-nonce	Disables the nonce extension of the OCSP request.
revocation-check	Specifies the method(s) to use for revocation checking, and the order in which to try them.

onscreen-keyboard

To insert an onscreen keyboard into the logon pane or all panes with a login/password requirement, use the **onscreen-keyboard** command in webvpn mode. To remove a previously configured onscreen keyboard, use the **no** version of the command.

onscreen-keyboard {logon | all}

no onscreen-keyboard [logon | all]

Syntax Description

logon	Inserts the onscreen keyboard for the logon pane.
all	Inserts the onscreen keyboard for the logon pane, and for all other panes with a login/password requirement.

Defaults

No onscreen keyboard.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The onscreen keyboard lets you enter user credentials without keystrokes.

Examples

The following example shows how to enable the onscreen keyboard for the logon page:

```
hostname(config)# webvpn
hostname(config-webvpn)# onscreen-keyboard logon
hostname(config-webvpn)#
```

Related Commands

Command	Description
webvpn	Enters webvpn mode, which lets you configure attributes for clientless SSLVPN connections.

ospf authentication

To enable the use of OSPF authentication, use the **ospf authentication** command in interface configuration mode. To restore the default authentication stance, use the **no** form of this command.

ospf authentication [**message-digest** | **null**]

no ospf authentication

Syntax Description

message-digest	(Optional) Specifies to use OSPF message digest authentication.
null	(Optional) Specifies to not use OSPF authentication.

Defaults

By default, OSPF authentication is not enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Before using the **ospf authentication** command, configure a password for the interface using the **ospf authentication-key** command. If you use the **message-digest** keyword, configure the message-digest key for the interface with the **ospf message-digest-key** command.

For backward compatibility, authentication type for an area is still supported. If the authentication type is not specified for an interface, the authentication type for the area will be used (the area default is null authentication).

When this command is used without any options, simple password authentication is enabled.

Examples

The following example shows how to enable simple password authentication for OSPF on the selected interface:

```
hostname(config-if)# ospf authentication
hostname(config-if)#
```

Related Commands

Command	Description
ospf authentication-key	Specifies the password used by neighboring routing devices.
ospf message-digest-key	Enables MD5 authentication and specifies the MD5 key.

ospf authentication-key

To specify the password used by neighboring routing devices, use the **ospf authentication-key** command in interface configuration mode. To remove the password, use the **no** form of this command.

ospf authentication-key [**0** | **8**] *password*

no ospf authentication-key

Syntax Description<

0	Specifies an unencrypted password will follow
8	Specifies an encrypted password will follow.
password	Assigns an OSPF authentication password for use by neighboring routing devices. The password must be less than 9 characters. You can include blank space between two characters. Spaces at the beginning or end of the password are ignored.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The password created by this command is used as a key that is inserted directly into the OSPF header when routing protocol packets are originated. A separate password can be assigned to each network on a per-interface basis. All neighboring routers on the same network must have the same password to be able to exchange OSPF information.

ExamplesNote

The following example shows how to specify a password for OSPF authentication:

```
hostname(config-if)# ospf authentication-key 8 yWIvi0qJAnGK5MRWQzrhIohkGP1wKb
```

Related Commands

Command	Description
area authentication	Enables OSPF authentication for the specified area.
ospf authentication	Enables the use of OSPF authentication.

ospf cost

To specify the cost of sending a packet through the interface, use the **ospf cost** command in interface configuration mode. To reset the interface cost to the default value, use the **no** form of this command.

ospf cost *interface_cost*

no ospf cost

Syntax Description

interface_cost	The cost (a link-state metric) of sending a packet through an interface. This is an unsigned integer value from 0 to 65535. 0 represents a network that is directly connected to the interface, and the higher the interface bandwidth, the lower the associated cost to send packets across that interface. In other words, a large cost value represents a low bandwidth interface and a small cost value represents a high bandwidth interface. The OSPF interface default cost on the ASA is 10. This default differs from Cisco IOS software, where the default cost is 1 for Fast Ethernet and Gigabit Ethernet and 10 for 10BaseT. This is important to take into account if you are using ECMP in your network.

Defaults

The default *interface_cost* is 10.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **ospf cost** command lets you explicitly specify the cost of sending a packet on an interface. The *interface_cost* parameter is an unsigned integer value from 0 to 65535.

The **no ospf cost** command allows you to reset the path cost to the default value.

Examples

The following example show how to specify the cost of sending a packet on the selected interface:

```
hostname(config-if)# ospf cost 4
```

Related Commands

Command	Description
show running-config interface	Displays the configuration of the specified interface.

ospf database-filter

To filter out all outgoing LSAs to an OSPF interface during synchronization and flooding, use the **ospf database-filter** command in interface configuration mode. To restore the LSAs, use the **no** form of this command.

ospf database-filter all out

no ospf database-filter all out

Syntax Description

all out	Filters all outgoing LSAs to an OSPF interface.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **ospf database-filter** command filters outgoing LSAs to an OSPF interface. The **no ospf database-filter all out** command restores the forwarding of LSAs to the interface.

Examples

The following example shows how to use the **ospf database-filter** command to filter outgoing LSAs:

```
hostname(config-if)# ospf database-filter all out
```

Related Commands

Command	Description
show interface	Displays interface status information.

ospf dead-interval

To specify the interval before neighbors declare a router down, use the **ospf dead-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

ospf dead-interval *seconds*

no ospf dead-interval *seconds*

Syntax Description

seconds	The length of time during which no hello packets are seen. The default for *seconds* is four times the interval set by the **ospf hello-interval** command (which ranges from 1 to 65535).

Defaults

The default value for *seconds* is four times the interval set by the **ospf hello-interval** command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **ospf dead-interval** command lets you set the dead interval before neighbors to declare the router down (the length of time during which no hello packets are seen). The *seconds* argument specifies the dead interval and must be the same for all nodes on the network. The default for *seconds* is four times the interval set by the **ospf hello-interval** command from 1 to 65535.

The **no ospf dead-interval** command restores the default interval value.

Examples

The following example sets the OSPF dead interval to 1 minute:

```
hostname(config-if)# ospf dead-interval 60
```

Related Commands

Command	Description
ospf hello-interval	Specifies the interval between hello packets sent on an interface.
show ospf interface	Displays OSPF-related interface information.

ospf hello-interval

To specify the interval between hello packets sent on an interface, use the **ospf hello-interval** command in interface configuration mode. To return the hello interval to the default value, use the **no** form of this command.

ospf hello-interval *seconds*

no ospf hello-interval

Syntax Description

seconds	Specifies the interval between hello packets that are sent on the interface; valid values are from 1 to 65535 seconds.

Defaults

The default value for **hello-interval** *seconds* is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

This value is advertised in the hello packets. The smaller the hello interval, the faster topological changes will be detected, but more routing traffic will ensue. This value must be the same for all routers and access servers on a specific network.

Examples

The following example sets the OSPF hello interval to 5 seconds:

```
hostname(config-if)# ospf hello-interval 5
```

Related Commands

Command	Description
ospf dead-interval	Specifies the interval before neighbors declare a router down.
show ospf interface	Displays OSPF-related interface information.

ospf message-digest-key

To enable OSPF MD5 authentication, use the **ospf message-digest-key** command in interface configuration mode. To remove an MD5 key, use the **no** form of this command.

ospf message-digest-key *key-id* **md5** [**0** | **8**] *key*

no ospf message-digest-key

Syntax Description

key-id	Enables MD5 authentication and specifies the numerical authentication key ID number; valid values are from 1 to 255.
md5 *key*	Alphanumeric password of up to 16 bytes. You can include spaces between key characters. Spaces at the beginning or end of the key are ignored. MD5 authentication verifies the integrity of the communication, authenticates the origin, and checks for timeliness.
0	Specifies an unencrypted password will follow
8	Specifies an encrypted password will follow.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **ospf message-digest-key** command lets you enable MD5 authentication. The **no** form of the command let you remove an old MD5 key. *key_id* is a numerical identifier from 1 to 255 for the authentication key. *key* is an alphanumeric password of up to 16 bytes. MD5 verifies the integrity of the communication, authenticates the origin, and checks for timeliness.

Examples

The following example shows how to specify an MD5 key for OSPF authentication:

```
hostname(config-if)# ospf message-digest-key 3 md5 8 yWIvi0qJAnGK5MRWQzrhIohkGP1wKb
```

Related Commands

Command	Description
area authentication	Enables OSPF area authentication.
ospf authentication	Enables the use of OSPF authentication.

ospf mtu-ignore

To disable OSPF maximum transmission unit (MTU) mismatch detection on receiving database packets, use the **ospf mtu-ignore** command in interface configuration mode. To restore MTU mismatch detection, use the **no** form of this command.

ospf mtu-ignore

no ospf mtu-ignore

Syntax Description

This command has no arguments or keywords.

Defaults

By default, **ospf mtu-ignore** is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

OSPF checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange Database Descriptor (DBD) packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency will not be established.The **ospf mtu-ignore** command disables OSPF MTU mismatch detection on receiving DBD packets. It is enabled by default.

Examples

The following example shows how to disable the **ospf mtu-ignore** command:

```
hostname(config-if)# ospf mtu-ignore
```

Related Commands

Command	Description
show interface	Displays interface status information.

ospf network point-to-point non-broadcast

To configure the OSPF interface as a point-to-point, non-broadcast network, use the **ospf network point-to-point non-broadcast** command in interface configuration mode. To remove this command from the configuration, use the **no** form of this command.

ospf network point-to-point non-broadcast

no ospf network point-to-point non-broadcast

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **ospf network point-to-point non-broadcast** command lets you to transmit OSPF routes over VPN tunnels.

When the interface is specified as point-to-point, the OSPF neighbors have to be manually configured; dynamic discovery is not possible. To manually configure OSPF neighbors, use the **neighbor** command in router configuration mode.

When an interface is configured as point-to-point, the following restrictions apply:

- You can define only one neighbor for the interface.
- You need to define a static route pointing to the crypto endpoint.
- The interface cannot form adjacencies unless neighbors are configured explicitly.
- If OSPF over the tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
- You should bind the crypto-map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto-map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so the OSPF adjacencies can be established over the VPN tunnel.

Examples

The following example shows how to configure the selected interface as a point-to-point, non-broadcast interface:

```
hostname(config-if)# ospf network point-to-point non-broadcast
hostname(config-if)#
```

Related Commands

Command	Description
neighbor	Specifies manually configured OSPF neighbors.
show interface	Displays interface status information.

ospf priority

To change the OSPF router priority, use the **ospf priority** command in interface configuration mode. To restore the default priority, use the **no** form of this command.

ospf priority *number*

no ospf priority [*number*]

Syntax Description

number	Specifies the priority of the router; valid values are from 0 to 255.

Defaults

The default value for *number* is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

When two routers attached to a network both attempt to become the designated router, the one with the higher router priority takes precedence. If there is a tie, the router with the higher router ID takes precedence. A router with a router priority set to zero is ineligible to become the designated router or backup designated router. Router priority is configured only for interfaces to multiaccess networks (in other words, not to point-to-point networks).

Examples

The following example shows how to change the OSPF priority on the selected interface:

```
hostname(config-if)# ospf priority 4
hostname(config-if)#
```

Related Commands

Command	Description
show ospf interface	Displays OSPF-related interface information.

ospf retransmit-interval

To specify the time between LSA retransmissions for adjacencies belonging to the interface, use the **ospf retransmit-interval** command in interface configuration mode. To restore the default value, use the **no** form of this command.

ospf retransmit-interval [*seconds*]

no ospf retransmit-interval [*seconds*]

Syntax Description

seconds	Specifies the time between LSA retransmissions for adjacent routers belonging to the interface; valid values are from 1 to 65535 seconds.

Defaults

The default value of **retransmit-interval** *seconds* is 5 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it will re-send the LSA.

The setting of this parameter should be conservative, or needless retransmission will result. The value should be larger for serial lines and virtual links.

Examples

The following example shows how to change the retransmit interval for LSAs:

```
hostname(config-if)# ospf retransmit-interval 15
hostname(config-if)#
```

Related Commands

Command	Description
show ospf interface	Displays OSPF-related interface information.

ospf transmit-delay

To set the estimated time required to send a link-state update packet on the interface, use the **ospf transmit-delay** command in interface configuration mode. To restore the default value, use the **no** form of this command.

ospf transmit-delay [*seconds*]

no ospf transmit-delay [*seconds*]

Syntax Description

seconds	Sets the estimated time required to send a link-state update packet on the interface. The default value is 1 second with a range from 1 to 65535 seconds.

Defaults

The default value of *seconds* is 1 second.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

LSAs in the update packet must have their ages incremented by the amount specified in the *seconds* argument before transmission. The value assigned should take into account the transmission and propagation delays for the interface.

If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. This setting has more significance on very low-speed links.

Examples

The following example sets the transmit delay to 3 seconds for the selected interface:

```
hostname(config-if)# ospf restransmit-delay 3
hostname(config-if)#
```

Related Commands

Command	Description
show ospf interface	Displays OSPF-related interface information.

otp expiration

To specify the duration in hours that an issued One-Time Password (OTP) for the local Certificate Authority (CA) enrollment page is valid, use the **otp expiration** command in ca server configuration mode. To reset the duration to the default number of hours, use the **no** form of this command.

otp expiration *timeout*

no otp expiration

Syntax Description

timeout	Specifies the time in hours users have to enroll for a certificate from the local CA before the OTP for the enrollment page expires. Valid values range from 1 to 720 hours (30 days).

Defaults

By default, a OTP expiration for certificate enrollment is 72 hours (3 days).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The OTP expiration period specifies the number of hours that a user has to log in to the enrollment page of the CA server. After the user logs in and enrolls for a certificate, the time period specified by the **enrollment retrieval** command starts.

Note The user OTP for enrolling for a certificate with the enrollment interface page is also used as the password to unlock the PKCS12 file containing the issued certificate and keypair for that user.

Examples

The following example specifies that the OTP for the enrollment page applies for 24 hours:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# otp expiration 24
hostname(config-ca-server)#
```

The following example resets the OTP duration to the default of 72 hours:

```
hostname(config)# crypto ca server
hostname(config-ca-server))# no otp expiration
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage the local CA.
enrollment-retrieval	Specifies the time in hours that an enrolled user can retrieve a PKCS12 enrollment file.
show crypto ca server	Displays the certificate authority configuration.

outstanding

To limit the number of unauthenticated e-mail proxy sessions, use the **outstanding** command in the applicable e-mail proxy configuration mode. To remove the attribute from the configuration, use the **no** form of this command.

outstanding {*number*}

no outstanding

Syntax Description

number	The number of unauthenticated sessions permitted. The range is from 1 to 1000.

Defaults

The default is 20.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Pop3s	•	—	•	—	—
Imap4s	•	—	•	—	—
Smtps	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **no** version of this command to remove the attribute from the configuration, which permits an unlimited number of unauthenticated sessions. This also limit s DOS attacks on the e-mail ports.

E-mail proxy connections have three states:

1. A new e-mail connection enters the “unauthenticated” state.
2. When the connection presents a username, it enters the “authenticating” state.
3. When the ASA authenticates the connection, it enters the “authenticated” state.

If the number of connections in the unauthenticated state exceeds the configured limit, the ASA terminates the oldest unauthenticated connection, preventing overload. It does not terminate authenticated connections.

Examples

The following example shows how to set a limit of 12 unauthenticated sessions for POP3S e-mail proxy.

```
hostname(config)# pop3s
hostname(config-pop3s)# outstanding 12
```

override-account-disable

To override an account-disabled indication from a AAA server, use the **override-account-disable** command in tunnel-group general-attributes configuration mode. To disable an override, use the **no** form of this command.

override-account-disable

no override-account-disable

Syntax Description

This command has no arguments or keywords.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.1.1	This command was introduced.

Usage Guidelines

This command is valid for servers, such as RADIUS with NT LDAP, and Kerberos, that return an "account-disabled" indication.

You can configure this attribute for IPsec RA and WebVPN tunnel-groups.

Examples

The following example allows overriding the "account-disabled" indicator from the AAA server for the WebVPN tunnel group "testgroup":

```
hostname(config)# tunnel-group testgroup type webvpn
hostname(config)# tunnel-group testgroup general-attributes
hostname(config-tunnel-general)# override-account-disable
hostname(config-tunnel-general)#
```

The following example allows overriding the "account-disabled" indicator from the AAA server for the IPsec remote access tunnel group "QAgroup":

```
hostname(config)# tunnel-group QAgroup type ipsec-ra
hostname(config)# tunnel-group QAgroup general-attributes
hostname(config-tunnel-general)# override-account-disable
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
clear configure tunnel-group	Clears the tunnel-group database or the configuration for a particular tunnel group.
tunnel-group general-attributes	Configures the tunnel-group general-attributes values.

override-svc-download

To configure the connection profile to override the group policy or username attributes configuration for downloading an AnyConnect or SSL VPN client, use the **override-svc-download** command from tunnel-group webvpn attributes configuration mode. To remove the command from the configuration, use the **no** form of the command:

override-svc-download enable

no override-svc-download enable

Defaults

The default is disabled. The ASA does not override the group policy or username attributes configuration for downloading the client.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The security appliance allows clientless, AnyConnect, or SSL VPN client connections for remote users based on whether clientless and/or SSL VPN is enabled in the group policy or username attributes with the **vpn-tunnel-protocol** command. The **svc ask** command further modifies the client user experience by prompting the user to download the client or return to the WebVPN home page.

However, you may want clientless users logging in under specific tunnel groups to not experience delays waiting for the download prompt to expire before being presented with the clientless SSL VPN home page. You can prevent delays for these users at the connection profile level with the **override-svc-download** command. This command causes users logging through a connection profile to be immediately presented with the clientless SSL VPN home page regardless of the **vpn-tunnel-protocol** or **svc ask** command settings.

Examples

In the following example, the user enters tunnel-group webvpn attributes configuration mode for the connection profile *engineering* and enables the connection profile to override the group policy and username attribute settings for client download prompts:

```
hostname(config)# tunnel-group engineering webvpn-attributes
hostname(config-tunnel-webvpn)# override-svc-download
```

Related Commands

Command	Description
show webvpn svc	Displays information about installed SSL VPN clients.
svc	Enables or requires the SSL VPN client for a specific group or user.
svc image	Specifies a client package file that the ASA expands in cache memory for downloading to remote PCs.

CHAPTER 38

packet-tracer through ping Commands

packet-tracer

To enable packet tracing capabilities for troubleshooting by specifying the 5-tuple to test firewall rules, use the **packet-tracer** command in privileged EXEC mode.

packet-tracer input [**1-255**] [**A.B.C.D**] [*ifc_name*] [**icmp** [*sip* | **user** *username* | **security-group** [**name** *name* | **tag** *tag*] **fqdn** *fqdn-string*] *type code ident* [*dip* **security-group** [**name** *name* | **tag** *tag*] | **fqdn** *fqdn-string*]] | [**tcp** [*sip* | **user** *username* | **fqdn** *fqdn-string*] *sport* [*dip* | **fqdn** *fqdn-string*] *dport*] | [**udp** [*sip* | **user** *username* | **fqdn** *fqdn-string*] *sport* [*dip* | **fqdn** *fqdn-string*] *dport*] | [**rawip** [*sip* | **user** *username* | **fqdn** *fqdn-string*] [*dip* | **fqdn** *fqdn-string*]] [**detailed**] [**xml**]

Syntax Description

1-255	Specifies the IP protocol ID or next header range.
A.B.C.D	Specifies the IPv4 source address.
code	Specifies the ICMP code.
detailed	(Optional) Provides detailed trace results information.
dip	Specifies the destination IP address for the packet trace.
dport	Specifies the destination port for the packet trace.
fqdn *fqdn-string*	Specifies the fully qualified domain name of the host, which can be both the source and destination IP address. Supports the FQDN for IPv4 only.
icmp	Specifies the protocol to use is ICMP.
ident	Specifies the ICMP identifier.
input *ifc_name*	Specifies the name of the source interface on which to trace the packets.
name *name*	Specifies the security group name.
rawip	Specifies the protocol to use is raw IP.
security-group	Specifies the source and destination security groups.
sip	Specifies the source IP address for the packet trace.
sport	Specifies the source port for the packet trace.
tag *tag*	Specifies the security group tag.
tcp	Specifies the protocol to use is TCP.
type	Specifies the ICMP type.
udp	Specifies the protocol to use is UDP.
user *username*	Specifies the user identity in the format of [domain\user] if the user is identified as the source IP address. The domain can be a maximum of 32 characters. The user can be a maximum of 64 characters. Only the most recent logon IP address for a user is used for testing.
xml	(Optional) Displays the trace results in XML format.
X:X:X:X::X	Specifies the IPv6 source address.

Defaults

This command has no default settings.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple	
				Context	System
Privileged EXEC mode	•	—	•	•	•

Command History

Release	Modification
7.2(1)	This command was introduced.
8.4(2)	Added two keyword-argument pairs: **user** *username* and **fqdn** *fqdn string*. Renamed and redefined several keywords. Added support for IPv6 source addresses.
9.0(1)	Support for user identity was added. Only IPv4 fully qualified domain names (FQDNs) are supported.

Usage Guidelines

In addition to capturing packets, it is possible to trace the lifespan of a packet through the ASA to see if it is behaving as expected. The **packet-tracer** command enables you to do the following:

- Debug all packet drops in production network.
- Verify the configuration is working as intended.
- Show all rules applicable to a packet along with the CLI lines that caused the rule addition.
- Show a time line of packet changes in a data path.
- Inject tracer packets into the data path.
- Search for an IPv4 or IPv6 address based on the user identity and the FQDN.

The **packet-tracer** command provides detailed information about the packets and how they are processed by the ASA. If a command from the configuration did not cause the packet to drop, the **packet-tracer** command provides information about the cause in an easily readable format. For example if a packet was dropped because of an invalid header validation, the following message appears: “packet dropped due to bad ip header (reason).”

You can specify a user identity in the format of domain\user in the source part of this command. The ASA searches for the user's IP address and uses it in packet trace testing. If a user is mapped to multiple IP addresses, the most recent login IP address is used and the output shows that more IP address-user mapping exists. If user identity is specified in the source part of this command, then the ASA searches for the user's IPv4 or IPv6 address based on the destination address type that the user entered.

This command supports a FQDN, which means that you can also specify a FQDN as both the source and destination address. The ASA performs DNS lookup first, then retrieves the first returned IP address for packet construction. If multiple IP addresses are resolved, the output shows that more DNS resolved IP addresses exist. Only an IPv4 FQDN is supported.

Examples

To enable packet tracing from inside host 10.2.25.3 to external host 209.165.202.158 with detailed information, enter the following:

```
hostname# packet-tracer input inside tcp 10.2.25.3 www 209.165.202.158 aol detailed
```

The following example shows how to enable packet tracing from inside host 10.0.0.2 to outside host 20.0.0.2 with the username of CISCO\abc:

```
hostname# packet-tracer input inside icmp user CISCO\abc 0 0 1 20.0.0.2

Source: CISCO\abc 10.0.0.2

Phase: 1
Type: ROUTE-LOOKUP
Subtype: input
Result: ALLOW
Config:
Additional Information:
in 20.0.0. 255.255.255.0 outside
...
Result:
input-interface: inside
input-status: up
input-line-status: up
output-interfce: outside
output-status: up
output-line-status: up
Action: allow
```

The following example shows how to enable packet tracing from inside host 20.0.0.2 with the username of CISCO\abc and map this username to IP address 10.0.0.2:

```
hostname# packet-tracer input inside tcp user CISCO\abc 1000 20.0.0.2 23

Mapping user CISCO\abc to IP address 10.0.0.2
(More mappings exist. Please run "show user-identity ip-of-user <username>" to check.)

Phase: 1
Type: ROUTE-LOOKUP
Subtype: input
Result: ALLOW
Config:
Additional Information:
in 20.0.0. 255.255.255.0 outside
...
```

The following example shows how to enable packet tracing from inside host 20.0.0.2 with the username of CISCO\abc, map this username to IP address 10.0.0.2, and display the trace results in XML format:

```
<Source>
<user>CISCO\abc</user>
<user-ip>10.0.0.2</user-ip>
<more-ip>1</more-ip>
</Source>

<Phase>
<id>1</id>
<type>ROUTE-LOOKUP</type>
<subtype>input</subtype>
<result>ALLOW</result>
<config>
</config>
<extra>
in 20.0.0.0 255.255.255.0 outside
</extra>
</Phase>
```

The following example shows the error message that results from a packet trace from inside host 1000::123 in a search for the destination IPv6 address for the username of CISCO\abc:

```
hostname# packet-tracer input inside tcp user CISCO\abc 1000 1000::123
ERROR: No active IPv6 address found for user cisco.com\abc
```

The following example shows the results in XML format from a packet trace from inside host 1000::123 in a search for the destination IPv6 address for the username of CISCO\abc after this username has been mapped to an IPv6 address:

```
hostname# user-i s user CISCO\abc 2000::2
hostname# packet-tracer input inside tcp user CISCO\abc 1000 1000::123 xml

<Source>
<user>CISCO\abc</user>
<user-ip>2000::2</user-ip>
<more-ip>0</more-ip>
</Source>

<Result>
<input-interface>inside</input-interface>
<input-status>up</input-status>
```

The following example shows the error message that results from a packet trace from inside host 1000::123 when the username of CISCO\ancdef has not yet been created on the ASA:

```
hostname# packet-tracer input inside tcp user CISCO\ancdef 1000 1000::123
ERROR: User CISCO\ancdef does not exist
```

The following example shows how to enable a packet trace from inside host example.com to external host abc.idfw.com, in which the inside host has been identified as the FQDN of the source IP address, and the external host has been identified as the FQDN of the destination IP address:

```
hostname# packet-tracer input inside tcp fqdn xyz.example.com 1000 fqdn abc.example.com 23
Mapping FQDN xyz.example.com to IP address 10.0.0.2
(More IP addresses resolved. Please run "show dns-host" to check.)

Mapping FQDN abc.example.com to IP address 20.0.0.2
(More IP addresses resolved. Please run "show dns-host" to check.)

Phase: 1
Type: ROUTE-LOOKUP
Subtype: input
Result: ALLOW
Config:
Additional Information:
```

The following example shows how to enable a packet trace from inside host xyz.example.com to external host abc.example.com, in which the inside host has been identified as the FQDN of the source IP address and the external host has been identified as the FQDN of the destination IP address, and display the input in XML format:

```
hostname# packet-tracer input inside tcp fqdn xyz.example.com 1000 fqdn abc.example.com 23
xml
<Source>
<fqdn>xyz.example.com</user>
<fqdn-ip>10.0.0.2</fqdn-ip>
<more-ip>1</more-ip>
</Source>

<Destination>
<fqdn>abc.example.com</user>
<fqdn-ip>20.0.0.2</fqdn-ip>
<more-ip>1</more-ip>
</Destination>
```

```
Phase: 1
Type: ROUTE-LOOKUP
Subtype: input
Result: ALLOW
Config:
Additional Information:
```

The following example shows the error message that results from a packet trace in which the FQDN of the source IP address cannot be resolved:

```
hostname# packet-tracer input inside icmp fqdn ns10.example.com 0 0 2 20.0.0.2
ERROR: Cannot resolve ns10.example.com
```

Related Commands

Command	Description
capture	Captures packet information, including trace packets.
show capture	Displays the capture configuration when no options are specified.

page style

To customize the WebVPN page displayed to WebVPN users when they connect to the security appliance, use the **page style** command in webvpn customization configuration mode. To remove the command from the configuration and cause the value to be inherited, use the **no** form of this command.

page style *value*

[**no**] **page style** *value*

Syntax Description

value	Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default page style is background-color:white;font-family:Arial,Helv,sans-serif

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn customization configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.
- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

The following example customizes the page style to large:

```
F1-asa1(config)# webvpn
F1-asa1(config-webvpn)# customization cisco
F1-asa1(config-webvpn-custom)# page style font-size:large
```

Related Commands

Command	Description
logo	Customizes the logo on the WebVPN page.
title	Customizes the title of the WebVPN page

pager

To set the default number of lines on a page before the "---More---" prompt appears for Telnet sessions, use the **pager** command in global configuration mode.

pager [**lines**] *lines*

Syntax Description

[**lines**] *lines*	Sets the number of lines on a page before the "---More---" prompt appears. The default is 24 lines; 0 means no page limit. The range is 0 through 2147483647 lines. The **lines** keyword is optional and the command is the same with or without it.

Defaults

The default is 24 lines.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from a privileged EXEC mode command to a global configuration mode command. The **terminal pager** command was added as the privileged EXEC mode command.

Usage Guidelines

This command changes the default pager line setting for Telnet sessions. If you want to temporarily change the setting only for the current session, use the **terminal pager** command.

If you Telnet to the admin context, then the pager line setting follows your session when you change to other contexts, even if the **pager** command in a given context has a different setting. To change the current pager setting, enter the **terminal pager** command with a new setting, or you can enter the **pager** command in the current context. In addition to saving a new pager setting to the context configuration, the **pager** command applies the new setting to the current Telnet session.

Examples

The following example changes the number of lines displayed to 20:

```
hostname(config)# pager 20
```

Related Commands

Command	Description
clear configure terminal	Clears the terminal display width setting.
show running-config terminal	Displays the current terminal settings.
terminal	Allows system log messsages to display on the Telnet session.
terminal pager	Sets the number of lines to display in a Telnet session before the "`---more---`" prompt. This command is not saved to the configuration.
terminal width	Sets the terminal display width in global configuration mode.

parameters

To enter parameters configuration mode to set parameters for an inspection policy map, use the **parameters** command in policy-map configuration mode.

parameters

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Policy-map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Modular Policy Framework lets you configure special actions for many application inspections. When you enable an inspection engine using the **inspect** command in the Layer 3/4 policy map (the **policy-map** command), you can also optionally enable actions as defined in an inspection policy map created by the **policy-map type inspect** command. For example, enter the **inspect dns dns_policy_map** command where dns_policy_map is the name of the inspection policy map.

An inspection policy map may support one or more **parameters** commands. Parameters affect the behavior of the inspection engine. The commands available in parameters configuration mode depend on the application.

Examples

The following example shows how to set the maximum message length for DNS packets in the default inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# message-length maximum 512
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

participate

To force the device to participate in the virtual load-balancing cluster, use the **participate** command in VPN load-balancing configuration mode. To remove a device from participation in the cluster, use the **no** form of this command.

participate

no participate

Syntax Description

This command has no arguments or keywords.

Defaults

The default behavior is that the device does not participate in the vpn load-balancing cluster.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
VPN load-balancing configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first configure the interface using the **interface** and **nameif** commands, and use the **vpn load-balancing** command to enter VPN load-balancing mode. You must also have previously configured the cluster IP address using the **cluster ip** command and configured the interface to which the virtual cluster IP address refers.

This command forces this device to participate in the virtual load-balancing cluster. You must explicitly issue this command to enable participation for a device.

All devices that participate in a cluster must share the same cluster-specific values: ip address, encryption settings, encryption key, and port.

Note When using encryption, you must have previously configured the command **isakmp enable** *inside*, where *inside* designates the load-balancing inside interface. If isakmp is not enabled on the load-balancing inside interface, you get an error message when you try to configure cluster encryption.

If isakmp was enabled when you configured the **cluster encryption** command, but was disabled before you configured the **participate** command, you get an error message when you enter the **participate** command, and the local device will not participate in the cluster.

Examples

The following is an example of a VPN load-balancing command sequence that includes a **participate** command that enables the current device to participate in the vpn load-balancing cluster:

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# participate
```

Related Commandsh

Command	Description
vpn load-balancing	Enter VPN load-balancing mode.

passive-interface (RIP)

To disable the transmission of RIP routing updates on an interface, use the **passive-interface** command in router configuration mode. To reenable RIP routing updates on an interface, use the **no** form of this command.

passive-interface {**default** | *if_name*}

no passive-interface {**default** | *if_name*}

Syntax Description

default	(Optional) Set all interfaces to passive mode.
if_name	(Optional) Sets the specified interface to passive mode.

Defaults

All interfaces are enabled for active RIP when RIP is enabled.

If an interface or the **default** keyword is not specified, the commands defaults to **default** and appears in the configuration as passive-interface default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

Enables passive RIP on the interface. The interface listens for RIP routing broadcasts and uses that information to populate the routing tables, but does not broadcast routing updates.

Examples

The following example sets the outside interface to passive RIP. The other interfaces on the security appliance send and receive RIP updates.

```
hostname(config)# router rip
hostname(config-router)# network 10.0.0.0
hostname(config-router)# passive-interface outside
```

Related Commands

Command	Description
clear configure rip	Clears all RIP commands from the running configuration.
router rip	Enables the RIP routing process and enters rip router configuration mode.
show running-config rip	Displays the RIP commands in the running configuration.

passive-interface (EIGRP)

To disable the sending and receiving of EIGRP routing updates on an interface, use the **passive-interface** command in router configuration mode. To reenable routing updates on an interface, use the **no** form of this command.

passive-interface {**default** | *if_name*}

no passive-interface {**default** | *if_name*}

Syntax Description

default	(Optional) Set all interfaces to passive mode.
if_name	(Optional) The name of the interface, as specified by the **nameif** command, to passive mode.

Defaults

All interfaces are enabled for active routing (sending and receiving routing updates) when routing is enabled for that interface.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	Support for EIGRP routing was added.

Usage Guidelines

Enables passive routing on the interface. For EIGRP, this disables the transmission and reception of routing updates on that interface.

You can have more than one **passive-interface** command in the EIGRP configuration. You can use the **passive-interface default** command to disable EIGRP routing on all interfaces, and then use the **no passive-interface** command to enable EIGRP routing on specific interfaces.

Examples

The following example sets the outside interface to passive EIGRP. The other interfaces on the security appliance send and receive EIGRP updates.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# passive-interface outside
```

The following example sets all interfaces except the inside interface to passive EIGRP. Only the inside interface will send and receive EIGRP updates.

```
hostname(config)# router eigrp 100
hostname(config-router)# network 10.0.0.0
hostname(config-router)# passive-interface default
hostname(config-router)# no passive-interface inside
```

Related Commands

Command	Description
show running-config router	Displays the router configuration commands in the running configuration.

passive-interface (OSPFv3)

To suppress the sending and receiving of routing updates on an interface or across all interfaces that are using an OSPFv3 process, use the **passive-interface** command in router configuration mode. To reenable routing updates on an interface or across all intterfaces that are using an OSPFv3 process, use the **no** form of this command.

passive-interface [*interface_name*]

no passive-interface [*interface_name*]

Syntax Description

interface_name	(Optional) Specifies the interface name on which the OSPFv3 process is running.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

This command enables passive routing on an interface.

Examples

The following example suppresses the sending and receiving of routing updates on the inside interface.

```
hostname(config)# ipv6 router ospf 10
hostname(config-rtr)# passive-interface interface
hostname(config-rtr)#
```

Related Commands

Command	Description
show running-config router	Displays the router configuration commands in the running configuration.

passwd, password

To set the login password for Telnet, use the **passwd** or **password** command in global configuration mode. To reset the password, use the **no** form of this command.

{**passwd** | **password**} *password* [**encrypted**]

no {**passwd** | **password**} *password*

Syntax Description

encrypted	(Optional) Specifies that the password is in encrypted form. The password is saved in the configuration in encrypted form, so you cannot view the original password after you enter it. If for some reason you need to copy the password to another ASA but do not know the original password, you can enter the **passwd** command with the encrypted password and this keyword. Normally, you only see this keyword when you enter the **show running-config passwd** command.
passwd | **password**	You can enter either command; they are aliased to each other.
password	Sets the password as a case-sensitive string of up to 80 characters. The password must not contains spaces.

Defaults

9.1(1): The default password is “cisco.”

9.1(2): No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(2)	The SSH default username is no longer supported; you can no longer connect to the ASA using SSH with the **pix** or **asa** username and the login password.
9.0(2), 9.1(2)	The default password, “cisco,” has been removed; you must actively set a login password. Using the **no passwd** or **clear configure passwd** command removes the password; formerly, it reset it to the default of “cisco.”

Usage Guidelines

When you enable Telnet with the **telnet** command, you can log in with the password set by the **passwd** comamnd. After you enter the login password, you are in user EXEC mode. If you configure CLI authentication per user for Telnet using the **aaa authentication telnet console** command, then this password is not used.

This password is also used for Telnet sessions from the switch to the ASASM (see the **session** command).

Examples

The following example sets the password to Pa$$w0rd:

```
hostname(config)# passwd Pa$$w0rd
```

The following example sets the password to an encrypted password that you copied from another ASA:

```
hostname(config)# passwd jMorNbK0514fadBh encrypted
```

Related Commands

Command	Description
clear configure passwd	Clears the login password.
enable	Enters privileged EXEC mode.
enable password	Sets the enable password.
show curpriv	Shows the currently logged in username and the user privilege level.
show running-config passwd	Shows the login password in encrypted form.

password encryption aes

To enable password encryption , use the password encryption aes command in global configuration mode. To disable password encryption, use the **no** form of this command.

password encryption aes

no password encryption aes

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

As soon as password encryption is turned on and master pass phrase is available all the user passwords will be encrypted. The running configuration will show the passwords in the encrypted format. If the pass phrase is not configured at the time of enabling password encryption the command will succeed in anticipation that the pass phrase will be available in future. This command will be automatically synchronized between the failover peers.

The **write erase** command when followed by the **reload** command will remove the master passphrase if it is lost.

Examples

The following example enables password encryption:

```
Router (config)# password encryption aes
```

Related Commands

Command	Description
key config-key password-encryption	Sets the passphrase used for generating the encryption key.
write erase	Removes the master passphrase if it is lost when followed by the **reload** command.

password (crypto ca trustpoint)

To specify a challenge phrase that is registered with the CA during enrollment, use the **password** command in crypto ca trustpoint configuration mode. To restore the default setting, use the **no** form of this command.

password *string*

no password

Syntax Description

string	Specifies the name of the password as a character string. The first character cannot be a number. The string can contain any alphanumeric characters, including spaces, up to 80 characters. You cannot specify the password in the format number-space-anything. The space after the number causes problems. For example, "hello 21" is a legal password, but "21 hello" is not. The password checking is case sensitive. For example, the password "Secret" is different from the password "secret".

Defaults

The default setting is to not include a password.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command lets you specify the revocation password for the certificate before actual certificate enrollment begins. The specified password is encrypted when the updated configuration is written to NVRAM by the ASA.

The CA typically uses a challenge phrase to authenticate a subsequent revocation request.

If this command is enabled, you will not be prompted for a password during certificate enrollment.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and includes a challenge phrase registered with the CA in the enrollment request for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# password zzxxyy
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.
default enrollment	Returns enrollment parameters to their defaults.

password-management

To enable password management, use the **password-management** command in tunnel-group general-attributes configuration mode. To disable password management, use the **no** form of this command. To reset the number of days to the default value, use the **no** form of the command with the **password-expire-in-days** keyword specified.

password-management [**password-expire-in-days** *days*]

no password-management

no password-management password-expire-in-days [*days*]

Syntax Description

days	Specifies the number of days (0 through 180) before the current password expires. This parameter is required if you specify the **password-expire-in-days** keyword.
password-expire-in-days	(Optional) Indicates that the immediately following parameter specifies the number of days before the current password expires that the ASA starts warning the user about the pending expiration. This option is valid only for LDAP servers. See the Usage Notes section for more information.

Defaults

The default is no password management. If you do not specify the **password-expire-in-days** keyword for an LDAP server, the default length of time to start warning before the current password expires is 14 days.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The ASA supports password management for the RADIUS and LDAP protocols. It supports the "password-expire-in-days" option for LDAP only.

You can configure password management for IPsec remote access and SSL VPN tunnel-groups.

When you configure the password-management command, the ASA notifies the remote user at login that the user's current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This command is valid for AAA servers that support such notification; that is, natively to LDAP servers and RADIUS proxied to an NT 4.0 or Active Directory server. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

Note Some RADIUS servers that support MSCHAP currently do not support MSCHAPv2. This command requires MSCHAPv2 so please check with your vendor.

The ASA, releases 7.1 and later, generally supports password management for the following connection types when authenticating with LDAP or with any RADIUS configuration that supports MS-CHAPv2:

- AnyConnect VPN Client (ASA software version 8.0 and higher)
- IPsec VPN Client
- Clientless SSL VPN (ASA software version 8.0 and higher)WebVPN (ASA software versions 7.1 through 7.2.x)
- SSL VPN Client full tunneling client

These RADIUS configurations include RADIUS with LOCAL authentication, RADIUS with Active Directory/Kerberos Windows DC, RADIUS with NT/4.0 Domain, and RADIUS with LDAP.

Password management is *not* supported for any of these connection types for Kerberos/Active Directory (Windows password) or NT 4.0 Domain. The RADIUS server (for example, Cisco ACS) could proxy the authentication request to another authentication server. However, from the ASA perspective, it is talking only to a RADIUS server.

Note For LDAP, the method to change a password is proprietary for the different LDAP servers on the market. Currently, the ASA implements the proprietary password management logic only for Microsoft Active Directory and Sun LDAP servers.

Native LDAP requires an SSL connection. You must enable LDAP over SSL before attempting to do password management for LDAP. By default, LDAP uses port 636.

Note that this command does not change the number of days before the password expires, but rather, the number of days ahead of expiration that the ASA starts warning the user that the password is about to expire.

If you do specify the **password-expire-in-days** keyword, you must also specify the number of days.

Specifying this command with the number of days set to 0 disables this command. The ASA does not notify the user of the pending expiration, but the user can change the password after it expires.

Note Radius does not provide a password change, or provide a password change prompt.

Examples

The following example sets the days before password expiration to begin warning the user of the pending expiration to 90 for the WebVPN tunnel group "testgroup":

```
hostname(config)# tunnel-group testgroup type webvpn
hostname(config)# tunnel-group testgroup general-attributes
hostname(config-tunnel-general)# password-management password-expire-in-days 90
hostname(config-tunnel-general)#
```

The following example uses the default value of 14 days before password expiration to begin warning the user of the pending expiration for the IPsec remote access tunnel group “QAgroup”:

```
hostname(config)# tunnel-group QAgroup type ipsec-ra
hostname(config)# tunnel-group QAgroup general-attributes
hostname(config-tunnel-general)# password-management
hostname(config-tunnel-general)#
```

Related Commands

Command	Description
clear configure passwd	Clears the login password.
passwd	Sets the login password.
radius-with-expiry	Enables negotiation of password update during RADIUS authentication (Deprecated).
show running-config passwd	Shows the login password in encrypted form.
tunnel-group general-attributes	Configures the tunnel-group general-attributes values.

password-parameter

To specify the name of the HTTP POST request parameter in which a user password must be submitted for SSO authentication, use the **password-parameter** command in aaa-server-host configuration mode. This is an SSO with the HTTP Forms command.

password-parameter *string*

Note To configure SSO with HTTP correctly, you must have a thorough working knowledge of authentication and HTTP exchanges.

Syntax Description

string	The name of the password parameter included in the HTTP POST request. The maximum password length is 128 characters.

Defaults

No default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server-host configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The WebVPN server of the ASA uses an HTTP POST request to submit a single sign-on authentication request to an authenticating web server. The required command **password-parameter** specifies that the POST request must include a user password parameter for SSO authentication.

Note At login, the user enters the actual password value, which is entered into the POST request and passed on to the authenticating web server.

Examples

The following example, entered in aaa-server-host configuration mode, specifies a password parameter named user_password:

```
hostname(config)# aaa-server testgrp1 host example.com
hostname(config-aaa-server-host)# password-parameter user_password
```

Related Commands

Command	Description
action-uri	Specifies a web server URI to receive a username and password for single sign-on authentication.
auth-cookie-name	Specifies a name for the authentication cookie.
hidden-parameter	Creates hidden parameters for exchange with the authenticating web server.
start-url	Specifies the URL at which to retrieve a pre-login cookie.
user-parameter	Specifies the name of the HTTP POST request parameter in which a username must be submitted for SSO authentication.

password-policy authenticate enable

To determine whether users are allowed to modify their own user account, use the **password-policy authenticate enable** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy authenticate enable

no password-policy authenticate enable

Syntax Description

This command has no arguments or keywords.

Defaults

Authentication is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

If authentication is enabled, the **username** command does not allow users to change their own password or delete their own account. In addition, the **clear configure username** command does not allow users to delete their own account.

Examples

The following example shows how to enable users to modify their user account:

```
hostname(config)# password-policy authenticate enable
```

Related Commands

Command	Description
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum length	Sets the minimum length of passwords.
password-policy minimum-lowercase	Sets the minimum number of lower case characters that passwords may have.

password-policy lifetime

To set password policy for the current context and the interval in days after which passwords expire, use the **password-policy lifetime** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy lifetime *value*

no password-policy lifetime *value*

Syntax Description

value	Specifies the password lifetime. Valid values range from 0 to 65535 days.

Defaults

The default lifetime value is 0 days.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

Passwords have a specified maximum lifetime. A lifetime interval of 0 days specifies that local user passwords never expire. Note that passwords expire at 12:00 a.m. of the day following lifetime expiration.

Examples

The following example specifies a password lifetime value of 10 days:

```
hostname(config)# password-policy lifetime 10
```

Related Commands

Command	Description
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum length	Sets the minimum length of passwords.
password-policy minimum-lowercase	Sets the minimum number of lower case characters that passwords may have.

password-policy minimum-changes

To set the minimum number of characters that must be changed between new and old passwords, use the **password-policy minimum-changes** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-changes *value*

no password-policy minimum-changes *value*

Syntax Description

value	Specifies the number of characters that must be changed between new and old passwords. Valid values range from 0 to 64 characters.

Defaults

The default number of changed characters is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

New passwords must include a minimum of 4 character changes from the current password and are considered changed only if they do not appear anywhere in the current password.

Examples

The following example specifies a minimum number of character changes between old and new passwords of 6 characters:

```
hostname(config)# password-policy minimum-changes 6
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime in days after which passwords expire.
password-policy minimum-length	Sets the minimum length of passwords.
password-policy minimum-lowercase	Sets the minimum number of lowercase characters that passwords may have.

password-policy minimum-length

To set the minimum length of passwords, use the **password-policy minimum-length** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-length *value*

no password-policy minimum-length *value*

Syntax Description

value	Specifies the minimum length for passwords. Valid values range from 0 to 64 characters.

Defaults

The default minimum length is 0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

If the minimum length is less than any of the other minimum attributes (changes, lower case, upper case, numeric, and special), an error message appears and the minimum length is not changed. The recommended password length is 8 charcters.

Examples

The following example specifies a minimum number of characters for passwords as 8:

```
hostname(config)# password-policy minimum-length 8
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime value in days after which passwords expire.
password-policy minimum-changes	Sets the minimum number of changed characters allowed between old and new passwords.
password-policy minimum-lowercase	Sets the minimum number of lower case characters that passwords may have.

password-policy minimum-lowercase

To set the minimum number of lower case characters that passwords may have, use the **password-policy minimum-lowercase** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-lowercase *value*

no password-policy minimum-lowercase *value*

Syntax Description

value	Specifies the minimum number of lower case characters for passwords. Valid values range from 0 to 64 characters.

Defaults

The default number of minimum lower case characters is 0, which means there is no minimum.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command sets the minimum number of lower case characters that passwords may have. Valid values range from 0 to 64 characters.

Examples

The following example specifies the minimum number of lower case characters that passwords may have as 6:

```
hostname(config)# password-policy minimum-lowercase 6
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime value in days after which passwords expire.
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum-length	Sets the minimum length of passwords.

password-policy minimum-numeric

To set the minimum number of numeric characters that passwords may have, use the **password-policy minimum-numeric** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-numeric *value*

no password-policy minimum-numeric *value*

Syntax Description

value	Specifies the minimum number of numeric characters for passwords. Valid values range from 0 to 64 characters.

Defaults

The default number of minimum numeric characters is 0, which means there is no minimum.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command sets the minimum number of numeric characters that passwords may have. Valid values range from 0 to 64 characters.

Examples

The following example specifies the minimum number of numeric characters that passwords may have as 8:

```
hostname(config)# password-policy minimum-numeric 8
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime value in days after which passwords expire.
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum-length	Sets the minimum length of passwords.

password-policy minimum-special

To set the minimum number of special characters that passwords may have, use the **password-policy minimum-special** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-special *value*

no password-policy minimum-special *value*

Syntax Description

value	Specifies the minimum numer of special characters for passwords. Valid values range from 0 to 64 characters.

Defaults

The default number of minimum special characters is 0, which means there is no minimum.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command sets the minimum number of special characters that passwords may have. Special characters include the following: !, @, #, $, %, ^, &, *, '(‘ and ‘)’.

Examples

The following example specifies the minimum number of special characters that passwords may have as 2:

```
hostname(config)# password-policy minimum-special 2
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime value in days after which passwords expire.
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum-length	Sets the minimum length of passwords.

password-policy minimum-uppercase

To set the minimum number of upper case characters that passwords may have, use the **password-policy minimum-uppercase** command in global configuration mode. To set the corresponding password policy attribute to its default value, use the **no** form of this command.

password-policy minimum-uppercase *value*

no password-policy minimum-uppercase *value*

Syntax Description

value	Specifies the minimum number of upper case characters for passwords. Valid values range from 0 to 64 characters.

Defaults

The default number of minimum upper case characters is 0, which means there is no minimum.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

This command sets the minimum number of upper case characters that passwords may have. Valid values range from 0 to 64 characters.

Examples

The following example specifies the minimum number of upper case characters that passwords may have as 4:

```
hostname(config)# password-policy minimum-uppercase 4
```

Related Commands

Command	Description
password-policy lifetime	Sets the password lifetime value in days after which passwords expire.
password-policy minimum-changes	Sets the minimum number of characters that must be changed between new and old passwords.
password-policy minimum-length	Sets the minimum length of passwords.

password-prompt

To customize the password prompt of the WebVPN page login box that is displayed to WebVPN users when they connect to the security appliance, use the **password-prompt** command from webvpn customization mode:

password-prompt {**text** | **style**} *value*

[**no**] **password-prompt** {**text** | **style**} *value*

To remove the command from the configuration and cause the value to be inherited, use the **no** form of the command.

Syntax Description

text	Specifies you are changing the text.
style	Specifies you are changing the style.
value	The actual text to display (maximum 256 characters), or Cascading Style Sheet (CSS) parameters (maximum 256 characters).

Defaults

The default text of the password prompt is "PASSWORD:".

The default style of the password prompt is color:black;font-weight:bold;text-align:right.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn customization	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The **style** option is expressed as any valid Cascading Style Sheet (CSS) parameters. Describing these parameters is beyond the scope of this document. For more information about CSS parameters, consult CSS specifications at the World Wide Web Consortium (W3C) website at www.w3.org. Appendix F of the CSS 2.1 Specification contains a convenient list of CSS parameters, and is available at www.w3.org/TR/CSS21/propidx.html.

Here are some tips for making the most common changes to the WebVPN pages—the page colors:

- You can use a comma-separated RGB value, an HTML color value, or the name of the color if recognized in HTML.
- RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others.

- HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue.

Note To easily customize the WebVPN pages, we recommend that you use ASDM, which has convenient features for configuring style elements, including color swatches and preview capabilities.

Examples

In the following example, the text is changed to "Corporate Password:", and the default style is changed with the font weight increased to bolder:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization cisco
hostname(config-webvpn-custom)# password-prompt text Corporate Username:
hostname(config-webvpn-custom)# password-prompt style font-weight:bolder
```

Related Commands

Command	Description
group-prompt	Customizes the group prompt of the WebVPN page
username-prompt	Customizes the username prompt of the WebVPN page

password-storage

To let users store their login passwords on the client system, use the **password-storage enable** command in group-policy configuration mode or username configuration mode. To disable password storage, use the **password-storage disable** command.

To remove the password-storage attribute from the running configuration, use the **no** form of this command. This enables inheritance of a value for password-storage from another group policy.

password-storage {enable | disable}

no password-storage

Syntax Description

disable	Disables password storage.
enable	Enables password storage.

Defaults

Password storage is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—
Username configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Enable password storage only on systems that you know to be in secure sites.

This command has no bearing on interactive hardware client authentication or individual user authentication for hardware clients.

Examples

The following example shows how to enable password storage for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# password-storage enable
```

peer-id-validate

To specify whether to validate the identity of the peer using the peer's certificate, use the **peer-id-validate** command in tunnel-group ipsec-attributes mode. To return to the default value, use the **no** form of this command.

peer-id-validate *option*

no peer-id-validate

Syntax Description

option	Specifies one of the following options: • **req**: required • **cert**: if supported by certificate • **nocheck**: do not check

Defaults

The default setting for this command is **req**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec attributes	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can apply this attribute to all IPsec tunnel-group types.

Examples

The following example entered in config-ipsec configuration mode, requires validating the peer using the identity of the peer's certificate for the IPsec LAN-to-LAN tunnel group named 209.165.200.225:

```
hostname(config)# tunnel-group 209.165.200.225 type IPsec_L2L
hostname(config)# tunnel-group 209.165.200.225 ipsec-attributes
hostname(config-tunnel-ipsec)# peer-id-validate req
hostname(config-tunnel-ipsec)#
```

Related Commands

Command	Description
clear-configure tunnel-group	Clears all configured tunnel groups.
show running-config tunnel-group	Shows the tunnel group configuration for all tunnel groups or for a particular tunnel group.
tunnel-group ipsec-attributes	Configures the tunnel-group ipsec-attributes for this group.

perfmon

To display performance information, use the **perfmon** command in privileged EXEC mode.

perfmon {**verbose** | **interval** *seconds* | **quiet** | **settings**} [*detail*]

Syntax Description

verbose	Displays performance monitor information at the ASA console.
interval *seconds*	Specifies the number of seconds before the performance display is refreshed on the console.
quiet	Disables the performance monitor displays.
settings	Displays the interval and whether it is quiet or verbose.
detail	Displays detailed information about performance.

Defaults

The *seconds* is 120 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	

Command History

Release	Modification
7.0	Support for this command was introduced on the ASA.
7.2(1)	Support for the **detail** keyword was added.

Usage Guidelines

The **perfmon** command allows you to monitor the performance of the ASA. Use the **show perfmon** command to display the information immediately. Use the **perfmon verbose** command to display the information every 2 minutes continuously. Use the **perfmon interval** *seconds* command with the **perfmon verbose** command to display the information continuously every number of seconds that you specify.

An example of the performance information is displayed as follows:

PERFMON STATS:	Current	Average
Xlates	33/s	20/s
Connections	110/s	10/s
TCP Conns	50/s	42/s
WebSns Req	4/s	2/s
TCP Fixup	20/s	15/s
HTTP Fixup	5/s	5/s

FTP Fixup	7/s	4/s
AAA Authen	10/s	5/s
AAA Author	9/s	5/s
AAA Account	3/s	3/s

This information lists the number of translations, connections, Websense requests, address translations (called “fixups”), and AAA transactions that occur each second.

Examples

This example shows how to display the performance monitor statistics every 30 seconds on the ASA console:

```
hostname(config)# perfmon interval 120
hostname(config)# perfmon quiet
hostname(config)# perfmon settings
interval: 120 (seconds)
quiet
```

Related Commands

Command	Description
show perfmon	Displays performance information.

periodic

To specify a recurring (weekly) time range for functions that support the time-range feature, use the **periodic** command in time-range configuration mode. To disable, use the **no** form of this command.

periodic *days-of-the-week time* **to** [*days-of-the-week*] *time*

no periodic *days-of-the-week time* **to** [*days-of-the-week*] *time*

Syntax Description

days-of-the-week	(Optional) The first occurrence of this argument is the starting day or day of the week that the associated time range is in effect. The second occurrence is the ending day or day of the week the associated statement is in effect. This argument is any single day or combinations of days: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday. Other possible values are: • daily—Monday through Sunday • weekdays—Monday through Friday • weekend—Saturday and Sunday If the ending days of the week are the same as the starting days of the week, you can omit them.
time	Specifies the time in the format HH:MM. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.
to	Entry of the **to** keyword is required to complete the range "from start-time to end-time."

Defaults

If a value is not entered with the **periodic** command, access to the ASA as defined with the **time-range** command is in effect immediately and always on.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Time-range configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To implement a time-based ACL, use the **time-range** command to define specific times of the day and week. Then use the with the **access-list extended time-range** command to bind the time range to an ACL.

The **periodic** command is one way to specify when a time range is in effect. Another way is to specify an absolute time period with the **absolute** command. Use either of these commands after the **time-range** global configuration command, which specifies the name of the time range. Multiple **periodic** entries are allowed per **time-range** command.

If the end days-of-the-week value is the same as the start value, you can omit them.

If a **time-range** command has both **absolute** and **periodic** values specified, then the **periodic** commands are evaluated only after the **absolute start** time is reached, and are not further evaluated after the **absolute end** time is reached.

The time-range feature relies on the system clock of the ASA; however, the feature works best with NTP synchronization.

Examples

Some examples follow:

If you want:	Enter this:
Monday through Friday, 8:00 a.m. to 6:00 p.m. only	**periodic weekdays 8:00 to 18:00**
Every day of the week, from 8:00 a.m. to 6:00 p.m. only	**periodic daily 8:00 to 18:00**
Every minute from Monday 8:00 a.m. to Friday 8:00 p.m.	**periodic monday 8:00 to friday 20:00**
All weekend, from Saturday morning through Sunday night	**periodic weekend 00:00 to 23:59**
Saturdays and Sundays, from noon to midnight	**periodic weekend 12:00 to 23:59**

The following example shows how to allow access to the ASA on Monday through Friday, 8:00 a.m. to 6:00 p.m. only:

```
hostname(config-time-range)# periodic weekdays 8:00 to 18:00
hostname(config-time-range)#
```

The following example shows how to allow access to the ASA on specific days (Monday, Tuesday, and Friday), 10:30 a.m. to 12:30 p.m.:

```
hostname(config-time-range)# periodic Monday Tuesday Friday 10:30 to 12:30
hostname(config-time-range)#
```

Related Commands

Command	Description
absolute	Defines an absolute time when a time range is in effect.
access-list extended	Configures a policy for permitting or denying IP traffic through the ASA.
default	Restores default settings for the **time-range** command **absolute** and **periodic** keywords.
time-range	Defines access control to the ASA based on time.

permit errors

To allow invalid GTP packets or packets that otherwise would fail parsing and be dropped, use the **permit errors** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. To return to the default behavior, where all invalid packets or packets that failed, during parsing, are dropped. use the **no** form of this command.

permit errors

no permit errors

Syntax Description

This command has no arguments or keywords.

Defaults

By default, all invalid packets or packets that failed, during parsing, are dropped.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Use the **permit errors** command in GTP map configuration mode to allow any packets that are invalid or encountered an error during inspection of the message to be sent through the ASA instead of being dropped.

Examples

The following example permits traffic containing invalid packets or packets that failed, during parsing:

```
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# permit errors
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.

Commands	Description
permit response	Supports load-balancing GSNs.
show service-policy inspect gtp	Displays the GTP configuration.

permit response

To support load-balancing GSNs, use the **permit response** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. Use the **no** form of this command to allow the ASA to drop GTP responses from GSNs other than the host to which the request was sent.

permit response to-object-group *to_obj_group_id* **from-object-group** *from_obj_group_id*

no permit response to-object-group *to_obj_group_id* **from-object-group** *from_obj_group_id*

Syntax Description

from-object-group *from_obj_group_id*	Specifies the name of the object-group configured with the **object-group** command which can send responses to the set of GSNs in the object-group specified by the *to_obj_group_id* argument. The ASA supports only object-groups containing network-objects with IPv4 addresses. IPv6 addresses are currently not supported with GTP.
to-object-group *to_obj_group_id*	Specifies the name of the object-group configured with the **object-group** command which can receive responses from the set of GSNs in the object-group specified by the *from_obj_group_id* argument. The ASA supports only object-groups containing network-objects with IPv4 addresses. IPv6 addresses are currently not supported with GTP.

Defaults

By default, the ASA drops GTP responses from GSNs other than the host to which the request was sent.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(4)	This command was introduced.

Usage Guidelines

Use the **permit response** command in GTP map configuration mode to support load-balancing GSNs. The **permit response** command configures the GTP map to allow GTP responses from a different GSN than the response was sent to.

You identify the pool of load-balancing GSNs as a network object. Likewise, you identify the SGSN as a network object. If the GSN responding belongs to the same object group as the GSN that the GTP request was sent to and if the SGSN is in a object group that the responding GSN is permitted to send a GTP response to, the ASA permits the response.

Examples

The following example permits GTP responses from any host on the 192.168.32.0 network to the host with the IP address 192.168.112.57:

```
hostname(config)# object-group network gsnpool32
hostname(config-network)# network-object 192.168.32.0 255.255.255.0
hostname(config)# object-group network sgsn1
hostname(config-network)# network-object host 192.168.112.57
hostname(config-network)# exit
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# permit response to-object-group sgsn1 from-object-group gsnpool32
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.
permit errors	Allow invalid GTP packets.
show service-policy inspect gtp	Displays the GTP configuration.

pfs

To enable PFS, use the **pfs enable** command in group-policy configuration mode. To disable PFS, use the **pfs disable** command. To remove the PFS attribute from the running configuration, use the **no** form of this command.

pfs {enable | disable}

no pfs

Syntax Description

disable	Disables PFS.
enable	Enables PFS.

Defaults

PFS is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The PFS setting on the VPN Client and the ASA must match.

Use the **no** form of this command to allow the inheritance of a value for PFS from another group policy.

In IPsec negotiations, PFS ensures that each new cryptographic key is unrelated to any previous key.

Examples

The following example shows how to set PFS for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# pfs enable
```

phone-proxy

To configure the Phone Proxy instance, use the **phone-proxy** command in global configuration mode.

To remove the Phone Proxy instance, use the **no** form of this command.

phone-proxy *phone_proxy_name*

no phone-proxy *phone_proxy_name*

Syntax Description

phone_proxy_name	Specifies the name of the Phone Proxy instance.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Only one Phone Proxy instance can be configured on the ASA.

If NAT is configured for the HTTP proxy server, the global or mapped IP address of the HTTP proxy server with respect to the IP phones is written to the Phone Proxy configuration file.

Examples

The following example shows the use of the **phone-proxy** command to configure the Phone Proxy instance:

```
hostname(config)# phone-proxy asa_phone_proxy
hostname(config-phone-proxy)# tftp-server address 128.106.254.8 interface outside
hostname(config-phone-proxy)# media-termination address 192.0.2.25 interface inside
hostname(config-phone-proxy)# media-termination address 128.106.254.3 interface outside
hostname(config-phone-proxy)# tls-proxy asa_tlsp
hostname(config-phone-proxy)# ctl-file asactl
hostname(config-phone-proxy)# cluster-mode nonsecure
hostname(config-phone-proxy)# timeout secure-phones 00:05:00
hostname(config-phone-proxy)# disable service-settings
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from Flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for Phone Proxy configuration.
tls-proxy	Configures the TLS proxy instance.

pim

To re-enable PIM on an interface, use the **pim** command in interface configuration mode. To disable PIM, use the **no** form of this command.

pim

no pim

Syntax Description

This command has no arguments or keywords.

Defaults

The **multicast-routing** command enables PIM on all interfaces by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **multicast-routing** command enables PIM on all interfaces by default. Only the **no** form of the **pim** command is saved in the configuration.

Note PIM is not supported with PAT. The PIM protocol does not use ports and PAT only works with protocols that use ports.

Examples

The following example disables PIM on the selected interface:

```
hostname(config-if)# no pim
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim accept-register

To configure the ASA to filter PIM register messages, use the **pim accept-register** command in global configuration mode. To remove the filtering, use the **no** form of this command.

pim accept-register {**list** *acl* | **route-map** *map-name*}

no pim accept-register

Syntax Description

list *acl*	Specifies an access list name or number. Use only extended host ACLs with this command.
route-map *map-name*	Specifies a route-map name. Use extended host ACLs in the referenced route-map.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is used to prevent unauthorized sources from registering with the RP. If an unauthorized source sends a register message to the RP, the ASA will immediately send back a register-stop message.

Examples

The following example restricts PIM register messages to those from sources defined in the access list named “no-ssm-range”:

```
hostname(config)# pim accept-register list no-ssm-range
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim bidir-neighbor-filter

To control which bidir-capable neighbors can participate in the DF election, use the **pim bidir-neighbor-filter** command in interface configuration mode. To remove the filtering, use the **no** form of this command.

pim bidir-neighbor-filter *acl*

no pim bidir-neighbor-filter *acl*

Syntax Description

acl	Specifies an access list name or number. The access list defines the neighbors that can participate in bidir DF elections. Use only standard ACLs with this command; extended ACLs are not supported.

Defaults

All routers are considered to be bidir capable.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled for bidir to elect a DF.

The **pim bidir-neighbor-filter** command enables the transition from a sparse-mode-only network to a bidir network by letting you specify the routers that should participate in DF election while still allowing all routers to participate in the sparse-mode domain. The bidir-enabled routers can elect a DF from among themselves, even when there are non-bidir routers on the segment. Multicast boundaries on the non-bidir routers prevent PIM messages and data from the bidir groups from leaking in or out of the bidir subset cloud.

When the **pim bidir-neighbor-filter** command is enabled, the routers that are permitted by the ACL are considered to be bidir-capable. Therefore:

- If a permitted neighbor does not support bidir, the DF election does not occur.
- If a denied neighbor supports bidir, then DF election does not occur.
- If a denied neighbor does not support bidir, the DF election can occur.

Examples

The following example allows 10.1.1.1 to become a PIM bidir neighbor:

```
hostname(config)# access-list bidir_test permit 10.1.1.1 255.255.255.55
hostname(config)# access-list bidir_test deny any
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# pim bidir-neighbor-filter bidir_test
```

Related Commands

Command	Description
multicast boundary	Defines a multicast boundary for administratively-scoped multicast addresses.
multicast-routing	Enables multicast routing on the ASA.

pim dr-priority

To configure the neighbor priority on the ASA used for designated router election, use the **pim dr-priority** command in interface configuration mode. To restore the default priority, use the **no** form of this command.

pim dr-priority *number*

no pim dr-priority

Syntax Description

number	A number from 0 to 4294967294. This number is used to determine the priority of the device when determining the designated router. Specifying 0 prevents the ASA from becoming the designated router.

Defaults

The default value is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The device with the largest priority value on an interface becomes the PIM designated router. If multiple devices have the same designated router priority, then the device with the highest IP address becomes the DR. If a device does not include the DR-Priority Option in hello messages, it is regarded as the highest-priority device and becomes the designated router. If multiple devices do not include this option in their hello messages, then the device with the highest IP address becomes the designated router.

Examples

The following example sets the DR priority for the interface to 5:

```
hostname(config-if)# pim dr-priority 5
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim hello-interval

To configure the frequency of the PIM hello messages, use the **pim hello-interval** command in interface configuration mode. To restore the hello-interval to the default value, use the **no** form of this command.

pim hello-interval *seconds*

no pim hello-interval [*seconds*]

Syntax Description

seconds	The number of seconds that the ASA waits before sending a hello message. Valid values range from 1 to 3600 seconds. The default value is 30 seconds.

Defaults

The interval default is 30 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the PIM hello interval to 1 minute:

```
hostname(config-if)# pim hello-interval 60
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim join-prune-interval

To configure the PIM join/prune interval, use the **pim join-prune-interval** command in interface configuration mode. To restore the interval to the default value, use the **no** form of this command.

pim join-prune-interval *seconds*

no pim join-prune-interval [*seconds*]

Syntax Description

seconds	The number of seconds that the ASA waits before sending a join/prune message. Valid values range from 10 to 600 seconds. 60 seconds is the default.

Defaults

The default interval is 60 seconds

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example sets the PIM join/prune interval to 2 minutes:

```
hostname(config-if)# pim join-prune-interval 120
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim neighbor-filter

To control which neighbor routers can participate in PIM, use the **pim neighbor-filter** command in interface configuration mode. To remove the filtering, use the **no** form of this command.

pim neighbor-filter *acl*

no pim neighbor-filter *acl*

Syntax Description

acl	Specifies an access list name or number. Use only standard ACLs with this command; extended ACLs are not supported.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command defines which neighbor routers can participate in PIM. If this command is not present in the configuration then there are no restrictions.

Multicast routing and PIM must be enabled for this command to appear in the configuration. If you disable multicast routing, this command is removed from the configuration.

Examples

The following example allows the router with the IP address 10.1.1.1 to become a PIM neighbor on interface GigabitEthernet0/2:

```
hostname(config)# access-list pim_filter permit 10.1.1.1 255.255.255.55
hostname(config)# access-list pim_filter deny any
hostname(config)# interface gigabitEthernet0/2
hostname(config-if)# pim neighbor-filter pim_filter
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim old-register-checksum

To allow backward compatibility on a rendezvous point (RP) that uses old register checksum methodology, use the **pim old-register-checksum** command in global configuration mode. To generate PIM RFC-compliant registers, use the **no** form of this command.

pim old-register-checksum

no pim old-register-checksum

Syntax Description

This command has no arguments or keywords.

Defaults

The ASA generates PIM RFC-compliant registers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA software accepts register messages with checksum on the PIM header and only the next 4 bytes rather than using the Cisco IOS method—accepting register messages with the entire PIM message for all PIM message types. The **pim old-register-checksum** command generates registers compatible with Cisco IOS software.

Examples

The following example configures the ASA to use the old checksum calculations:

```
hostname(config)# pim old-register-checksum
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

pim rp-address

To configure the address of a PIM rendezvous point (RP), use the **pim rp-address** command in global configuration mode. To remove an RP address, use the **no** form of this command.

pim rp-address *ip_address* [*acl*] [**bidir**]

no pim rp-address *ip_address*

Syntax Description

acl	(Optional) The name or number of a standard access list that defines which multicast groups the RP should be used with. Do not use a host ACL with this command.
bidir	(Optional) Indicates that the specified multicast groups are to operate in bidirectional mode. If the command is configured without this option, the specified groups operate in PIM sparse mode.
ip_address	IP address of a router to be a PIM RP. This is a unicast IP address in four-part dotted-decimal notation.

Defaults

No PIM RP addresses are configured.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

All routers within a common PIM sparse mode (PIM-SM) or bidir domain require knowledge of the well-known PIM RP address. The address is statically configured using this command.

Note The ASA does not support Auto-RP; you must use the **pim rp-address** command to specify the RP address.

You can configure a single RP to serve more than one group. The group range specified in the access list determines the PIM RP group mapping. If the an access list is not specified, the RP for the group is applied to the entire IP multicast group range (224.0.0.0/4).

Note The ASA always advertises the bidir capability in the PIM hello messages regardless of the actual bidir configuration.

Examples

The following example sets the PIM RP address to 10.0.0.1 for all multicast groups:

```
hostname(config)# pim rp-address 10.0.0.1
```

Related Commands

Command	Description
pim accept-register	Configures candidate RPs to filter PIM register messages.

pim spt-threshold infinity

To change the behavior of the last hop router to always use the shared tree and never perform a shortest-path tree (SPT) switchover, use the **pim spt-threshold infinity** command in global configuration mode. To restore the default value, use the **no** form of this command.

pim spt-threshold infinity [**group-list** *acl*]

no pim spt-threshold

Syntax Description

group-list *acl*	(Optional) Indicates the source groups restricted by the access list. The *acl* argument must specify a standard ACL; extended ACLs are not supported.

Defaults

The last hop PIM router switches to the shortest-path source tree by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the **group-list** keyword is not used, this command applies to all multicast groups.

Examples

The following example causes the last hop PIM router to always use the shared tree instead of switching to the shortest-path source tree:

```
hostname(config)# pim spt-threshold infinity
```

Related Commands

Command	Description
multicast-routing	Enables multicast routing on the ASA.

ping

To test connectivity from a specified interface to an IP address, use the **ping** command in privileged EXEC mode.

ping {**tcp**] [*if_name*] [*host*] [*port*] [**repeat** *count*] [**timeout** *seconds*][**source** *host ports*] [**data** *pattern*] [**size** *bytes*] [**validate**]}

Note The **source** and *port* options are only available with the **tcp** option; the **data**, **size**, and **validate** options are not available with the **tcp** option.

Syntax Description

data *pattern*	(Optional) Specifies the 16-bit data pattern in hexidecimal format.
host	Specifies the IPv4 or IPv6 address or name of the host to ping. The name can be a DNS name or a name assigned with the **name** command. The maximum number of characters for DNA names is 128, and the maximum number of characters for names created with the **name** command is 63.
if_name	(Optional) For ICMP, this is the interface name, as configured by the **nameif** command, by which the *host* is accessible. If not supplied, then the *host* is resolved to an IP address and the routing table is consulted to determine the destination interface. For TCP, this is the input interface through which the source sends SYN packets.
pattern	(Optional) Specifies the 16-bit data pattern in hexidecimal format.
port	(Optional) Specifies the associated port number from 1-65535.
repeat *count*	(Optional) Specifies the number of times to repeat the ping request.
size *bytes*	(Optional) Specifies the datagram size in bytes.
source	(Optional) Specifies a certain IP address and port to send from (Use port = 0 for a random port).
tcp	(Optional) Tests a connection over TCP (the default is ICMP). The available interfaces are the following: • DMZ—Name of interface GigabitEthernet0/2 • Hostname or A.B.C.D—Ping destination IPv4 address or hostname • Hostname or X:X:X:X::X—Ping destination IPv6 address or hostname • internal—Name of interface GigabitEthernet0/3 • management—Name of interface Management0/0 • outside—Name of interface GigabitEthernet0/0 • publicl4tm—Name of interface GigabitEthernet0/1 **Note** TCP does not use the source interface address for pings.
timeout *seconds*	(Optional) Specifies the number of seconds of the timeout interval.
validate	(Optional) Validates reply data.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Support for DNS names added.
8.4(1)	Added the **tcp** option.

Usage Guidelines

The **ping** command allows you to determine if the ASA has connectivity or if a host is available on the network. If the ASA has connectivity, make sure that the **icmp permit any** *interface* command is configured. This configuration is required to allow the ASA to respond and accept messages generated from the **ping** command. The **ping** command output shows if the response was received. If a host is not responding after you enter the **ping** command, a message similar to the following appears:

```
hostname(config)# ping 10.1.1.1
Sending 5, 100-byte ICMP Echos to 10.1.1.1, timeout is 2 seconds:
?????
Success rate is 0 percent (0/5)
```

Use the **show interface** command to ensure that the ASA is connected to the network and is passing traffic. The address of the specified *if_name* is used as the source address of the ping.

If you want internal hosts to ping external hosts over ICMP, you must do one of the following:

- Create an ICMP **access-list** command for an echo reply; for example, to give ping access to all hosts, use the **access-list acl_grp permit icmp any any** command and bind the **access-list** command to the interface that you want to test using the **access-group** command.
- Configure the ICMP inspection engine using the **inspect icmp** command. For example, adding the **inspect icmp** command to the **class default_inspection** class for the global service policy allows echo replies through the ASA for echo requests initiated by internal hosts.

You can also perform an extended ping, which allows you to enter the keywords one line at a time.

If you are pinging through the ASA between hosts or routers, but the pings are not successful, use the **capture** command to monitor the success of the ping.

The ASA **ping** command does not require an interface name. If you do not specify an interface name, the ASA checks the routing table to find the address that you specify. You can specify an interface name to indicate through which interface the ICMP echo requests are sent.

The **ping tcp** command requires the **enable** password and allows a maximum of two users to initiate simultaneous ping requests. In addition, this command does not support IPv6.

Examples

The following example shows how to determine if other IP addresses are visible from the ASA:

```
hostname# ping 171.69.38.1
Sending 5, 100-byte ICMP Echos to 171.69.38.1, timeout is 2 seconds:
```

```
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The following example specifies a host using a DNS name:

```
hostname# ping www.example.com
Sending 5, 100-byte ICMP Echos to www.example.com, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The following is an example of an extended ping:

```
hostname# ping
Interface: outside
Target IP address: 171.69.38.1
Repeat count: [5]
Datagram size: [100]
Timeout in seconds: [2]
Extended commands [n]:
Sweep range of sizes [n]:
Sending 5, 100-byte ICMP Echos to 171.69.38.1, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The following are examples of the **ping tcp** command:

```
hostname# ping
TCP [n]: yes
Interface: dmz
Target IP address: 10.0.0.1
Target IP port: 21
Specify source? [n]: y
Source IP address: 192.168.2.7
Source IP port: [0] 465
Repeat count: [5]
Timeout in seconds: [2] 5
Type escape sequence to abort.
Sending 5 TCP SYN requests to 10.0.0.1 port 21
from 192.168.2.7 starting port 465, timeout is 5 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms

hostname# ping tcp
Interface: dmz
Target IP address: 10.0.0.1
Target IP port: 21
Specify source? [n]:
Repeat count: [5] 3
Timeout in seconds: [2]
Type escape sequence to abort.
No source specified. Pinging from identity interface.
Sending 3 TCP SYN requests to 10.0.0.1 port 21
from 10.0.0.10, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms

hostname# ping tcp 10.0.0.1 21
Type escape sequence to abort.
No source specified. Pinging from identity interface.
Sending 5 TCP SYN requests to 10.0.0.1 port 21
from 10.0.0.10, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

```
hostname# ping tcp 10.0.0.1 21 source 192.168.1.1 2002 repeat 10
Type escape sequence to abort.
Sending 10 TCP SYN requests to 10.0.0.1 port 21
from 192.168.1.1 starting port 2002, timeout is 2 seconds:
!!!!!!!!!!
Success rate is 100 percent (10/10), round-trip min/avg/max = 1/2/2 ms

hostname(config)# ping tcp www.example.com 80
Type escape sequence to abort.
No source specified. Pinging from identity interface.
Sending 5 TCP SYN requests to 74.125.19.103 port 80
from 171.63.230.107, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 3/4/4 ms

hostname# ping tcp 192.168.1.7 23 source 192.168.2.7 24966
Type escape sequence to abort.
Source port 24966 in use! Using port 24967 instead.
Sending 5 TCP SYN requests to 192.168.1.7 port 23
from 192.168.2.7 starting port 24967, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms

hostname(config)# ping tcp www.example.com 80
Type escape sequence to abort.
No source specified. Pinging from identity interface.
Error! Too many concurrent TCP ping sessions. Please wait...
```

Related Commands

Command	Description
capture	Captures packets at an interface.
icmp	Configures access rules for ICMP traffic that terminates at an interface.
show interface	Displays information about the VLAN configuration.

CHAPTER 39

police through pppoe client secondary Commands

police

To apply QoS policing to a class map, use the **police** command in class configuration mode. To remove the rate-limiting requirement, use the **no** form of this command. Policing is a way of ensuring that no traffic exceeds the maximum rate (in bits/second) that you configure, thus ensuring that no one traffic flow can take over the entire resource. When traffic exceeds the maximum rate, the ASA drops the excess traffic. Policing also sets the largest single burst of traffic allowed.

police {**output** | **input**} *conform-rate* [*conform-burst*] [**conform-action** [**drop** | **transmit**] [**exceed-action** [**drop** | **transmit**]]]

no police

Syntax Description

conform-burst	Specifies the maximum number of instantaneous bytes allowed in a sustained burst before throttling to the conforming rate value, between 1000 and 512000000 bytes.
conform-action	Sets the action to take when the rate is less than the *conform_burst* value.
conform-rate	Sets the rate limit for this traffic flow; between 8000 and 2000000000 bits per second.
drop	Drops the packet.
exceed-action	Sets the action to take when the rate is between the *conform-rate* value and the *conform-burst* value.
input	Enables policing of traffic flowing in the input direction.
output	Enables policing of traffic flowing in the output direction.
transmit	Transmits the packet.

Defaults

No default behavior or variables.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Added the **input** option. Policing traffic in the inbound direction is now supported.

Usage Guidelines

To enable policing, use the Modular Policy Framework:

1. **class-map**—Identify the traffic on which you want to perform policing.

2. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **police**—Enable policing for the class map.
3. **service-policy**—Assigns the policy map to an interface or globally.

Note The **police** command merely enforces the maximum speed and burst rate, forcing them to the conforming rate value. It does not enforce the **conform-action** or the **exceed-action** specification if these are present.

Note When the conform-burst parameter is omitted, the default value is assumed to be 1/32 of the conform-rate in bytes (that is, with a conform rate of 100,000, the default conform-burst value would be 100,000/32 = 3,125). Note that the conform-rate is in bits/second, whereas the conform-burst is in bytes.

You can configure each of the QoS features alone if desired for the ASA. Often, though, you configure multiple QoS features on the ASA so you can prioritize some traffic, for example, and prevent other traffic from causing bandwidth problems.

See the following supported feature combinations per interface:

- Standard priority queuing (for specific traffic) + Policing (for the rest of the traffic).

  You cannot configure priority queueing and policing for the same set of traffic.
- Traffic shaping (for all traffic on an interface) + Hierarchical priority queueing (for a subset of traffic).

Typically, if you enable traffic shaping, you do not also enable policing for the same traffic, although the ASA does not restrict you from configuring this.

See the following guidelines:

- QoS is applied unidirectionally; only traffic that enters the interface to which you apply the policy map is affected (or exits the interface, depending on the whether you specify **input** or **output**).
- If a service policy is applied or removed from an interface that has existing traffic already established, the QoS policy is not applied or removed from the traffic stream. To apply or remove the QoS policy for such connections, you must clear the connections and re-establish them. See the **clear conn** command.
- To-the-box traffic is not supported.
- Traffic to and from a VPN tunnel bypass interface is not supported.
- When you match a tunnel group class map, only outbound policing is supported.

Examples

The following is an example of a **police** command for the output direction that sets the conform rate to 100,000 bits per second, a burst value of 20,000 bytes, and specifies that traffic that exceeds the burst rate will be dropped:

```
hostname(config)# policy-map localpolicy1
hostname(config-pmap)# class-map firstclass
hostname(config-cmap)# class localclass
hostname(config-pmap-c)# police output 100000 20000 exceed-action drop
hostname(config-cmap-c)# class class-default
hostname(config-pmap-c)#
```

The following example shows how to do rate-limiting on traffic destined to an internal web server:

```
hostname# access-list http_traffic permit tcp any 10.1.1.0 255.255.255.0 eq 80
hostname# class-map http_traffic
hostname(config-cmap)# match access-list http_traffic
hostname(config-cmap)# policy-map outside_policy
hostname(config-pmap)# class http_traffic
hostname(config-pmap-c)# police input 56000
hostname(config-pmap-c)# service-policy outside_policy interface outside
hostname(config)#
```

Related Commands

class	Specifies a class-map to use for traffic classification.
clear configure policy-map	Remove all policy-map configuration, except that if a policy-map is in use in a service-policy command, that policy-map is not removed.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Display all current policy-map configurations.

policy

To specify the source for retrieving the CRL, use the **policy** command in ca-crl configuration mode.

policy {**static** | **cdp** | **both**}

Syntax Description

both	Specifies that if obtaining a CRL using the CRL distribution point fails, retry using static CDPs up to a limit of five.
cdp	Uses the CDP extension embedded within the certificate being checked. In this case, the ASA retrieves up to five CRL distributions points from the CDP extension of the certificate being verified and augments their information with the configured default values, if necessary. If the ASA attempt to retrieve a CRL using the primary CDP fails, it retries using the next available CDP in the list. This continues until either the ASA retrieves a CRL or exhausts the list.
static	Uses up to five static CRL distribution points. If you specify this option, specify also the LDAP or HTTP URLs with the **protocol** command.

Defaults

The default setting is **cdp**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
crl configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters ca-crl configuration mode, and configures CRL retrieval to occur using the CRL distribution point extension in the certificate being checked or if that fails, to use static CDPs:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# policy both
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
url	Creates and maintains a list of static URLs for retrieving CRLs.

policy-map

When using the Modular Policy Framework, assign actions to traffic that you identified with a Layer 3/4 class map (the **class-map** or **class-map type management** command) by using the **policy-map** command (without the **type** keyword) in global configuration mode. To remove a Layer 3/4 policy map, use the **no** form of this command.

policy-map *name*

no policy-map *name*

Syntax Description

name	Specifies the name for this policy map up to 40 characters in length. All types of policy maps use the same name space, so you cannot reuse a name already used by another type of policy map.

Defaults

By default, the configuration includes a policy that matches all default application inspection traffic and applies certain inspections to the traffic on all interfaces (a global policy). Not all inspections are enabled by default. You can only apply one global policy, so if you want to alter the global policy, you need to either edit the default policy or disable it and apply a new one. (An interface policy overrides the global policy for a particular feature.)

The default policy includes the following application inspections:

- DNS inspection for the maximum message length of 512 bytes
- FTP
- H323 (H225)
- H323 (RAS)
- RSH
- RTSP
- ESMTP
- SQLnet
- Skinny (SCCP)
- SunRPC
- XDMCP
- SIP
- NetBios
- TFTP
- IP Options

The default policy configuration includes the following commands:

```
class-map inspection_default
 match default-inspection-traffic
policy-map type inspect dns preset_dns_map
 parameters
message-length maximum client auto
message-length maximum 512
```

```
dns-guard
protocol-enforcement
nat-rewrite
policy-map global_policy
 class inspection_default
  inspect dns preset_dns_map
  inspect ftp
  inspect h323 h225 _default_h323_map
  inspect h323 ras _default_h323_map
  inspect ip-options _default_ip_options_map
  inspect netbios
  inspect rsh
  inspect rtsp
  inspect skinny
  inspect esmtp _default_esmtp_map
  inspect sqlnet
  inspect sunrpc
  inspect tftp
  inspect sip
  inspect xdmcp
```

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Configuring Modular Policy Framework consists of four tasks:

1. Identify the Layer 3 and 4 traffic to which you want to apply actions using the **class-map** or **class-map type management** command.
2. (Application inspection only) Define special actions for application inspection traffic using the **policy-map type inspect** command.
3. Apply actions to the Layer 3 and 4 traffic using the **policy-map** command.
4. Activate the actions on an interface using the **service-policy** command.

The maximum number of policy maps is 64, but you can only apply one policy map per interface. You can apply the same policy map to multiple interfaces. You can identify multiple Layer 3/4 class maps in a Layer 3/4 policy map (see the **class** command), and you can assign multiple actions from one or more feature types to each class map.

Examples

The following is an example of a **policy-map** command for connection policy. It limits the number of connections allowed to the web server 10.1.1.1:

```
hostname(config)# access-list http-server permit tcp any host 10.1.1.1
```

```
hostname(config)# class-map http-server
hostname(config-cmap)# match access-list http-server

hostname(config)# policy-map global-policy
hostname(config-pmap)# description This policy map defines a policy concerning connection
to http server.
hostname(config-pmap)# class http-server
hostname(config-pmap-c)# set connection conn-max 256
```

The following example shows how multi-match works in a policy map:

```
hostname(config)# class-map inspection_default
hostname(config-cmap)# match default-inspection-traffic
hostname(config)# class-map http_traffic
hostname(config-cmap)# match port tcp eq 80

hostname(config)# policy-map outside_policy
hostname(config-pmap)# class inspection_default
hostname(config-pmap-c)# inspect http http_map
hostname(config-pmap-c)# inspect sip
hostname(config-pmap)# class http_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:10:0
```

The following example shows how traffic matches the first available class map, and will not match any subsequent class maps that specify actions in the same feature domain:

```
hostname(config)# class-map telnet_traffic
hostname(config-cmap)# match port tcp eq 23
hostname(config)# class-map ftp_traffic
hostname(config-cmap)# match port tcp eq 21
hostname(config)# class-map tcp_traffic
hostname(config-cmap)# match port tcp range 1 65535
hostname(config)# class-map udp_traffic
hostname(config-cmap)# match port udp range 0 65535
hostname(config)# policy-map global_policy
hostname(config-pmap)# class telnet_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:0:0
hostname(config-pmap-c)# set connection conn-max 100
hostname(config-pmap)# class ftp_traffic
hostname(config-pmap-c)# set connection timeout tcp 0:5:0
hostname(config-pmap-c)# set connection conn-max 50
hostname(config-pmap)# class tcp_traffic
hostname(config-pmap-c)# set connection timeout tcp 2:0:0
hostname(config-pmap-c)# set connection conn-max 2000
```

When a Telnet connection is initiated, it matches **class telnet_traffic**. Similarly, if an FTP connection is initiated, it matches **class ftp_traffic**. For any TCP connection other than Telnet and FTP, it will match **class tcp_traffic**. Even though a Telnet or FTP connection can match **class tcp_traffic**, the ASA does not make this match because they previously matched other classes.

NetFlow events are configured through Modular Policy Framework. If Modular Policy Framework is not configured for NetFlow, no events are logged. Traffic is matched based on the order in which classes are configured. After a match is detected, no other classes are checked. For NetFlow events, the configuration requirements are as follows:

- A flow-export destination (that is, a NetFlow collector) is uniquely identified by its IP address.
- Supported event types are flow-create, flow-teardown, flow-denied, flow-update, and all, which include the four previously listed event types.
- Use the **flow-export event-type** {**all** | **flow-create** | **flow-denied** | **flow-update** | **flow-teardown**} **destination** command to configure the address of NetFlow collectors and filters to determine which NetFlow records should be sent to each collector.

- Flow-export actions are not supported in interface policies.
- Flow-export actions are only supported in the **class-default** command and in classes with the **match any** or **match access-list** command.
- If no NetFlow collector has been defined, no configuration actions occur.
- NetFlow Secure Event Logging filtering is order-independent.

The following example exports all NetFlow events between hosts 10.1.1.1 and 20.1.1.1 to destination 15.1.1.1.

```
hostname(config)# access-list flow_export_acl permit ip host 10.1.1.1 host 20.1.1.1
hostname(config)# class-map flow_export_class
hostname(config-cmap)# match access-list flow_export_acl
hostname(config)# policy-map global_policy
hostname(config-pmap)# class flow_export_class
hostname(config-pmap-c)# flow-export event-type all destination 15.1.1.1
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
clear configure policy-map	Removes all policy map configuration. If a policy map is in use in a **service-policy** command, that policy map is not removed.
class-map	Defines a traffic class map.
service-policy	Assigns the policy map to an interface or globally to all interfaces.
show running-config policy-map	Display all current policy map configurations.

policy-map type inspect

When using the Modular Policy Framework, define special actions for inspection application traffic by using the **policy-map type inspect** command in global configuration mode. To remove an inspection policy map, use the **no** form of this command.

policy-map type inspect *application policy_map_name*

no policy-map [**type inspect** *application*] *policy_map_name*

Syntax Description

application	Specifies the type of application traffic you want to act upon. Available types include: • **dcerpc** • **dns** • **esmtp** • **ftp** • **gtp** • **h323** • **http** • **im** • **ip-options** • **ipsec-pass-thru** • **ipv6** • **mgcp** • **netbios** • **radius-accounting** • **rtsp** • **scansafe** • **sip** • **skinny** • **snmp**
policy_map_name	Specifies the name for this policy map up to 40 characters in length. Names that begin with "_internal" or "_default" are reserved and cannot be used. All types of policy maps use the same name space, so you cannot reuse a name already used by another type of policy map.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.2(1)	Added the **ipv6** keyword to support IPv6 inspection.
9.0(1)	Added the **scansafe** keyword to support Cloud Web Security.

Usage Guidelines

Modular Policy Framework lets you configure special actions for many application inspections. When you enable an inspection engine using the **inspect** command in the Layer 3/4 policy map (the **policy-map** command), you can also optionally enable actions as defined in an inspection policy map created by the **policy-map type inspect** command. For example, enter the **inspect http http_policy_map** command where http_policy_map is the name of the inspection policy map.

An inspection policy map consists of one or more of the following commands entered in policy-map configuration mode. The exact commands available for an inspection policy map depends on the application.

- **match** command—You can define a **match** command directly in the inspection policy map to match application traffic to criteria specific to the application, such as a URL string. Then you enable actions in match configuration mode such as **drop**, **reset**, **log**, and so on. The **match** commands available depend on the application.
- **class** command—This command identifies an inspection class map in the policy map (see the **class-map type inspect** command to create the inspection class map). An inspection class map includes **match** commands that match application traffic with criteria specific to the application, such as a URL string, for which you then enable actions in the policy map. The difference between creating a class map and using a **match** command directly in the inspection policy map is that you can group multiple matches, and you can reuse class maps.
- **parameters** command—Parameters affect the behavior of the inspection engine. The commands available in parameters configuration mode depend on the application.

You can specify multiple **class** or **match** commands in the policy map.

Some **match** commands can specify regular expressions to match text inside a packet. See the **regex** command and the **class-map type regex** command, which groups multiple regular expressions.

The default inspection policy map configuration includes the following commands:

```
policy-map type inspect dns preset_dns_map
 parameters
 message-length maximum client auto
 message-length maximum 512
 dns-guard
 protocol-enforcement
 nat-rewrite
```

If a packet matches multiple different **match** or **class** commands, then the order in which the ASA applies the actions is determined by internal ASA rules, and not by the order they are added to the policy map. The internal rules are determined by the application type and the logical progression of parsing a packet, and are not user-configurable. For example for HTTP traffic, parsing a Request Method field precedes parsing the Header Host Length field; an action for the Request Method field occurs before the action for the Header Host Length field. For example, the following match commands can be entered in any order, but the **match request method get** command is matched first.

```
hostname(config-pmap)# match request header host length gt 100
hostname(config-pmap-c)# reset
hostname(config-pmap-c)# match request method get
hostname(config-pmap-c)# log
```

If an action drops a packet, then no further actions are performed. For example, if the first action is to reset the connection, then it will never match any further **match** commands. If the first action is to log the packet, then a second action, such as resetting the connection, can occur. (You can configure both the **reset** (or **drop-connection**, and so on.) and the **log** action for the same **match** command, in which case the packet is logged before it is reset for a given match.)

If a packet matches multiple **match** or **class** commands that are the same, then they are matched in the order they appear in the policy map. For example, for a packet with the header length of 1001, it will match the first command below, and be logged, and then will match the second command and be reset. If you reverse the order of the two **match** commands, then the packet will be dropped and the connection reset before it can match the second **match** command; it will never be logged.

```
hostname(config-pmap)# match request header length gt 100
hostname(config-pmap-c)# log
hostname(config-pmap-c)# match request header length gt 1000
hostname(config-pmap-c)# reset
```

A class map is determined to be the same type as another class map or **match** command based on the lowest priority **match** command in the class map (the priority is based on the internal rules). If a class map has the same type of lowest priority **match** command as another class map, then the class maps are matched according to the order they are added to the policy map. If the lowest priority command for each class map is different, then the class map with the higher priority **match** command is matched first.

See the following guidelines when modifying an inspection policy-map:

- HTTP inspection policy maps—If you modify an in-use HTTP inspection policy map (**policy-map type inspect http**), you must remove and reapply the **inspect http** *map* action for the changes to take effect. For example, if you modify the “http-map” inspection policy map, you must remove and readd the **inspect http http-map** command from the layer 3/4 policy:

  ```
  hostname(config)# policy-map test
  hostname(config-pmap)# class http0
  hostname(config-pmap-c)# no inspect http http-map
  hostname(config-pmap-c)# inspect http http-map
  ```

- All inspection policy maps—If you want to exchange an in-use inspection policy map for a different map name, you must remove the **inspect** *protocol map* command, and readd it with the new map. For example:

  ```
  hostname(config)# policy-map test
  hostname(config-pmap)# class sip
  hostname(config-pmap-c)# no inspect sip sip-map1
  hostname(config-pmap-c)# inspect sip sip-map2
  ```

Examples

The following is an example of an HTTP inspection policy map and the related class maps. This policy map is activated by the Layer 3/4 policy map, which is enabled by the service policy.

```
hostname(config)# regex url_example example\.com
hostname(config)# regex url_example2 example2\.com
hostname(config)# class-map type regex match-any URLs
hostname(config-cmap)# match regex example
hostname(config-cmap)# match regex example2

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
parameters	Enters parameter configuration mode for an inspection policy map.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

policy-server-secret

To configure a secret key used to encrypt authentication requests to a SiteMinder SSO server, use the **policy-server-secret** command in webvpn-sso-siteminder configuration mode. To remove a secret key, use the **no** form of this command.

policy-server-secret *secret-key*

no policy-server-secret

Note This command is required for SiteMinder SSO authentication.

Syntax Description

secret-key	The character string used as a secret key to encrypt authentication communications. There is no minimum or maximum number of characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Config-webvpn-sso-siteminder configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. You first create the SSO server using the **sso-server** command. For SiteMinder SSO servers, the **policy-server-secret** command secures authentication communications between the ASA and the SSO server.

The command argument, *secret-key*, is similar to a password: you create it, save it, and configure it. It is configured on both the ASA using the **`policy-server-secret`** command and on the SiteMinder Policy Server using the Cisco Java plug-in authentication scheme.

This command applies only to the SiteMinder type of SSO server.

Examples

The following command, entered in config-webvpn-sso-siteminder mode and including a random character string as an argument, creates a secret key for SiteMinder SSO server authentication communications:

```
hostname(config-webvpn)# sso-server my-sso-server type siteminder
hostname(config-webvpn-sso-siteminder)# policy-server-secret @#ET&
hostname(config-webvpn-sso-siteminder)#
```

Related Commands

Command	Description
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
request-timeout	Specifies the number of seconds before a failed SSO authentication attempt times out.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device
sso-server	Creates a single sign-on server.
test sso-server	Tests an SSO server with a trial authentication request.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

polltime interface

To specify the data interface poll and hold times in an Active/Active failover configuration, use the **polltime interface** command in failover group configuration mode. To restore the default value, use the **no** form of this command.

polltime interface [**msec**] *time* [**holdtime** *time*]

no polltime interface [**msec**] *time* [**holdtime** *time*]

Syntax Description

holdtime *time*	(Optional) Sets the time during which a data interface must receive a hello message from the peer interface, after which the peer interface is declared failed. Valid values are from 5 to 75 seconds.
interface *time*	Specifies data interface polling period. Valid values are from 3 to 15 seconds. If the optional **msec** keyword is used, the valid values are from 500 to 999 milliseconds.
msec	(Optional) Specifies that the given time is in milliseconds.

Defaults

The poll *time* is 5 seconds.

The **holdtime** *time* is 5 times the poll *time*.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The command was changed to include the optional **holdtime** *time* value and the ability to specify the poll time in milliseconds.

Usage Guidelines

Use the **polltime interface** command to change the frequency that hello packets are sent out on interfaces associated with the specified failover group. This command is available for Active/Active failover only. Use the **failover polltime interface** command in Active/Standby failover configurations.

You cannot enter a **holdtime** value that is less than 5 times the poll time. With a faster poll time, the ASA can detect failure and trigger failover faster. However, faster detection can cause unnecessary switchovers when the network is temporarily congested. Interface testing begins when a hello packet is not heard on the interface for over half the hold time.

You can include both **failover polltime unit** and **failover polltime interface** commands in the configuration.

Note When CTIQBE traffic is passed through a ASA in a failover configuration, you should decrease the failover hold time on the ASA to below 30 seconds. The CTIQBE keepalive timeout is 30 seconds and may time out before failover occurs in a failover situation. If CTIQBE times out, Cisco IP SoftPhone connections to Cisco CallManager are dropped, and the IP SoftPhone clients need to reregister with the CallManager.

Examples

The following partial example shows a possible configuration for a failover group. The interface poll time is set to 500 milliseconds and the hold time to 5 seconds for data interfaces in failover group 1.

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# polltime interface msec 500 holdtime 5
hostname(config-fover-group)# exit
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
failover polltime	Specifies the unit failover poll and hold times.
failover polltime interface	Specifies the interface poll and hold times for Active/Standby failover configurations.

pop3s

To enter POP3S configuration mode, use the **pop3s** command in global configuration mode. To remove any commands entered in POP3S command mode, use the **no** version of this command.

POP3 is a client/server protocol in which your Internet server receives and holds e-mail for you. Periodically, you (or your client e-mail receiver) check your mail-box on the server and download any mail. This standard protocol is built into most popular e-mail products. POP3S lets you receive e-mail over an SSL connection.

pop3s

no pop3

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to enter POP3S configuration mode:

```
hostname(config)# pop3s
hostname(config-pop3s)#
```

Related Commands

Command	Description
clear configure pop3s	Removes the POP3S configuration.
show running-config pop3s	Displays the running configuration for POP3S.

port

To specify the port an e-mail proxy listens to, use the **port** command in the applicable e-mail proxy command mode. To revert to the default value, use the **no** version of this command.

port {*portnum*}

no port

Syntax Description

portnum	The port for the e-mail proxy to use. To avoid conflicts with local TCP services, use port numbers in the range 1024 to 65535.

Defaults

The default ports for e-mail proxies are as follows:

E-mail Proxy	Default Port
IMAP4S	993
POP3S	995
SMTPS	988

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Pop3s	•	—	•	—	—
Imap4s	•	—	•	—	—
Smtps	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To avoid conflicts with local TCP services, use port numbers in the range 1024 to 65535.

Examples

The following example shows how to set port 1066 for the IMAP4S e-mail proxy:

```
hostname(config)# imap4s
hostname(config-imap4s)# port 1066
```

port-channel load-balance

For EtherChannels, to specify the load-balancing algorithm, use the **port-channel load-balance** command in interface configuration mode. To set the value to the default, use the **no** form of this command.

port-channel load-balance {**dst-ip** | **dst-ip-port** | **dst-mac** | **dst-port** | **src-dst-ip** | **src-dst-ip-port** | **src-dst-mac** | **src-dst-port** | **src-ip** | **src-ip-port** | **src-mac** | **src-port** | **vlan-dst-ip** | **vlan-dst-ip-port** | **vlan-only** | **vlan-src-dst-ip** | **vlan-src-dst-ip-port** | **vlan-src-ip** | **vlan-src-ip-port**}

no port-channel load-balance

Syntax Description

dst-ip	Balances the packet load on interfaces according to the following characteristics of the packet: • Destination IP address
dst-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Destination IP address • Destination Port
dst-mac	Balances the packet load on interfaces according to the following characteristics of the packet: • Destination MAC address
dst-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Destination port
src-dst-ip	(Default) Balances the packet load on interfaces according to the following characteristics of the packet: • Source IP address • Destination IP address
src-dst-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Source IP address • Destination IP address • Source Port • Destination Port
src-dst-mac	Balances the packet load on interfaces according to the following characteristics of the packet: • Source MAC address • Destination MAC address

src-dst-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Source port • Destination port
src-ip	Balances the packet load on interfaces according to the following characteristics of the packet: • Source IP address
src-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Source IP address • Source port
src-mac	Balances the packet load on interfaces according to the following characteristics of the packet: • Source MAC address
src-port	Balances the packet load on interfaces according to the following characteristics of the packet: • Source port
vlan-dst-ip	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Destination IP address
vlan-dst-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Destination IP address • Destination port
vlan-only	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN
vlan-src-dst-ip	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Source IP address • Destination IP address
vlan-src-dst-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Source IP address • Destination IP address • Source port • Destination port

vlan-src-ip	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Source IP address
vlan-src-ip-port	Balances the packet load on interfaces according to the following characteristics of the packet: • VLAN • Source IP address • Source port

Command Default

The default is **src-dst-ip**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

By default, the ASA balances the packet load on interfaces according to the source and destination IP address (**src-dst-ip**) of the packet. If you want to change the properties on which the packet is categorized, use this command. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic.

The ASA distributes packets to the interfaces in the EtherChannel by hashing the load-balancing criteria. The hash result is a 3-bit value (0 to 7).

The eight hash result values are distributed in a round robin fashion between the channel group interfaces, starting with the interface with the lowest ID (slot/port). For example, all packets with a hash result of 0 go to GigabitEthernet 0/0, packets with a hash result of 1 go to GigabitEthernet 0/1, packets with a hash result of 2 go to GigabitEthernet 0/2, and so on.

Because there are eight hash result values regardless of how many active interfaces are in the EtherChannel, packets might not be distributed evenly depending on the number of active interfaces.

Table 39-1 shows the load balancing amounts per interface for each number of active interfaces. The active interfaces in **bold** have even distribution.

Table 39-1 Load Distribution per Interface

# of Active Interfaces	% Distribution Per Interface							
	1	2	3	4	5	6	7	8
1	**100%**	—	—	—	—	—	—	—
2	**50%**	**50%**	—	—	—	—	—	—
3	37.5%	37.5%	25%	—	—	—	—	—
4	**25%**	**25%**	**25%**	**25%**	—	—	—	—
5	25%	25%	25%	12.5%	12.5%	—	—	—
6	25%	25%	12.5%	12.5%	12.5%	12.5%	—	—
7	25%	12.5%	12.5%	12.5%	12.5%	12.5%	12.5%	—
8	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**	**12.5%**

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

Examples

The following example sets the load-balancing algorithm to use the source and destination IP addresses and ports:

```
hostname(config)# interface port-channel 1
hostname(config-if)# port-channel load-balance src-dst-ip-port
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel min-bundle	Specifies the minimum number of active interfaces required for the port-channel interface to become active.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

port-channel min-bundle

For EtherChannels, to specify the minimum number of active interfaces required for the port-channel interface to become active, use the **port-channel min-bundle** command in interface configuration mode. To set the value to the default, use the **no** form of this command.

port-channel min-bundle *number*

no port-channel min-bundle

Syntax Description

number	Specifies the minimum number of active interfaces required for the port-channel interface to become active, between 1 and 8.

Command Default

The default is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	•	•	—	•

Command History

Release	Modification
8.4(1)	We introduced this command.

Usage Guidelines

Enter this command for a port-channel interface. If the active interfaces in the channel group falls below this value, then the port-channel interface goes down, and could trigger a device-level failover.

Examples

The following example sets the minimum number of active interfaces required for the port-channel to become active to two:

```
hostname(config)# interface port-channel 1
hostname(config-if)# port-channel min-bundle 2
```

Related Commands

Command	Description
channel-group	Adds an interface to an EtherChannel.
interface port-channel	Configures an EtherChannel.
lacp max-bundle	Specifies the maximum number of active interfaces allowed in the channel group.

Command	Description
lacp port-priority	Sets the priority for a physical interface in the channel group.
lacp system-priority	Sets the LACP system priority.
port-channel load-balance	Configures the load-balancing algorithm.
show lacp	Displays LACP information such as traffic statistics, system identifier and neighbor details.
show port-channel	Displays EtherChannel information in a detailed and one-line summary form. This command also displays the port and port-channel information.
show port-channel load-balance	Displays port-channel load-balance information along with the hash result and member interface selected for a given set of parameters.

port-channel span-cluster

To sets this EtherChannel as a spanned EtherChannel in an ASA cluster, use the **port-channel span-cluster** command in interface configuration mode. To disable spanning, use the **no** form of this command.

port-channel span-cluster [**vss-load-balance**]

no port-channel span-cluster [**vss-load-balance**]

Syntax Description

vss-load-balance	(Optional) Enables VSS load balancing. If you are connecting the ASA to two switches in a VSS or vPC, then you should enable VSS load balancing. This feature ensures that the physical link connections between the ASAs to the VSS (or vPC) pair are balanced. You must configure the **vss-id** keyword in the **channel-group** command for each member interface before enabling load balancing.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You must be in spanned EtherChannel mode (**cluster interface-mode spanned**) to use this feature.

This feature lets you group one or more interfaces per unit into an EtherChannel that spans all units in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel. A spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the bridge group, not to the interface. The EtherChannel inherently provides load balancing as part of basic operation.

Examples

The following example creates an EtherChannel (port-channel 2) with the tengigabitethernet 0/8 interface as the only member, and then spans the EtherChannel across the cluster. Two subinterfaces are added to port-channel 2.

```
interface tengigabitethernet 0/8
```

```
    channel-group 2 mode active
    no shutdown
interface port-channel 2
    port-channel span-cluster
interface port-channel 2.10
    vlan 10
    nameif inside
    ip address 10.10.10.5 255.255.255.0
    ipv6 address 2001:DB8:1::5/64
    mac-address 000C.F142.4CDE
interface port-channel 2.20
    vlan 20
    nameif outside
    ip address 209.165.201.1 255.255.255.224
    ipv6 address 2001:DB8:2::8/64
    mac-address 000C.F142.5CDE
```

Related Commands

Command	Description
interface	Enters interface configuration mode.
cluster interface-mode	Sets the cluster interface mode, for either Spanned EtherChannels or individual interfaces.

port-forward

To configure the set of applications that users of clientless SSL VPN session can access over forwarded TCP ports, use the **port-forward** command in webvpn configuration mode.

port-forward {*list_name local_port remote_server remote_port description*}

To configure access to multiple applications, use this command with the same *list_name* multiple times, once for each application.

To remove a configured application from a list, use the **no port-forward** *list_name local_port* command (you need not include the *remote_server* and *remote_port* parameters).

no port-forward *listname localport*

To remove an entire configured list, use the **no port-forward** *list_name* command.

no port-forward *list_name*

Syntax Description

description	Provides the application name or short description that displays on the end user Port Forwarding Java applet screen. Maximum 64 characters.
list_name	Groups the set of applications (forwarded TCP ports) users of clientless SSL VPN sessions can access. Maximum 64 characters.
local_port	Specifies the local port that listens for TCP traffic for an application. You can use a local port number only once for a *list_name*. Enter a port number in the range 1-65535. To avoid conflicts with existing services, use a port number greater than 1024.
remote_port	Specifies the port to connect to for this application on the remote server. This is the actual port the application uses. Enter a port number in the range 1-65535 or port name.
remote_server	Provides the DNS name or IP address of the remote server for an application. If you enter the IP address, you may enter it in either IPv4 or IPv6 format. We recommend using a host name so that you do not have to configure the client applications for a specific IP addresses. The dns server-group command **name-server** must resolve the host name to an IP address.

Defaults

There is no default port forwarding list.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	The command mode was changed to webvpn.

Usage Guidelines

Port forwarding does not support Microsoft Outlook Exchange (MAPI) proxy. However, you can configure Smart Tunnel support for Microsoft Outlook Exchange 2010.

Examples

The following table shows the values used for example applications.

Application	Local Port	Server DNS Name	Remote Port	Description
IMAP4S e-mail	20143	IMAP4Sserver	143	Get Mail
SMTPS e-mail	20025	SMTPSserver	25	Send Mail
DDTS over SSH	20022	DDTSserver	22	DDTS over SSH
Telnet	20023	Telnetserver	23	Telnet

The following example shows how to create a port forwarding list called *SalesGroupPorts* that provides access to these applications:

```
hostname(config)# webvpn
hostname(config-webvpn)# port-forward SalesGroupPorts 20143 IMAP4Sserver 143 Get Mail
hostname(config-webvpn)# port-forward SalesGroupPorts 20025 SMTPSserver 25 Send Mail
hostname(config-webvpn)# port-forward SalesGroupPorts 20022 DDTSserver 22 DDTS over SSH
hostname(config-webvpn)# port-forward SalesGroupPorts 20023 Telnetserver 23 Telnet
```

Related Commands

Command	Description
port-forward auto-start	Entered in group-policy webvpn or username webvpn mode, this command starts port forwarding automatically and assigns the specified port forwarding list when the user logs onto a clientless SSL VPN session.
port-forward enable	Entered in group-policy webvpn or username webvpn mode, this command starts assigns the specified port forwarding list when the user logs on, but requires the user to start port forwarding manually, using the **Application Access > Start Applications** button on the clientless SSL VPN portal page.
port-forward disable	Entered in group-policy webvpn or username webvpn mode, this command turns off port forwarding.

port-forward-name

To configure the display name that identifies TCP port forwarding to end users for a particular user or group policy, use the **port-forward-name** command in webvpn mode, which you enter from group-policy or username mode. To delete the display name, including a null value created by using the **port-forward-name none** command**,** use the no form of the command. The **no** option restores the default name, "Application Access." To prevent a display name, use the **port-forward none** command.

port-forward-name {**value** *name* | **none**}

no port-forward-name

Syntax Description

none	Indicates that there is no display name. Sets a null value, thereby disallowing a display name. Prevents inheriting a value.
value *name*	Describes port forwarding to end users. Maximum of 255 characters.

Defaults

The default name is "Application Access."

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set the name, "Remote Access TCP Applications," for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# port-forward-name value Remote Access TCP Applications
```

Related Commands

Command	Description
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.
webvpn	Use in global configuration mode. Lets you configure global settings for WebVPN.

port-object

To add a port object to a service object group of the type TCP, UDP, or TCP-UDP, use the **port-object** command in object-group service configuration mode. To remove port objects, use the **no** form of this command.

port-object {**eq** *port* | **range** *begin_port end_port*}

no port-object {**eq** *port* | **range** *begin_port end_port*}

Syntax Description

range *begin_port end_port*	Specifies a range of ports (inclusive), between 0 and 65535.
eq *port*	Specifies the decimal number (between 0 and 65535) or name of a TCP or UDP port for a service object.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object-network service configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	We introduced this command.

Usage Guidelines

The **port-object** command is used with the **object-group service** *protocol* command to define an object that is either a specific port or a range of ports.

If a name is specified for a TCP or UDP service, it must be one of the supported TCP or/and UDP names, and must be consistent with the protocol type of the object group. For instance, for a protocol types of tcp, udp, and tcp-udp, the names must be a valid TCP service name, a valid UDP service name, or a valid TCP and UDP service name, respectively.

If a number is specified, translation to its corresponding name (if one exists) based on the protocol type will be made when showing the object.

The following service names are supported:

TCP	UDP	TCP and UDP
bgp	biff	discard
chargen	bootpc	domain
cmd	bootps	echo
daytime	dnsix	pim-auto-rp
exec	nameserver	sunrpc
finger	mobile-ip	syslog
ftp	netbios-ns	tacacs
ftp-data	netbios-dgm	talk
gopher	ntp	
ident	rip	
irc	snmp	
h323	snmptrap	
hostname	tftp	
http	time	
klogin	who	
kshell	xdmcp	
login	isakmp	
lpd		
nntp		
pop2		
pop3		
smtp		
sqlnet		
telnet		
uucp		
whois		
www		

Examples

This example shows how to use the **port-object** command in service configuration mode to create a new port (service) object group:

```
hostname(config)# object-group service eng_service tcp
hostname(config-service)# port-object eq smtp
hostname(config-service)# port-object eq telnet
hostname(config)# object-group service eng_service udp
hostname(config-service)# port-object eq snmp
hostname(config)# object-group service eng_service tcp-udp
hostname(config-service)# port-object eq domain
hostname(config-service)# port-object range 2000 2005
```

```
hostname(config-service)# quit
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object-group** commands from the configuration.
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
show running-config object-group	Displays the current object groups.

portal-access-rule

This command allows customers to configure a global clientless SSL VPN access policy to permit or deny clientless SSL VPN sessions based on the data present in HTTP header. If denied, an error code is returned to the clients. This denial is performed before user authentication and thus minimizes the use of processing resources.

portal-access-rule none

portal-access-rule ***priority*** **[{permit | deny [code** ***code***]} **{any | user-agent match** ***string***}

no portal-access-rule ***priority*** **[{permit | deny [code** ***code***]} **{any | user-agent match** ***string***}]

clear configure webvpn portal-access-rule

Syntax Description

none	Removes all portal access rules. Clientless SSL VPN sessions will not restricted based on HTTP header.
priority	Priority of rule. Range: 1-65535.
permit	Permit access based upon HTTP header.
deny	Deny access based upon HTTP header.
code	Permit or deny access based on a returned HTTP status code. Default: 403.
code	The HTTP status code number based on which you want to permit or deny access. Range: 200-599.
any	Match any HTTP header string.
user-agent match	Enable comparison of strings in HTTP headers.
string	Specify the string to match in the HTTP header. Surround the string you are searching for with wildcards (*) for a match that contains your string or do not use wildcards to specify an exact match of your string. **Note** We recommend using wildcards in your search string. Without them, the rule may not match any strings or many fewer than you expect. If the string you are searching for has a space in it, the string must be enclosed in quotations; for example, "*a string*". When using both quotations and wild cards, your search string would look like this: "**a string**".
no portal-access-rule	Use to delete a single portal-access-rule.
clear configure webvpn portal-access-rule	Equivalent to portal-access-rule none command.

Defaults

portal-access-rule none

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.2(5)	This command was introduced simultaneously in ASA 8.2.5 and 8.4(2)
8.4(2)	This command was introduced simultaneously in ASA 8.2.5 and 8.4(2)

Usage Guidelines

This check is performed prior to user authentication.

Examples

The following example creates three portal access rules:

- Portal access rule 1 denies attempted clientless SSL VPN connections when the ASA returns code 403 and Thunderbird is in the HTTP header.
- Portal access rule 10 permits attempted clientless SSL VPN connections when MSIE 8.0 (Microsoft Internet Explorer 8.0) is in the HTTP header.
- Portal access rule 65535 permits all other attempted clientless SSL VPN connections.

```
hostname(config)# webvpn
hostname(config-webvpn)# portal-access-rule 1 deny code 403 user-agent match *Thunderbird*
hostname(config-webvpn)# portal-access-rule 10 permit user-agent match "*MSIE 8.0*"
hostname(config-webvpn)# portal-access-rule 65535 permit any
```

Related Commands

Command	Description
show run webvpn	Displays webvpn configuration including all portal-access-rules.
show vpn-sessiondb detail webvpn	Display information about VPN sessions. The command includes options for displaying information in full or in detail, lets you specify type of sessions to display, and provides options to filter and sort the information.
debug webvpn request *n*	Enables logging of debug messages at a particular level of debugging. Default: 1. Range: 1-255.

post-max-size

To specify the maximum size allowed for an object to post, use the **post-max-size** command in group-policy webvpn configuration mode. To remove this object from the configuration, use the **no** version of this command.

post-max-size <*size*>

no post-max-size

Syntax Description

size	Specifies the maximum size allowed for a posted object. The range is 0 through 2147483647.

Defaults

The default size is 2147483647.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy webvpn configuration mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Setting the size to 0 effectively disallows object posting.

Examples

The following example sets the maximum size for a posted object to 1500 bytes:

```
hostname(config)# group-policy test attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# post-max-size 1500
```

Related Commands

Command	Description
download-max-size	Specifies the maximum size of an object to download.
upload-max-size	Specifies the maximum size of an object to upload.

Command	Description
webvpn	Use in group-policy configuration mode or in username configuration mode. Lets you enter webvpn mode to configure parameters that apply to group policies or usernames.
webvpn	Use in global configuration mode. Lets you configure global settings for WebVPN.

pppoe client route distance

To configure an administrative distance for routes learned through PPPoE, use the **pppoe client route distance** command in interface configuration mode. To restore the default setting, use the **no** form of this command.

pppoe client route distance *distance*

no pppoe client route distance *distance*

Syntax Description

distance	The administrative distance to apply to routes learned through PPPoE. Valid values are from 1 to 255.

Defaults

Routes learned through PPPoE are given an administrative distance of 1 by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **pppoe client route distance** command is checked only when a route is learned from PPPoE. If the **pppoe client route distance** command is entered after a route is learned from PPPoE, the administrative distance specified does not affect the existing learned route. Only routes learned after the command was entered have the specified administrative distance.

You must specify the **setroute** option on the **ip address pppoe** command to obtain routes through PPPoE.

If PPPoE is configured on multiple interfaces, you must use the **pppoe client route distance** command on each of the interfaces to indicate the priority of the installed routes. Enablgin PPPoE clients on multiple interfaces is only supported with object tracking.

You cannot configure failover if you obtain IP addresses using PPPoE.

Examples

The following example obtains the default route through PPPoE on GigabitEhternet0/2. The route is tracked by tracking entry object 1. The SLA operation monitors the availability of the 10.1.1.1 gateway off of the outside interface. If the SLA operation fails, then the secondary route obtained on GigabitEthernet0/3 through PPPoE is used.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# pppoe client route track 1
hostname(config-if)# ip address pppoe setroute
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# pppoe client secondary track 1
hostname(config-if)# pppoe client route distance 254
hostname(config-if)# ip address pppoe setroute
```

Related Commands

Command	Description
ip address pppoe	Configures the specified interface with an IP address obtained through PPPoE.
ppoe client secondary	Configures tracking for secondary PPPoE client interface.
pppoe client route track	Associates routes learned through PPPoE with a tracking entry object.
sla monitor	Defines an SLA monitoring operation.
track rtr	Creates a tracking entry to poll the SLA.

pppoe client route track

To configure the PPPoE client to associate added routes with a specified tracked object number, use the **pppoe client route track** command in interface configuration mode. To remove the PPPoE route tracking, use the **no** form of this command.

pppoe client route track *number*

no pppoe client route track

Syntax Description

number	The tracking entry object ID. Valid values are from 1 to 500.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **pppoe client route track** command is checked only when a route is learned from PPPoE. If the **pppoe client route track** command is entered after a route is learned from PPPoE, the existing learned routes are not associated with a tracking object. Only routes learned after the command was entered are associated with the specified tracking object.

You must specify the **setroute** option on the **ip address pppoe** command to obtain routes through PPPoE.

If PPPoE is configured on multiple interfaces, you must use the **pppoe client route distance** command on each of the interfaces to indicate the priority of the installed routes. Enabling PPPoE clients on multiple interfaces is only supported with object tracking.

You cannot configure failover if you obtain IP addresses using PPPoE.

Examples

The following example obtains the default route through PPPoE on GigabitEhternet0/2. The route is tracked by tracking entry object 1. The SLA operation monitors the availability of the 10.1.1.1 gateway off of the outside interface. If the SLA operation fails, then the secondary route obtained on GigabitEthernet0/3 through PPPoE is used.

```
hostname(config)# sla monitor 123
```

```
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# pppoe client route track 1
hostname(config-if)# ip address pppoe setroute
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# pppoe client secondary track 1
hostname(config-if)# pppoe client route distance 254
hostname(config-if)# ip address pppoe setroute
```

Related Commands

Command	Description
ip address pppoe	Configures the specified interface with an IP address obtained through PPPoE.
ppoe client secondary	Configures tracking for secondary PPPoE client interface.
pppoe client route distance	Assigns an administrative distance to routes learned through PPPoE.
sla monitor	Defines an SLA monitoring operation.
track rtr	Creates a tracking entry to poll the SLA.

pppoe client secondary

To configure the PPPoE client to register as a client of a tracked object and to be brought up or down based on the tracking state, use the **pppoe client secondary** command in interface configuration mode. To remove the client registration, use the **no** form of this command.

pppoe client secondary track *number*

no pppoe client secondary track

Syntax Description

number	The tracking entry object ID. Valid values are from 1 to 500.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **pppoe client secondary** command is checked only when PPPoE session starts. If the **pppoe client route track** command is entered after a route is learned from PPPoE, the existing learned routes are not associated with a tracking object. Only routes learned after the command was entered are associated with the specified tracking object.

You must specify the **setroute** option on the **ip address pppoe** command to obtain routes through PPPoE.

If PPPoE is configured on multiple interfaces, you must use the **pppoe client route distance** command on each of the interfaces to indicate the priority of the installed routes. Enabling PPPoE clients on multiple interfaces is only supported with object tracking.

You cannot configure failover if you obtain IP addresses using PPPoE.

Examples

The following example obtains the default route through PPPoE on GigabitEhternet0/2. The route is tracked by tracking entry object 1. The SLA operation monitors the availability of the 10.1.1.1 gateway off of the outside interface. If the SLA operation fails, then the secondary route obtained on GigabitEthernet0/3 through PPPoE is used.

```
hostname(config)# sla monitor 123
```

```
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# interface GigabitEthernet0/2
hostname(config-if)# pppoe client route track 1
hostname(config-if)# ip address pppoe setroute
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# pppoe client secondary track 1
hostname(config-if)# pppoe client route distance 254
hostname(config-if)# ip address pppoe setroute
```

Related Commands

Command	Description
ip address pppoe	Configures the specified interface with an IP address obtained through PPPoE.
ppoe client secondary	Configures tracking for secondary PPPoE client interface.
pppoe client route distance	Assigns an administrative distance to routes learned through PPPoE.
pppoe client route track	Associates routes learned through PPPoE with a tracking entry object.
sla monitor	Defines an SLA monitoring operation.

CHAPTER 40

pre-fill-username through pwd Commands

pre-fill-username

To enable extracting a username from a client certificate for use in authentication and authorization, use the **pre-fill-username** command in tunnel-group webvpn-attributes mode. To remove the attribute from the configuration, use the **no** form of this command.

pre-fill-username {**ssl-client** | **clientless**}

no pre-fill-username

Syntax Description

ssl-client	Enables this feature for AnyConnect VPN client connections.
clientless	Enables this feature for clientless connections.

Defaults

No default value or behavior.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group webvpn-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

The **pre-fill-username** command enables the use of a username extracted from the certificate field specified in the **username-from-certificate** command as the username for username/password authentication and authorization. To use this pre-fill username from certificate feature, you must configure both commands.

To enable this feature, you must also configure the **username-from-certificate** command in tunnel-group general-attributes mode.

Note In Releases 8.0.4 and 8.1.2, the username is not pre-filled; instead, any data sent in the username field is ignored.

Examples

The following example, entered in global configuration mode, creates an IPsec remote access tunnel group named remotegrp and specifies that the name for an authentication or authorization query for an SSL VPN client must be derived from a digital certificate:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
```

```
hostname(config)# tunnel-group remotegrp webvpn-attributes
hostname(config-tunnel-webvpn)# pre-fill-username ssl-client
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
pre-fill-username	Enables the pre-fill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel-group.
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.

preempt

To cause the unit to become active on boot if it has the higher priority, use the **preempt** command in failover group configuration mode. To remove the preemption, use the **no** form of this command.

preempt [*delay*]

no preempt [*delay*]

Syntax Description

seconds	The wait time, in seconds, before the peer is preempted. Valid values are from 1 to 1200 seconds.

Defaults

By default, there is no delay.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Assigning a primary or secondary priority to a failover group specifies which unit the failover group becomes active on when both units boot simultaneously (within a unit polltime). However, if one unit boots before the other, then both failover groups become active on that unit. When the other unit comes online, any failover groups that have the second unit as a priority do not become active on the second unit unless the failover group is configured with the **preempt** command or is manually forced to the other unit with the **no failover active** command. If the failover group is configured with the **preempt** command, the failover group automatically becomes active on the designated unit.

Note If Stateful Failover is enabled, the preemption is delayed until the connections are replicated from the unit on which the failover group is currently active.

Examples

The following example configures failover group 1 with the primary unit as the higher priority and failover group 2 with the secondary unit as the higher priority. Both failover groups are configured with the **preempt** command with a wait time of 100 seconds, so the groups will automatically become active on their preferred unit 100 seconds after the units become available.

```
hostname(config)# failover group 1
```

```
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)# failover group 2
hostname(config-fover-group)# secondary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# mac-address e1 0000.a000.a011 0000.a000.a012
hostname(config-fover-group)# exit
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
primary	Gives the primary unit in a failover pair priority for the failover group being configured.
secondary	Gives the secondary unit in a failover pair priority for the failover group being configured.

prefix-list

To create an entry in a prefix list for ABR type 3 LSA filtering, use the **prefix-list** command in global configuration mode. To remove a prefix list entry, use the **no** form of this command.

prefix-list *prefix-list-name* [**seq** *seq_num*] {**permit | deny**} *network/len* [**ge** *min_value*] [**le** *max_value*]

no prefix-list *prefix-list-name* [**seq** *seq_num*] {**permit | deny**} *network/len* [**ge** *min_value*] [**le** *max_value*]

Syntax Description

/	A required separator between the *network* and *len* values.
deny	Denies access for a matching condition.
ge *min_value*	(Optional) Specifies the minimum prefix length to be matched. The value of the *min_value* argument must be greater than the value of the *len* argument and less than or equal to the *max_value* argument, if present.
le *max_value*	(Optional) Specifies the maximum prefix length to be matched. The value of the *max_value* argument must be greater than or equal to the value of the *min_value* argument, if present, or greater than the value of the *len* argument if the *min_value* argument is not present.
len	The length of the network mask. Valid values are from 0 to 32.
network	The network address.
permit	Permits access for a matching condition.
prefix-list-name	The name of the prefix list. The prefix-list name cannot contain spaces.
seq *seq_num*	(Optional) Applies the specified sequence number to the prefix list being created.

Defaults

If you do not specify a sequence number, the first entry in a prefix list is assigned a sequence number of 5, and the sequence number for each subsequent entry is increased by 5.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **prefix-list** commands are ABR type 3 LSA filtering commands. ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one area to another area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. The ASA begins the search at the top of the prefix list, with the entry with the lowest sequence number. Once a mach is made, the ASA does not go through the rest of the list. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number.

By default, the sequence numbers are automatically generated. They can be suppressed with the **no prefix-list sequence-number** command. Sequence numbers are generated in increments of 5. The first sequence number generated in a prefix list would be 5. The next entry in that list would have a sequence number of 10, and so on. If you specify a value for an entry, and then do not specify values for subsequent entries, the generated sequence numbers are increased from the specified value in increments of 5. For example, if you specify that the first entry in the prefix list has a sequence number of 3, and then add two more entries without specifying a sequence number for the additional entries, the automatically generated sequence numbers for those two entries would be 8 and 13.

You can use the **ge** and **le** keywords to specify the range of the prefix length to be matched for prefixes that are more specific than the *network/len* argument. Exact match is assumed when neither the **ge** or **le** keywords are specified. The range is from *min_value* to 32 if only the **ge** keyword is specified.The range is from *len* to *max_value* if only the **le** keyword is specified.

The value of the *min_value* and *max_value* arguments must satisfy the following condition:

len < *min_value* <= *max_value* <= 32

Use the **no** form of the command to remove specific entries from the prefix list. Use the **clear configure prefix-list** command to remove a prefix list. The clear **configure prefix-list** command also removes the associated **prefix-list description** command, if any, from the configuration.

Examples

The following example denies the default route 0.0.0.0/0:

```
hostname(config)# prefix-list abc deny 0.0.0.0/0
```

The following example permits the prefix10.0.0.0/8:

```
hostname(config)# prefix-list abc permit 10.0.0.0/8
```

The following example shows how to accept a mask length of up to 24 bits in routes with the prefix 192/8:

```
hostname(config)# prefix-list abc permit 192.168.0.0/8 le 24
```

The following example shows how to deny mask lengths greater than 25 bits in routes with a prefix of 192/8:

```
hostname(config)# prefix-list abc deny 192.168.0.0/8 ge 25
```

The following example shows how to permit mask lengths from 8 to 24 bits in all address space:

```
hostname(config)# prefix-list abc permit 0.0.0.0/0 ge 8 le 24
```

The following example shows how to deny mask lengths greater than 25 bits in all address space:

```
hostname(config)# prefix-list abc deny 0.0.0.0/0 ge 25
```

The following example shows how to deny all routes with a prefix of 10/8:

```
hostname(config)# prefix-list abc deny 10.0.0.0/8 le 32
```

The following example shows how to deny all masks with a length greater than 25 bits for routes with a prefix of 192.168.1/24:

```
hostname(config)# prefix-list abc deny 192.168.1.0/24 ge 25
```

The following example shows how to permit all routes with a prefix of 0/0:

```
hostname(config)# prefix-list abc permit 0.0.0.0/0 le 32
```

Related Commands

Command	Description
clear configure prefix-list	Removes the **prefix-list** commands from the running configuration.
prefix-list description	Lets you to enter a description for a prefix list.
prefix-list sequence-number	Enables prefix list sequence numbering.
show running-config prefix-list	Displays the **prefix-list** commands in the running configuration.

prefix-list description

To add a description to a prefix list, use the **prefix-list description** command in global configuration mode. To remove a prefix list description, use the **no** form of this command.

prefix-list *prefix-list-name* **description** *text*

no prefix-list *prefix-list-name* **description** [*text*]

Syntax Description

prefix-list-name	The name of a prefix list.
text	The text of the prefix list description. You can enter a maximum of 80 characters.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can enter **prefix-list** and **prefix-list description** commands in any order for a particular prefix list name; you do not need to create the prefix list before entering a prefix list description. The **prefix-list description** command will always appear on the line before the associated prefix list in the configuration, no matter what order you enter the commands.

If you enter a **prefix-list description** command for a prefix list entry that already has a description, the new description replaces the original description.

You do not need to enter the text description when using the **no** form of this command.

Examples

The following example adds a description for a prefix list named MyPrefixList. The **show running-config prefix-list** command shows that although the prefix list description has been added to the running configuration, the prefix-list itself has not been configured.

```
hostname(config)# prefix-list MyPrefixList description A sample prefix list description
hostname(config)# show running-config prefix-list

!
prefix-list MyPrefixList description A sample prefix list description
```

!

Related Commands

Command	Description
clear configure prefix-list	Removes the **prefix-list** commands from the running configuration.
prefix-list	Defines a prefix list for ABR type 3 LSA filtering.
show running-config prefix-list	Displays the **prefix-list** commands in the running configuration.

prefix-list sequence-number

To enable prefix list sequence numbering, use the **prefix-list sequence-number** command in global configuration mode. To disable prefix list sequence numbering, use the **no** form of this command.

prefix-list sequence-number

Syntax Description

This command has no arguments or keywords.

Defaults

Prefix list sequence numbering is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Only the **no** form of this command appears in the configuration. When the **no** form of this command is in the configuration, the sequence numbers, including the manually configured ones, are removed from the **prefix-list** commands in the configuration and new prefix lists entries are not assigned a sequence number.

When prefix list sequence numbering is enabled, all prefix list entries are assigned sequence numbers using the default numbering method (starting with 5 and incrementing each number by 5). If a sequence number was manually assigned to a prefix list entry before numbering was disabled, the manually assigned number is restored. Sequence numbers that are manually assigned while automatic numbering is disabled are also restored, even though they are not displayed while numbering is disabled.

Examples

The following example disables prefix list sequence numbering:

```
hostname(config)# no prefix-list sequence-number
```

Related Commands

Command	Description
prefix-list	Defines a prefix list for ABR type 3 LSA filtering.
show running-config prefix-list	Displays the **prefix-list** commands in the running configuration.

prf

To specify the pseudo-random function (PRF) in an IKEv2 security association (SA) for AnyConnect IPsec connections, use the **prf** command in IKEv2 policy configuration mode. To remove the command and use the default setting, use the **no** form of this command:

prf {**md5** | **sha** | **sha256** | **sha384** | **sha512**}

no prf {**md5** | **sha** | **sha256** | **sha384** | **sha512**}

Syntax Description

md5	Specifies the MD5 algorithm.
sha	(Default) Specifies the Secure Hash Algorithm SHA 1.
sha256	Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
sha384	Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
sha512	Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.

Defaults

The default is **sha** (SHA 1).

Usage Guidelines

An IKEv2 SA is a key used in phase 1 to enable IKEv2 peers to communicate securely in phase 2. After entering the **crypto ikev2 policy** command, use the **prf** command to select the pseudo-random function used for the construction of keying material for all of the cryptographic algorithms used in the SA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was added.
8.4(2)	The **sha256**, **sha384**, and **sha512** keywords were added for SHA 2 support.

Examples

The following example enters IKEv2 policy configuration mode and sets the PRF to MD5:

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)# prf md5
```

Related Commands

Command	Description
encryption	Specifies the encryption algorithm in an IKEv2 SA for AnyConnect IPsec connections.
group	Specifies the Diffie-Hellman group in an IKEv2 SA for AnyConnect IPsec connections.
integrity	Specifies the ESP integrity algorithm in an IKEv2 SA for AnyConnect IPsec connections.
lifetime	Specifies the SA lifetime for the IKEv2 SA for AnyConnect IPsec connections.

primary

To give the primary unit higher priority for a failover group, use the **primary** command in failover group configuration mode. To restore the default value, use the **no** form of this command.

primary

no primary

Syntax Description

This command has no arguments or keywords.

Defaults

If **primary** or **secondary** is not specified for a failover group, the failover group defaults to **primary**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Assigning a primary or secondary priority to a failover group specifies which unit the failover group becomes active on when both units boot simultaneously (within a unit polltime). If one unit boots before the other, then both failover groups become active on that unit. When the other unit comes online, any failover groups that have the second unit as a priority do not become active on the second unit unless the failover group is configured with the **preempt** command or is manually forced to the other unit with the **no failover active** command.

Examples

The following example configures failover group 1 with the primary unit as the higher priority and failover group 2 with the secondary unit as the higher priority. Both failover groups are configured with the **preempt** command, so the groups will automatically become active on their preferred unit as the units become available.

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)# failover group 2
hostname(config-fover-group)# secondary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# mac-address e1 0000.a000.a011 0000.a000.a012
hostname(config-fover-group)# exit
```

```
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
preempt	Forces the failover group to become active on its preferred unit when the unit becomes available.
secondary	Gives the secondary unit a higher priority than the primary unit.

priority (class)

To enable QoS priority queueing, use the **priority** command in class configuration mode. For critical traffic that cannot tolerate latency, such as voice over IP (VoIP), you can identify traffic for low latency queueing (LLQ) so that it is always transmitted at a minimum rate. To remove the priority requirement, use the **no** form of this command.

Note This command is not supported on the ASA Services Module.

priority

no priority

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or variables.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

LLQ priority queueing lets you prioritize certain traffic flows (such as latency-sensitive traffic like voice and video) ahead of other traffic.

The ASA supports two types of priority queueing:

- Standard priority queueing—Standard priority queueing uses an LLQ priority queue on an interface (see the **priority-queue** command), while all other traffic goes into the "best effort" queue. Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped. This is called *tail drop*. To avoid having the queue fill up, you can increase the queue buffer size. You can also fine-tune the maximum number of packets allowed into the transmit queue. These options let you control the latency and robustness of the priority queuing. Packets in the LLQ queue are always transmitted before packets in the best effort queue.

- Hierarchical priority queueing—Hierarchical priority queueing is used on interfaces on which you enable a traffic shaping queue (the **shape** command). A subset of the shaped traffic can be prioritized. The standard priority queue is not used. See the following guidelines about hierarchical priority queueing:
  - Priority packets are always queued at the head of the shape queue so they are always transmitted ahead of other non-priority queued packets.
  - Priority packets are never dropped from the shape queue unless the sustained rate of priority traffic exceeds the shape rate.
  - For IPsec-encrypted packets, you can only match traffic based on the DSCP or precedence setting.
  - IPsec-over-TCP is not supported for priority traffic classification.

Configuring QoS with Modular Policy Framework

To enable priority queueing, use the Modular Policy Framework. You can use standard priority queueing or hierarchical priority queueing.

For standard priority queueing, perform the following tasks:

1. **class-map**—Identify the traffic on which you want to perform priority queueing.
2. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **priority**—Enable priority queueing for the class map.
3. **service-policy**—Assigns the policy map to an interface or globally.

For hierarchical priority-queueing, perform the following tasks:

1. **class-map**—Identify the traffic on which you want to perform priority queueing.
2. **policy-map** (for priority queueing)—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **priority**—Enable priority queueing for the class map. You can only include the priority command in this policy map if you want to use is hierarchically.
3. **policy-map** (for traffic shaping)—Identify the actions associated with the **class-default** class map.
   a. **class class-default**—Identify the **class-default** class map on which you want to perform actions.
   b. **shape**—Apply traffic shaping to the class map.
   c. **service-policy**—Call the priority queueing policy map in which you configured the **priority** command so you can apply priority queueing to a subset of shaped traffic.
4. **service-policy**—Assigns the policy map to an interface or globally.

Examples

The following is an example of the **priority** command in policy-map configuration mode:

```
hostname(config)# policy-map localpolicy1
hostname(config-pmap)# class firstclass
hostname(config-pmap-c)# priority
hostname(config-pmap-c)# class class-default
hostname(config-pmap-c)#
```

Related Commands

class	Specifies a class map to use for traffic classification.
clear configure policy-map	Remove all policy-map configuration, except that if a policy-map is in use in a service-policy command, that policy-map is not removed.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Display all current policy-map configurations.

priority (cluster group)

To set the priority of this unit for master unit elections in an ASA cluster, use the **priority** command in cluster group configuration mode. To remove the priority, use the **no** form of this command.

priority *priority_number*

no priority [*priority_number*]

Syntax Description

priority_number	Sets the priority of this unit for master unit elections, between 1 and 100, where 1 is the highest priority.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Cluster group configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

Members of the cluster communicate over the cluster control link to elect a master unit, as follows:

1. When you enable clustering for a unit (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other units with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes master.

Note If multiple units tie for the highest priority, the cluster unit name, and then the serial number is used to determine the master.

4. If a unit later joins the cluster with a higher priority, it does not automatically become the master unit; the existing master unit always remains as the master unless it stops responding, at which point a new master unit is elected.

Note You can manually force a unit to become the master using the **cluster master unit** command. For centralized features, if you force a master unit change, then all connections are dropped, and you have to re-establish the connections on the new master unit. See the configuration guide for a list of centralized features.

Examples

The following example sets the priority to 1 (the highest):

```
hostname(config)# cluster group cluster1
hostname(cfg-cluster)# priority 1
```

Related Commands

Command	Description
clacp system-mac	When using spanned EtherChannels, the ASA uses cLACP to negotiate the EtherChannel with the neighbor switch.
cluster group	Names the cluster and enters cluster configuration mode.
cluster-interface	Specifies the cluster control link interface.
cluster interface-mode	Sets the cluster interface mode.
conn-rebalance	Enables connection rebalancing.
console-replicate	Enables console replication from slave units to the master unit.
enable (cluster group)	Enables clustering.
health-check	Enables the cluster health check feature, which includes unit health monitoring and interface health monitoring.
key	Sets an authentication key for control traffic on the cluster control link.
local-unit	Names the cluster member.
mtu cluster-interface	Specifies the maximum transmission unit for the cluster control link interface.

priority (vpn load balancing)

To set the priority of the local device participating in the virtual load-balancing cluster, use the **priority** command in VPN load-balancing mode. To revert to the default priority specification, use the **no** form of this command.

priority *priority*

no priority

Syntax Description

priority	The priority, in the range of 1 to 10, that you want to assign to this device.

Defaults

The default priority depends on the model number of the device:

Model Number	Default Priority
5520	5
5540	7

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
VPN load-balancing	—	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You must first use the **vpn load-balancing** command to enter VPN load-balancing mode.

This command sets the priority of the local device participating in the virtual load-balancing cluster.

The priority must be an integer in the range of 1 (lowest) to 10 (highest).

The priority is used in the master-election process as one way to determine which of the devices in a VPN load-balancing cluster becomes the master or primary device for the cluster. See CLI configuration guide for details about the master-election process.

The **no** form of the command reverts the priority specification to the default value.

Examples

The following is an example of a VPN load-balancing command sequence that includes a **priority** command that sets the priority of the current device to 9:

```
hostname(config)# interface GigabitEthernet 0/1
```

```
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# priority 9
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
vpn load-balancing	Enter VPN load-balancing mode.

priority-queue

To create a standard priority queue on an interface for use with the **priority** command, use the **priority-queue** command in global configuration mode. To remove the queue, use the **no** form of this command.

Note This command is not supported on ASA 5580 Ten Gigabit Ethernet interfaces. (Ten Gigabit Ethernet interfaces are supported for priority queues on the ASA 5585-X.) This command is also not supported for the ASA 5512-X through ASA 5555-X Management interface.

This command is not supported on the ASA Services Module.

priority-queue *interface-name*

no priority queue *interface-name*

Syntax Description

interface-name	Specifies the name of the physical interface on which you want to enable the priority queue, or for the ASA 5505 or ASASM, the name of the VLAN interface.

Defaults

By default, priority queuing is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(3)/8.4(1)	Support for Ten Gigabit Ethernet interfaces was added for the ASA 5585-X.

Usage Guidelines

LLQ priority queueing lets you prioritize certain traffic flows (such as latency-sensitive traffic like voice and video) ahead of other traffic.

The ASA supports two types of priority queueing:

- Standard priority queueing—Standard priority queueing uses an LLQ priority queue on an interface that yopu create using the **priority-queue** command, while all other traffic goes into the "best effort" queue. Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped. This is called *tail drop*. To avoid having the queue fill up, you can increase the queue buffer size (the **queue-limit** command).

You can also fine-tune the maximum number of packets allowed into the transmit queue (the **tx-ring-limit** command). These options let you control the latency and robustness of the priority queuing. Packets in the LLQ queue are always transmitted before packets in the best effort queue.

- Hierarchical priority queueing—Hierarchical priority queueing is used on interfaces on which you enable a traffic shaping queue. A subset of the shaped traffic can be prioritized. The standard priority queue is not used.

Note On the ASA 5505 only, configuring a priority queue on one interface overwrites the same configuration on all other interfaces; only the last applied configuration is present on all interfaces. Also, if the priority queue configuration is removed from one interface, it is removed from all interfaces. To work around this issue, configure the **priority-queue** command on only one interface. If different interfaces need different settings for the **queue-limit** and/or **tx-ring-limit** commands, use the largest of all queue limits and smallest of all tx-ring-limits on any one interface (CSCsi13132).

Examples

The following example configures a priority queue for the interface named test, specifying a queue limit of 30,000 packets and a transmit queue limit of 256 packets.

```
hostname(config)# priority-queue test
hostname(priority-queue)# queue-limit 30000
hostname(priority-queue)# tx-ring-limit 256
hostname(priority-queue)#
```

Related Commands

Command	Description
queue-limit	Specifies the maximum number of packets that can be enqueued to a priority queue before it drops data.
tx-ring-limit	Sets the maximum number of packets that can be queued at any given time in the Ethernet transmit driver.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
clear configure priority-queue	Removes the current priority queue configuration.
show running-config [all] priority-queue	Shows the current priority queue configuration. If you specify the **all** keyword, this command displays all the current priority queue, queue-limit, and tx-ring-limit configuration values.

privilege

To configure command privilege levels for use with command authorization (local, RADIUS, and LDAP (mapped) only), use the **privilege** command in global configuration mode. To disallow the configuration, use the **no** form of this command.

privilege [**show | clear | configure**] **level** *level* [**mode** {**enable | configure**}] **command** *command*

no privilege [**show | clear | configure**] **level** *level* [**mode** {**enable | configure**}] **command** *command*

Syntax Description

clear	(Optional) Sets the privilege only for the clear form of the command. If you do not use the **clear**, **show**, or **configure** keywords, all forms of the command are affected.
command *command*	Specifies the command you are configuring. You can only configure the privilege level of the *main* command. For example, you can configure the level of all **aaa** commands, but not the level of the **aaa authentication** command and the **aaa authorization** command separately. Also, you cannot configure the privilege level of subcommands separately from the main command. For example, you can configure the **context** command, but not the **allocate-interface** command, which inherits the settings from the **context** command.
configure	(Optional) Sets the privilege only for the configure form of the command. The configure form of the command is typically the form that causes a configuration change, either as the unmodified command (without the **show** or **clear** prefix) or as the **no** form. If you do not use the **clear**, **show**, or **configure** keywords, all forms of the command are affected.
level *level*	Specifies the privilege level; valid values are from 0 to 15. Lower privilege level numbers are lower privilege levels.
mode enable	(Optional) If a command can be entered in user EXEC/privileged EXEC mode as well as configuration mode, and the command performs different actions in each mode, you can set the privilege level for these modes separately. The **mode enable** keyword specifies both user EXEC mode and privileged EXEC mode.
mode configure	(Optional) If a command can be entered in user EXEC/privileged EXEC mode as well as configuration mode, and the command performs different actions in each mode, you can set the privilege level for these modes separately. The mode **configure** keyword specifies configuration mode, accessed using the **configure terminal** command.
show	(Optional) Sets the privilege only for the show form of the command. If you do not use the **clear**, **show**, or **configure** keywords, all forms of the command are affected.

Defaults

By default, the following commands are assigned to privilege level 0. All other commands are at level 15.

- **show checksum**
- **show curpriv**

- **enable**
- **help**
- **show history**
- **login**
- **logout**
- **pager**
- **show pager**
- **clear pager**
- **quit**
- **show version**

If you move any configure mode commands to a lower level than 15, be sure to move the **configure** command to that level as well, otherwise, the user will not be able to enter configuration mode.

To view all privilege levels, see the **show running-config all privilege all** command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	Support for RADIUS users with Cisco VSA CVPN3000-Privilege-Level was added. LDAP users are supported if you map the LDAP attribute to the CVPN3000-Privilege-Level using the **ldap map-attributes** command.

Usage Guidelines

The **privilege** command lets you set privilege levels for ASA commands when you configure the **aaa authorization command LOCAL** command. Even though the command uses the **LOCAL** keyword, this keyword enables local, RADIUS, and LDAP (mapped) authorization.

Examples

For example, the **filter** command has the following forms:

- **filter** (represented by the **configure** option)
- **show running-config filter**
- **clear configure filter**

You can set the privilege level separately for each form, or set the same privilege level for all forms by omitting this option. For example, set each form separately as follows:

```
hostname(config)# privilege show level 5 command filter
hostname(config)# privilege clear level 10 command filter
hostname(config)# privilege cmd level 10 command filter
```

Alternatively, you can set all filter commands to the same level:

```
hostname(config)# privilege level 5 command filter
```

The **show privilege** command separates the forms in the display.

The following example shows the use of the **mode** keyword. The **enable** command must be entered from user EXEC mode, while the **enable password** command, which is accessible in configuration mode, requires the highest privilege level.

```
hostname(config)# privilege cmd level 0 mode enable command enable
hostname(config)# privilege cmd level 15 mode cmd command enable
hostname(config)# privilege show level 15 mode cmd command enable
```

The following example shows an additional command, the **configure** command, which uses the **mode** keyword:

```
hostname(config)# privilege show level 5 mode cmd command configure
hostname(config)# privilege clear level 15 mode cmd command configure
hostname(config)# privilege cmd level 15 mode cmd command configure
hostname(config)# privilege cmd level 15 mode enable command configure
```

Note This last line is for the **configure terminal** command.

Related Commands

Command	Description
clear configure privilege	Removes privilege command statements from the configuration.
show curpriv	Displays current privilege level.
show running-config privilege	Displays privilege levels for commands.

prompt

To customize the CLI prompt, use the **prompt** command in global configuration mode. To revert to the default prompt, use the **no** form of this command.

prompt {[**hostname**] [**context**] [**domain**] [**slot**] [**state**] [**priority**] [**cluster-unit**]}

no prompt [**hostname**] [**context**] [**domain**] [**slot**] [**state**] [**priority**] [**cluster-unit**]

Syntax Description

cluster-unit	Displays the cluster unit name. Each unit in a cluster can have a unique name.
context	(Multiple mode only) Displays the current context.
domain	Displays the domain name.
hostname	Displays the hostname.
priority	Displays the failover priority as pri (primary) or sec (secondary). Set the priority using the **failover lan unit** command.
state	Displays the traffic-passing state or role of the unit. For failover, the following values are displayed for the **state** keyword: • act—Failover is enabled, and the unit is actively passing traffic. • stby— Failover is enabled, and the unit is not passing traffic and is in a standby, failed, or other non-active state. • actNoFailover—Failover is not enabled, and the unit is actively passing traffic. • stbyNoFailover—Failover is not enabled, and the unit is not passing traffic. This might happen when there is an interface failure above the threshold on the standby unit. For clustering, the following values are displayed for the **state** keyword: • master • slave For example, if you set **prompt hostname cluster-unit state**, then in the prompt "ciscoasa/cl2/slave>", the hostname is ciscoasa, the unit name is cl2, and the state name is slave.

Defaults

The default prompt is the hostname. In multiple context mode, the hostname is followed by the current context name (*hostname*/*context*).

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.2(1)	This command was introduced.
9.0(1)	The **cluster-unit** option was added. The **state** keyword was updated for clustering.

Usage Guidelines

The order in which you enter the keywords determines the order of the elements in the prompt, which are separated by a slash (/).

In multiple context mode, you can view the extended prompt when you log in to the system execution space or the admin context. Within a non-admin context, you only see the default prompt, which is the hostname and the context name.

The ability to add information to a prompt allows you to see at-a-glance which ASA you are logged into when you have multiple modules. During a failover, this feature is useful when both ASAs have the same hostname.

Examples

The following example shows all available elements in the prompt available for failover:

```
hostname(config)# prompt hostname context slot state priority
```

The prompt changes to the following string:

```
hostname/admin/pri/act(config)#
```

Related Commands

Command	Description
clear configure prompt	Clears the configured prompt.
show running-config prompt	Displays the configured prompt.

protocol

To specify the protocol and encryption types for an IPsec proposal for IKEv2 connections, use the **protocol** command from IPsec proposal configuration mode. To remove the protocol and encryption types, use the **no** form of the command:

protocol esp {**encryption** {**des | 3des | aes | aes-192 | aes-256 | aes-gcm | aes-gcm-192 | aes-gcm-256 | aes-gmac | aes-gmac-192 | aes-gmac-256 | null**} | **integrity** {**md5 | sha-1 | sha-256 | sha-384 | sha-512 | null**}

no protocol esp {**encryption** {**des | 3des | aes | aes-192 | aes-256 | | aes-gcm | aes-gcm-192 | aes-gcm-256 | aes-gmac | aes-gmac-192 | aes-gmac-256 | null**} | **integrity** {**md5 | sha-1 | sha-256 | sha-384 | sha-512 | null**}

Syntax Description

esp	Specifies the Encapsulating Security Payload (ESP) IPsec protocol (currently the only supported protocol for IPsec).
des	Specifies 56-bit DES-CBC encryption for ESP.
3des	(Default) Specifies the triple DES encryption algorithm for ESP.
aes	Specifies AES with a 128-bit key encryption for ESP.
aes-192	Specifies AES with a 192-bit key encryption for ESP.
aes-256	Specifies AES with a 256-bit key encryption for ESP.
aes-gcm	Specifies which AES-GCM or AES-GMAC algorithm to use.
aes-gcm-192	Specifies which AES-GCM or AES-GMAC algorithm to use.
aes-gcm-256	Specifies which AES-GCM or AES-GMAC algorithm to use.
aes-gmac	Specifies which AES-GCM or AES-GMAC algorithm to use.
aes-gmac-192	Specifies which AES-GCM or AES-GMAC algorithm to use.
aes-gmac-256	Specifies which AES-GCM or AES-GMAC algorithm to use.
null	Does not use encryption for ESP.
integrity	Specifies the integrity algorithm for the IPsec protocol.
md5	Specifies the md5 algorithm for the ESP integrity protection.
sha-1	(Default) Specifies the Secure Hash Algorithm (SHA) SHA-1, defined in the U.S. Federal Information Processing Standard (FIPS), for ESP integrity protection.
sha-256	Specifies which algorithm to use as an IPsec integrity algorithm.
sha-384	Specifies which algorithm to use as an IPsec integrity algorithm.
sha-512	Specifies which algorithm to use as an IPsec integrity algorithm.
null	Choose if AES-GCM/GMAC is configured as the encryption algorithm.

Defaults

The default settings for an IPsec proposal are the encryption type 3DES and the integrity type SHA-1.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
IPsec proposal configuration	•	•	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.
9.0(1)	Added AES-GCM or AES-GMAC algorithm support. Added ability to choose an algorithm to use as an IPsec integrity algorithm.

Usage Guidelines

IKEv2 IPsec proposals can have multiple encryption and integrity types. Use this command to specify the types, which allows the peer to pick and choose as desired.

You must choose the null integrity algorithm if AES-GMC/GMAC is configured as the encryption algorithm.

Examples

The following example creates the IPsec proposal *proposal_1*, configures the ESP encryption types DES and 3DES, and specifies the crypto algorithms MD5 and SHA-1 for integrity protection:

```
hostname(config)# crypto ipsec ikev2 ipsec-proposal proposal_1
hostname(config-ipsec-proposal)# protocol ESP encryption des 3des
hostname(config-ipsec-proposal)# protocol ESP integrity md5 sha-1
```

Related Commands

Command	Description
crypto ikev2 enable	Enables ISAKMP IKEv2 negotiation on the interface on which the IPsec peer communicates.
crypto ipsec ikev2 ipsec-proposal	Creates an IPsec proposal and enters IPsec proposal configuration mode where you specify multiple encryption and integrity types for the proposal.
show running-config ipsec	Displays the configuration of all transform sets.
crypto map set transform-set	Specifies the transform sets to use in a crypto map entry.
crypto dynamic-map set transform-set	Specifies the transform sets to use in a dynamic crypto map entry.
show running-config crypto map	Displays the crypto map configuration.
show running-config crypto dynamic-map	Displays the dynamic crypto map configuration.

protocol-enforcement

To enable the domain name, label length, and format check, including compression and looped pointer check, use the **protocol-enforcement** command in parameters configuration mode. To disable protocol enforcement, use the **no** form of this command.

protocol-enforcement

no protocol-enforcement

Syntax Description

This command has no arguments or keywords.

Defaults

Protocol enforcement is enabled by default. This feature can be enabled when **inspect dns** is configured even if a **policy-map type inspect dns** is not defined. To disable, **no protocol-enforcement** must explicitly be stated in the policy map configuration. If **inspect dns** is not configured, NAT rewrite is not performed.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

Under certain conditions, protocol enforcement is performed even if the command is disabled. This occurs when parsing a DNS resource record is required for other purposes, such as DNS resource record classification, NAT or TSIG check.

Examples

The following example shows how to enable protocol enforcement in a DNS inspection policy map:

```
hostname(config)# policy-map type inspect dns preset_dns_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# protocol-enforcement
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

protocol http

To specify HTTP as a permitted distribution point protocol for retrieving a CRL, use the **protocol http** command in ca-crl configuration mode. To remove HTTP as the permitted method of CRL retrieval, use the **no** form of this command.

protocol http

no protocol http

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is to permit HTTP.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-crl configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you use this command, be sure to assign HTTP rules to the public interface filter. Subject to permission, the content of the CRL distribution point determines the retrieval method (HTTP, LDAP, and/or SCEP).

Examples

The following example enters ca-crl configuration mode, and permits HTTP as a distribution point protocol for retrieving a CRL for trustpoint central:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# protocol http
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.

Command	Description
protocol ldap	Specifies LDAP as a retrieval method for CRLs.
protocol scep	Specifies SCEP as a retrieval method for CRLs.

protocol ldap

To specify LDAP as a distribution point protocol for retrieving a CRL, use the **protocol ldap** command in ca-crl configuration mode. Subject to permission, the content of the CRL distribution point determines the retrieval method (HTTP, LDAP, and/or SCEP).

To remove the LDAP protocol as the permitted method of CRL retrieval, use the **no** form of this command.

protocol ldap

no protocol ldap

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is to permit LDAP.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
crl configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters ca-crl configuration mode, and permits LDAP as a distribution point protocol for retrieving a CRL for trustpoint central:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# protocol ldap
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
protocol http	Specifies HTTP as a retrieval method for CRLs
protocol scep	Specifies SCEP as a retrieval method for CRLs

protocol scep

To specify SCEP as a distribution point protocol for retrieving a CRL, use the **protocol scep** command in crl configure mode. Subject to permission, the content of the CRL distribution point determines the retrieval method (HTTP, LDAP, and/or SCEP).

To remove the SCEP protocol as the permitted method of CRL retrieval, use the **no** form of this command.

protocol scep

no protocol scep

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is to permit SCEP.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crl configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters ca-crl configuration mode, and permits SCEP as a distribution point protocol for retrieving a CRL for trustpoint central:

```
hostname(configure)# crypto ca trustpoint central
hostname(ca-trustpoint)# crl configure
hostname(ca-crl)# protocol scep
hostname(ca-crl)#
```

Related Commands

Command	Description
crl configure	Enters ca-crl configuration mode.
crypto ca trustpoint	Enters trustpoint configuration mode.
protocol http	Specifies HTTP as a retrieval method for CRLs
protocol ldap	Specifies LDAP as a retrieval method for CRLs

protocol-object

To add a protocol object to a protocol object group, use the **protocol-object** command in protocol configuration mode. To remove port objects, use the **no** form of this command.

protocol-object *protocol*

no protocol-object *protocol*

Syntax Description

protocol	Protocol name or number.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Protocol configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **protocol-object** command is used with the **object-group** command to define a protocol object in protocol configuration mode.

You can specify an IP protocol name or number using the *protocol* argument. The udp protocol number is 17, the tcp protocol number is 6, and the egp protocol number is 47.

Examples

The following example shows how to define protocol objects:

```
hostname(config)# object-group protocol proto_grp_1
hostname(config-protocol)# protocol-object udp
hostname(config-protocol)# protocol-object tcp
hostname(config-protocol)# exit
hostname(config)# object-group protocol proto_grp
hostname(config-protocol)# protocol-object tcp
hostname(config-protocol)# group-object proto_grp_1
hostname(config-protocol)# exit
hostname(config)#
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object group** commands from the configuration.
group-object	Adds network object groups.
network-object	Adds a network object to a network object group.
object-group	Defines object groups to optimize your configuration.
show running-config object-group	Displays the current object groups.

protocol-violation

To define actions when a protocol violation occurs with HTTP and NetBIOS inspection, use the **protocol-violation** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

protocol-violation action [**drop** [**log**] | **log**]

no protocol-violation action [**drop** [**log**] | **log**]

Syntax Description

drop	Specifies to drop packets that do not conform to the protocol.
log	Specifies to log the protocol violations.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

This command can be configured in an HTTP or NetBIOS policy map. A syslog is issued when the HTTP or NetBIOS parser cannot detect a valid HTTP or NetBIOS message in the first few bytes of the message. This occurs, for instance, when a chunked encoding is malformed and the message cannot be parsed.

Examples

The following example shows how to set up an action for protocol violation in a policy map:

```
hostname(config)# policy-map type inspect http http_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# protocol-violation action drop
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

Command	Description
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

proxy-auth

To flag the tunnel group as a specific proxy authentication tunnel group, use the **proxy-auth** command in webvpn configuration mode.

proxy-auth [**sdi**]

Syntax Description

sdi	Parses RADIUS/TACACS SDI proxy messages into native SDI directives.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use the **proxy-auth** command for enabling the parsing of aaa-server proxy authentication text messages into native protocol directives.

proxy-auth_map sdi

To map RADIUS challenge messages returned from a RADIUS proxy server to native SDI messages, use the **proxy-auth_map sdi** command in aaa-server configuration mode.

proxy-auth_map sdi [**sdi_message**] [**radius_challenge_message**]

Syntax Description

radius_challenge_message	Specifies the RADIUS challenge messages that are used to map specific SDI messages, which can any of the following: • new-pin-meth—New PIN Method, [default] Do you want to enter your own pin • new-pin-reenter—Reenter new PIN, [default] Reenter PIN: • new-pin-req—New PIN requested, [default] Enter your new Alpha-Numerical PIN • new-pin-sup—New PIN supplied, [default] Please remember your new PIN • new-pin-sys-ok—New PIN accepted, [default] New PIN Accepted • next-ccode-and-reauth—Reauthenticate on token change, [default] new PIN with the next card code • next-code—Provide the tokencode without PIN, [default] Enter Next PASSCODE • ready-for-sys-pin—Accept system generated PIN, [default] ACCEPT A SYSTEM GENERATED PIN
sdi_message	Specifies the native SDI messages.

Defaults

The default mapping on the ASA corresponds to default settings on the Cisco ACS (including the system administration, configuration, and RSA SecureID prompts), which also synchronizes with default settings on the RSA Authentication Manager.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Aaa-server configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

To enable parsing and mapping of RADIUS challenge messages from a RADIUS proxy, you must enable the **proxy-auth** command in tunnel-group configuration mode. Then default mapping values are used. You can change the default mapping values using the **proxy-auth_map** command.

A remote user connects to the ASA with the AnyConnect client and tries to authenticate using an RSA SecurID token. The ASA can be configured to use a RADIUS proxy server which in turn, communicates with the SDI server about that authentication.

During authentication, the RADIUS server presents access challenge messages to the ASA. Within these challenge messages are reply messages containing text from the SDI server. The message text is different when the ASA is communicating directly with an SDI server than when the ASA is communicating through the RADIUS proxy.

Therefore, to appear as a native SDI server to the AnyConnect client, the ASA must interpret the messages from the RADIUS server. Also, because the SDI messages are configurable on the SDI server, the message text on the ASA must match (in whole or in part) the message text on the SDI server. Otherwise, the prompts displayed to the remote client user may not be appropriate for the action required during authentication. The AnyConnect client might fail to respond, and authentication might fail.

Related Commands

Command	Description
proxy-auth	Enables parsing and mapping of RADIUS challenge messages from a RADIUS proxy.

proxy-bypass

To configure the ASA to perform minimal content rewriting, and to specify the types of content to rewrite—external links and/or XML—use the **proxy-bypass** command in webvpn configuration mode. To disable proxy bypass, use the **no** form of the command.

proxy-bypass interface *interface name* **{port** *port number***| path-mask** *path mask***} target** *url* **[rewrite {link | xml | none}]**

no proxy-bypass interface *interface name* **{port** *port number***| path-mask** *path mask***} target** *url* **[rewrite {link | xml | none}]**

Syntax Description

host	Identifies the host to forward traffic to. Use either the host IP address or a hostname.
interface	Identifies the ASA interface for proxy bypass.
interface name	Specifies an ASA interface by name.
link	Specifies rewriting of absolute external links.
none	Specifies no rewriting.
path-mask	Specifies the pattern to match.
path-mask	Specifies a pattern to match that can contain a regular expression. You can use the following wildcards: * — Matches everything. You cannot use this wildcard by itself. It must accompany an alphanumeric string. ? —Matches any single character. [!seq] — Matches any character not in sequence. [seq] — Matches any character in sequence. Maximum 128 bytes.
port	Identifies the port reserved for proxy bypass.
port number	Specifies a high numbered port reserved for proxy bypass. The port range is 20000-21000. You can use a port for one proxy bypass rule only.
rewrite	(Optional) Specifies the additional rules for rewriting: none or a combination of XML and links.
target	Identifies the remote server to forward the traffic to.
url	Enter the URL in the format **http(s)://***fully_qualified_domain_name*[:*port*]. Maximum 128 bytes. The port for HTTP is 80 and for HTTPS it is 443, unless you specify another port.
xml	Specifies rewriting XML content.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
WebVPN configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use proxy bypass for applications and web resources that work better with minimum content rewriting. The proxy-bypass command determines how to treat specific web applications that travel through the ASA.

You can use this command multiple times. The order in which you configure entries is unimportant. The interface and path mask or interface and port uniquely identify a proxy bypass rule.

If you configure proxy bypass using ports rather than path masks, depending on your network configuration, you might need to change your firewall configuration to allow these ports access to the ASA. Use path masks to avoid this restriction. Be aware, however, that path masks can change, so you might need to use multiple pathmask statements to exhaust the possibilities.

A path is everything in a URL after the .com or .org or other types of domain name. For example, in the URL www.example.com/hrbenefits, *hrbenefits* is the path. Similarly, for the URL www.example.com/hrinsurance, *hrinsurance* is the path. If you want to use proxy bypass for all hr sites, you can avoid using the command multiple times by using the * wildcard as follows: /hr*.

Examples

The following example shows how to configure the ASA to use port 20001 for proxy bypass over the webvpn interface, using HTTP and its default port 80, to forward traffic to example.com and to rewrite XML content.

```
hostname(config)# webvpn
hostname(config-webvpn)# proxy-bypass interface webvpn port 20001 target
http://example.com rewrite xml
```

The next example shows how to configure the ASA to use the path mask mypath/* for proxy bypass on the outside interface, using HTTP and its default port 443 to forward traffic to example.com, and to rewrite XML and link content.

```
hostname(config)# webvpn
hostname(config-webvpn)# proxy-bypass interface outside path-mask /mypath/* target
https://example.com rewrite xml,link
```

Related Commands

Command	Description
apcf	Specifies nonstandard rules to use for a particular application.
rewrite	Determines whether traffic travels through the ASA.

proxy-ldc-issuer

To issue TLS proxy local dynamic certificates, use the **proxy-ldc-issuer** command in crypto ca trustpoint configuration mode. To remove the configuration, use the **no** form of this command.

proxy-ldc-issuer

no proxy-ldc-issuer

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **proxy-ldc-issuer** command to issue TLS proxy local dynamic certificates. The **proxy-ldc-issuer** command grants a crypto trustpoint the role as local CA to issue the LDC and can be accessed from crypto ca trustpoint configuration mode.

The **proxy-ldc-issuer** command defines the local CA role for the trustpoint to issue dynamic certificates for TLS proxy. This command can only be configured under a trustpoint with “enrollment self.”

Examples

The following example shows how to create an internal local CA to sign the LDC for phones. This local CA is created as a regular self-signed trustpoint with **proxy-ldc-issuer** enabled.

```
hostname(config)# crypto ca trustpoint ldc_server
hostname(config-ca-trustpoint)# enrollment self
hostname(config-ca-trustpoint)# proxy-ldc-issuer
hostname(config-ca-trustpoint)# fqdn my _ldc_ca.example.com
hostname(config-ca-trustpoint)# subject-name cn=FW_LDC_SIGNER_172_23_45_200
hostname(config-ca-trustpoint)# keypair ldc_signer_key
hostname(config)# crypto ca enroll ldc_server
```

Related Commands

Commands	Description
ctl-provider	Defines a CTL provider instance and enters provider configuration mode.
server trust-point	Specifies the proxy trustpoint certificate to be presented during the TLS handshake.
show tls-proxy	Shows the TLS proxies.
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

proxy-server

To configure an HTTP proxy for the Phone Proxy feature that is written into the IP phone's configuration file under the <proxyServerURL> tag, use the **proxy-server** command in phone-proxy configuration mode. To remove the HTTP proxy configuration from the Phone Proxy, use the **no** form of this command.

proxy-server address *ip_address* [*listen_port*] **interface** *ifc*

no proxy-server address *ip_address* [*listen_port*] **interface** *ifc*

Syntax Description

interface *ifc*	Specifies the interface on which the HTTP proxy resides on the ASA.
ip_address	Specifies the IP address of the HTTP proxy.
listen_port	Specifies the listening port of the HTTP proxy. If not specified, the default will be 8080.

Defaults

If the listen port is not specified, the port is configured to be 8080 by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Setting the proxy server configuration option for the Phone Proxy allows for an HTTP proxy on the DMZ or external network in which all the IP phone URLs are directed to the proxy server for services on the phones. This setting accommodates nonsecure HTTP traffic, which is not allowed back into the corporate network.

The *ip_address* you enter should be the global IP address based on where the IP phone and HTTP proxy server is located.

If the proxy server is located in a DMZ and the IP phones are located outside the network, the ASA does a lookup to see if there is a NAT rule and uses the global IP address to write into the configuration file.

You can enter a hostname in the *ip_address* argument when that hostname can be resolved to an IP address by the ASA (for example, DNS lookup is configured) because the ASA will resolve the hostname to an IP address.

By default, the Phone URL Parameters configured under the Enterprise Parameters use an FQDN in the URLs. The parameters might need to be changed to use an IP address if the DNS lookup for the HTTP proxy does not resolve the FQDNs.

To make sure the proxy server URL was written correctly to the IP phones configuration files, check the URL on an IP phone under Settings > Device Configuration > HTTP configuration >Proxy Server URL.

The Phone Proxy does not inspect this HTTP traffic to the proxy server.

If the ASA is in the path of the IP phone and the HTTP proxy server, use existing debugging techniques (such as syslogs and captures) to troubleshoot the proxy server.

You can configure only one proxy server while the Phone Proxy is in use; however, if the IP phones have already downloaded their configuration files after you have configured the proxy server, you must restart the IP phones so that they get the configuration file with the proxy server's address in the file.

Examples

The following example shows the use of the **proxy-server** command to configure the HTTP proxy server for the Phone Proxy:

```
hostname(config-phone-proxy)# proxy-server 192.168.1.2 interface inside
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

publish-crl

To allow other ASAs to validate the revocation status of certificates issued by the local CA, use the **publish-crl** command in ca-server configuration mode to allow downloading of the CRL directly from and interface on the ASA. To make the CRL unavailable for downloading, use the **no** form of this command.

[**no**] **publish-crl interface** *interface* [**port** *portnumber*]

Syntax Description

interface *interface*	Specifies the *nameif* used for the interface, such as **gigabitethernet0/1**. See the **interface** command for details.
port *portnumber*	(Optional) Specifies the port on which the interface device expects to download the CRL. Port numbers can be in the range of 1-65535.

Defaults

The default **publish-crl** status is **no publish**. TCP port 80 is the default for HTTP.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ca-server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The CRL is inaccessible by default. You must enable access to the CRL file on the interface and port required.

TCP port 80 is the HTTP default port number. If you configure a non-default port (other than port 80), be sure the **cdp-url** configuration includes the new port number so other devices know to access this specific port.

The CRL Distribution Point (CDP) is the location of the CRL on the local CA ASA. The URL you configure with the **cdp-url** command is embedded into any issued certificates. If you do not configure a specific location for the CDP, the default CDP URL is: http://hostname.domain/+CSCOCA+/asa_ca.crl.

An HTTP redirect and a CRL download request are handled by the same HTTP listener, if Clientless SSL VPN is enabled on the same interface. The listener checks for the incoming URL and if it matches the one configured with the **cdp-url** command, the CRL file downloads. If the URL does not match the **cdp-url** command, the connection is redirected to HTTPS (if HTTP redirect is enabled).

Examples

The **publish-crl** command example, entered in ca-server configuration mode, enables port 70 of the outside interface for CRL download:

```
hostname(config)# crypto ca server
hostname (config-ca-server)#publish-crl outside 70
hostname(config-ca-server)#
```

Related Commands

Command	Description
cdp-url	Specifies a particular location for the automatically generated CRL.
show interface	Displays the runtime status and statistics of interfaces.

pwd

To display the current working directory, use the **pwd** command in privileged EXEC mode.

pwd

Syntax Description

This command has no arguments or keywords.

Defaults

The root directory (/) is the default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0	This command was introduced.

Usage Guidelines

This command is similar in functionality to the **dir** command.

Examples

The following example shows how to display the current working directory:

```
hostname# pwd
disk0:/
hostname# pwd
flash:
```

Related Commands

Command	Description
cd	Changes the current working directory to the one specified.
dir	Displays the directory contents.
more	Displays the contents of a file.

CHAPTER 41

queue-limit through reset Commands

queue-limit (priority-queue)

To specify the depth of the priority queues, use the **queue-limit** command in priority-queue configuration mode. To remove this specification, use the **no** form of this command.

Note This command is not supported on ASA 5580 Ten Gigabit Ethernet interfaces. (Ten Gigabit Ethernet interfaces are supported for priority queues on the ASA 5585-X.) This command is also not supported for the ASA 5512-X through ASA 5555-X Management interface.

This command is not supported on the ASA Services Module.

queue-limit *number-of-packets*

no queue-limit *number-of-packets*

Syntax Description

number-of-packets	Specifies the maximum number of low-latency or normal priority packets that can be queued (that is, buffered) before the interface begins dropping packets. The upper limit of the range of values is determined dynamically at run time. To view this limit, enter **help** or **?** on the command line. The key determinant is the memory needed to support the queues and the memory available on the device. The queues must not exceed the available memory. The theoretical maximum number of packets is 2147483647.

Defaults

The default queue limit is 1024 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Priority-queue configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The ASA allows two classes of traffic: low-latency queuing (LLQ) for higher priority, latency sensitive traffic (such as voice and video) and best-effort, the default, for all other traffic. The ASA recognizes priority traffic and enforces appropriate quality of service (QoS) policies. You can configure the size and depth of the priority queue to fine-tune the traffic flow.

Note You *must* configure the **priority-queue** command in order to enable priority queueing for the interface.

You can apply one **priority-queue** command to any interface that can be defined by the **nameif** command.

The **priority-queue** command enters priority-queue configuration mode, as shown by the prompt. In priority-queue configuration mode, you can configure the maximum number of packets allowed in the transmit queue at any given time (**tx-ring-limit** command) and the number of packets of either type (priority or best -effort) allowed to be buffered before dropping packets (**queue-limit** command).

The tx-ring-limit and the queue-limit that you specify affect both the higher priority low-latency queue and the best-effort queue. The tx-ring-limit is the number of either type of packets allowed into the driver before the driver pushes back to the queues sitting in front of the interface to let them buffer packets until the congestion clears. In general, you can adjust these two parameters to optimize the flow of low-latency traffic.

Because queues are not of infinite size, they can fill and overflow. When a queue is full, any additional packets cannot get into the queue and are dropped. This is *tail drop*. To avoid having the queue fill up, you can use the **queue-limit** command to increase the queue buffer size.

Examples

The following example configures a priority queue for the interface named test, specifying a queue limit of 234 packets and a transmit queue limit of 3 packets.

```
hostname(config)# priority-queue test
hostname(priority-queue)# queue-limit 234
hostname(priority-queue)# tx-ring-limit 3
```

Related Commands

Command	Description
clear configure priority-queue	Removes the current priority queue configuration on the named interface.
priority-queue	Configures priority queuing on an interface.
show priority-queue statistics	Shows the priority-queue statistics for the named interface.
show running-config [all] priority-queue	Shows the current priority queue configuration. If you specify the **all** keyword, this command displays all the current priority queue, queue-limit, and tx-ring-limit configuration values.
tx-ring-limit	Sets the maximum number of packets that can be queued at any given time in the Ethernet transmit driver.

queue-limit (tcp-map)

To configure the maximum number of out-of-order packets that can be buffered and put in order for a TCP connection, use the **queue-limit** command in tcp-map configuration mode. To set the value back to the default, use the **no** form of this command. This command is part of the TCP normalization policy enabled using the **set connection advanced-options** command.

queue-limit *pkt_num* [**timeout** *seconds*]

no queue-limit

Syntax Description

pkt_num	Specifies the maximum number of out-of-order packets that can be buffered and put in order for a TCP connection, between 1 and 250. The default is 0, which means this setting is disabled and the default system queue limit is used depending on the type of traffic. See the "Usage Guidelines" section for more information.
timeout *seconds*	(Optional) Sets the maximum amount of time that out-of-order packets can remain in the buffer, between 1 and 20 seconds. The default is 4 seconds. If packets are not put in order and passed on within the timeout period, then they are dropped. You cannot change the timeout for any traffic if the *pkt_num* argument is set to 0; you need to set the limit to be 1 or above for the **timeout** keyword to take effect.

Defaults

The default setting is 0, which means this command is disabled.

The default timeout is 4 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(4)/8.0(4)	The **timeout** keyword was added.

Usage Guidelines

To enable TCP normalization, use the Modular Policy Framework:

1. **tcp-map**—Identifies the TCP normalization actions.
   a. **queue-limit**—In tcp-map configuration mode, you can enter the **queue-limit** command and many others.

2. **class-map**—Identify the traffic on which you want to perform TCP normalization.
3. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced-options**—Identify the tcp-map you created.
4. **service-policy**—Assigns the policy map to an interface or globally.

If you do not enable TCP normalization, or if the **queue-limit** command is set to the default of 0, which means it is disabled, then the default system queue limit is used depending on the type of traffic:

- Connections for application inspection (the **inspect** command), IPS (the **ips** command), and TCP check-retransmission (the TCP map **check-retransmission** command) have a queue limit of 3 packets. If the ASA receives a TCP packet with a different window size, then the queue limit is dynamically changed to match the advertized setting.
- For other TCP connections, out-of-order packets are passed through untouched.

If you set the **queue-limit** command to be 1 or above, then the number of out-of-order packets allowed for all TCP traffic matches this setting. For example, for application inspection, IPS, and TCP check-retransmission traffic, any advertised settings from TCP packets are ignored in favor of the **queue-limit** setting. For other TCP traffic, out-of-order packets are now buffered and put in order instead of passed through untouched.

Examples

The following example sets the queue limit to 8 packets and the buffer timeout to 6 seconds for all Telnet connections:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# queue-limit 8 timeout 6
hostname(config)# class-map cmap
hostname(config-cmap)# match port tcp eq telnet
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class-map	Identifies traffic for a service policy.
policy-map	dentifies actions to apply to traffic in a service policy.
set connection advanced-options	Enables TCP normalization.
service-policy	Applies a service policy to interface(s).
show running-config tcp-map	Shows the TCP map configuration.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

quit

To exit the current configuration mode, or to logout from privileged or user EXEC modes, use the **quit** command.

quit

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
User EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

You can also use the key sequence **Ctrl Z** to exit global configuration (and higher) modes. This key sequence does not work with privileged or user EXEC modes.

When you enter the **quit** command in privileged or user EXEC modes, you log out from the ASA. Use the **disable** command to return to user EXEC mode from privileged EXEC mode.

Examples

The following example shows how to use the **quit** command to exit global configuration mode, and then logout from the session:

```
hostname(config)# quit
hostname# quit

Logoff
```

The following example shows how to use the **quit** command to exit global configuration mode, and then use the **disable** command to exit privileged EXEC mode:

```
hostname(config)# quit
hostname# disable
hostname>
```

Related Commands

Command	Description
exit	Exits a configuration mode or logs out from privileged or user EXEC modes.

quota management-session

To set the maximum number of simultaneous ASDM, SSH, and Telnet sessions that are allowed on the ASA, use the **quota management-session** command in global configuration mode. To set the quota to the default value, use the **no** form of this command.

quota management-session *number*

no quota management-session *number*

Syntax Description

number	Specifies the maximum number of simultaneous ASDM, SSH, and Telnet sessions that are allowed. Valid values are from 0 to 10,000.

Defaults

The default is 0, which means there is no session limit.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	—

Command History

Release	Modification
9.1(2)	This command was introduced.

Usage Guidelines

When the quota is reached, subsequent management session requests are denied and a syslog message is generated. The console session is never blocked by the management session quota mechanism to prevent device lockout.

Examples

The following example configures the management session quota to 100:

```
hostname(config)# quota management-session 100
```

Related Commands

Command	Description
show run quota management-session	Displays the current value of the management-session quota.
show quota management-session	Displays statistics for management sessions.

radius-common-pw

To specify a common password to be used for all users who are accessing a RADIUS authorization server through the ASA, use the **radius-common-pw** command in aaa-server host configuration mode. To remove this specification, use the **no** form of this command.

radius-common-pw *string*

no radius-common-pw

Syntax Description

string	A case-sensitive, alphanumeric keyword of up to 127 characters to be used as a common password for all authorization transactions with the RADIUS server.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
aaa-server host	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is valid only for RADIUS authorization servers.

The RADIUS authorization server requires a password and username for each connecting user. The ASA provides the username automatically. You enter the password here. The RADIUS server administrator must configure the RADIUS server to associate this password with each user authorizing to the server via this ASA. Be sure to provide this information to your RADIUS server administrator.

If you do not specify a common user password, each user password is the username. If you are using usernames for common user passwords, as a security precaution, do not use the RADIUS server for authorization anywhere else on your network.

Note The *string* argument is essentially a space-filler. The RADIUS server expects and requires it, but does not use it. Users do not need to know it.

Examples

The following example configures a RADIUS AAA server group named "svrgrp1" on host "1.2.3.4," sets the timeout interval to 9 seconds, sets the retry interval to 7 seconds, and configures the RADIUS commnon password as "allauthpw."

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 9
hostname(config-aaa-server-host)# retry 7
hostname(config-aaa-server-host)# radius-common-pw allauthpw
hostname(config-aaa-server-host)# exit
hostname(config)#
```

Related Commands

Command	Description
aaa-server host	Enters aaa-server host configuration mode, so that you can configure AAA server parameters that are host-specific.
clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

radius-reject-message

To enable the display of a RADIUS reject message on the login screen when authentication is rejected, use the **radius-eject-message** command from tunnel-group webvpn attributes configuration mode. To remove the command from the configuration, use the **no** form of the command:

radius-reject-message

no radius-reject-message

Defaults

The default is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Tunnel-group webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Enable this command if you want to display to remote users a RADIUS message about an authentication failure.

Examples

The following example enables the display of a RADIUS rejection message for the connection profile named engineering:

```
hostname(config)# tunnel-group engineering webvpn-attributes
hostname(config-tunnel-webvpn)# radius-reject-message
```

radius-with-expiry (removed)

To have the ASA use MS-CHAPv2 to negotiate a password update with the user during authentication, use the **radius-with-expiry** command in tunnel-group ipsec-attributes configuration mode. To return to the default value, use the **no** form of this command.

radius-with-expiry

no radius-with-expiry

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting for this command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group ipsec-attributes configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	This command was deprecated. The **password-management** command replaces it. The **no** form of the **radius-with-expiry** command is no longer supported.
8.0(2)	This command was deprecated.

Usage Guidelines

You can apply this attribute only to the IPSec remote-access tunnel-group type. The ASA ignores this command if RADIUS authentication has not been configured.

Examples

The following example entered in config-ipsec configuration mode, configures Radius with Expiry for the remote-access tunnel group named remotegrp:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp ipsec-attributes
hostname(config-tunnel-ipsec)# radius-with-expiry
```

Related Commands

Command	Description
clear configure tunnel-group	Clears all configured tunnel groups.
password-management	Enables password management. This command, in the tunnel-group general-attributes configuration mode, replaces the **radius-with-expiry** command.
show running-config tunnel-group	Shows the indicated certificate map entry.
tunnel-group ipsec-attributes	Configures the tunnel-group ipsec-attributes for this group.

range

To configure a range of addresses for a network object, use the **range** command in object configuration mode. Use the **no** form of this command to remove the object from the configuration.

range *ip_addr_1 ip_addr2*

no range *ip_addr_1 ip_addr2*

Syntax Description

ip_addr_1	Identifies the first IP address in the range, either IPv4 or IPv6.
ip_addr_2	Identifies the last IP address in the range.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object network configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.
9.0(1)	We added support for IPv6 addresses.

Usage Guidelines

If you configure an existing network object with a different IP address, the new configuration will replace the existing configuration.

Examples

The following example shows how to create a range network object:

```
hostname (config)# object network OBJECT_RANGE
hostname (config-network-object)# range 10.1.1.1 10.1.1.8
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
description	Adds a description to the network object.
fqdn	Specifies a fully-qualified domain name network object.
host	Specifies a host network object.

Command	Description
nat	Enables NAT for the network object.
object network	Creates a network object.
object-group network	Creates a network object group.
show running-config object network	Shows the network object configuration.
subnet	Specifies a subnet network object.

ras-rcf-pinholes

To enable call setup between H.323 endpoints when the Gatekeeper is inside the network, use the **ras-rcf-pinholes** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

ras-rcf-pinholes enable

no ras-rcf-pinholes enable

Syntax Description

enable	Enables call setup between H.323 endpoints.

Defaults

By default, this option is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.0(5)	This command was introduced.

Usage Guidelines

The ASA includes options to open pinholes for calls based on the RegistrationRequest/RegistrationConfirm (RRQ/RCF) messages. Because these RRQ/RCF messages are sent to and from the Gatekeeper, the calling endpoint's IP address is unknown and the ASA opens a pinhole through source IP address/port 0/0.

Examples

The following example shows how to set up an action in a policy map to open pinholes for these calls:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# ras-rcf-pinholes enable
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.

Command	Description
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

rate-limit

When using the Modular Policy Framework, limit the rate of messages for packets that match a **match** command or class map by using the **rate-limit** command in match or class configuration mode. This rate limit action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic; however, not all applications allow this action. To disable this action, use the **no** form of this command.

rate-limit *messages_per_second*

no rate-limit *messages_per_second*

Syntax Description

messages_per_second	Limits the messages per second.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **rate-limit** command to limit the rate of messages.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action, for example, enter the **inspect dns dns_policy_map** command where dns_policy_map is the name of the inspection policy map.

Examples

The following example limits the invite requests to 100 messages per second:

```
hostname(config-cmap)# policy-map type inspect sip sip-map1
hostname(config-pmap-c)# match request-method invite
hostname(config-pmap-c)# rate-limit 100
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

reactivation-mode

To specify the method by which failed servers in a group are reactivated, use the **reactivation-mode** command in aaa-server protocol mode. To remove this specification, use the **no** form of this command.

reactivation-mode {**depletion** [**deadtime** *minutes*] | **timed**}

no reactivation-mode [**depletion** [**deadtime** *minutes*] | **timed**]

Syntax Description

deadtime *minutes*	(Optional) Specifies the amount of time in minutes, between 0 and 1440, that elapses between the disabling of the last server in the group and the subsequent re-enabling of all servers. The default is 10 minutes.
depletion	Reactivates failed servers only after all of the servers in the group are inactive.
timed	Reactivates failed servers after 30 seconds of down time.

Defaults

The default reactivation mode is depletion, and the default deadtime value is 10.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server protcocol configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Each server group has an attribute that specifies the reactivation policy for its servers.

In **depletion** mode, when a server is deactivated, it remains inactive until all other servers in the group are inactive. When and if this occurs, all servers in the group are reactivated. This approach minimizes the occurrence of connection delays due to failed servers. When **depletion** mode is in use, you can also specify the **deadtime** parameter. The **deadtime** parameter specifies the amount of time (in minutes) that will elapse between the disabling of the last server in the group and the subsequent re-enabling of all servers. This parameter is meaningful only when the server group is being used in conjunction with the local fallback feature.

In **timed** mode, failed servers are reactivated after 30 seconds of down time. This is useful when customers use the first server in a server list as the primary server and prefer that it is online whenever possible. This policy breaks down in the case of UDP servers. Since a connection to a UDP server will

not fail, even if the server is not present, UDP servers are put back on line blindly. This could lead to slowed connection times or connection failures if a server list contains multiple servers that are not reachable.

Accounting server groups that have simultaneous accounting enabled are forced to use the **timed** mode. This implies that all servers in a given list are equivalent.

Examples

The following example configures a TACACS+ AAA server named "srvgrp1" to use the depletion reactivation mode, with a deadtime of 15 minutes:

```
hostname(config)# aaa-server svrgrp1 protocol tacacs+
hostname(config-aaa-sersver-group)# reactivation-mode depletion deadtime 15
hostname(config-aaa-server)# exit
hostname(config)#
```

The following example configures a TACACS+ AAA server named "srvgrp1" to use timed reactivation mode:

```
hostname(config)# aaa-server svrgrp2 protocol tacacs+
hostname(config-aaa-server)# reactivation-mode timed
hostname(config-aaa-server)#
```

Related Commands

accounting-mode	Indicates whether accounting messages are sent to a single server or sent to all servers in the group.
aaa-server protocol	Enters aaa-server group configuration mode so you can configure AAA server parameters that are group-specific and common to all hosts in the group.
max-failed-attempts	Specifies the number of failures that will be tolerated for any given server in the server group before that server is deactivated.
clear configure aaa-server	Removes all AAA server configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

record-entry

To specify the trustpoints to be used for the creation of the CTL file, use the record-entry command in ctl-file configuration mode. To remove a record entry from a CTL, use the **no** form of this command.

record-entry [**capf** | **cucm** | **cucm-tftp** | **tftp**] **trustpoint** *trustpoint* **address** *ip_address* [**domain-name** *domain_name*]

no record-entry [**capf** | **cucm** | **cucm-tftp** | **tftp**] **trustpoint** *trust_point* **address** *ip_address* [**domain-name** *domain_name*]

Syntax Description

capf	Specifies the role of this trustpoint to be CAPF. Only one CAPF trustpoint can be configured.
cucm	Specifies the role of this trustpoint to be CCM. Multiple CCM trustpoints can be configured.
cucm-tftp	Specifies the role of this trustpoint to be CCM+TFTP. Multiple CCM+TFTP trustpoints can be configured.
domain-name *domain_name*	(Optional) Specifies the domain name of the trustpoint used to create the DNS field for the trustpoint. This is appended to the Common Name field of the Subject DN to create the DNS Name. The domain name should be configured when the FQDN is not configured for the trustpoint.
address *ip_address*	Specifies the IP address of the trustpoint.
tftp	Specifies the role of this trustpoint to be TFTP. Multiple TFTP trustpoints can be configured.
trustpoint *trust_point*	Sets the name of the trustpoint installed.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
CTL-file configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Only one domain-name can be specified. If the CTL file does not exist, manually export this certificate from CUCM to the ASA.

Use this command only when you have not configured a CTL file for the Phone Proxy. Do not use this command when you have already configured a CTL file.

The IP address you specify in the *ip_address* argument must be the global address or address as seen by the IP phones because it will be the IP address used for the CTL record for the trustpoint.

Add additional record-entry configurations for each entity that is required in the CTL file.

Examples

The following example shows the use of the **record-entry** command to specify the trustpoints to be used for the creation of the CTL file:

```
hostname(config-ctl-file)# record-entry cucm-tftp trustpoint cucm1 address 192.168.1.2
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from Flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for Phone Proxy configuration.
phone-proxy	Configures the Phone Proxy instance.

redirect-fqdn

To enable or disable redirection using a fully qualified domain name in vpn load-balancing mode, use the **redirect-fqdn enable** command in global configuration mode.

redirect-fqdn {enable | disable}

no redirect-fqdn {enable | disable}

Note To use VPN load balancing, you must have an ASA Model 5510 with a Plus license or an ASA Model 5520 or higher. VPN load balancing also requires an active 3DES/AES license. The security appliance checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the security appliance prevents the enabling of load balancing and also prevents internal configuration of 3DES by the load balancing system unless the license permits this usage.

Syntax Description

disable	Disables redirection with fully qualified domain names.
enable	Enables redirection with fully qualified domain names.

Defaults

This behavior is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Vpn load-balancing mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

By default, the ASA sends only IP addresses in load-balancing redirection to a client. If certificates are in use that are based on DNS names, the certificates will be invalid when redirected to a secondary device.

As a VPN cluster master, this ASA can send a fully qualified domain name (FQDN), using reverse DNS lookup, of a cluster device (another ASA in the cluster), instead of its outside IP address, when redirecting VPN client connections to that cluster device.

All of the outside and inside network interfaces on the load-balancing devices in a cluster must be on the same IP network.

To do WebVPN load Balancing using FQDNs rather than IP addresses, you must do the following configuration steps:

Step 1 Enable the use of FQDNs for Load Balancing with the **redirect-fqdn enable** command.

Step 2 Add an entry for each of your ASA outside interfaces into your DNS server, if such entries are not already present. Each ASA outside IP address should have a DNS entry associated with it for lookups. These DNS entries must also be enabled for Reverse Lookup.

Step 3 Enable DNS lookups on your ASA with the command - "dns domain-lookup inside" (or whichever interface has a route to your DNS server).

Step 4 Define your DNS server IP address on the ASA; for example: `dns name-server 10.2.3.4` (IP address of your DNS server)

Examples

The following is an example of the **redirect-fqdn** command that disables redirection:

```
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# redirect-fqdn disable
hostname(config-load-balancing)#
```

The following is an example of a VPN load-balancing command sequence that includes an interface command that enables redirection for a fully qualified domain name, specifies the public interface of the cluster as "test" and the private interface of the cluster as "foo":

```
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# nat 192.168.10.10
hostname(config-load-balancing)# priority 9
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster key 123456789
hostname(config-load-balancing)# cluster encryption
hostname(config-load-balancing)# cluster port 9023
hostname(config-load-balancing)# redirect-fqdn enable
hostname(config-load-balancing)# participate
```

Related Commands

Command	Description
clear configure vpn load-balancing	Removes the load-balancing runtime configuration and disables load balancing.
show running-config vpn load-balancing	Displays the the current VPN load-balancing virtual cluster configuration.
show vpn load-balancing	Displays VPN load-balancing runtime statistics.
vpn load-balancing	Enters vpn load-balancing mode.

redistribute (EIGRP)

To redistribute routes from one routing domain into the EIGRP routing process, use the **redistribute** command in router configuration mode. To remove the redistribution, use the **no** form of this command.

redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **rip** | **static** | **connected**} [**metric** *bandwidth delay reliability load mtu*] [**route-map** *map_name*]

no redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **rip** | **static** | **connected**} [**metric** *bandwidth delay reliability load mtu*] [**route-map** *map_name*]

Syntax Description

bandwidth	EIGRP bandwidth metric in Kilobits per second. Valid values are from 1 to 4294967295.
connected	Specifies redistributing a network connected to an interface into the EIGRP routing process.
delay	EIGRP delay metric, in 10 microsecond units. Valid values are from 0 to 4294967295.
external *type*	Specifies the OSPF metric routes that are external to a specified autonomous system; valid values are **1** or **2**.
internal *type*	Specifies OSPF metric routes that are internal to a specified autonomous system.
load	EIGRP effective bandwidth (loading) metric. Valid values are from 1 to 255, where 255 indicates 100% loaded.
match	(Optional) Specifies the conditions for redistributing routes from OSPF into EIGRP.
metric	(Optional) Specifies the values for the EIGRP metrics of routes redistributed into the EIGRP routing process.
mtu	The MTU of the path. Valid values are from 1 to 65535.
nssa-external *type*	Specifies the OSPF metric type for routes that are external to an NSSA; valid values are **1** or **2**.
ospf *pid*	Used to redistribute an OSPF routing process into the EIGRP routing process. The *pid* specifies the internally used identification parameter for an OSPF routing process; valid values are from 1 to 65535.
reliability	EIGRP reliability metric. Valid values are from 0 to 255, where 255 indicates 100% reliability.
rip	Specifies redistributing a network from the RIP routing process into the EIGRP routing process.
route-map *map_name*	(Optional) Name of the route map used to filter the imported routes from the source routing protocol to the EIGRP routing process. If not specified, all routes are redistributed.
static	Used to redistribute a static route into the EIGRP routing process.

Defaults

The following are the command defaults:

- **match**: **Internal**, **external 1**, **external 2**

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

You must specify the **metric** with the redistribute command if you do not have a **default-metric** command in your EIGRP configuration.

Examples

The following example redistributes static and connected routes into the EIGRP routing process:

```
hostname(config)# router eigrp 100
hostname(config-router)# redistribute static
hostname(config-router)# redistribute connected
```

Related Commands

Command	Description
router eigrp	Creates an EIGRP routing process and enters configuration mode for that process.
show running-config router	Displays the commands in the global router configuration.

redistribute (OSPF)

To redistribute routes from one routing domain into an OSPF routing process, use the **redistribute** command in router configuration mode. To remove the redistribution when no options are included, use the **no** form of this command. The **no** form of the command with an option removes only the configuration for that option.

redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **rip** | **static** | **connected** | **eigrp** *as-number*} [**metric** *metric_value*] [**metric-type** *metric_type*] [**route-map** *map_name*] [**tag** *tag_value*] [**subnets**]

no redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **rip** | **static** | **connected**} [**metric** *metric_value*] [**metric-type** *metric_type*] [**route-map** *map_name*] [**tag** *tag_value*] [**subnets**]

Syntax Description

connected	Specifies redistributing a network connected to an interface into an OSPF routing process.
eigrp *as-number*	Used to redistribute EIGRP routes into the OSPF routing process. The *as-number* specifies the autonomous system number of the EIGRP routing process. Valid values are from 1 to 65535.
external *type*	Specifies the OSPF metric routes that are external to a specified autonomous system; valid values are **1** or **2**.
internal *type*	Specifies OSPF metric routes that are internal to a specified autonomous system.
match	(Optional) Specifies the conditions for redistributing routes from one routing protocol into another.
metric *metric_value*	(Optional) Specifies the OSPF default metric value from 0 to 16777214.
metric-type *metric_type*	(Optional) The external link type associated with the default route advertised into the OSPF routing domain. It can be either of the following two values: **1** (Type 1 external route) or **2** (Type 2 external route).
nssa-external *type*	Specifies the OSPF metric type for routes that are external to an NSSA; valid values are **1** or **2**.
ospf *pid*	Used to redistribute an OSPF routing process into the current OSPF routing process. The *pid* specifies the internally used identification parameter for an OSPF routing process; valid values are from 1 to 65535.
rip	Specifies redistributing a network from the RIP routing process into the current OSPF routing process.
route-map *map_name*	(Optional) Name of the route map used to filter the imported routes from the source routing protocol to the current OSPF routing process. If not specified, all routes are redistributed.
static	Used to redistribute a static route into an OSPF process.

subnets	(Optional) For redistributing routes into OSPF, scopes the redistribution for the specified protocol. If not used, only classful routes are redistributed.
tag *tag_value*	(Optional) A 32-bit decimal value attached to each external route. This value is not used by OSPF itself. It may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP; for other protocols, zero (0) is used. Valid values range from 0 to 4294967295.

Defaults

The following are the command defaults:

- **metric** *metric-value*: 0
- **metric-type** *type-value*: **2**
- **match**: **Internal**, **external 1**, **external 2**
- **tag** *tag-value*: 0

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	This command was modified to include the **rip** keyword.
8.0(2)	This command was modified to include the **eigrp** keyword.
9.0(1)	Multiple context mode is supported.

Examples

The following example shows how to redistribute static routes into the current OSPF process:

```
hostname(config)# router ospf 1
hostname(config-rtr)# redistribute static
```

Related Commands

Command	Description
redistribute (RIP)	Redistributes routes into the RIP routing process.
router ospf	Enters router configuration mode.
show running-config router	Displays the commands in the global router configuration.

redistribute (OSPFv3)

To redistribute IPv6 routes from one OSPFv3 routing domain into OSPFv3 routing domain, use the **redistribute** command in IPv6 router configuration mode. To disable the redistribution, use the **no** form of this command.

redistribute *source-protocol* [*process-id*] [**include-connected** {**level-1** | **level-1-2** | **level-2**}] [*as-number*] [**metric** {*metric-value* | **transparent**}] [**metric-type** *type-value*] [**match** {**external** [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**]}] [**tag** *tag-value*] [**route-map** *map-tag*]

no redistribute *source-protocol* [*process-id*] [**include-connected** {**level-1** | **level-1-2** | **level-2**}] [*as-number*] [**metric** {*metric-value* | **transparent**}] [**metric-type** *type-value*] [**match** {**external** [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**]}] [**tag** *tag-value*] [**route-map** *map-tag*]

Syntax Description

as-number	Specifies the autonomous system number of the routing process. Valid values range from 1 to 65535.
external	Specifies the OSPFv3 metric routes that are external to a specified autonomous system, but are imported into OSPFv3 as type 1 or type 2 external routes. Valid values are 1 or 2.
include-connected	(Optional) Allows the target protocol to redistribute routes that have been learned by the source protocol and connected prefixes on thosed interfces over which the source protocol is running.
internal	Specifies OSPFv3 metric routes that are internal to a specified autonomous system.
level-1	Specifies that for Intermediate System-to-Intermediate System (IS-IS), the level 1 routes are redistributed into other IP routing protocols independently.
level-1-2	Specifies that for IS-IS, both level 1 and level 2 routes are redistributed into other IP routing protocols independently.
level-2	Specifies that for IS-IS, level 2 routes are redistributed into other IP routing protocols independently.
map-tag	Specifies the identifier of a configured route map.
match	(Optional) Redistributes routes into other routing domains.
metric *metric_value*	(Optional) Specifies the OSPFv3 default metric value, which ranges from 0 to 16777214.
metric-type *metric_type*	(Optional) Specifies the external link type that is associated with the default route advertised into the OSPFv3 routing domain. It can be either of the following two values: 1 for type 1 external routes or 2 for type 2 external routes.
nssa-external	Specifies routes that are external to the autonomous system, but are imported into OSPFv3 in a not so stubby area (NSSA) for IPv6 as type 1 or type 2 external routes.
process-id	(Optional) Specifies the number that is assigned administratively when the OSPFv3 routing process is enabled.
route-map *map_name*	(Optional) Specifies the name of the route map that is used to filter the routes that are imported from the source routing protocol to the current OSPFv3 routing protocol. If specified but no route maps tags are listed, no routes are imported. If not specified, all routes are redistributed.

source-protocol	Specifies the source protocol from which routes are being redistributed. Valid values can be one of the following: connected, ospf, or static.
tag *tag_value*	(Optional) Specifies the 32-bit decimal value that is attached to each external route. This value is not used by OSPFv3 itself, but may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP; for other protocols, zero is used. Valid values range from 0 to 4294967295.
transparent	(Optional) Causes RIP to use the routing table metric for redistributed routes as the RIP metric.

Defaults

The following are the command defaults:

- **metric** *metric-value*: **0**
- **metric-type** *type-value*: **2**
- **match**: **internal**, **external 1**, **external 2**
- **tag** *tag-value*: **0**

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
IPv6 router configuration	•	—	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Examples

The following example shows how to redistribute static routes into the current OSPFv3 process:

```
hostname(config-if)# ipv6 router ospf 1
hostname(config-rtr)# redistribute static
```

Related Commands

Command	Description
ipv6 router ospf	Enters router configuration mode for OSPFv3.
show running-config ipv6 router	Displays the commands in the router configuration for OSPFv3.

redistribute (RIP)

To redistribute routes from another routing domain into the RIP routing process, use the **redistribute** command in router configuration mode. To remove the redistribution, use the **no** form of this command.

redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **static** | **connected** | **eigrp** *as-number*} [**metric** {*metric_value* | **transparent**}] [**route-map** *map_name*]

no redistribute {{**ospf** *pid* [**match** {**internal** | **external** [**1** | **2**] | **nssa-external** [**1** | **2**]}]} | **static** | **connected** | **eigrp** *as-number*} [**metric** {*metric_value* | **transparent**}] [**route-map** *map_name*]

Syntax Description

connected	Specifies redistributing a network connected to an interface into the RIP routing process.
eigrp *as-number*	Used to redistribute EIGRP routes into the RIP routing process. The *as-number* specifies the autonomous system number of the EIGRP routing process. Valid values are from 1 to 65535.
external *type*	Specifies the OSPF metric routes that are external to a specified autonomous system; valid values are **1** or **2**.
internal *type*	Specifies OSPF metric routes that are internal to a specified autonomous system.
match	(Optional) Specifies the conditions for redistributing routes from OSPF to RIP.
metric {*metric_value* | **transparent**}	(Optional) Specifies the RIP metric value for the route being redistributed. Valid values for *metric_value* are from 0 to 16. Setting the metric to **transparent** causes the current route metric to be used.
nssa-external *type*	Specifies the OSPF metric type for routes that are external to a not-so-stubby area (NSSA); valid values are **1** or **2**.
ospf *pid*	Used to redistribute an OSPF routing process into the RIP routing process. The *pid* specifies the internally used identification parameter for an OSPF routing process; valid values are from 1 to 65535.
route-map *map_name*	(Optional) Name of the route map used to filter the imported routes from the source routing protocol to the RIP routing process. If not specified, all routes are redistributed.
static	Used to redistribute a static route into an OSPF process.

Defaults

The following are the command defaults:

- **metric** *metric-value*: 0
- **match**: **Internal**, **external 1**, **external 2**

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
	Routed	Transparent	Single	Multiple Context	System
Router configuration	•	—	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.
8.0(2)	This command was modified to include the **eigrp** keyword.
9.0(1)	Multiple context mode is supported.

Examples

The following example shows how to redistribute static routes into the current RIP process:

```
hostname(config)# router rip
hostname(config-rtr)# network 10.0.0.0
hostname(config-rtr)# redistribute static metric 2
```

Related Commands

Command	Description
redistribute (EIGRP)	Redistributes routes from other routing domains into EIGRP.
redistribute (OSPF)	Redistributes routes from other routing domains into OSPF.
router rip	Enables the RIP routing process and enters router configuration mode for that process.
show running-config router	Displays the commands in the global router configuration.

redundant-interface

To set which member interface of a redundant interface is active, use the **redundant-interface** command in privileged EXEC mode.

redundant-interface redundant*number* **active-member** *physical_interface*

Syntax Description

active-member *physical_interface*	Sets the active member. See the **interface** command for accepted values. Both member interfaces must be the same physical type.
redundant *number*	Specifies the redundant interface ID, such as **redundant1**.

Defaults

By default, the active interface is the first member interface listed in the configuration, if it is available.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

To view which interface is active, enter the following command:

```
hostname# show interface redundantnumber detail | grep Member
```

For example:

```
hostname# show interface redundant1 detail | grep Member
      Members GigabitEthernet0/3(Active), GigabitEthernet0/2
```

Examples

The following example creates a redundant interface. By default, gigabitethernet 0/0 is active because it is first in the configuration. The redundant-interface command sets gigabitethernet 0/1 as the active interface.

```
hostname(config-if)# interface redundant 1
hostname(config-if)# member-interface gigabitethernet 0/0
hostname(config-if)# member-interface gigabitethernet 0/1

hostname(config-if)# redundant-interface redundant1 active-member gigabitethernet0/1
```

Related Commands

Command	Description
clear interface	Clears counters for the **show interface** command.
debug redundant-interface	Displays debug messages related to redundant interface events or errors.
interface redundant	Creates a redundant interface.
member-interface	Assigns a member interface to a redundant interface pair.
show interface	Displays the runtime status and statistics of interfaces.

regex

To create a regular expression to match text, use the **regex** command in global configuration mode. To delete a regular expression, use the **no** form of this command.

regex *name regular_expression*

no regex *name* [*regular_expression*]

Syntax Description

name	Specifies the regular expression name, up to 40 characters in length.
regular_expression	Specifies the regular expression up to 100 characters in length. See "Usage Guidelines" for a list of metacharacters you can use in the regular expression.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **regex** command can be used for various features that require text matching. For example, you can configure special actions for application inspection using Modular Policy Framework using an *inspection policy map* (see the **policy map type inspect** command). In the inspection policy map, you can identify the traffic you want to act upon by creating an inspection class map containing one or more **match** commands or you can use **match** commands directly in the inspection policy map. Some **match** commands let you identify text in a packet using a regular expression; for example, you can match URL strings inside HTTP packets. You can group regular expressions in a regular expression class map (see the **class-map type regex** command).

A regular expression matches text strings either literally as an exact string, or by using *metacharacters* so you can match multiple variants of a text string. You can use a regular expression to match the content of certain application traffic; for example, you can match body text inside an HTTP packet.

Note As an optimization, the ASA searches on the deobfuscated URL. Deobfuscation compresses multiple forward slashes (/) into a single slash. For strings that commonly use double slashes, like "http://", be sure to search for "http:/" instead.

Table 41-1 lists the metacharacters that have special meanings.

Table 41-1 regex Metacharacters

Character	Description	Notes
.	Dot	Matches any single character. For example, **d.g** matches dog, dag, dtg, and any word that contains those characters, such as doggonnit.
(*exp*)	Subexpression	A subexpression segregates characters from surrounding characters, so that you can use other metacharacters on the subexpression. For example, **d(o|a)g** matches dog and dag, but **do|ag** matches do and ag. A subexpression can also be used with repeat quantifiers to differentiate the characters meant for repetition. For example, **ab(xy){3}z** matches abxyxyxyz.
|	Alternation	Matches either expression it separates. For example, **dog|cat** matches dog or cat.
?	Question mark	A quantifier that indicates that there are 0 or 1 of the previous expression. For example, **lo?se** matches lse or lose. **Note** You must enter **Ctrl+V** and then the question mark or else the help function is invoked.
*	Asterisk	A quantifier that indicates that there are 0, 1 or any number of the previous expression. For example, **lo*se** matches lse, lose, loose, and so on.
+	Plus	A quantifier that indicates that there is at least 1 of the previous expression. For example, **lo+se** matches lose and loose, but not lse.
{*x*} or {*x*,}	Minimum repeat quantifier	Repeat at least *x* times. For example, **ab(xy){2,}z** matches abxyxyz, abxyxyxyz, and so on.
[*abc*]	Character class	Matches any character in the brackets. For example, **[abc]** matches a, b, or c.
[^*abc*]	Negated character class	Matches a single character that is not contained within the brackets. For example, **[^abc]** matches any character other than a, b, or c. **[^A-Z]** matches any single character that is not an uppercase letter.
[*a*-*c*]	Character range class	Matches any character in the range. **[a-z]** matches any lowercase letter. You can mix characters and ranges: **[abcq-z]** matches a, b, c, q, r, s, t, u, v, w, x, y, z, and so does [**a-cq-z]**. The dash (-) character is literal only if it is the last or the first character within the brackets: **[abc-]** or **[-abc]**.
""	Quotation marks	Preserves trailing or leading spaces in the string. For example, **" test"** preserves the leading space when it looks for a match.
^	Caret	Specifies the beginning of a line.

Table 41-1 regex Metacharacters (continued)

Character	Description	Notes
\	Escape character	When used with a metacharacter, matches a literal character. For example, **\[** matches the left square bracket.
char	Character	When character is not a metacharacter, matches the literal character.
\r	Carriage return	Matches a carriage return 0x0d.
\n	Newline	Matches a new line 0x0a.
\t	Tab	Matches a tab 0x09.
\f	Formfeed	Matches a form feed 0x0c.
\x*NN*	Escaped hexadecimal number	Matches an ASCII character using hexadecimal (exactly two digits).
NNN	Escaped octal number	Matches an ASCII character as octal (exactly three digits). For example, the character 040 represents a space.

To test a regular expression to make sure it matches what you think it will match, enter the **test regex** command.

The regular expression performance impact is determined by two main factors:

- The length of text that needs to be searched for a regular expression match.

  The regular expression engine has only a small impact to the ASA performance when the search length is small.

- The number of regular expression chained tables that need to be searched for a regular expression match.

How the Search Length Impacts Performance

When you configure a regular expression search, every byte of the searched text is usually examined against a regular expression database to find a match. The longer the searched text is, the longer the search time will be. Below is a performance test case which illustrates this phenomenon.

- An HTTP transaction includes one 300-byte long GET request and one 3250-byte long response.
- 445 regular expressions for URI search and 34 regular expressions for request body search.
- 55 regular expressions for response body search.

When a policy is configured to search the URI and the body in the HTTP GET request only, the throughput is:

- 420 mbps when the corresponding regular expression database is not searched.
- 413 mbps when the corresponding regular expression database is searched (this demonstrates a relatively small overhead of using regular expression).

But when a policy is configured to also search the whole HTTP response body, the throughput drops down to 145 mbps because of the long response body (3250 bytes) search.

Following is a list of factors that will increase the length of text for a regular expression search:

- A regular expression search is configured on multiple, different protocol fields. For example, in HTTP inspection, if only URI is configured for a regular expression match, then only the URI field is searched for a regular expression match, and the search length is then limited to the URI length. But if additional protocol fields are also configured for a regular expression match, such as Headers, Body, and so on, then the search length will increase to include the header length and body length.
- The field to be searched is long. For example, if the URI is configured for a regular expression search, then a long URI in a GET request will have a long search length. Also, currently the HTTP body search length is limited by default to 200 bytes. If, however, a policy is configured to search the body, and the body search length is changed to 5000 bytes, then there will be severe impact on the performance because of the long body search.

How the Number of Chained Regular Expression Tables Impact Performance

Currently, all regular expressions that are configured for the same protocol field, such as all regular expressions for URI, are built into a database consisting of one or more regular expression chained tables. The number of tables is determined by the total memory required and the availability of memory at the time the tables are built. A regular expression database will be split into multiple tables under any of the following conditions:

- When the total memory required is greater than 32 MB since the maximum table size is limited to 32 MB.
- When the size of the largest contiguous memory is not sufficient to build a complete regular expression database, then smaller but multiple tables will be built to accommodate all the regular expressions. Note that the degree of memory fragmentation varies depending on many factors that are interrelated and are almost impossible to predict the level of fragmentation.

With multiple chained tables, each table must be searched for regular expression matches and hence the search time increases in proportion to the number of tables that are searched.

Certain types of regular expressions tend to increase the table size significantly. It is prudent to design regular expressions in a way to avoid wildcard and repeating factors if possible. See Table 41-1 for a description of the following metacharacters:

- Regular expressions with wildcard type of specifications:
  - Dot (.)
- Various character classes that match any character in a class:
  - [^a-z]
  - [a-z]
  - [abc]]
- Regular expressions with repeating type of specifications:
  - *
  - +
  - {n,}
- Combination of the wild-card and repeating types of regular expressions can increase the table size dramatically, for examples:
  - 123.*xyz
  - 123.+xyz
  - [^a-z]+
  - [^a-z]*

  - .*123.* (This should not be done because this is equivalent to matching "123").

The following examples illustrate how memory consumptions are different for regular expressions with and without wildcards and repetition.

- Database size for the following 4 regular expressions is 958,464 bytes.

```
regex r1 "q3rfict9(af.*12)*ercvdf"
regex r2 "qtaefce.*qeraf.*adasdfev"
regex r3 "asdfdfdfds.*wererewr0e.*aaaxxxx.*xxx"
regex r4 "asdfdfdfds.*wererewr0e.*afdsvcvr.*aefdd"
```

- Database size for the following 4 regular expressions is only 10240 bytes.

```
regex s1 "abcde"
regex s2 "12345"
regex s3 "123xyz"
regex s4 "xyz123"
```

A large number of regular expressions will increase the total memory that is needed for the regular expression database and hence increases the probabilities of more tables if memory is fragmented. Following are examples of memory consumptions for different numbers of regular expressions:

- 100 sample URIs: 3,079,168 bytes
- 200 sample URIs: 7,156,224 bytes
- 500 sample URIs: 11,198,971 bytes

Note The maximum number of regular expressions per context is 2048.

The **debug menu regex 40 10** command can be used to display how many chained tables there are in each regex database.

Examples

The following example creates two regular expressions for use in an inspection policy map:

```
hostname(config)# regex url_example example\.com
hostname(config)# regex url_example2 example2\.com
```

Related Commands

Command	Description
class-map type inspect	Creates ain inspection class map to match traffic specific to an application.
policy-map	Creates a policy map by associating the traffic class with one or more actions.
policy-map type inspect	Defines special actions for application inspection.
class-map type regex	Creates a regular expression class map.
test regex	Tests a regular expression.

reload

To reboot and reload the configuration, use the **reload** command in privileged EXEC mode.

reload [**at** *hh*:*mm* [*month day* | *day month*]] [**cancel**] [**in** [*hh*:]*mm*] [**max-hold-time** [*hh*:]*mm*] [**noconfirm**] [**quick**] [**reason** *text*] [**save-config**]

Syntax Description

at *hh*:*mm*	(Optional) Schedules a reload of the software to take place at the specified time (using a 24-hour clock). If you do not specify the month and day, the reload occurs at the specified time on the current day (if the specified time is later than the current time), or on the next day (if the specified time is earlier than the current time). Specifying 00:00 schedules the reload for midnight. The reload must take place within 24 hours.
cancel	(Optional) Cancels a scheduled reload.
day	(Optional) Number of the day in the range from 1 to 31.
in [*hh*:]*mm*	(Optional) Schedules a reload of the software to take effect in the specified minutes or hours and minutes. The reload must occur within 24 hours.
max-hold-time [*hh*:]*mm*	(Optional) Specifies the maximum hold time the ASA waits to notify other subsystems before a shutdown or reboot. After this time elapses, a quick (forced) shutdown/reboot occurs.
month	(Optional) Specifies the name of the month. Enter enough characters to create a unique string for the name of the month. For example, "Ju" is not unique because it could represent June or July, but "Jul" is unique because no other month beginning with those exact three letters.
noconfirm	(Optional) Permits the ASA to reload without user confirmation.
quick	(Optional) Forces a quick reload, without notifying or correctly shutting down all the subsystems.
reason *text*	(Optional) Specifies the reason for the reload, 1 to 255 characters. The reason text is sent to all open IPsec VPN client, terminal, console, Telnet, SSH, and ASDM connections/sessions. **Note** Some applications, like ISAKMP, require additional configuration to send the reason text to IPsec VPN clients. See the VPN CLI Configuration Guide for more information.
save-config	(Optional) Saves the running configuration to memory before shutting down. If you do not enter the **save-config** keyword, any configuration changes that have not been saved will be lost after the reload.
save-show-tech	(Optional) Saves the output of the **show tech** command to a file before the reload occurs.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was modified to add the following new arguments and keywords: *day*, *hh*, *mm*, *month*, **quick**, **save-config**, and *text*.
9.1(3)	The **save-show-tech** keyword was added.

Usage Guidelines

The command lets you reboot the ASA and reload the configuration from flash memory.

By default, the **reload** command is interactive. The ASA first checks whether the configuration has been modified but not saved. If so, the ASA prompts you to save the configuration. In multiple context mode, the ASA prompts for each context with an unsaved configuration. If you specify the **save-config** keyword, the configuration is saved without prompting you. The ASA then prompts you to confirm that you really want to reload the system. Only a response of **y** or pressing the **Enter** key causes a reload. After confirmation, the ASA starts or schedules the reload process, depending on whether you have specified a delay keyword (**in** or **at**).

By default, the reload process operates in "graceful" mode. All registered subsystems are notified when a reboot is about to occur, allowing these subsystems to shut down properly before the reboot. To avoid waiting until for such a shutdown to occur, specify the **max-hold-time** keyword to specify a maximum time to wait. Alternatively, you can use the **quick** keyword to force the reload process to begin abruptly, without notifying the affected subsystems or waiting for a graceful shutdown.

You can force the **reload** command to operate noninteractively by specifying the **noconfirm** keyword. In this case, the ASA does not check for an unsaved configuration unless you have specified the **save-config** keyword. The ASA does not prompt you for confirmation before rebooting the system. It starts or schedules the reload process immediately, unless you have specified a delay keyword, although you can specify the **max-hold-time** or **quick** keyword to control the behavior or the reload process.

Use the **reload cancel** command to cancel a scheduled reload. You cannot cancel a reload that is already in progress.

Note Configuration changes that are not written to the flash partition are lost after a reload. Before rebooting, enter the **write memory** command to store the current configuration in the flash partition.

Examples

The following example shows how to reboot and reload a configuration:

```
hostname# reload
Proceed with ?  [confirm] y

Rebooting...

XXX Bios VX.X
...
```

Related Commands

Command	Description
show reload	Displays the reload status of the ASA.

remote-access threshold session-threshold-exceeded

To set threshold values, use the **remote-access threshold** command in global configuration mode. To remove threshold values, use the **no** version of this command. This command specifies the number of active remote access sessions, at which point the ASA sends traps.

remote-access threshold session-threshold-exceeded {*threshold-value*}

no **remote-access threshold session-threshold-exceeded**

Syntax Description

threshold-value	Specifies an integer less than or equal to the session limit the ASA supports.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	—	—	•

Command History

Release	Modification
7.0 (1)	This command was introduced.

Examples

The following example shows how to set a threshold value of 1500:

```
hostname# remote-access threshold session-threshold-exceeded 1500
```

Related Commands

Command	Description
snmp-server enable trap remote-access	Enables threshold trapping.

rename

To rename a file or a directory from the source filename to the destination filename, use the **rename** command in privileged EXEC mode.

rename [**/noconfirm***]* [**disk0**: | **disk1**: | **flash:**] *source-path* [**disk0**: | **disk1**: | **flash:**] *destination-path*

Syntax Description

/noconfirm	(Optional) Suppresses the confirmation prompt.
destination-path	Specifies the path of the destination file.
disk0*:*	(Optional) Specifies the internal flash memory, followed by a colon.
disk1:	(Optional) Specifies the external flash memory card, followed by a colon.
flash:	(Optional) Specifies the internal flash memory, followed by a colon.
source-path	Specifies the path of the source file.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **rename flash: flash:** command prompts you to enter a source and destination filename.

You cannot rename a file or directory across file systems.

For example:

```
hostname# rename flash: disk1:
Source filename []? new-config
Destination filename []? old-config
%Cannot rename between filesystems
```

Examples

The following example shows how to rename a file named “test” to “test1”:

```
hostname# rename flash: flash:
Source filename [running-config]? test
Destination filename [n]? test1
```

Related Commands

Command	Description
mkdir	Creates a new directory.
rmdir	Removes a directory.
show file	Displays information about the file system.

rename (class-map)

To rename a class map, enter the **rename** command in class-map configuration mode.

rename *new_name*

Syntax Description

new_name	Specifies the new name of the class map, up to 40 characters in length. The name "class-default" is reserved.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to rename a class map from test to test2:

```
hostname(config)# class-map test
hostname(config-cmap)# rename test2
```

Related Commands

Command	Description
class-map	Creates a class map.

renewal-reminder

To specify the number of days before user certificate expiration that an initial reminder to re-enroll is sent to certificate owners, use the **renewal-reminder** command in ca server configuration mode. To reset the time to the default of 14 days, use the **no** form of this command.

renewal-reminder *days*

no renewal-reminder

Syntax Description

days	Specifies the time in days before the expiration of an issued certificate that the certificate owner is first reminded to re-enroll. Valid values range from 1 to 90 days.

Defaults

The default value is 14 days.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
ca server configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

There are three reminders in all. An e-mail is sent automatically to the certificate owner for each of the three reminders if an e-mail address is specified in the user database. If no e-mail address exists, a syslog message is generated to alert the administrator of the renewal.

By default, the CA server sends the following three e-mail messages in the specified order before certificate expiration:

1. Certification Enrollment Invitation
2. Reminder: Certification Enrollment Invitation
3. Last Reminder: Certification Enrollment Invitation

The first e-mail is the invitation, the second e-mail is a reminder, and the third e-mail is a final reminder. The default setting for this notification is 14 days, which means that the initial invitation goes out 14 days before certificate expiration, the reminder e-mail goes out 7 days before certificate expiration, and the final reminder e-mail goes out 3 days before certificate expiration.

You can customize the renewal-reminder interval using the **renewal-reminder** *days* command.

Examples

The following example specifies that the ASA send an expiration notice to users 7 days before certificate expiration:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# renewal-reminder 7
hostname(config-ca-server)#
```

The following example resets the expiration notice time to the default of 14 days before certificate expiration:

```
hostname(config)# crypto ca server
hostname(config-ca-server)# no renewal-reminder
hostname(config-ca-server)#
```

Related Commands

Command	Description
crypto ca server	Provides access to the ca server configuration mode command set, which allows you to configure and manage the local CA.
lifetime	Specifies the lifetimes of the CA certificate, all issued certificates, and the CRL.
show crypto ca server	Displays the configuration details of the local CA server.

replication http

To enable HTTP connection replication for the failover group, use the **replication http** command in failover group configuration mode. To disable HTTP connection replication, use the **no** form of this command.

replication http

no replication http

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

By default, the ASA does not replicate HTTP session information when Stateful Failover is enabled. Because HTTP sessions are typically short-lived, and because HTTP clients typically retry failed connection attempts, not replicating HTTP sessions increases system performance without causing serious data or connection loss. The **replication http** command enables the stateful replication of HTTP sessions in a Stateful Failover environment, but could have a negative effect on system performance.

This command is available for Active/Active failover only. It provides the same functionality as the **failover replication http** command for Active/Standby failover, except for failover groups in Active/Active failover configurations.

Examples

The following example shows a possible configuration for a failover group:

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# replication http
hostname(config-fover-group)# exit
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
failover replication http	Configures stateful failover to replicate HTTP connections.

request-command deny

To disallow specific commands within FTP requests, use the **request-command deny** command in FTP map configuration mode, which is accessible by using the **ftp-map** command. To remove the configuration, use the **no** form of this command.

request-command deny { **appe** | **cdup** | **dele** | **get** | **help** | **mkd** | **put** | **rmd** | **rnfr** | **rnto** | **site** | **stou** }

no request-command deny { **appe** | **cdup** | **help** | **retr** | **rnfr** | **rnto** | **site** | **stor** | **stou** }

Syntax Description

appe	Disallows the command that appends to a file.
cdup	Disallows the command that changes to the parent directory of the current working directory.
dele	Disallows the command that deletes a file on the server.
get	Disallows the client command for retrieving a file from the server.
help	Disallows the command that provides help information.
mkd	Disallows the command that makes a directory on the server.
put	Disallows the client command for sending a file to the server.
rmd	Disallows the command that deletes a directory on the server.
rnfr	Disallows the command that specifies rename-from filename.
rnto	Disallows the command that specifies rename-to filename.
site	Disallows the command that is specific to the server system. Usually used for remote administration.
stou	Disallows the command that stores a file using a unique file name.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
FTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

This command is used for controlling the commands allowed within FTP requests traversing the ASA when using strict FTP inspection.

Examples

The following example causes the ASA to drop FTP requests containing **stor**, **stou**, or **appe** commands:

```
hostname(config)# ftp-map inbound_ftp
hostname(config-ftp-map)# request-command deny put stou appe
```

Related Commands

Commands	Description
class-map	Defines the traffic class to which to apply security actions.
ftp-map	Defines an FTP map and enables FTP map configuration mode.
inspect ftp	Applies a specific FTP map to use for application inspection.
mask-syst-reply	Hides the FTP server response from clients.
policy-map	Associates a class map with specific security actions.

request-data-size

To set the size of the payload in the SLA operation request packets, use the **request-data-size** command in sla monitor protocol configuration mode. To restore the default value, use the **no** form of this command.

request-data-size *bytes*

no request-data-size

Syntax Description

bytes	The size, in bytes, of the request packet payload. Valid values are from 0 to 16384. The minimum value depends upon the protocol used. For echo types, the minimum value is 28 bytes. Do not set this value higher than the maximum allowed by the protocol or the PMTU. **Note** The ASA adds an 8-byte timestamp to the payload, so the actual payload is *bytes* + 8.

Defaults

The default *bytes* is 28.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
sla monitor protocol configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

For reachability, it may be necessary to increase the default data size to detect PMTU changes between the source and the target. Low PMTU will likely affect session performance and, if detected, may indicate that the secondary path be used.

Examples

The following example configures an SLA operation with an ID of 123 that uses an ICMP echo request/response time probe operation. It sets the payload size of the echo request packets to 48 bytes and the number of echo requests sent during an SLA operation to 5.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# num-packets 5
hostname(config-sla-monitor-echo)# request-data-size 48
hostname(config-sla-monitor-echo)# timeout 4000
```

```
hostname(config-sla-monitor-echo)# threshold 2500
hostname(config-sla-monitor-echo)# frequency 10
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
```

Related Commands

Command	Description
num-packets	Specifies the number of request packets to send during an SLA operation.
sla monitor	Defines an SLA monitoring operation.
type echo	Configures the SLA operation as an echo response time probe operation.

request-queue

To specify the maximum number of GTP requests that will be queued waiting for a response, use the **request-queue** command in GTP map configuration mode, which is accessed by using the **gtp-map** command. Use the **no** form of this command to return this number to the default of 200.

request-queue *max_requests*

no request-queue *max_requests*

Syntax Description

max_requests	The maximum number of GTP requests that will be queued waiting for a response. The range values is 1 to 4294967295.

Defaults

The *max_requests* default is 200.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
GTP map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **gtp request-queue** command specifies the maximum number of GTP requests that are queued waiting for a response. When the limit has been reached and a new request arrives, the request that has been in the queue for the longest time is removed. The Error Indication, the Version Not Supported and the SGSN Context Acknowledge messages are not considered as requests and do not enter the request queue to wait for a response.

Examples

The following example specifies a maximum request queue size of 300 bytes:

```
hostname(config)# gtp-map qtp-policy
hostname(config-gtpmap)# request-queue-size 300
```

Related Commands

Commands	Description
clear service-policy inspect gtp	Clears global GTP statistics.
debug gtp	Displays detailed information about GTP inspection.

Commands	Description
gtp-map	Defines a GTP map and enables GTP map configuration mode.
inspect gtp	Applies a specific GTP map to use for application inspection.
show service-policy inspect gtp	Displays the GTP configuration.

request-timeout

To configure the number of seconds before a failed SSO authentication attempt times out, use the **request-timeout** command in webvpn configuration mode.

To return to the default value, use the **no** form of this command.

request-timeout *seconds*

no request-timeout

Syntax Description

seconds	The number of seconds before a failed SSO authentication attempt times out. The range is 1 to 30 seconds. Fractions are not supported.

Defaults

The default value for this command is 5 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1.1	This command was introduced.

Usage Guidelines

Single sign-on support, available only for WebVPN, lets users access different secure services on different servers without entering a username and password more than once. The ASA currently supports SiteMinder and SAML POST type SSO servers.

This command applies to both types of SSO Servers.

Once you have configured the ASA to support SSO authentication, you have the option to adjust two timeout parameters:

- The number of seconds before a failed SSO authentication attempt times out using the **request-timeout** command.
- The number of times the ASA retries a failed SSO authentication attempt. (See the **max-retry-attempts** command.)

Examples

The following example, entered in webvpn-config-sso-siteminder mode, configures an authentication timeout at ten seconds for the SiteMinder type SSO server, “example”:

```
hostname(config-webvpn)# sso-server example type siteminder
hostname(config-webvpn-sso-siteminder)# request-timeout 10
```

Related Commands

Command	Description
max-retry-attempts	Configures the number of times the ASA retries a failed SSO authentication attempt.
policy-server-secret	Creates a secret key used to encrypt authentication requests to a SiteMinder SSO server.
show webvpn sso-server	Displays the operating statistics for all SSO servers configured on the security device.
sso-server	Creates a single sign-on server.
test sso-server	Tests an SSO server with a trial authentication request.
web-agent-url	Specifies the SSO server URL to which the ASA makes SiteMinder SSO authentication requests.

reserve-port-protect

To restrict usage on the reserve port during media negotiation, use the **reserve-port-protect** command in parameters configuration mode. Parameters configuration mode is accessible from policy map configuration mode. To disable this feature, use the **no** form of this command.

reserve-port-protect

no reserve-port-protect

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Examples

The following example shows how to protect the reserve port in an RTSP inspection policy map:

```
hostname(config)# policy-map type inspect rtsp rtsp_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# reserve-port-protect
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

reserved-bits

To clear reserved bits in the TCP header, or drop packets with reserved bits set, use the **reserved-bits** command in tcp-map configuration mode. To remove this specification, use the **no** form of this command.

reserved-bits {**allow** | **clear** | **drop**}

no reserved-bits {**allow** | **clear** | **drop**}

Syntax Description

allow	Allows packet with the reserved bits in the TCP header.
clear	Clears the reserved bits in the TCP header and allows the packet.
drop	Drops the packet with the reserved bits in the TCP header.

Defaults

The reserved bits are allowed by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The **tcp-map** command is used along with the Modular Policy Framework infrastructure. Define the class of traffic using the **class-map** command and customize the TCP inspection with **tcp-map** commands. Apply the new TCP map using the **policy-map** command. Activate TCP inspection with **service-policy** commands.

Use the **tcp-map** command to enter tcp-map configuration mode. Use the **reserved-bits** command in tcp-map configuration mode to remove ambiguity as to how packets with reserved bits are handled by the end host, which may lead to desynchronizing the ASA. You can choose to clear the reserved bits in the TCP header or even drop packets with the reserved bits set.

Examples

The following example shows how to clear packets on all TCP flows with the reserved bit set:

```
hostname(config)# access-list TCP extended permit tcp any any
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# reserved-bits clear
hostname(config)# class-map cmap
hostname(config-cmap)# match access-list TCP
```

```
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configures connection values.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

reset

When using the Modular Policy Framework, drop packets, close the connection, and send a TCP reset for traffic that matches a **match** command or class map by using the **reset** command in match or class configuration mode. This reset action is available in an inspection policy map (the **policy-map type inspect** command) for application traffic; however, not all applications allow this action. To disable this action, use the **no** form of this command.

reset [**log**]

no reset [**log**]

Syntax Description

log	Logs the match. The system log message number depends on the application.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Match and class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

An inspection policy map consists of one or more **match** and **class** commands. The exact commands available for an inspection policy map depends on the application. After you enter the **match** or **class** command to identify application traffic (the **class** command refers to an existing **class-map type inspect** command that in turn includes **match** commands), you can enter the **reset** command to drop packets and close the connection for traffic that matches the **match** command or **class** command.

If you reset a connection, then no further actions are performed in the inspection policy map. For example, if the first action is to reset the connection, then it will never match any further **match** or **class** commands. If the first action is to log the packet, then a second action, such as resetting the connection, can occur. You can configure both the **reset** and the **log** action for the same **match** or **class** command, in which case the packet is logged before it is reset for a given match.

When you enable application inspection using the **inspect** command in a Layer 3/4 policy map (the **policy-map** command), you can enable the inspection policy map that contains this action, for example, enter the **inspect http http_policy_map** command where http_policy_map is the name of the inspection policy map.

Examples

The following example resets the connection and sends a log when they match the http-traffic class map. If the same packet also matches the second **match** command, it will not be processed because it was already dropped.

```
hostname(config-cmap)# policy-map type inspect http http-map1
hostname(config-pmap)# class http-traffic
hostname(config-pmap-c)# reset log
hostname(config-pmap-c)# match req-resp content-type mismatch
hostname(config-pmap-c)# reset log
```

Related Commands

Commands	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
policy-map type inspect	Defines special actions for application inspection.
show running-config policy-map	Display all current policy map configurations.

CHAPTER 42

retries through rtp-min-port rtp-max-port Commands

retries

To specify the number of times to retry the list of DNS servers when the ASA does not receive a response, use the **dns retries** command in global configuration mode. To restore the default setting, use the **no** form of this command.

retries *number*

no retries [*number*]

Syntax Description

number	Specifies the number of retries, from 0 through 10. The default is 2.

Defaults

The default number of retries is 2.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Add DNS servers using the **name-server** command.

This command replaces the **dns name-server** command.

Examples

The following example sets the number of retries to 0. The ASA tries each server only once.

```
hostname(config)# dns server-group dnsgroup1
hostname(config-dns-server-group)# dns retries 0
```

Related Commands

Command	Description
clear configure dns	Removes all DNS commands.
dns server-group	Enters the dns server-group mode.
show running-config dns server-group	Shows one or all the existing dns-server-group configurations.

retry-count

To set the value for the number of consecutive polling failures to the Cloud Web Security proxy server before determining the server is unreachable, enter the **retry-count** command in scansafe general-options configuration mode. To restore the default, use the **no** form of this command.

retry-count *value*

no retry-count [*value*]

Syntax Description

value	Enters the retry counter value, from 2 to 100. The default is 5.

Command Default

The default value is 5.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Scansafe general-options configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

When you subscribe to the Cisco Cloud Web Security service, you are assigned a primary Cloud Web Security proxy server and backup proxy server.

If any client is unable to reach the primary server, then the ASA starts polling the tower to determine availability. (If there is no client activity, the ASA polls every 15 miniutes.) If the proxy server is unavailable after a configured number of retries (the default is 5; this setting is configurable), the server is declared unreachable, and the backup proxy server becomes active.

If a client or the ASA can reach the server at least twice consecutively before the retry count is reached, the polling stops and the tower is determined to be reachable.

After a failover to the backup server, the ASA continues to poll the primary server. If the primary server becomes reachable, then the ASA returns to using the primary server.

Examples

The following example configures a retry value of 7:

```
scansafe general-options
 server primary ip 180.24.0.62 port 8080
 retry-count 7
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

retry-interval

To configure the amount of time between retry attempts for a particular AAA server designated in a previous **aaa-server host** command, use the **retry-interval** command in aaa-server host mode. To reset the retry interval to the default value, use the **no** form of this command.

retry-interval *seconds*

no retry-interval

Syntax Description

seconds	Specify the retry interval (1-10 seconds) for the request. This is the time the ASA waits before retrying a connection request.

Defaults

The default retry interval is 10 seconds.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
AAA-server host	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was modified to conform to CLI guidelines.

Usage Guidelines

Use the **retry-interval** command to specify or reset the number of seconds the ASA waits between connection attempts. Use the **timeout** command to specify the length of time during which the ASA attempts to make a connection to a AAA server.

Examples

The following examples show the **retry-interval** command in context.

```
hostname(config)# aaa-server svrgrp1 protocol radius
hostname(config-aaa-server-group)# aaa-server svrgrp1 host 1.2.3.4
hostname(config-aaa-server-host)# timeout 7
hostname(config-aaa-server-host)# retry-interval 9
hostname(config-aaa-server-host)#
```

Related Commands

Command	Description
aaa-server host	Enters aaa-server host configuration mode, so that you can configure AAA server parameters that are host-specific.

clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol
timeout	Specifies the length of time during which the ASA attempts to make a connection to a AAA server.

reval-period

To specify the interval between each successful posture validation in a NAC Framework session, use the **reval-period** command in nac-policy-nac-framework configuration mode. To remove the command from the NAC Framework policy, use the **no** form of this command.

reval-period *seconds*

no reval-period [*seconds*]

Syntax Description

seconds	Number of seconds between each successful posture validation. The range is 300 to 86400.

Defaults

The default value is 36000.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
nac-policy-nac-framework configuration	•	—	•	—	—

Command History

Release	Modification
7.3(0)	"nac-" removed from command name. Command moved from group-policy configuration mode to nac-policy-nac-framework configuration mode.
7.2(1)	This command was introduced.

Usage Guidelines

The ASA starts the revalidation timer after each successful posture validation. The expiration of this timer triggers the next unconditional posture validation. The ASA maintains posture validation during revalidation. The default group policy becomes effective if the Access Control Server is unavailable during posture validation or revalidation.

Examples

The following example changes the revalidation timer to 86400 seconds:

```
hostname(config-nac-policy-nac-framework)# reval-period 86400
hostname(config-nac-policy-nac-framework)
```

The following example removes the revalidation timer from the NAC policy:

```
hostname(config-nac-policy-nac-framework)# no reval-period
hostname(config-nac-policy-nac-framework)
```

Related Commands

Command	Description
eou timeout	Changes the number of seconds to wait after sending an EAP over UDP message to the remote host in a NAC Framework configuration.
sq-period	Specifies the interval between each successful posture validation in a NAC Framework session and the next query for changes in the host posture.
nac-policy	Creates and accesses a Cisco NAC policy, and specifies its type.
debug nac	Enables logging of NAC Framework events.
eou revalidate	Forces immediate posture revalidation of one or more NAC Framework sessions.

revert webvpn all

To remove all web-related data (customization, plug-in, translation table, URL list, and web content) from the ASA flash memory, enter the **revert webvpn all** command in privileged EXEC mode.

revert webvpn all

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn all** command to disable and remove all web-related information (customization, plug-in, translation table, URL list, and web content) from the flash memory of the ASA. Removal of all web-related data returns default settings when applicable.

Examples

The following command removes all of the web-related configuration data from the ASA:

```
hostname# revert webvpn all
hostname
```

Related Commands

Command	Description
show import webvpn (*option*)	Displays various imported WebVPN data and plug-ins. currently present in flash memory on the ASA.

revert webvpn AnyConnect-customization

To remove a file from the ASA that customizes the AnyConnect client GUI, use the **revert webvpn AnyConnect-customization** command in privileged EXEC mode.

revert webvpn AnyConnect-customization type *type* **platform** *platform* **name** *name*

Syntax Description

type	The type of customizing file: • binary—An executable that replaces the AnyConnect GUI. • resource—A resource file, such as the corporate logo. • transform—A transform that customizes the MSI.
platform	The OS of the endpoint device running the AnyConnect client. Specify one of the following: **linux**, **mac-intel**, **mac-powerpc**, **win**, or **win-mobile**.
name	The name that identifies the file to remove (maximum 64 characters).

Defaults

There is no default behavior for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

For detailed procedures for customizing the AnyConnect client GUI, see the *AnyConnect VPN Client Administrator Guide*.

Examples

The following example removes the Cisco logo that was previously imported as a resource file to customize the AnyConnect GUI:

```
hostname# revert webvpn AnyConnect-customization type resource platform win name
cisco_logo.gif
```

Related Commands

Command	Description
`customization`	Specifies the customization object to use for a tunnel-group, group, or user.
`export customization`	Exports a customization object.
`import customization`	Installs a customization object.
`revert webvpn all`	Removes all webvpn-related data (customization, plug-in, translation table, URL list, and web content).
`show webvpn customization`	Displays the current customization objects present on the flash device of the ASA.

revert webvpn customization

To remove a customization object from the ASA cache memory, enter the **revert webvpn customization** command in privileged EXEC mode.

revert webvpn customization *name*

Syntax Description

name	Specifies the name of the customization object to be deleted.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn customization** command to remove Clientless SSL VPN support for the specified customization and to remove it from the cache memory on the ASA. Removal of a customization object returns default settings when applicable. A customization object contains the configuration parameters for a specific, named portal page.

Version 8.0 software extends the functionality for configuring customization, and the new process is incompatible with previous versions. During the upgrade to 8.0 software, the security appliance preserves a current configuration by using old settings to generate new customization objects. This process occurs only once, and is more than a simple transformation from the old format to the new one because the old values are only a partial subset of the new ones.

Note Version 7.2 portal customizations and URL lists work in the Beta 8.0 configuration only if clientless SSL VPN (WebVPN) is enabled on the appropriate interface in the Version 7.2(x) configuration file before you upgrade to Version 8.0.

Examples

The following command removes the customization object named GroupB:

```
hostname# revert webvpn customization groupb
hostname
```

Related Commands

Command	Description
customization	Specifies the customization object to use for a tunnel-group, group, or user.
export customization	Exports a customization object.
import customization	Installs a customization object.
revert webvpn all	Removes all webvpn-related data (customization, plug-in, translation table, URL list, and web content).
show webvpn customization	Displays the current customization objects present on the flash device of the ASA.

revert webvpn plug-in protocol

To remove a plug-in from the flash device of the ASA, enter the **revert webvpn plug-in protocol** command in privileged EXEC mode.

revert plug-in protocol *protocol*

Syntax Description

protocol	Enter one of the following strings: • **rdp** The Remote Desktop Protocol plug-in lets the remote user connect to a computer running Microsoft Terminal Services. • **ssh** The Secure Shell plug-in lets the remote user establish a secure channel to a remote computer, or lets the remote user use Telnet to connect to a remote computer. • **vnc** The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing turned on.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn plug-in protocol** command to disable and remove Clientless SSL VPN support for the specified Java-based client application, as well as to remove it from the flash drive of the ASA.

Examples

The following command removes support for RDP:

```
hostname# revert webvpn plug-in protocol rdp
hostname
```

Related Commands

Command	Description
import webvpn plug-in protocol	Copies the specified plug-in from a URL to the flash device of the ASA. Clientless SSL VPN automatically supports the use of the Java-based client application for future sessions when you issue this command.
show import webvpn plug-in	Lists the plug-ins present on the flash device of the ASA.

revert webvpn translation-table

To remove a translation table from the ASA flash memory, enter the **revert webvpn translation-table** command in privileged EXEC mode.

revert webvpn translation-table *translationdomain language*

Syntax Description

translationdomain	Available translation domains: • AnyConnect • PortForwarder • Banners • CSD • Customization • URL List • (Translations of messages from RDP, SSH, and VNC plug-ins.)
language	Specifies the character-encoding method to be deleted.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn translation-table** command to disable and remove an imported translation table and to remove it from the flash memory on the ASA. Removal of a translation table returns default settings when applicable.

Examples

The following command removes the AnyConnect translation table, Dutch:

```
hostname# revert webvpn translation-table anyconnect dutch
hostname
```

Related Commands

Command	Description
revert webvpn all	Removes all webvpn-related data (customization, plug-in, translation table, URL-list, and web content) .
show webvpn translation-table	Displays the current translation tables currently present on the flash device of the ASA.

revert webvpn url-list

To remove a URL list from the ASA, enter the **revert webvpn url-list** command in privileged EXEC mode.

revert webvpn url-list template *name*

Syntax Description

template *name*	Specifies the name of a URL list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn url-list** command to disable and remove a current URL list from the flash drive of the ASA. Removal of a url-list returns default settings when applicable.

The template argument used with the **revert webvpn url-list** command specifies the name of a previously configured list of URLs. To configure such a list, use the **url-list** command in global configuration mode.

Examples

The following command removes the URL list, servers2:

```
hostname# revert webvpn url-list servers2
hostname
```

Related Commands

Command	Description
revert webvpn all	Removes all webvpn-related data (customization, plug-in, translation table, URL list, and web content) .
show running-configuration url-list	Displays the current set of configured URL list commands.
url-list (WebVPN mode)	Applies a list of WebVPN servers and URLs to a particular user or group policy.

revert webvpn webcontent

To remove a specified web object from a location in the ASA flash memory, enter the **revert webvpn webcontent** command in privileged EXEC mode.

revert webvpn webcontent *filename*

Syntax Description

filename	Specifies the name of the flash memory file with the web content to be deleted.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **revert webvpn content** command to disable and remove a file containing the web content and to remove it from the flash memory of the ASA. Removal of web content returns default settings when applicable.

Examples

The following command removes the web content file, ABCLogo, from the ASA flash memory:

```
hostname# revert webvpn webcontent abclogo
hostname
```

Related Commands

Command	Description
revert webvpn all	Removes all webvpn-related data (customization, plug-in, translation table, URL list, and web content).
show webvpn webcontent	Displays the web content currently present in flash memory on the ASA.

revocation-check

To define whether revocation checking is needed for the trustpool policy, use the **revocation-check** command in crypto ca trustpool configuration mode. To restore the default revocation checking method, which is *none*, use the **no** form of this command.

revocation-check {[**crl**] [**ocsp**] [**none**] }

no revocation-check {[**crl**] [**ocsp**] [**none**]}

Syntax Description

crl	Specifies that the ASA should use CRL as the revocation checking method.
none	Specifies that the ASA should interpret the certificate status as valid, even if all methods return an error.
ocsp	Specifies that the ASA should use OCSP as the revocation checking method.

Defaults

The default value is *none*.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Crypto ca trustpool configuration mode	•	•	•	—	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The signer of the OCSP response is usually the OCSP server (responder) certificate. After receiving the response, devices try to verify the responder certificate.

Normally a CA sets the lifetime of its OCSP responder certificate to a relatively short period to minimize the chance of compromising its security. The CA includes an ocsp-no-check extension in the responder certificate that indicates it does not need revocation status checking. But if this extension is not present, the device tries to check the certificate revocation status using the revocation methods you configure for the trustpoint with this **revocation-check** command.The OCSP responder certificate must be verifiable if it does not have an ocsp-no-check extension since the OCSP revocation check fails unless you also set the *none* option to ignore the status check.

Note With any permutation of the optional arguments, *none* must be the last keyword used.

The ASA tries the methods in the order in which you configure them, trying the second and third methods only if the previous method returns an error (for example, server down), instead of finding the status as revoked.

You can set a revocation checking method in the client certificate validating trustpoint and also configure no revocation checking (**revocation-check none)** in the responder certificate validating trustpoint. See the **match certificate** command for a configuration example.

If you have configured the ASA with the **revocation-check crl none** command, when a client connects to the ASA, it automatically starts downloading the CRL because it has not been cached, then validates the certificate, and finishes downloading the CRL. In this case, if the CRL is not cached, the ASA validates the certificate before downloading the CRL.

Examples

```
hostname(config-ca-trustpoint)# revocation-check ?

crypto-ca-trustpoint mode commands/options:
  crl   Revocation check by CRL
  none  Ignore revocation check
  ocsp  Revocation check by OCSP
(config-ca-trustpoint)#
```

Related Commands

Command	Description
crypto ca trustpool policy	Enters a submode that provides the commands that define the trustpool policy.
match certificate allow expired-certificate	Allows the administrator to exempt certain certificates from expiration checking.
match certificate skip revocation-check	Allows the administrator to exempt certain certificates from revocation checking.

rewrite

To disable content rewriting a particular application or type of traffic over a WebVPN connection, use the **rewrite** command in webvpn mode. To eliminate a rewrite rule, use the **no** form of this command with the rule number, which uniquely identifies the rule. To eliminate all rewriting rules, use the **no** form of the command without the rule number.

By default, the ASA rewrites, or transforms, all WebVPN traffic.

rewrite order *integer* **{enable | disable} resource-mask** *string* **[name** *resource name***]**

no rewrite order *integer* **{enable | disable} resource-mask** *string* **[name** *resource name***]**

Syntax Description

disable	Defines this rewrite rule as a rule that disables content rewriting for the specified traffic. When you disable content rewriting, traffic does not go through the security appliance.
enable	Defines this rewrite rule as a rule that enables content rewriting for the specified traffic.
integer	Sets the order of the rule among all of the configured rules. The range is 1-65534.
name	(Optional) Identifies the name of the application or resource to which the rule applies.
order	Defines the order in which the ASA applies the rule.
resource-mask	Identifies the application or resource for the rule.
resource name	(Optional) Specifies the application or resource to which the rule applies. Maximum 128 bytes.
string	Specifies the name of the application or resource to match that can contain a regular expression. You can use the following wildcards: Specifies a pattern to match that can contain a regular expression. You can use the following wildcards: * — Matches everything. You cannot use this wildcard by itself. It must accompany an alphanumeric string. ? —Matches any single character. [!seq] — Matches any character not in sequence. [seq] — Matches any character in sequence. Maximum 300 bytes.

Defaults

The default is to rewrite everything.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

The ASA performs content rewriting for applications to insure that they render correctly over WebVPN connections. Some applications do not require this processing, such as external public websites. For these applications, you might choose to turn off content rewriting.

You can turn off content rewriting selectively by using the rewrite command with the disable option to let users browse specific sites directly without going through the ASA. This is similar to split-tunneling in IPsec VPN connections.

You can use this command multiple times. The order in which you configure entries is important because the ASA searches rewrite rules by order number and applies the first rule that matches.

Examples

The following example shows how to configure a rewrite rule, order number of 1, that turns off content rewriting for URLS from cisco.com domains:

```
hostname(config-webpn)# rewrite order 2 disable resource-mask *cisco.com/*
```

Related Commands

Command	Description
apcf	Specifies nonstandard rules to use for a particular application.
proxy-bypass	Configures minimal content rewriting for a particular application.

re-xauth

To require that IPsec users reauthenticate on IKE rekey, issue the **re-xauth enable** command in group-policy configuration mode. To disable user reauthentication on IKE rekey, use the **re-xauth disable** command.

To remove the re-xauth attribute from the running configuration, use the **no** form of this command. This enables inheritance of a value for reauthentication on IKE rekey from another group policy.

re-xauth {**enable** [**extended**] | **disable**}

no re-xauth

Syntax Description

disable	Disables reauthentication on IKE rekey
enable	Enables reauthentication on IKE rekey
extended	Extends the time allowed for reentering authentication credentials until the maximum lifetime of the configured SA.

Defaults

Reauthentication on IKE rekey is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0.4	The **extended** keyword was added.

Usage Guidelines

Reauthentication on IKE rekey applies only to IPsec connections.

If you enable reauthentication on IKE rekey, the ASA prompts the user to enter a username and password during initial Phase 1 IKE negotiation and also prompts for user authentication whenever an IKE rekey occurs. Reauthentication provides additional security.

The user has 30 seconds to enter credentials, and up to three attempts before the SA expires at approximately two minutes and the tunnel terminates. Use the **extended** keyword to allow users to reenter authentication credentials until the maximum lifetime of the configured SA.

To check the configured rekey interval, in monitoring mode, issue the **show crypto ipsec sa** command to view the security association lifetime in seconds and lifetime in kilobytes of data.

Note The reauthentication fails if there is no user at the other end of the connection.

Examples

The following example shows how to enable reauthentication on rekey for the group policy named FirstGroup:

```
hostname(config) #group-policy FirstGroup attributes
hostname(config-group-policy)# re-xauth enable
```

rip send version

To specify the RIP version used to send RIP updates on an interface, use the **rip send version** command in interface configuration mode. To restore the defaults, use the **no** form of this command.

rip send version {[**1**] [**2**]}

no rip send version

Syntax Description

1	Specifies RIP Version 1.
2	Specifies RIP Version 2.

Defaults

The ASA sends RIP Version 1 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can override the global RIP send version setting on a per-interface basis by entering the **rip send version** command on an interface.

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Examples

The following example configures the ASA to send and receive RIP Versions 1 and 2 packets on the specified interface:

```
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# rip send version 1 2
hostname(config-if)# rip receive version 1 2
```

Related Commands

Command	Description
rip receive version	Specifies the RIP version to accept when receiving updates on a specific interface.
router rip	Enables the RIP routing process and enter router configuration mode for that process.
version	Specifies the version of RIP used globally by the ASA.

rip receive version

To specify the version of RIP accepted on an interface, use the **rip receive version** command in interface configuration mode. To restore the defaults, use the **no** form of this command.

version {[**1**] [**2**]}

no version

Syntax Description

1	Specifies RIP Version 1.
2	Specifies RIP Version 2.

Defaults

The ASA accepts Version 1 and Version 2 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can override the global setting on a per-interface basis by entering the **rip receive version** command on an interface.

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Examples

The following example configures the ASA to receive RIP Versions 1 and 2 packets the specified interface:

```
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# rip send version 1 2
hostname(config-if)# rip receive version 1 2
```

Related Commands

Command	Description
rip send version	Specifies the RIP version to use when sending update out of a specific interface.
router rip	Enables the RIP routing process and enter router configuration mode for that process.
version	Specifies the version of RIP used globally by the ASA.

rip authentication mode

To specify the type of authentication used in RIP Version 2 packets, use the **rip authentication mode** command in interface configuration mode. To restore the default authentication method, use the **no** form of this command.

rip authentication mode {**text** | **md5**}

no rip authentication mode

Syntax Description

md5	Uses MD5 for RIP message authentication.
text	Uses clear text for RIP message authentication (not recommended).

Defaults

Clear text authentication is used by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Use the **show interface** command to view the **rip authentication** commands on an interface.

Examples

The following examples shows RIP authentication configured on interface GigabitEthernet0/3:

```
hostname(config)# interface Gigabit0/3
hostname(config-if)# rip authentication mode md5
hostname(config-if)# rip authentication key thisismykey key_id 5
```

Related Commands

Command	Description
rip authentication key	Enables RIP Version 2 authentication and specifies the authentication key.
rip receive version	Specifies the RIP version to accept when receiving updates on a specific interface.

Command	Description
rip send version	Specifies the RIP version to use when sending update out of a specific interface.
show running-config interface	Displays the configuration commands for the specified interface.
version	Specifies the version of RIP used globally by the ASA.

rip authentication key

To enable authentication of RIP Version 2 packets and specify the authentication key, use the **rip authentication key** command in interface configuration mode. To disable RIP Version 2 authentication, use the **no** form of this command.

rip authentication key [0 | 8] *string* **key_id** *id*

no rip authentication key

Syntax Description

0	Specifies an unencrypted password will follow.
8	Specifies an encrypted password will follow.
id	Specifies the key identification value; valid values range from 1 to 255.
key	Specifies the shared key to be used for the authentication key string. The key can contain up to 16 characters.
string	Specifies the unencrypted (cleartext) user password.

Defaults

RIP authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates. When you enable neighbor authentication, you must ensure that the *key* and *key_id* arguments are the same as those used by neighbor devices that provide RIP version 2 updates. The *key* is a text string of up to 16 characters.

Use the **show interface** command to view the **rip authentication** commands on an interface.

Examples

The following examples shows RIP authentication configured on interface GigabitEthernet0/3:

```
hostname(config)# interface Gigabit0/3
hostname(config-if)# rip authentication mode md5
hostname(config-if)# rip authentication key 8 yWIvi0qJAnGK5MRWQzrhIohkGP1wKb 5
```

Related Commands

Command	Description
rip authentication mode	Specifies the type of authentication used in RIP Version 2 packets.
rip receive version	Specifies the RIP version to accept when receiving updates on a specific interface.
rip send version	Specifies the RIP version to use when sending update out of a specific interface.
show running-config interface	Displays the configuration commands for the specified interface.
version	Specifies the version of RIP used globally by the ASA.

rip receive version

To specify the version of RIP accepted on an interface, use the **rip receive version** command in interface configuration mode. To restore the defaults, use the **no** form of this command.

version {[**1**] [**2**]}

no version

Syntax Description

1	Specifies RIP Version 1.
2	Specifies RIP Version 2.

Defaults

The ASA accepts Version 1 and Version 2 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can override the global setting on a per-interface basis by entering the **rip receive version** command on an interface.

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Examples

The following example configures the ASA to receive RIP Versions 1 and 2 packets the specified interface:

```
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# rip send version 1 2
hostname(config-if)# rip receive version 1 2
```

Related Commands

Command	Description
rip send version	Specifies the RIP version to use when sending update out of a specific interface.
router rip	Enables the RIP routing process and enters router configuration mode for that process.
version	Specifies the version of RIP used globally by the ASA.

rip send version

To specify the RIP version used to send RIP updates on an interface, use the **rip send version** command in interface configuration mode. To restore the defaults, use the **no** form of this command.

rip send version {[**1**] [**2**]}

no rip send version

Syntax Description

1	Specifies RIP Version 1.
2	Specifies RIP Version 2.

Defaults

The ASA sends RIP Version 1 packets.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Interface configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

You can override the global RIP send version setting on a per-interface basis by entering the **rip send version** command on an interface.

If you specify RIP version 2, you can enable neighbor authentication and use MD5-based encryption to authenticate the RIP updates.

Examples

The following example configures the ASA to send and receive RIP Versions 1 and 2 packets on the specified interface:

```
hostname(config)# interface GigabitEthernet0/3
hostname(config-if)# rip send version 1 2
hostname(config-if)# rip receive version 1 2
```

Related Commands

Command	Description
rip receive version	Specifies the RIP version to accept when receiving updates on a specific interface.
router rip	Enables the RIP routing process and enter router configuration mode for that process.
version	Specifies the version of RIP used globally by the ASA.

rmdir

To remove the existing directory, use the **rmdir** command in privileged EXEC mode.

rmdir [**/noconfirm**] [**disk0: | disk1: | flash:**]*path*

Syntax Description

/noconfirm	(Optional) Suppresses the confirmation prompt.
disk0*:*	(Optional) Specifies the nonremovable internal flash memory, followed by a colon.
disk1:	(Optional) Specifies the removable external flash memory card, followed by a colon.
flash:	(Optional) Specifies the nonremovable internal flash, followed by a colon. In the ASA 5500 series adaptive security appliances, the **flash** keyword is aliased to **disk0**.
path	(Optional) The absolute or relative path of the directory to remove.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If the directory is not empty, the **rmdir** command fails.

Examples

The following example shows how to remove an existing directory named “test”:

```
hostname# rmdir test
```

Related Commands

Command	Description
dir	Displays the directory contents.
mkdir	Creates a new directory.
pwd	Displays the current working directory.
show file	Displays information about the file system.

route

To enter a static or default route for the specified interface, use the **route** command in global configuration mode. To remove routes from the specified interface, use the **no** form of this command.

route *interface_name ip_address netmask gateway_ip* [[*metric*] [**track** *number*] | **tunneled**]

no route *interface_name ip_address netmask gateway_ip* [[*metric*] [**track** *number*] | **tunneled**]

Syntax Description

gateway_ip	Specifies the IP address of the gateway router (the next-hop address for this route). **Note** The *gateway_ip* argument is optional in transparent mode.
interface_name	Specifies the internal or external network interface name through which the traffic is routed.
ip_address	Specifies the internal or external network IP address.
metric	(Optional) Specifies the administrative distance for this route. Valid values range from 1 to 255. The default value is 1.
netmask	Specifies a network mask to apply to *ip_address*.
track *number*	(Optional) Associates a tracking entry with this route. Valid values are from 1 to 500. **Note** The **track** option is only available in single, routed mode.
tunneled	Specifies the route as the default tunnel gateway for VPN traffic.

Defaults

The *metric* default is 1.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **track** *number* value was added.

Usage Guidelines

Use the **route** command to enter a default or static route for an interface. To enter a default route, set *ip_address* and *netmask* to **0.0.0.0,** or use the shortened form of **0**. All routes that are entered using the **route** command are stored in the configuration when it is saved.

You can define a separate default route for tunneled traffic along with the standard default route. When you create a default route with the **tunneled** option, all traffic from a tunnel terminating on the ASA that cannot be routed using learned or static routes, is sent to this route. For traffic emerging from a tunnel, this route overrides over any other configured or learned default routes.

The following restrictions apply to default routes with the **tunneled** option:

- Do not enable unicast RPF (**ip verify reverse-path**) on the egress interface of a tunneled route. Enabling uRPF on the egress interface of a tunneled route causes the session to fail.
- Do not enable TCP intercept on the egress interface of the tunneled route, because the session will fail.
- Do not use the VoIP inspection engines (CTIQBE, H.323, GTP, MGCP, RTSP, SIP, SKINNY), the DNS inspect engine, or the DCE RPC inspection engine with tunneled routes. These inspection engines ignore the tunneled route.

You cannot define more than one default route with the **tunneled** option; ECMP for tunneled traffic is not supported.

Create static routes to access networks that are connected outside a router on any interface. For example, the ASA sends all packets that are destined to the 192.168.42.0 network through the 192.168.1.5 router with the following static **route** command.

```
hostname(config)# route dmz 192.168.42.0 255.255.255.0 192.168.1.5 1
```

After you enter the IP address for each interface, the ASA creates a CONNECT route in the route table. This entry is not deleted when you use the **clear route** or **clear configure route** commands.

If the **route** command uses the IP address from one of the interfaces on the ASA as the gateway IP address, the ASA will ARP for the destination IP address in the packet instead of ARPing for the gateway IP address.

Examples

The following example shows how to specify one default **route** command for an outside interface:

```
hostname(config)# route outside 0 0 209.165.201.1 1
```

The following example shows how to add these static **route** commands to provide access to the networks:

```
hostname(config)# route dmz1 10.1.2.0 255.0.0.0 10.1.1.4 1
hostname(config)# route dmz1 10.1.3.0 255.0.0.0 10.1.1.4 1
```

The following example uses an SLA operation to install a default route to the 10.1.1.1 gateway on the outside interface. The SLA operation monitors the availability of that gateway. If the SLA operation fails, then the backup route on the DMZ interface is used.

```
hostname(config)# sla monitor 123
hostname(config-sla-monitor)# type echo protocol ipIcmpEcho 10.1.1.1 interface outside
hostname(config-sla-monitor-echo)# timeout 1000
hostname(config-sla-monitor-echo)# frequency 3
hostname(config)# sla monitor schedule 123 life forever start-time now
hostname(config)# track 1 rtr 123 reachability
hostname(config)# route outside 0.0.0.0 0.0.0.0 10.1.1.1 track 1
hostname(config)# route dmz 0.0.0.0 0.0.0.0 10.2.1.1 254
```

Related Commands

Command	Description
clear configure route	Removes statically configured **route** commands.
clear route	Removes routes learned through dynamic routing protocols such as RIP.
show route	Displays route information.
show running-config route	Displays configured routes.

route-map

To define the conditions for redistributing routes from one routing protocol into another, use the **route-map** command in global configuration mode. To remove a map, use the **no** form of this command.

route-map *map_tag* [**permit** | **deny**] [*seq_num*]

no route-map *map_tag* [**permit** | **deny**] [*seq_num*]

Syntax Description

deny	(Optional) Specifies that if the match criteria are met for the route map, the route is not redistributed.
map_tag	Text for the route map tag; the text can be up to 57 characters in length.
permit	(Optional) Specifies that if the match criteria is met for this route map, the route is redistributed as controlled by the set actions.
seq_num	(Optional) Route map sequence number; valid values are from 0 to 65535. Indicates the position that a new route map will have in the list of route maps already configured with the same name.

Defaults

The defaults are as follows:

- **permit.**
- If you do not specify a *seq_num*, a *seq_num* of 10 is assigned to the first route map.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **route-map** command lets you redistribute routes.

The **route-map** global configuration command and the **match** and **set** configuration commands define the conditions for redistributing routes from one routing protocol into another. Each **route-map** command has **match** and **set** commands that are associated with it. The **match** commands specify the match criteria that are the conditions under which redistribution is allowed for the current **route-map** command. The **set** commands specify the set actions, which are the redistribution actions to perform if the criteria enforced by the **match** commands are met. The **no route-map** command deletes the route map.

The **match route-map** configuration command has multiple formats. You can enter the **match** commands in any order, and all **match** commands must pass to cause the route to be redistributed according to the set actions given with the **set** commands. The **no** form of the **match** commands removes the specified match criteria.

Use route maps when you want detailed control over how routes are redistributed between routing processes. You specify the destination routing protocol with the **router ospf** global configuration command. You specify the source routing protocol with the **redistribute** router configuration command.

When you pass routes through a route map, a route map can have several parts. Any route that does not match at least one match clause relating to a **route-map** command is ignored; the route is not advertised for outbound route maps and is not accepted for inbound route maps. To modify only some data, you must configure a second route map section with an explicit match specified.

The *seq_number* argument is as follows:

1. If you do not define an entry with the supplied tag, an entry is created with the *seq_number* argument set to 10.
2. If you define only one entry with the supplied tag, that entry becomes the default entry for the following **route-map** command. The *seq_number* argument of this entry is unchanged.
3. If you define more than one entry with the supplied tag, an error message is printed to indicate that the *seq_number* argument is required.

If the **no route-map** *map-tag* command is specified (with no *seq-num* argument), the whole route map is deleted (all **route-map** entries with the same *map-tag* text).

If the match criteria are not met, and you specify the **permit** keyword, the next route map with the same *map_tag* is tested. If a route passes none of the match criteria for the set of route maps sharing the same name, it is not redistributed by that set.

Examples

The following example shows how to configure a route map in OSPF routing:

```
hostname(config)# route-map maptag1 permit 8
hostname(config-route-map)# set metric 5
hostname(config-route-map)# match metric 5
hostname(config-route-map)# show running-config route-map
route-map maptag1 permit 8
    set metric 5
    match metric 5
hostname(config-route-map)# exit
hostname(config)#
```

Related Commands

Command	Description
clear configure route-map	Removes the conditions for redistributing the routes from one routing protocol into another routing protocol.
match interface	Distributes distribute any routes that have their next hop out one of the interfaces specified,
router ospf	Starts and configures an OSPF routing process.
set metric	Specifies the metric value in the destination routing protocol for a route map.
show running-config route-map	Displays the information about the route map configuration.

router-alert

To define an action when the Router Alert IP option occurs in a packet with IP Options inspection, use the **router-alert** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

router-alert action {allow | clear}

no router-alert action {allow | clear}

Syntax Description

allow	Instructs the ASA to allow a packet containing the Router Alert IP option to pass.
clear	Instructs the ASA to clear the Router Alert IP option from a packet and then allow the packet to pass.

Defaults

By default, IP Options inspection, drops packets containing the Router Alert IP option.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
8.2(2)	This command was introduced.

Usage Guidelines

This command can be configured in an IP Options inspection policy map.

You can configure IP Options inspection to control which IP packets with specific IP options are allowed through the ASA. Configuring this inspection instructs the ASA to allow a packet to pass or to clear the specified IP options and then allow the packet to pass.

The Router Alert (RTRALT) or IP Option 20 notifies transit routers to inspect the contents of the packet even when the packet is not destined for that router. This inspection is valuable when implementing RSVP and similar protocols require relatively complex processing from the routers along the packets delivery path.

Examples

The following example shows how to set up an action for protocol violation in a policy map:

```
hostname(config)# policy-map type inspect ip-options ip-options_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# eool action allow
hostname(config-pmap-p)# nop action allow
```

```
hostname(config-pmap-p)# router-alert action allow
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

router-id

To use a fixed router ID, use the **router-id** command in router configuration mode for OSPFv2 or IPv6 router configuration mode for OSPFv3. To reset OSPF to use the previous router ID behavior, use the **no** form of this command.

router-id *id*

no router-id [*id*]

Syntax Description

id	Specifies the router ID in IP address format.

Defaults

If not specified, the highest-level IP address on the ASA is used as the router ID.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	•	—
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(2)	The processing order for this command was changed. The command is now processed before the **network** commands in an OSPFv2 configuration.
9.0(1)	Multiple context mode and OSPFv3 are supported.

Usage Guidelines

By default, the ASA uses the highest-level IP address on an interface that is covered by a **network** command in the OSPF configuration. If the highest-level IP address is a private address, then that address is sent in hello packets and database definitions. To use a specific router ID, use the **router-id** command to specify a global address for the router ID.

Router IDs must be unique within an OSPF routing domain. If two routers in the same OSPF domain are using the same router ID, routing may not work correctly.

You should enter the **router-id** command before entering **network** commands in an OSPF configuration. This prevents possible conflicts with the default router ID generated by the ASA. If you do have a conflict, you will receive the message:

```
ERROR: router-id id in use by ospf process pid
```

To enter the conflicting ID, remove the **network** command that contains the IP address causing the conflict, enter the **router-id** command, and then re-enter the **network** command.

Clustering

In Layer 2 clustering, you either need to configure the **router-id** *id* command or leave the router ID blank, provided all units receive the same router ID.

Examples

The following example sets the router ID to 192.168.1.1:

```
hostname(config-rtr)# router-id 192.168.1.1
hostname(config-rtr)#
```

Related Commands

Command	Description
router ospf	Enters router configuration mode.
show ospf	Displays general information about the OSPFv2 routing processes.

router-id cluster-pool

To specify the router ID cluster pool for a Layer 3 clustering deployment, use the **router-id cluster-pool** command in router configuration mode for OSPFv2 or IPv6 router configuration mode for OSPFv3.

router-id cluster-pool hostname | A.B.C.D *ip_pool*

Syntax Description

cluster-pool	Enables configuration of an IP address pool when Layer 3 clustering is configured.
hostname | A.B.C.D	Specifies the OSPF router ID for this OSPF process.
ip_pool	Specifies the name of the IP address pool.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Router configuration	•	—	•	—	—
IPv6 router configuration	•	—	•	•	—

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

Router IDs must be unique within an OSPFv2 or OSPFv3 routing domain in clustering. If two routers in the same OSPFv2 or OSPFv3 domain are using the same router ID, routing in clustering may not work correctly.

In Layer 2 clustering, you either need to configure the **router-id** *id* command or leave the router ID blank, provided all units receive the same router ID.

When a Layer 3 cluster interface is configured, each unit must have a unique interface IP address. To make sure that each unit has a unique interface IP address, you can configure a local pool of IP addresses for OSPFv2 or OSPFv3 with the **router-id cluster-pool** command.

Examples

The following example shows how to configure an IP address pool when Layer 3 clustering is configured for OSPFv2:

```
hostname(config)# ip local pool rpool 1.1.1.1-1.1.1.4
hostname(config)# router ospf 1
hostname(config-rtr)# router-id cluster-pool rpool
hostname(config-rtr)# network 17.5.0.0 255.255.0.0 area 1
```

```
hostname(config-rtr)# log-adj-changes
```

The following example shows how to configure an IP address pool when Layer 3 clustering is configured for OSPFv3:

```
hostname(config)# ipv6 router ospf 2
hostname(config-rtr)# router-id cluster-pool rpool
hostname(config-rtr)# interface gigabitEthernet0/0
hostname(config-rtr)# nameif inside
hostname(config-rtr)# security-level 0
hostname(config-rtr)# ip address 17.5.33.1 255.255.0.0 cluster-pool inside_pool
hostname(config-rtr)# ipv6 address 8888::1/64 cluster-pool p6
hostname(config-rtr)# ipv6 nd suppress-ra
hostname(config-rtr)# ipv6 ospf 2 area 0.0.0.0
```

Related Commands

Command	Description
ipv6 router ospf	Enters IPv6 router configuration mode.
router ospf	Enters router configuration mode.
show ipv6 ospf	Displays general information about the OSPFv3 routing processes.
show ospf	Displays general information about the OSPFv2 routing processes.

router eigrp

To start an EIGRP routing process and configure parameters for that process, use the **router eigrp** command in global configuration mode. To disable EIGRP routing, use the **no** form of this command.

router eigrp *as-number*

no router eigrp *as-number*

Syntax Description

as-number	Autonomous system number that identifies the routes to the other EIGRP routers. It is also used to tag the routing information. Valid values are from 1 to 65535.

Defaults

EIGRP routing is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

The **router eigrp** command creates an EIGRP routing process or enters router configuration mode for an existing EIGRP routing process. You can only create a single EIGRP routing process on the ASA.

Use the following router configuration mode commands to configure the EIGRP routing processes:

- **auto-summary**—Enable/disable automatic route summarization.
- **default-information**—Enable/disable the reception and sending of default route information.
- **default-metric**—Define the default metrics for routes redistributed into the EIGRP routing process.
- **distance eigrp**—Configure the administrative distance for internal and external EIGRP routes.
- **distribute-list**—Filter the networks received and sent in routing updates.
- **eigrp log-neighbor-changes**—Enable/disable the logging of neighbor state changes.
- **eigrp log-neighbor-warnings**—Enable/disable the logging of neighbor warning messages.
- **eigrp router-id**—Creates a fixed router ID.
- **eigrp stub**—Configures the ASA for stub EIGRP routing.
- **neighbor**—Statically define an EIGRP neighbor.

- **network**—Configure the networks that participate in the EIGRP routing process.
- **passive-interface**—Configure an interface to act as a passive interface.
- **redistribute**—Redistribute routes from other routing processes into EIGRP.

Use the following interface configuration mode commands to configure interface-specific EIGRP parameters:

- **authentication key eigrp**—Define the authentication key used for EIGRP message authentication.
- **authentication mode eigrp**—Define the authentication algorithm used for EIGRP message authentication.
- **delay**—Configure the delay metric for an interface.
- **hello-interval eigrp**—Change the interval at which EIGRP hello packets are sent out of an interface.
- **hold-time eigrp**—Change the hold time advertised by the ASA.
- **split-horizon eigrp**—Enable/disable EIGRP split-horizon on an interface.
- **summary-address eigrp**—Manually define a summary address.

Examples

The following example shows how to enter the configuration mode for the EIGRP routing process with the autonomous system number 100:

```
hostname(config)# router eigrp 100
hostname(config-rtr)#
```

Related Commands

Command	Description
clear configure eigrp	Clears the EIGRP router configuration mode commands from the running configuration.
show running-config router eigrp	Displays the EIGRP router configuration mode commands in the running configuration.

router ospf

To start an OSPF routing process and configure parameters for that process, use the **router ospf** command in global configuration mode. To disable OSPF routing, use the **no** form of this command.

router ospf *pid*

no router ospf *pid*

Syntax Description

pid	Internally used identification parameter for an OSPF routing process; valid values are from 1 to 65535. The *pid* does not need to match the ID of OSPF processes on other routers.

Defaults

OSPF routing is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **router ospf** command is the global configuration command for OSPF routing processes running on the ASA. Once you enter the **router ospf** command, the command prompt appears as (config-router)#, indicating that you are in router configuration mode.

When using the **no router ospf** command, you do not need to specify optional arguments unless they provide necessary information. The **no router ospf** command terminates the OSPF routing process specified by its *pid.* You assign the *pid* locally on the ASA. You must assign a unique value for each OSPF routing process.

The **router ospf** command is used with the following OSPF-specific commands to configure OSPF routing processes:

- **area**—Configures a regular OSPF area.
- **compatible rfc1583**—Restores the method used to calculate summary route costs per RFC 1583.
- **default-information originate**—Generates a default external route into an OSPF routing domain.
- **distance**—Defines the OSPF route administrative distances based on the route type.

- **ignore**—Suppresses the sending of syslog messages when the router receives a link-state advertisement (LSA) for type 6 Multicast OSPF (MOSPF) packets.
- **log-adj-changes**—Configures the router to send a syslog message when an OSPF neighbor goes up or down.
- **neighbor**—Specifies a neighbor router. Used to allow adjacency to be established over VPN tunnels.
- **network**—Defines the interfaces on which OSPF runs and the area ID for those interfaces.
- **redistribute**—Configures the redistribution of routes from one routing domain to another according to the parameters specified.
- **router-id**—Creates a fixed router ID.
- **summary-address**—Creates the aggregate addresses for OSPF.
- **timers lsa-group-pacing**—OSPF LSA group pacing timer (interval between group of LSA being refreshed or max-aged).
- **timers spf**—Delay between receiving a change to the SPF calculation.

Examples

The following example shows how to enter the configuration mode for the OSPF routing process numbered 5:

```
hostname(config)# router ospf 5
hostname(config-rtr)#
```

Related Commands

Command	Description
clear configure router	Clears the OSPF router commands from the running configuration.
show running-config router ospf	Displays the OSPF router commands in the running configuration.

router rip

To start a RIP routing process and configure parameters for that process, use the **router rip** command in global configuration mode. To disable the RIP routing process, use the **no** form of this command.

router rip

no router rip

Syntax Description

This command has no arguments or keywords.

Defaults

RIP routing is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	—	•	—	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Usage Guidelines

The **router rip** command is the global configuration command for configuring the RIP routing processes on the ASA. You can only configure one RIP process on the ASA. The **no router rip** command terminates the RIP routing process and removes all router configuration for that process.

When you enter the **router rip** command, the command prompt changes to hostname(config-router)#, indicating that you are in router configuration mode.

The **router rip** command is used with the following router configuration commands to configure RIP routing processes:

- **auto-summary**—Enable/disable automatic summarization of routes.
- **default-information originate**—Distribute a default route.
- **distribute-list in**—Filter networks in incoming routing updates.
- **distribute-list out**—Filter networks in outgoing routing updates.
- **network**—Add/remove interfaces from the routing process.
- **passive-interface**—Set specific interfaces to passive mode.
- **redistribute**—Redistribute routes from other routing processes into the RIP routing process.
- **version**—Set the RIP protocol version used by the ASA.

Additionally, you can use the following commands in interface configuration mode to configure RIP properties on a per-interface basis:

- **rip authentication key**—Set an authentication key.
- **rip authentication mode**—Set the type of authentication used by RIP Version 2.
- **rip send version**—Set the version of RIP used to send updates out of the interface. This overrides the version set in global router configuration mode, if any.
- **rip receive version**—Set the version of RIP accepted by the interface. This overrides the version set in global router configuration mode, if any.

RIP is not supported in transparent mode. By default, the ASA denies all RIP broadcast and multicast packets. To permit these RIP messages to pass through an ASA operating in transparent mode you must define access list entries to permit this traffic. For example, to permit RIP version 2 traffic through the ASA, create an access list entry such as the following:

```
hostname(config)# access-list myriplist extended permit ip any host 224.0.0.9
```

To permit RIP version 1 broadcasts, create an access list entry such as the following:

```
hostname(config)# access-list myriplist extended permit udp any any eq rip
```

Apply these access list entries to the appropriate interface using the **access-group** command.

You can enable both RIP and OSPF routing on the ASA at the same time.

Examples

The following example shows how to enter the configuration mode for the OSPF routing process numbered 5:

```
hostname(config)# router rip
hostname(config-rtr)# network 10.0.0.0
hostname(config-rtr)# version 2
```

Related Commands

Command	Description
clear configure router rip	Clears the RIP router commands from the running configuration.
show running-config router rip	Displays the RIP router commands in the running configuration.

rtp-conformance

To check RTP packets flowing on the pinholes for protocol conformance in H.323 and SIP, use the **rtp-conformance** command in parameters configuration mode. To disable this feature, use the **no** form of this command.

rtp-conformance [enforce-payloadtype]

no rtp-conformance [enforce-payloadtype]

Syntax Description

enforce-payloadtype	Enforces payload type to be audio/video based on the signaling exchange.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Parameters configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to check RTP packets flowing on the pinholes for protocol conformance on an H.323 call:

```
hostname(config)# policy-map type inspect h323 h323_map
hostname(config-pmap)# parameters
hostname(config-pmap-p)# rtp-conformance
```

Related Commands

Command	Description
class	Identifies a class map name in the policy map.
class-map type inspect	Creates an inspection class map to match traffic specific to an application.
debug rtp	Displays debug information and error messages for RTP packets associated with H.323 and SIP inspection.
policy-map	Creates a Layer 3/4 policy map.
show running-config policy-map	Display all current policy map configurations.

rtp-min-port rtp-max-port

To configure the rtp-min-port and rtp-max-port limits for the phone proxy feature, use the **rtp-min-port** *port1* **rtp-max-port** *port2* command in phone-proxy configuration mode.

To remove the rtp-min-port and rtp-max-port limits from the phone proxy configuration, use the **no** form of this command.

rtp-min-port *port1* **rtp-maxport** *port2*

no rtp-min-port *port1* **rtp-maxport** *port2*

Syntax Description

port1	Specifies the minimum value for the RTP port range for the media termination point, where *port1* can be a value from 1024 to 16384.
port2	Specifies the maximum value for the RTP port range for the media termination point, where *port2* can be a value from 32767 to 65535.

Defaults

By default, the *port1* value for the **rtp-min-port** keyword is 16384 and the *port2* value for the **rtp-max-port** keyword is 32767.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Phone-proxy configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	The command was introduced.

Usage Guidelines

Configure the RTP port range for the media termination point when you need to scale the number of calls that the Phone Proxy supports.

Examples

The following example shows the use of the **media-termination address** command to specify the IP address to use for media connections:

```
hostname(config-phone-proxy)# rtp-min-port 2001 rtp-maxport 32770
```

Related Commands

Command	Description
phone-proxy	Configures the Phone Proxy instance.

CHAPTER 43

same-security-traffic through shape Commands

same-security-traffic

To permit communication between interfaces with equal security levels, or to allow traffic to enter and exit the same interface, use the **same-security-traffic** command in global configuration mode. To disable the same-security traffic, use the **no** form of this command.

same-security-traffic permit {**inter-interface** | **intra-interface**}

no same-security-traffic permit {**inter-interface** | **intra-interface**}

Syntax Description

inter-interface	Permits communication between different interfaces that have the same security level.
intra-interface	Permits communication in and out of the same interface.

Defaults

This command is disabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	The **intra-interface** keyword now allows all traffic to enter and exit the same interface, and not just IPsec traffic.

Usage Guidelines

Allowing communication between same security interfaces (enabled by the **same-security-traffic inter-interface** command) provides the following benefits:

- You can configure more than 101 communicating interfaces. If you use different levels for each interface, you can configure only one interface per level (0 to 100).
- You can allow traffic to flow freely between all same security interfaces without access lists.

The **same-security-traffic intra-interface** command lets traffic enter and exit the same interface, which is normally not allowed. This feature might be useful for VPN traffic that enters an interface, but is then routed out the same interface. The VPN traffic might be unencrypted in this case, or it might be reencrypted for another VPN connection. For example, if you have a hub and spoke VPN network, where the ASA is the hub, and remote VPN networks are spokes, for one spoke to communicate with another spoke, traffic must go into the ASA and then out again to the other spoke.

Note All traffic allowed by the **same-security-traffic intra-interface** command is still subject to firewall rules. Be careful not to create an asymmetric routing situation that can cause return traffic not to traverse the ASA.

Examples

The following example shows how to enable the same-security interface communication:

```
hostname(config)# same-security-traffic permit inter-interface
```

The following example shows how to enable traffic to enter and exit the same interface:

```
hostname(config)# same-security-traffic permit intra-interface
```

Related Commands

Command	Description
show running-config same-security-traffic	Displays the **same-security-traffic** configuration.

sasl-mechanism

To specify a SASL (Simple Authentication and Security Layer) mechanism for authenticating an LDAP client to an LDAP server, use the **sasl-mechanism** command in aaa-server host configuration mode. The SASL authentication mechanism options are **digest-md5** and **kerberos**.

To disable an authentication mechanism, use the **no** form of this command.

sasl-mechanism {**digest-md5** | **kerberos** *server-group-name*}

no sasl-mechanism {**digest-md5** | **kerberos** *server-group-name*}

Note Because the ASA serves as a client proxy to the LDAP server for VPN users, the LDAP client referred to here is the ASA.

Syntax Description

digest-md5	The ASA responds with an MD5 value computed from the username and password.
kerberos	The ASA responds by sending the username and realm using the GSSAPI (Generic Security Services Application Programming Interface) Kerberos mechanism.
server-group-name	Specifies the Kerberos aaa-server group, up to 64 characters.

Defaults

No default behavior or values. The ASA passes the authentication parameters to the LDAP server in plain text.

Note We recommend that you secure LDAP communications with SSL using the **ldap-over-ssl** command if you have not configured SASL.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.

Usage Guidelines

Use this command to specify ASA authentication to an LDAP server using SASL mechanisms.

Both the ASA and the LDAP server can support multiple SASL authentication mechanisms. When negotiating SASL authentication, the ASA retrieves the list of SASL mechanisms configured on the server and sets the authentication mechanism to the strongest mechanism configured on both the ASA and the server. The Kerberos mechanism is stronger than the Digest-MD5 mechanism. To illustrate, if both the LDAP server and the ASA support both mechanisms, the ASA selects Kerberos, the stronger of the mechanisms.

When disabling the SASL mechanisms, you must enter a separate **no** command for each mechanism you want to disable because they are configured independently. Mechanisms that you do not specifically disable remain in effect. For example, you must enter both of the following commands to disable both SASL mechanisms:

no sasl-mechanism digest-md5

no sasl-mechanism kerberos <*server-group-name*>

Examples

The following examples, entered in aaa-server host configuration mode, enable the SASL mechanisms for authentication to an LDAP server named ldapsvr1 with an IP address of 10.10.0.1. This example enables the SASL digest-md5 authentication mechanism:

```
hostname(config)# aaa-server ldapsvr1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# sasl-mechanism digest-md5
```

The following example enables the SASL Kerberos authentication mechanism and specifies kerb-servr1 as the Kerberos AAA server:

```
hostname(config)# aaa-server ldapsvr1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# sasl-mechanism kerberos kerbsvr1
```

Related Commands

Command	Description
ldap-over-ssl	Specifies that SSL secures the LDAP client-server connection.
server-type	Specifies the LDAP server vendor as either Microsoft or Sun.
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.

sast

To specify the number of SAST certificates to create in the CTL record, use the **sast** command in ctl-file configuration mode. To set the number of SAST certificates in the CTL file back to the default value of 2, use the **no** form of this command.

sast *number_sasts*

no sast *number_sasts*

Syntax Description

number_sasts	Specifies the number of SAST keys to create. The default is 2. maximum allowed is 5.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl-file configuration	•	—	•	—	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

CTL files are signed by a System Administrator Security Token (SAST).

Because the Phone Proxy generates the CTL file, it needs to create the SAST key to sign the CTL file itself. This key can be generated on the ASA. A SAST is created as a self-signed certificate.

Typically, a CTL file contains more than one SAST. In case a SAST is not recoverable, the other one can be used to sign the file later.

Examples

The following example shows the use of the **sast** command to create 5 SAST certificates in the CTL file:

```
hostname(config-ctl-file)# sast 5
```

Related Commands

Command	Description
ctl-file (global)	Specifies the CTL file to create for Phone Proxy configuration or the CTL file to parse from Flash memory.
ctl-file (phone-proxy)	Specifies the CTL file to use for Phone Proxy configuration.
phone-proxy	Configures the Phone Proxy instance.

scansafe

To enable Cloud Web Security inspection for a context, use the **scansafe** command in context configuration mode. To disable Cloud Web Security, use the **no** form of this command.

scansafe [**license** *key*]

no scansafe [**license** *key*]

Syntax Description

license *key*	Enters an authentication key for this context. If you do not specify a key, the context uses the license configured in the system configuration. The ASA sends the authentication key to the Cloud Web Security proxy servers to indicate from which organization the request comes. The authentication key is a 16-byte hexidecimal number.

Command Default

By default, the context uses the license entered in the system configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

In multiple context mode, you must allow Cloud Web Security per context.

Examples

The following sample configuration enables Cloud Web Security in context one with the default license and in context two with the license key override:

```
! System Context
!
scansafe general-options
server primary ip 180.24.0.62 port 8080
retry-count 5
license 366C1D3F5CE67D33D3E9ACEC265261E5
!
context one
 allocate-interface GigabitEthernet0/0.1
 allocate-interface GigabitEthernet0/1.1
 allocate-interface GigabitEthernet0/3.1
 scansafe
```

```
 config-url disk0:/one_ctx.cfg
!
context two
 allocate-interface GigabitEthernet0/0.2
 allocate-interface GigabitEthernet0/1.2
 allocate-interface GigabitEthernet0/3.2
 scansafe license 366C1D3F5CE67D33D3E9ACEC26789534
 config-url disk0:/two_ctx.cfg
!
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

scansafe general-options

To configure communication with the Cloud Web Security proxy server, use the **scansafe general-options** command in global configuration mode. To remove the server configuration, use the **no** form of this command.

scansafe general-options

no scansafe general-options

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You can configure a primary and backup proxy server for Cloud Web Security.

Examples

The following example configures a primary server:

```
scansafe general-options
 server primary ip 180.24.0.62 port 8080
 retry-count 5
 license 366C1D3F5CE67D33D3E9ACEC265261E5
```

whitelist	Performs the whitelist action on the class of traffic.

scep-enrollment enable

To enable or disable the Simple Certificate Enrollment Protocol for a tunnel group, use the **scep-enrollment enable** command in tunnel-group general-attributes mode.

To remove the command from the configuration, use the **no** form of this command.

scep-enrollment enable

no scep-enrollment enable

Syntax Description

This command has no arguments or keywords.

Defaults

By default, this command is not present in the tunnel group configuration.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Only the Cisco AnyConnect Secure Mobility Client, Release 3.0 and later, supports this feature.

The ASA can proxy SCEP requests between AnyConnect and a third-party certificate authority. The certificate authority only needs to be accessible to the ASA if it is acting as the proxy. For the ASA to provide this service, the user must authenticate using any of the methods supported by AAA before the ASA sends an enrollment request. You can also use Host Scan and dynamic access policies to enforce rules of eligibility to enroll.

The ASA supports this feature only with an AnyConnect SSL or IKEv2 VPN session. It supports all SCEP-compliant certificate authorities, including IOS CS, Windows Server 2003 CA, and Windows Server 2008 CA.

Clientless (browser-based) access does not support SCEP Proxy, although WebLaunch—clientless-initiated AnyConnect—does support it.

The ASA does not support polling for certificates.

The ASA supports load balancing for this feature.

Example

The following example, entered in global configuration mode, creates a remote access tunnel group named remotegrp and enables SCEP for the group policy:

```
hostname(config)# tunnel-group remotegrp type remote-access
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# scep-enrollment enable
INFO: 'authentication aaa certificate' must be configured to complete setup of this
option.
```

Related Commands

Command	Description
crypto ikev2 enable	Enables IKEv2 negotiation on the interface on which IPsec peers communicate.
scep-forwarding-url	Enrolls the SCEP certificate authority for the group policy.
secondary-pre-fill-username clientless	Supplies a common, secondary password when a certificate is unavailable for WebLaunch support of the SCEP proxy.
secondary-authentication-server-group	Supplies the username when a certificate is unavailable.

scep-forwarding-url

To enroll an SCEP certificate authority for a group policy, use the **scep-forwarding-url** command in group-policy configuration mode.

To remove the command from the configuration, use the **no** form of this command.

scep-forwarding-url {**none** | **value** [*URL*]}

no scep-forwarding-url

Syntax Description

none	Specifies no certificate authority for the group policy.
URL	Specifies the SCEP URL of the certificate authority.
value	Enables this feature for clientless connections.

Defaults

By default, this command is not present.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Enter this command once per group policy to support a third-party digital certificate.

Example

The following example, entered in global configuration mode, creates a group policy named FirstGroup and enrolls a certificate authority for the group policy:

```
hostname(config)# group-policy FirstGroup internal
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# scep-forwarding-url value http://ca.example.com:80/
Attempting to retrieve the CA/RA certificate(s) using the URL. Please wait ...
```

Related Commands

Command	Description
crypto ikev2 enable	Enables IKEv2 negotiation on the interface on which IPsec peers communicate.
scep-enrollment enable	Enables Simple Certificate Enrollment Protocol for a tunnel group.
secondary-pre-fill-username clientless	Supplies a common, secondary password when a certificate is unavailable for WebLaunch support of the SCEP proxy.
secondary-authentication-server-group	Supplies the username when a certificate is unavailable.

secondary

To give the secondary unit higher priority in a failover group, use the **secondary** command in failover group configuration mode. To restore the default, use the **no** form of this command.

secondary

no secondary

Syntax Description

This command has no arguments or keywords.

Defaults

If **primary** or **secondary** is not specified for a failover group, the failover group defaults to **primary**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Failover group configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Assigning a primary or secondary priority to a failover group specifies which unit the failover group becomes active on when both units boot simulataneously (within a unit polltime). If one unit boots before the other, then both failover groups become active on that unit. When the other unit comes online, any failover groups that have the second unit as a priority do not become active on the second unit unless the failover group is configured with the **preempt** command or is manually forced to the other unit with the **no failover active** command.

Examples

The following example configures failover group 1 with the primary unit as the higher priority and failover group 2 with the secondary unit as the higher priority. Both failover groups are configured with the **preempt** command, so the groups will automatically become active on their preferred unit as the units become available.

```
hostname(config)# failover group 1
hostname(config-fover-group)# primary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# exit
hostname(config)# failover group 2
hostname(config-fover-group)# secondary
hostname(config-fover-group)# preempt 100
hostname(config-fover-group)# mac-address e1 0000.a000.a011 0000.a000.a012
hostname(config-fover-group)# exit
```

```
hostname(config)#
```

Related Commands

Command	Description
failover group	Defines a failover group for Active/Active failover.
preempt	Forces the failover group to become active on its preferred unit when the unit becomes available.
primary	Gives the primary unit a higher priority than the secondary unit.

secondary-authentication-server-group

To specify a secondary authentication server group to associate with the session when double authentication is enabled, use the **secondary-authentication-server-group** command in tunnel-group general-attributes mode. To remove the attribute from the configuration, use the **no** form of this command.

secondary-authentication-server-group [*interface_name*] {**none | LOCAL |** *groupname* [**LOCAL**]} [**use-primary-username**] }

no secondary-authentication-server-group

Syntax Description

interface_name	(Optional) Specifies the interface where the IPsec tunnel terminates.
LOCAL	(Optional) Requires authentication against the local user database if all of the servers in the server group have been deactivated due to communication failures. If the server group name is either **LOCAL** or **NONE,** do not use the **LOCAL** keyword here.
none	(Optional) Specifies the server group name as **NONE**, indicating that authentication is not required.
groupname [**LOCAL**]	Identifies the previously configured authentication server or group of servers. Optionally, this can be the LOCAL group.
use-primary-username	Use the primary username as the username for the secondary authentication.

Defaults

The default value is **none**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command is meaningful only when double authentication is enabled. The **secondary-authentication-server-group** command specifies the secondary AAA server group. The secondary server group cannot be an SDI server group.

If the use-primary-username keyword is configured, then only one username is requested in the login dialog.

If the usernames are extracted from a digital certificate, only the primary username is used for authentication.

Examples

The following example, entered in global configuration mode, creates a remote access tunnel group named remotegrp and specifies the use of the group sdi_server as the primary server group and the group ldap_ server as the secondary authentication server group for the connection:

```
hostname(config)# tunnel-group remotegrp type remote-access
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-webvpn)# authentication-server-group sdi_server
hostname(config-tunnel-webvpn)# secondary-authentication-server-group ldap_server
hostname(config-tunnel-webvpn)#
```

Related Commands

Command	Description
pre-fill-username	Enables the pre-fill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel-group.
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.

secondary-color

To set a secondary color for the WebVPN login, home page, and file access page, use the **secondary-color** command in webvpn mode. To remove a color from the configuration and reset the default, use the **no** form of this command.

secondary-color [*color***]**

no secondary-color

Syntax Description

color	(Optional) Specifies the color. You can use a comma separated RGB value, an HTML color value, or the name of the color if recognized in HTML. • RGB format is 0,0,0, a range of decimal numbers from 0 to 255 for each color (red, green, blue); the comma separated entry indicates the level of intensity of each color to combine with the others. • HTML format is #000000, six digits in hexadecimal format; the first and second represent red, the third and fourth green, and the fifth and sixth represent blue. • Name length maximum is 32 characters

Defaults

The default secondary color is HTML #CCCCFF, a lavender shade.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The number of RGB values recommended for use is 216, many fewer than the mathematical possibilities. Many displays can handle only 256 colors, and 40 of those look differently on MACs and PCs. For best results, check published RGB tables. To find RGB tables online, enter RGB in a search engine.

Examples

The following example shows how to set an HTML color value of #5F9EAO, which is a teal shade:

```
hostname(config)# webvpn
hostname(config-webvpn)# secondary-color #5F9EAO
```

Related Commands

Command	Description
title-color	Sets a color for the WebVPN title bar on the login, home page, and file access page

secondary-pre-fill-username

To enable the extraction of a username from a client certificate for use in double authentication for a clientless or an AnyConnect connection, use the **secondary-pre-fill-username** command in tunnel-group webvpn-attributes mode. To remove the attribute from the configuration, use the **no** form of this command.

secondary-pre-fill-username {**clientless** | **ssl-client**} [**hide**]

secondary-pre-fill-username {**clientless** | **ssl-client**} **hide** [**use-primary-password** | **use-common-password** [*type_num*] *password*]

no secondary-no pre-fill-username

Syntax Description

clientless	Enables this feature for clientless connections.
hide	Hides the username to be used for authentication from the VPN user.
password	Enter the password string.
ssl-client	Enables this feature for AnyConnect VPN client connections.
type_num	Enter one of the following options: • 0 if the password to be entered is plain text. • 8 if the password to be entered is encrypted. The password appears as asterisks as you type.
use-common-password	Specifies a common secondary authentication password to use without prompting the user for it.
use-primary-password	Reuses the primary authentication password for secondary authentication without prompting the user for it.

Defaults

This feature is disabled by default. Entering this command without the **hide** keyword reveals the extracted username to the VPN user. The user receives a password prompt if you specify neither the **use-primary-password** nor the **use-common-password** keywords. The default value of *type_num* is 8.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Tunnel-group webvpn-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.
8.3(2)	Added [**use-primary-password** | **use-common-password** [*type_num*] *password*] to the command.

Usage Guidelines

To enable this feature, you must also enter the **secondary-username-from-certificate** command in tunnel-group general-attributes mode.

This command is meaningful only if double authentication is enabled. The **secondary-pre-fill-username** command enables the use of a username extracted from the certificate field specified in the **secondary-username-from-certificate** command as the username for secondary username/password authentication. To use this secondary-pre-fill username-from-certificate feature, you must configure both commands.

Note Clientless and SSL-client connections are not mutually exclusive options. Only one can be specified per command line, but both can be enabled at the same time.

If you hide the second username and use a primary or common password, the user experience is similar to single authentication. Using the primary or common password makes the use of device certificates to authenticate a device a seamless user experience.

The **use-primary-password** keyword specifies the use of the primary password as the secondary password for all authentications.

The **use-common-password** keyword specifies the use of a common secondary password for all secondary authentications. If a device certificate installed on the endpoint contains a BIOS ID or some other identifier, a secondary authentication request can use the pre-filled BIOS ID as the second username and use a common password configured for all authentications in that tunnel group.

Examples

The following example creates an IPsec remote access tunnel group named remotegrp, and specifies the reuse of a name from the digital certificate on the endpoint as the name to be used for an authentication or authorization query when the connections are browser-based.

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp webvpn-attributes
hostname(config-tunnel-webvpn)# secondary-pre-fill-username clientless
```

The following example performs the same function as the previous command, but hides the extracted username from the user:

```
hostname(config-tunnel-webvpn)# secondary-pre-fill-username clientless hide
```

The following example performs the same function as the previous command, except that it applies only to AnyConnect connections:

```
hostname(config-tunnel-webvpn)# secondary-pre-fill-username ssl-client hide
```

The following example hides the username and reuses the primary authentication password for secondary authentication without prompting the user:

```
hostname(config-tunnel-webvpn)# secondary-pre-fill-username ssl-client hide
use-primary-password
```

The following example hides the username and uses the password you enter for secondary authentication:

```
hostname(config-tunnel-webvpn)# secondary-pre-fill-username ssl-client hide
use-common-password **********
```

Related Commands

Command	Description
pre-fill-username	Enables the pre-fill username feature.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
tunnel-group general-attributes	Specifies the general attributes for the named tunnel-group.
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.

secondary-text-color

To set the secondary text color for the WebVPN login, home page and file access page, use the **secondary-text-color** command in webvpn mode. To remove the color from the configuration and reset the default, use the **no** form of this command.

secondary-text-color [*black* | *white*]

no secondary-text-color

Syntax Description

auto	Chooses black or white based on the settings for the text-color command. That is, if the primary color is black, this value is white.
black	The default secondary text color is black.
white	You can change the text color to white.

Defaults

The default secondary text color is black.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Webvpn	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set the secondary text color to white:

```
hostname(config)# webvpn
hostname(config-webvpn)# secondary-text-color white
```

Related Commands

Command	Description
text-color	Sets a color for text in the WebVPN title bar on the login, home page and file access page

secure-unit-authentication

To enable secure unit authentication, use the **secure-unit-authentication enable** command in group-policy configuration mode. To disable secure unit authentication, use the **secure-unit-authentication disable** command. To remove the secure unit authentication attribute from the running configuration, use the **no** form of this command. **secure-unit-authentication** {**enable** | **disable**}

no secure-unit-authentication

Syntax Description

disable	Disables secure unit authentication.
enable	Enables secure unit authentication.

Defaults

Secure unit authentication is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Group-policy configuration	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Secure unit authentication requires that you have an authentication server group configured for the tunnel group the hardware client(s) use.

If you require secure unit authentication on the primary ASA, be sure to configure it on any backup servers as well.

The **no** option allows inheritance of a value for secure unit authentication from another group policy.

Secure unit authentication provides additional security by requiring VPN hardware clients to authenticate with a username and password each time the client initiates a tunnel. With this feature enabled, the hardware client does not have a saved username and password.

Note With this feature enabled, to bring up a VPN tunnel, a user must be present to enter the username and password.

Examples

The following example shows how to enable secure unit authentication for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# secure-unit-authentication enable
```

Related Commands

Command	Description
ip-phone-bypass	Lets IP phones connect without undergoing user authentication. Secure unit authentication remains in effect.
leap-bypass	Lets LEAP packets from wireless devices behind a VPN hardware client travel across a VPN tunnel prior to user authentication, when enabled. This lets workstations using Cisco wireless access point devices establish LEAP authentication. Then they authenticate again per user authentication.
user-authentication	Requires users behind a hardware client to identify themselves to the ASA before connecting.

secondary-username-from-certificate

To specify the field in a certificate to use as the secondary username for double authentication for a clientless or AnyConnect (SSL-client) connection, use the **secondary-username-from-certificate** command in tunnel-group general-attributes mode.

To remove the attribute from the configuration and restore default values, use the **no** form of this command.

secondary-username-from-certificate {*primary-attr* [*secondary-attr*] | **use-entire-name** | **use-script**}

no secondary-username-from-certificate

Syntax Description

primary-attr	Specifies the attribute to use to derive a username for an authorization query from a certificate. If pre-fill-username is enabled, the derived name can also be used in an authentication query.
secondary-attr	(Optional) Specifies an additional attribute to use with the primary attribute to derive a username for an authentication or authorization query from a digital certificate. If pre-fill-username is enable, the derived name can also be used in an authentication query.
use-entire-name	Specifies that the ASA must use the entire subject DN (RFC1779) to derive a name for an authorization query from a digital certificate.
use-script	Specifies the use of a script file generated by ASDM to extract the DN fields from a certificate for use as a username.

Defaults

This feature is disabled by default and is meaningful only when double authentication is enabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tunnel-group general-attributes configuration	•	—	•	—	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

This command is meaningful only when double authentication is enabled.

When double authentication is enabled. this command selects one or more fields in a certificate to use as the username. The **secondary-username-from-certificate** command forces the security appliance to use the specified certificate field as the second username for the second username/password authentication.

To use this derived username in the pre-fill username from certificate feature for the secondary username/password authentication or authorization, you must also configure the **pre-fill-username** and **secondary-pre-fill-username** commands in tunnel-group webvpn-attributes mode. That is, to use the secondary pre-fill username feature, you must configure both commands.

Possible values for primary and secondary attributes include the following:

Attribute	Definition
C	Country: the two-letter country abbreviation. These codes conform to ISO 3166 country abbreviations.
CN	Common Name: the name of a person, system, or other entity. Not available a s a secondary attribute.
DNQ	Domain Name Qualifier.
EA	E-mail address.
GENQ	Generational Qualifier.
GN	Given Name.
I	Initials.
L	Locality: the city or town where the organization is located.
N	Name.
O	Organization: the name of the company, institution, agency, association or other entity.
OU	Organizational Unit: the subgroup within the organization (O).
SER	Serial Number.
SN	Surname.
SP	State/Province: the state or province where the organization is located
T	Title.
UID	User Identifier.
UPN	User Principal Name.
use-entire-name	Use entire DN name. Not available a s a secondary attribute.
use-script	Use a script file generated by ASDM.

Note If you also specify the **secondary-authentication-server-group** command, along with the **secondary-username-from-certificate command, only** the primary username is used for authentication.

Examples

The following example, entered in global configuration mode, creates a remote access tunnel group named remotegrp and specifies the use of CN (Common Name) as the primary attribute and OU as the secondary attribute to use to derive a name for an authorization query from a digital certificate:

```
hostname(config)# tunnel-group remotegrp type remote-access
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# username-from-certificate CN
hostname(config-tunnel-general)# secondary-username-from-certificate OU
```

```
hostname(config-tunnel-general)#
```

The following example shows how to modify the tunnel-group attributes to configure the pre-fill username.

```
username-from-certificate {use-entire-name | use-script | <primary-attr>} [secondary-attr]
secondary-username-from-certificate {use-entire-name | use-script | <primary-attr>}
[secondary-attr] ; used only for double-authentication
```

Related Commands

Command	Description
pre-fill-username	Enables the pre-fill username feature.
secondary-pre-fill-username	Enables username extraction for clientless or AnyConnect client connection
username-from-certificate	Specifies the field in a certificate to use as the username for authorization.
show running-config tunnel-group	Shows the indicated tunnel-group configuration.
secondary-authentication-server-group	Specifies the secondary AAA server group. If the usernames are extracted from a digital certificate, only the primary username is used for authentication.

security-group

To add a security group to a security object group for use with Cisco TrustSec, use the **security-group** command in object-group security configuration mode. To remove the security group, use the **no** form of this command.

security-group {**tag** *sgt#* | **name** *sg_name*}

no security-group {**tag** *sgt#* | **name** *sg_name*}

Syntax Description

tag *sgt#*	Specifies the security group object as an inline tag. Enter a number from 1 to 65533 for a Tag security type. An SGT is assigned to a device through IEEE 802.1X authentication, web authentication, or MAC authentication bypass (MAB) by the ISE. Security group names are created on the ISE and provide user-friendly names for security groups. The security group table maps SGTs to security group names.
name *sg_name*	Specifies the security group object as a named object. Enter a 32-byte case-sensitive string for a Name security type. The *sg_name* can contain any character including [a-z], [A-Z], [0-9], [!@#$%^&()-_{}.].

Command Default

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Object-group security configuration	•	•	•	•	—

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

You can create security group object groups for use in features that support Cisco TrustSec by including the group in an extended ACL, which in turn can be used in an access rule, for example.

When integrated with Cisco TrustSec, the ASA downloads security group information from the ISE. The ISE acts as an identity repository, by providing Cisco TrustSec tag to user identity mapping and Cisco TrustSec tag to server resource mapping. You provision and manage security group access lists centrally on the ISE.

However, the ASA might have localized network resources that are not defined globally that require local security groups with localized security policies. Local security groups can contain nested security groups that are downloaded from the ISE. The ASA consolidates local and central security groups.

To create local security groups on the ASA, you create a local security object group. A local security object group can contain one or more nested security object groups or Security IDs or security group names. User can also create a new Security ID or security group name that does not exist on the ASA.

You can use the security object groups you create on the ASA to control access to network resources. You can use the security object group as part of an access group or service policy.

Examples

The following example shows how to configure a security group object:

```
hostname(config)# object-group security mktg-sg
hostname(config)# security-group name mktg
hostname(config)# security-group tag 1
```

The following example shows how to configure a security group object:

```
hostname(config)# object-group security mktg-sg-all
hostname(config)# security-group name mktg-managers
hostname(config)# group-object mktg-sg // nested object-group
```

Related Commands

Command	Description
object-group security	Creates a security group object.

security-level

To set the security level of an interface, use the **security-level** command in interface configuration mode. To set the security level to the default, use the **no** form of this command. The security level protects higher security networks from lower security networks by imposing additional protection between the two.

security-level *number*

no security-level

Syntax Description

number	An integer between 0 (lowest) and 100 (highest).

Defaults

By default, the security level is 0.

If you name an interface "inside" and you do not set the security level explicitly, then the ASA sets the security level to 100 (see the **nameif** command). You can change this level if desired.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Interface configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was moved from a keyword of the **nameif** command to an interface configuration mode command.

Usage Guidelines

The level controls the following behavior:

- Network access—By default, there is an implicit permit from a higher security interface to a lower security interface (outbound). Hosts on the higher security interface can access any host on a lower security interface. You can limit access by applying an access list to the interface.

  For same security interfaces, there is an implicit permit for interfaces to access other interfaces on the same security level or lower.

- Inspection engines—Some inspection engines are dependent on the security level. For same security interfaces, inspection engines apply to traffic in either direction.
  - NetBIOS inspection engine—Applied only for outbound connections.
  - OraServ inspection engine—If a control connection for the OraServ port exists between a pair of hosts, then only an inbound data connection is permitted through the ASA.

- Filtering—HTTP(S) and FTP filtering applies only for outbound connections (from a higher level to a lower level).

  For same security interfaces, you can filter traffic in either direction.

- NAT control—When you enable NAT control, you must configure NAT for hosts on a higher security interface (inside) when they access hosts on a lower security interface (outside).

  Without NAT control, or for same security interfaces, you can choose to use NAT between any interface, or you can choose not to use NAT. Keep in mind that configuring NAT for an outside interface might require a special keyword.

- **established** command—This command allows return connections from a lower security host to a higher security host if there is already an established connection from the higher level host to the lower level host.

  For same security interfaces, you can configure **established** commands for both directions.

Normally, interfaces on the same security level cannot communicate. If you want interfaces on the same security level to communicate, see the **same-security-traffic** command. You might want to assign two interfaces to the same level and allow them to communicate if you want to create more than 101 communicating interfaces, or you want protection features to be applied equally for traffic between two interfaces; for example, you have two departments that are equally secure.

If you change the security level of an interface, and you do not want to wait for existing connections to time out before the new security information is used, you can clear the connections using the **clear local-host** command.

Examples

The following example configures the security levels for two interfaces to be 100 and 0:

```
hostname(config)# interface gigabitethernet0/0
hostname(config-if)# nameif inside
hostname(config-if)# security-level 100
hostname(config-if)# ip address 10.1.1.1 255.255.255.0
hostname(config-if)# no shutdown
hostname(config-if)# interface gigabitethernet0/1
hostname(config-if)# nameif outside
hostname(config-if)# security-level 0
hostname(config-if)# ip address 10.1.2.1 255.255.255.0
hostname(config-if)# no shutdown
```

Related Commands

Command	Description
clear local-host	Resets all connections.
interface	Configures an interface and enters interface configuration mode.
nameif	Sets the interface name.
vlan	Assigns a VLAN ID to a subinterface.

send response

To send a RADIUS Accounting-Response Start and Accounting-Response Stop message to the sender of the RADIUS Accounting-Request Start and Stop messages, use the **send response** command in radius-accounting parameter configuration mode, which is accessed by using the **inspect radius-accounting** command.

This option is disabled by default.

send response

no send response

Syntax Description

This command has no arguments or keywords.

Defaults

No default behaviors or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Radius-accounting parameter configuration	•	•	•	•	—

Command History

Release	Modification
7.2(1)	This command was introduced.

Examples

The following example shows how to send a response with RADIUS accounting:

```
hostname(config)# policy-map type inspect radius-accounting ra
hostname(config-pmap)# send response
hostname(config-pmap-p)# send response
```

Related Commands

Commands	Description
inspect radius-accounting	Sets inspection for RADIUS accounting.
parameters	Sets parameters for an inspection policy map.

seq-past-window

To set the action for packets that have past-window sequence numbers (the sequence number of a received TCP packet is greater than the right edge of the TCP receiving window), use the **seq-past-window** command in tcp-map configuration mode. To set the value back to the default, use the **no** form of this command. This command is part of the TCP normalization policy enabled using the **set connection advanced-options** command.

seq-past-window {**allow** | **drop**}

no seq-past-window

Syntax Description

allow	Allows packets that have past-window sequence numbers. This action is only allowed if the **queue-limit** command is set to 0 (disabled).
drop	Drops packets that have past-window sequence numbers.

Defaults

The default action is to drop packets that have past-window sequence numbers.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tcp-map configuration	•	•	•	•	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.

Usage Guidelines

To enable TCP normalization, use the Modular Policy Framework:

1. **tcp-map**—Identifies the TCP normalization actions.
   a. **seq-past-window**—In tcp-map configuration mode, you can enter the **seq-past-window** command and many others.
2. **class-map**—Identify the traffic on which you want to perform TCP normalization.
3. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced-options**—Identify the tcp-map you created.
4. **service-policy**—Assigns the policy map to an interface or globally.

Examples

The following example sets the ASA to allow packets that have past-window sequence numbers:

```
hostname(config)# tcp-map tmap
hostname(config-tcp-map)# seq-past-window allow
hostname(config)# class-map cmap
hostname(config-cmap)# match any
hostname(config)# policy-map pmap
hostname(config-pmap)# class cmap
hostname(config-pmap)# set connection advanced-options tmap
hostname(config)# service-policy pmap global
hostname(config)#
```

Related Commands

Command	Description
class-map	Identifies traffic for a service policy.
policy-map	dentifies actions to apply to traffic in a service policy.
queue-limit	Sets the out-of-order packet limit.
set connection advanced-options	Enables TCP normalization.
service-policy	Applies a service policy to interface(s).
show running-config tcp-map	Shows the TCP map configuration.
tcp-map	Creates a TCP map and allows access to tcp-map configuration mode.

serial-number

To include the ASA serial number in the certificate during enrollment, use the **serial-number** command in crypto ca trustpoint configuration mode. To restore the default setting, use the **no** form of the command.

serial-number

no serial-number

Syntax Description

This command has no arguments or keywords.

Defaults

The default setting is to not include the serial number.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Crypto ca trustpoint configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example enters crypto ca trustpoint configuration mode for trustpoint central, and includes the ASA serial number in the enrollment request for trustpoint central:

```
hostname(config)# crypto ca trustpoint central
hostname(ca-trustpoint)# serial-number
```

Related Commands

Command	Description
crypto ca trustpoint	Enters trustpoint configuration mode.

server (pop3s, imap4s, smtps)

To specify a default e-mail proxy server, use the **server** command in the applicable e-mail proxy configuration mode. To remove the attribute from the configuration, use the **no** version of this command. The ASA sends requests to the default e-mail server when the user connects to the e-mail proxy without specifying a server. If you do not configure a default server, and a user does not specify a server, the ASA returns an error.

server {*ipaddr or hostname*}

no server

Syntax Description

hostname	The DNS name of the default e-mail proxy server.
ipaddr	The IP address of the default e-mail proxy server.

Defaults

There is no default e-mail proxy server by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Pop3s configuration	•	•	—	—	•
Imap4s configuration	•	•	—	—	•
Smtps configuration	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example shows how to set a default POP3S e-mail server with an IP address. of 10.1.1.7:

```
hostname(config)# pop3s
hostname(config-pop3s)# server 10.1.1.7
```

server authenticate-client

To enable the ASA to authenticate the TLS client during TLS handshake, use the **server authenticate-client** command in tls-proxy configuration mode.

To bypass client authenticaion, use the **no** form of this command.

server authenticate-client

no server authenticate-client

Syntax Description

This command has arguments or keywords.

Defaults

This command is enabled by default, which means the TLS client is required to present a certificate during handshake with the ASA.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Tls-proxy configuration	•	•	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

Use the **server authenticate-client** command to control whether a client authentication is required during TLS Proxy handshake. When enabled (by default), the security appliance sends a Certificate Request TLS handshake message to the TLS client, and the TLS client is required to present its certificate.

Use the **no** form of this command to disable client authentication. Disabling TLS client authentication is suitable when the ASA must interoperate with CUMA client or clients such as a Web browser that are incapable of sending a client certificate.

Examples

The following example configures a TLS proxy instance with client authentication disabled:

```
hostname(config)# tls-proxy mmp_tls
hostname(config-tlsp)# no server authenticate-client
hostname(config-tlsp)# server trust-point cuma_server_proxy
```

Related Commands

Command	Description
tls-proxy	Configures the TLS proxy instance.

server backup

To configure the backup Cloud Web Security proxy server, use the **server backup** command in scansafe general-options configuration mode. To remove the server, use the **no** form of this command.

server backup {**ip** *ip_address* | **fqdn** *fqdn*} [**port** *port*]

no server backup [**ip** *ip_address* | **fqdn** *fqdn*] [**port** *port*]

Syntax Description

ip *ip_address*	Specifies the server IP address.
fqdn *fqdn*	Specifies the server fully-qualified domain name (FQDN).
port *port*	(Optional) By default, the Cloud Web Security proxy server uses port 8080 for both HTTP and HTTPS traffic; do not change this value unless directed to do so.

Command Default

The default port is 8080.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Scansafe general-options configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

When you subscribe to the Cisco Cloud Web Security service, you are assigned a primary Cloud Web Security proxy server and backup proxy server. See the **server primary** command to configure the primary server. These servers are routinely polled to check for their availability. If your ASA is unable to reach the Cloud Web Security proxy server (for example, if no SYN/ACK packets arrive from the proxy server), then the proxy server is polled through a TCP three-way handshake to check its availability. If the proxy server is unavailable after a configured number of retries (default is five), the server is declared as unreachable, and the backup proxy server becomes active.

The ASA automatically falls back to the primary Cloud Web Security proxy server from the backup server after continued polling shows that the primary server is active for two consecutive retry count periods. You can change this polling interval using the **retry-count** command.

Traffic Conditions Under Which Proxy Server Is Not Reachable	Server Timeout Calculation	Connection Timeout Result
High traffic	Client half open connection timeout + ASA TCP connection timeout	(30 + 30) = 60 seconds
Single connection failure	Client half open connection timeout + ((retry threshold - 1) x (ASA TCP connection timeout))	(30 + ((5-1) x (30)) = 150 seconds
Idle—No connections are passing	15 minutes + ((retry threshold) x (ASA TCP connection timeout))	900 + (5 x (30) = 1050 seconds

Examples

The following example configures a primary and backup server:

```
scansafe general-options
 server primary ip 10.24.0.62 port 8080
 server backup ip 10.10.0.7 port 8080
 retry-count 7
 license 366C1D3F5CE67D33D3E9ACEC265261E5
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.
show scansafe statistics	Shows total and current http connections.

Command	Description
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

server primary

To configure the primary Cloud Web Security proxy server, use the **server primary** command in scansafe general-options configuration mode. To remove the server, use the **no** form of this command.

server primary {**ip** *ip_address* | **fqdn** *fqdn*} [**port** *port*]

no server primary [**ip** *ip_address* | **fqdn** *fqdn*] [**port** *port*]

Syntax Description

ip *ip_address*	Specifies the server IP address.
fqdn *fqdn*	Specifies the server fully-qualified domain name (FQDN).
port *port*	(Optional) By default, the Cloud Web Security proxy server uses port 8080 for both HTTP and HTTPS traffic; do not change this value unless directed to do so.

Command Default

The default port is 8080.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Scansafe general-options configuration	•	•	•	—	•

Command History

Release	Modification
9.0(1)	We introduced this command.

Usage Guidelines

When you subscribe to the Cisco Cloud Web Security service, you are assigned a primary Cloud Web Security proxy server and backup proxy server. See the **server backup** command to configure the backup server. These servers are routinely polled to check for their availability. If your ASA is unable to reach the Cloud Web Security proxy server (for example, if no SYN/ACK packets arrive from the proxy server), then the proxy server is polled through a TCP three-way handshake to check its availability. If the proxy server is unavailable after a configured number of retries (default is five), the server is declared as unreachable, and the backup proxy server becomes active.

The ASA automatically falls back to the primary Cloud Web Security proxy server from the backup server after continued polling shows that the primary server is active for two consecutive retry count periods. You can change this polling interval using the **retry-count** command.

Traffic Conditions Under Which Proxy Server Is Not Reachable	Server Timeout Calculation	Connection Timeout Result
High traffic	Client half open connection timeout + ASA TCP connection timeout	(30 + 30) = 60 seconds
Single connection failure	Client half open connection timeout + ((retry threshold - 1) x (ASA TCP connection timeout))	(30 + ((5-1) x (30)) = 150 seconds
Idle—No connections are passing	15 minutes + ((retry threshold) x (ASA TCP connection timeout))	900 + (5 x (30) = 1050 seconds

Examples

The following example configures a primary and backup server:

```
scansafe general-options
 server primary ip 10.24.0.62 port 8080
 server backup ip 10.10.0.7 port 8080
 retry-count 7
 license 366C1D3F5CE67D33D3E9ACEC265261E5
```

Related Commands

Command	Description
class-map type inspect scansafe	Creates an inspection class map for whitelisted users and groups.
default user group	Specifies the default username and/or group if the ASA cannot determine the identity of the user coming into the ASA.
http[**s**] (parameters)	Specifies the service type for the inspection policy map, either HTTP or HTTPS.
inspect scansafe	Enables Cloud Web Security inspection on the traffic in a class.
license	Configures the authentication key that the ASA sends to the Cloud Web Security proxy servers to indicate from which organization the request comes.
match user group	Matches a user or group for a whitelist.
policy-map type inspect scansafe	Creates an inspection policy map so you can configure essential parameters for the rule and also optionally identify the whitelist.
retry-count	Enters the retry counter value, which is the amount of time that the ASA waits before polling the Cloud Web Security proxy server to check its availability.
scansafe	In multiple context mode, allows Cloud Web Security per context.
scansafe general-options	Configures general Cloud Web Security server options.
server {**primary** | **backup**}	Configures the fully qualified domain name or IP address of the primary or backup Cloud Web Security proxy servers.
show conn scansafe	Shows all Cloud Web Security connections, as noted by the capitol Z flag.
show scansafe server	Shows the status of the server, whether it's the current active server, the backup server, or unreachable.

Command	Description
show scansafe statistics	Shows total and current HTTP(S) connections.
user-identity monitor	Downloads the specified user or group information from the AD agent.
whitelist	Performs the whitelist action on the class of traffic.

server trust-point

To specify the proxy trustpoint certificate to present during TLS handshake, use the **server trust-point** command in TLS server configuration mode.

server trust-point *proxy_trustpoint*

Syntax Description

proxy_trustpoint	Specifies the trustpoint defined by the **crypto ca trustpoint** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
TLS-proxy configuration	•	•	•	•	—

Command History

Release	Modification
8.0(4)	The command was introduced.

Usage Guidelines

The trustpoint can be self-signed, enrolled with a certificate authority, or from an imported credential. The **server trust-point** command has precedence over the global **ssl trust-point** command.

The **server trust-point** command specifies the proxy trustpoint certificate presented during TLS handshake. The certificate must be owned by the ASA (identity certificate). The certificate can be self-signed, enrolled with a certificate authority, or from an imported credential.

Create TLS proxy instances for each entity that can initiate a connection. The entity that initiates the TLS connection is in the role of TLS client. Because the TLS Proxy has strict definition of client proxy and server proxy, two TLS proxy instances must be defined if either of the entities could initiate the connection.

Note When you are creating the TLS proxy instance to use with the Phone Proxy, the server trustpoint is the internal Phone Proxy trustpoint created the CTL file instance. The trustpoint name is in the form *internal_PP_<ctl-file_instance_name>*

Examples

The following example shows the use of the **server trust-point** command to specify the proxy trustpoint certificate to present during TLS handshake:

```
hostname(config-tlsp)# server trust-point ent_y_proxy
```

Related Commands

Command	Description
client (tls-proxy)	Configures trustpoints, keypairs, and cipher suites for a TLS proxy instance.
client trust-point	Specifies the proxy trustpoint certificate to present during TLS handshake.
ssl trust-point	Specifies the certificate trustpoint that represents the SSL certificate for an interface.
tls-proxy	Configures a TLS proxy instance.

server-port

To configure a AAA server port for a host, use the **server-port** command in aaa-server host mode. To remove the designated server port, use the **no** form of this command.

server-port *port-number*

no server-port *port-number*

Syntax Description

port-number	A port number in the range of 0 through 65535.

Defaults

The default server ports are as follows:

- SDI—5500
- LDAP—389
- Kerberos—88
- NT—139
- TACACS+—49

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Aaa-server group	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following example configures an SDI AAA server named srvgrp1 to use server port number 8888:

```
hostname(config)# aaa-server srvgrp1 protocol sdi
hostname(config-aaa-server-group)# aaa-server srvgrp1 host 192.168.10.10
hostname(config-aaa-server-host)# server-port 8888
```

Related Commands

Command	Description
aaa-server host	Configures host-specific AAA server parameters.

clear configure aaa-server	Removes all AAA server configurations.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

server-separator

To specify a character as a delimiter between the e-mail and VPN server names, use **server-separator** command in the applicable e-mail proxy mode. To revert to the default, ":", use the no form of this command.

server-separator {*symbol*}

no server-separator

Syntax Description

symbol	The character that separates the e-mail and VPN server names. Choices are "@," (at) "|" (pipe), ":"(colon), "#" (hash), "," (comma), and ";" (semi-colon).

Defaults

The default is "@" (at).

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Pop3s	•	—	•	—	—
Imap4s	•	—	•	—	—
Smtps	•	—	•	—	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

The server separator must be different from the name separator.

Examples

The following example shows how to set a pipe (|) as the server separator for IMAP4S:

```
hostname(config)# imap4s
hostname(config-imap4s)# server-separator |
```

Related Commands

Command	Description
name-separator	Separates the e-mail and VPN usernames and passwords.

server-type

To manually configure the LDAP server model, use the **server-type** command in aaa-server host configuration mode. The ASA supports the following server models:

- Microsoft Active Directory
- Sun Microsystems JAVA System Directory Server, formerly named the Sun ONE Directory Server
- Generic LDAP directory servers that comply with LDAPv3 (no password management)

To disable this command, use the **no** form of this command.

server-type {**auto-detect | microsoft | sun | generic | openldap | novell**}

no server-type {**auto-detect | microsoft | sun | generic | openldap | novell**}

Syntax Description

auto-detect	Specifies that the ASA determines the LDAP server type through auto-detection.
generic	Specifies LDAP v3-compliant directory servers other than Sun and Microsoft LDAP directory servers. Password management is not supported with generic LDAP servers.
microsoft	Specifies that the LDAP server is a Microsoft Active Directory.
openldap	Specifies that the LDAP server is an OpenLDAP server.
novell	Specifies that the LDAP server is a Novell server.
sun	Specifies that the LDAP server is a Sun Microsystems JAVA System Directory Server.

Defaults

By default, auto-detection attempts to determine the server type.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Aaa-server host configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	This command was introduced.
8.0(2)	Support for the OpenLDAP and Novell server types was added.

Usage Guidelines

The ASA supports LDAP version 3 and is compatible with the Sun Microsystems JAVA System Directory Server, the Microsoft Active Directory, and other LDAPv3 directory servers.

Note

- Sun—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.
- Microsoft—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.
- Generic—Password management features are not supported.

By default, the ASA auto-detects whether it is connected to a Microsoft directory server, a Sun LDAP directory server, or a generic LDAPv3 server. However, if auto-detection fails to determine the LDAP server type and if you know the server is either a Microsoft or Sun server, you can use the **server-type** command to manually configure the server as either a Microsoft or a Sun Microsystems LDAP server.

Examples

The following example, entered in aaa-server host configuration mode, configures the server type for the LDAP server ldapsvr1 at IP address 10.10.0.1. The first example configures a Sun Microsystems LDAP server.

```
hostname(config)# aaa-server ldapsvr1 protocol ldap
hostname(config-aaa-server-group)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# server-type sun
```

The following example specifies that the ASA use auto-detection to determine the server type:

```
hostname(config)# aaa-server ldapsvr1 protocol LDAP
hostname(config-aaa-server-group)# aaa-server ldapsvr1 host 10.10.0.1
hostname(config-aaa-server-host)# server-type auto-detect
```

Related Commands

Command	Description
ldap-over-ssl	Specifies that SSL secures the LDAP client-server connection.
sasl-mechanism	Configures SASL authentication between the LDAP client and server.
ldap attribute-map (global configuration mode)	Creates and names an LDAP attribute map for mapping user-defined attribute names to Cisco LDAP attribute names.

service

To enable resets for denied TCP connections, use the **service** command in global configuration mode. To disable resets, use the **no** form of this command.

service {**resetinbound** [**interface** *interface_name*] | **resetoutbound** [**interface** *interface_name*] | **resetoutside**}

no service {**resetinbound** [**interface** *interface_name*] | **resetoutbound** [**interface** *interface_name*] | **resetoutside**}

Syntax Description

interface *interface_name*	Enables or disables resets for the specified interface.
resetinbound	Sends TCP resets for all inbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. The ASA also sends resets for packets that are allowed by an access list or AAA, but do not belong to an existing connection and are denied by the stateful firewall. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets. If you do not specify an interface, then this setting applies to all interfaces.
resetoutbound	Sends TCP resets for all outbound TCP sessions that attempt to transit the ASA and are denied by the ASA based on access lists or AAA settings. The ASA also sends resets for packets that are allowed by an access list or AAA, but do not belong to an existing connection and are denied by the stateful firewall. Traffic between same security level interfaces is also affected. When this option is not enabled, the ASA silently discards denied packets. This option is enabled by default. You might want to disable outbound resets to reduce the CPU load during traffic storms, for example.
resetoutside	Enables resets for TCP packets that terminate at the least secure interface and are denied by the ASA based on access lists or AAA settings. The ASA also sends resets for packets that are allowed by an access list or AAA, but do not belong to an existing connection and are denied by the stateful firewall. When this option is not enabled, the ASA silently discards the packets of denied packets. We recommend that you use the **resetoutside** keyword with interface PAT. This keyword allows the ASA to terminate the IDENT from an external SMTP or FTP server. Actively resetting these connections avoids the 30-second timeout delay.

Defaults

By default, **service resetoutbound** is enabled for all interfaces.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.1(1)	The **interface** keyword and the **resetoutbound** command were added.

Usage Guidelines

You might want to explicitly send resets for inbound traffic if you need to reset identity request (IDENT) connections. When you send a TCP RST (reset flag in the TCP header) to the denied host, the RST stops the incoming IDENT process so that you do not have to wait for IDENT to time out. Waiting for IDENT to time out can cause traffic to slow because outside hosts keep retransmitting the SYN until the IDENT times out, so the **service resetinbound** command might improve performance.

Examples

The following example disables outbound resets for all interfaces except for the inside interface:

```
hostname(config)# no service resetoutbound
hostname(config)# service resetoutbound interface inside
```

The following example enables inbound resets for all interfaces except for the DMZ interface:

```
hostname(config)# service resetinbound
hostname(config)# no service resetinbound interface dmz
```

The following example enables resets for connections that terminate on the outside interface:

```
hostname(config)# service resetoutside
```

Related Commands

Command	Description
show running-config service	Displays the service configuration.

service (ctl-provider)

To specify the port to which the Certificate Trust List provider listens, use the **service** command in CTL provider configuration mode. To remove the configuration, use the **no** form of this command.

service port *listening_port*

no service port *listening_port*

Syntax Description

port *listening_port*	Specifies the certificate to be exported to the client.

Defaults

Default port is 2444.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Ctl provider configuration	•	•	•	•	—

Command History

Release	Modification
8.0(2)	This command was introduced.

Usage Guidelines

Use the **service** command in CTL provider configuration mode to specify the port to which the CTL provider listens. The port must be the one listened to by the CallManager servers in the cluster (as configured under Enterprise Parameters on the CallManager administration page). The default port is 2444.

Examples

The following example shows how to create a CTL provider instance:

```
hostname(config)# ctl-provider my_ctl
hostname(config-ctl-provider)# client interface inside 172.23.45.1
hostname(config-ctl-provider)# client username CCMAdministrator password XXXXXX encrypted
hostname(config-ctl-provider)# export certificate ccm_proxy
hostname(config-ctl-provider)# ctl install
```

Related Commands

Commands	Description
client	Specifies clients allowed to connect to the CTL provider and also username and password for client authentication.
ctl	Parses the CTL file from the CTL client and install trustpoints.

Commands	Description
ctl-provider	Configures a CTL provider instance in CTL provider mode.
export	Specifies the certificate to be exported to the client
tls-proxy	Defines a TLS proxy instance and sets the maximum sessions.

service (object service)

To define the protocol and optional port for a service object, use the **service** command in object service configuration mode. Use the **no** form of this command to remove the definition.

service {*protocol* | {**tcp** | **udp**} [**source** *operator number*] [**destination** *operator number*] | **icmp** [*icmp_type*] | **icmp6** [*icmp6_type*]}

no service {*protocol* | {**tcp** | **udp**} [**source** *operator number*] [**destination** *operator number*] | **icmp** [*icmp_type*] | **icmp6** [*icmp6_type*]}

Syntax Description

destination *operator number*	(Optional) For **tcp** and **udp** protocols, specifies the destination port name or number, between 0 and 65535. For a list of supported names, see the CLI help. Operators include: • **eq**—Equals the port number. • **gt**—Greater than the port number. • **lt**—Less than the port number. • **neq**—Not equal to the port number. • **range**—A range of ports. Specify two numbers separated by a space, such as **range 1024 4500**.
icmp [*icmp_type*]	Specifies that the service type is for ICMP connections. You can optionally specify the ICMP type by name or number, between 0 and 255. For available optional ICMP type names, see the CLI help.
icmp6 [*icmp6_type*]	Specifies that the service type is for ICMP version 6 connections. You can optionally specify the ICMPv6 type by name or number, between 0 and 255. For available optional ICMPv6 type names, see the CLI help.
protocol	Identifies the protocol name or number, between 0 and 255. For a list of supported names, see the CLI help.
source *operator number*	(Optional) For **tcp** and **udp** protocols, specifies the source port name or number, between 0 and 65535. For a list of supported names, see the CLI help. Operators include: • **eq**—Equals the port number. • **gt**—Greater than the port number. • **lt**—Less than the port number. • **neq**—Not equal to the port number. • **range**—A range of ports. Specify two numbers separated by a space, such as **range 1024 4500**.
tcp	Specifies that the service type is for TCP connections.
udp	Specifies that the service type is for UDP connections.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Object service configuration	•	•	•	•	—

Command History

Release	Modification
8.3(1)	This command was introduced.

Usage Guidelines

You can use service objects by name in other parts of your configuration, for example ACLs (the **access-list** command) and NAT (the **nat** command).

If you configure an existing service object with a different protocol and port, the new configuration replaces the existing protocol and port with the new ones.

Examples

The following example shows how to create a service object for SSH traffic:

```
hostname(config)# service object SSH
hostname(config-service-object)# service tcp destination eq ssh
```

The following example shows how to create a service object for EIGRP traffic:

```
hostname(config)# service object EIGRP
hostname(config-service-object)# service eigrp
```

The following example shows how to create a service object for traffic coming from port 0 through 1024 to HTTPS:

```
hostname(config)# service object HTTPS
hostname(config-service-object)# service tcp source range 0 1024 destination eq https
```

Related Commands

Command	Description
clear configure object	Clears all objects created.
object-group service	Configures a service object.
show running-config object service	Shows the current service object configuration.

service call-home

To enable the Call Home service, use the **service call-home** command in global configuration mode. To disable the Call Home service, use the **no** form of this command.

service call-home

no service call-home

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the service Call Home command is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
8.2(2)	This command was introduced.

Examples

The following example shows how to enable the Call Home service:

```
hostname(config)# service call-home
```

The followingexample shows how to disable the Call Home service:

```
hostname(config)# no service call-home
```

Related Commands

Command	Description
call-home (global configuration)	Enters Call Home configuration mode.
call-home test	Manually sends a Call Home test message.
show call-home	Displays Call Home configuration information.

service password-recovery

To enable password recovery, use the **service password-recovery** command in global configuration mode. To disable password recovery, use the **no** form of this command. Password recovery is enabled by default, but you might want to disable it to ensure that unauthorized users cannot use the password recovery mechanism to compromise the ASA.

service password-recovery

no service password-recovery

Syntax Description

This command has no arguments or keywords.

Defaults

Password recovery is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

On the ASA 5500 series adaptive security appliance, if you forget the passwords, you can boot the ASA into ROMMON by pressing the **Escape** key on the terminal keyboard when prompted during startup. Then set the ASA to ignore the startup configuration by changing the configuration register (see the **config-register** command). For example if your configuration register is the default 0x1, then change the value to 0x41 by entering the **confreg 0x41** command. After reloading the ASA, it loads a default configuration, and you can enter privileged EXEC mode using the default passwords. Then load the startup configuration by copying it to the running configuration and reset the passwords. Finally, set the ASA to boot as before by setting the configuration register to the original setting. For example, enter the **config-register 0x1** command in global configuration mode.

On the PIX 500 series security appliance, boot the ASA into monitor mode by pressing the **Escape** key on the terminal keyboard when prompted during startup. Then download the PIX password tool to the ASA, which erases all passwords and **aaa authentication** commands.

On the ASA 5500 series adaptive security appliance, the **no service password-recovery** command prevents a user from entering ROMMON with the configuration intact. When a user enters ROMMON, the ASA prompts the user to erase all Flash file systems. The user cannot enter ROMMON without first performing this erasure. If a user chooses not to erase the Flash file system, the ASA reloads. Because password recovery depends on using ROMMON and maintaining the existing configuration, this erasure prevents you from recovering a password. However, disabling password recovery prevents unauthorized

users from viewing the configuration or inserting different passwords. In this case, to recover the system to an operating state, load a new image and a backup configuration file, if available. The **service password-recovery** command appears in the configuration file for informational purposes only; when you enter the command at the CLI prompt, the setting is saved in NVRAM. The only way to change the setting is to enter the command at the CLI prompt. Loading a new configuration with a different version of the command does not change the setting. If you disable password recovery when the ASA is configured to ignore the startup configuration at startup (in preparation for password recovery), then the ASA changes the setting to boot the startup configuration as usual. If you use failover, and the standby unit is configured to ignore the startup configuration, then the same change is made to the configuration register when the **no service password recovery** command replicates to the standby unit.

On the PIX 500 series security appliance, the **no service password-recovery** command forces the PIX password tool to prompt the user to erase all Flash file systems. The user cannot use the PIX password tool without first performing this erasure. If a user chooses not to erase the Flash file system, the ASA reloads. Because password recovery depends on maintaining the existing configuration, this erasure prevents you from recovering a password. However, disabling password recovery prevents unauthorized users from viewing the configuration or inserting different passwords. In this case, to recover the system to an operating state, load a new image and a backup configuration file, if available.

Examples

The following example disables password recovery for the ASA 5500 series:

```
hostname(config)# no service password-recovery
WARNING: Executing "no service password-recovery" has disabled the password recovery
mechanism and disabled access to ROMMON.  The only means of recovering from lost or
forgotten passwords will be for ROMMON to erase all file systems including configuration
files and images.  You should make a backup of your configuration and have a mechanism to
restore images from the ROMMON command line.
```

The following example for the ASA 5500 series shows when to enter ROMMON at startup and how to complete a password recovery operation.

```
Use BREAK or ESC to interrupt boot.
Use SPACE to begin boot immediately.
Boot interrupted.

Use ? for help.
rommon #0> confreg

Related Commands

Command	Description
config-register	Sets the ASA to ignore the startup configuration when it reloads.
enable password	Sets the enable password.
password	Sets the login password.

service-object

To add a service or service object to a service object group that is not pre-defined as TCP, UDP, or TCP-UDP, use the **service-object** command in object-group service configuration mode. To remove a service, use the **no** form of this command.

service-object {*protocol* | {**tcp** | **udp** | **tcp-udp**} [**source** *operator number*] [**destination** *operator number*] | **icmp** [*icmp_type*] | **icmp6** [*icmp6_type*] | **object** *name*}

no service-object {*protocol* | {**tcp** | **udp** | **tcp-udp**} [**source** *operator number*] [**destination** *operator number*] | **icmp** [*icmp_type*] | **icmp6** [*icmp6_type*] | **object** *name*}

Syntax Description

destination *operator number*	(Optional) For **tcp**, **udp**, or **tcp-udp** protocols, specifies the destination port name or number, between 0 and 65535. For a list of supported names, see the CLI help. Operators include: • **eq**—Equals the port number. • **gt**—Greater than the port number. • **lt**—Less than the port number. • **neq**—Not equal to the port number. • **range**—A range of ports. Specify two numbers separated by a space, such as **range 1024 4500**.
icmp [*icmp_type*]	Specifies that the service type is for ICMP connections. You can optionally specify the ICMP type by name or number, between 0 and 255. For available optional ICMP type names, see the CLI help.
icmp6 [*icmp6_type*]	Specifies that the service type is for ICMP version 6 connections. You can optionally specify the ICMPv6 type by name or number, between 0 and 255. For available optional ICMPv6 type names, see the CLI help.
protocol	Identifies the protocol name or number, between 0 and 255. For a list of supported names, see the CLI help.
source *operator number*	(Optional) For **tcp**, **udp**, or **tcp-udp** protocols, specifies the source port name or number, between 0 and 65535. For a list of supported names, see the CLI help. Operators include: • **eq**—Equals the port number. • **gt**—Greater than the port number. • **lt**—Less than the port number. • **neq**—Not equal to the port number. • **range**—A range of ports. Specify two numbers separated by a space, such as **range 1024 4500**.
tcp	Specifies that the service type is for TCP connections.
tcp-udp	Specifies that the service type is for TCP or UDP connections.
udp	Specifies that the service type is for UDP connections.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Object-group service configuration	•	•	•	•	—

Command History

Release	Modification
8.0(1)	This command was introduced.
8.3(1)	The **object** keyword was added to support service objects (the **object service** command).

Usage Guidelines

When you create a service object group with the **object-group service** command, and you do not pre-define the protocol type for the whole group, then you can add multiple services and service objects to the group of various protocols and/or ports using the **service-object** command. When you create a service object group for a specific protocol type using the **object-group service** [**tcp** | **udp** | **tcp-udp**] command, then you can only identify the destination ports for the object group using the **port-object** command.

Examples

The following example shows how to add both TCP and UDP services to a service object group:

```
hostname(config)# object-group service CommonApps
hostname(config-service-object-group)# service-object destination tcp eq ftp
hostname(config-service-object-group)# service-object destination tcp-udp eq www
hostname(config-service-object-group)# service-object destination tcp eq h323
hostname(config-service-object-group)# service-object destination tcp eq https
hostname(config-service-object-group)# service-object destination udp eq ntp
```

The following example shows how to add multiple service objects to a service object group:

```
hostname(config)# service object SSH
hostname(config-service-object)# service tcp destination eq ssh

hostname(config)# service object EIGRP
hostname(config-service-object)# service eigrp

hostname(config)# service object HTTPS
hostname(config-service-object)# service tcp source range 0 1024 destination eq https

hostname(config)# object-group service Group1
hostname(config-service-object-group)# service-object object SSH
hostname(config-service-object-group)# service-object object EIGRP
hostname(config-service-object-group)# service-object object HTTPS
```

Related Commands

Command	Description
clear configure object-group	Removes all the **object-group** commands from the configuration.
network-object	Adds a network object to a network object group.
object service	Adds a service object.
object-group	Defines object groups to optimize your configuration.
port-object	Adds a port object to a service object group.
show running-config object-group	Displays the current object groups.

service-policy (class)

To apply a hierarchical policy map under another policy map, use the **service-policy** command in class configuration mode. To disable the service policy, use the **no** form of this command. Hierarchical policies are supported only for QoS traffic shaping when you want to perform priority queueing on a subset of shaped traffic.

service-policy *policymap_name*

no service-policy *policymap_name*

Syntax Description

policymap_name	Specifies the policy map name that you configured in the **policy-map** command. You can only specify a Layer 3/4 policy map that includes the **priority** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.

Usage Guidelines

Hierarchical priority queueing is used on interfaces on which you enable a traffic shaping queue. A subset of the shaped traffic can be prioritized. The standard priority queue is not used (the **priority-queue** command).

For hierarchical priority-queueing, perform the following tasks using Modular Policy Framework:

1. **class-map**—Identify the traffic on which you want to perform priority queueing.
2. **policy-map** (for priority queueing)—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **priority**—Enable priority queueing for the class map. You can only include the priority command in this policy map if you want to use is hierarchically.
3. **policy-map** (for traffic shaping)—Identify the actions associated with the **class-default** class map.
   a. **class class-default**—Identify the **class-default** class map on which you want to perform actions.
   b. **shape**—Apply traffic shaping to the class map.

c. **service-policy**—Call the priority queueing policy map in which you configured the **priority** command so you can apply priority queueing to a subset of shaped traffic.

4. **service-policy**—Assigns the policy map to an interface or globally.

Examples

The following example enables traffic shaping for all traffic on the outside interface, and prioritizes traffic within VPN tunnel-grp1 with the DSCP bit set to ef:

```
hostname(config)# class-map TG1-voice
hostname(config-cmap)# match tunnel-group tunnel-grp1
hostname(config-cmap)# match dscp ef

hostname(config)# policy-map priority-sub-policy
hostname(config-pmap)# class TG1-voice
hostname(config-pmap-c)# priority

hostname(config-pmap-c)# policy-map shape_policy
hostname(config-pmap)# class class-default
hostname(config-pmap-c)# shape
hostname(config-pmap-c)# service-policy priority-sub-policy

hostname(config-pmap-c)# service-policy shape_policy interface outside
```

Related Commands

Command	Description
class (policy-map)	Identifies a class map for a policy map.
clear configure service-policy	Clears service policy configurations.
clear service-policy	Clears service policy statistics.
policy-map	Identifies actions to perform on class maps.
priority	Enables priority queueing.
service-policy (global)	Applies a policy map to an interface.
shape	Enables traffic shaping.
show running-config service-policy	Displays the service policies configured in the running configuration.
show service-policy	Displays the service policy statistics.

service-policy (global)

To activate a policy map globally on all interfaces or on a targeted interface, use the **service-policy** command in global configuration mode. To disable the service policy, use the **no** form of this command. Use the **service-policy** command to enable a set of policies on an interface.

service-policy *policymap_name* [**global** | **interface** *intf*] [**fail-close**]

no service-policy *policymap_name* [**global** | **interface** *intf*] [**fail-close**]

Syntax Description

fail-close	Generates a syslog (767001) for IPv6 traffic that is dropped by application inspections that do not support IPv6 traffic. By default, syslogs are not generated.
global	Applies the policy map to all interfaces.
interface *intf*	Applies the policy map to a specific interface.
policymap_name	Specifies the policy map name that you configured in the **policy-map** command. You can only specify a Layer 3/4 policy map, and not an inspection policy map (**policy-map type inspect**).

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	We added the **fail-close** keyword.

Usage Guidelines

To enable the service policy, use the Modular Policy Framework:

1. **class-map**—Identify the traffic on which you want to perform priority queueing.
2. **policy-map**—Identify the actions associated with each class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. *commands for supported features*—For a given class map, you can configure many actions for various features, including QoS, application inspection, CSC or AIP SSM, TCP and UDP connections limits and timeout, and TCP normalization. See the CLI configuration guide for more details about the commands available for each feature.

3. **service-policy**—Assigns the policy map to an interface or globally.

Interface service policies take precedence over the global service policy for a given feature. For example, if you have a global policy with inspections, and an interface policy with TCP normalization, then both inspections and TCP normalization are applied to the interface. However, if you have a global policy with inspections, and an interface policy with inspections, then only the interface policy inspections are applied to that interface.

By default, the configuration includes a global policy that matches all default application inspection traffic and applies inspection to the traffic globally. You can only apply one global policy, so if you want to alter the global policy, you need to either edit the default policy or disable it and apply a new one.

The default service policy includes the following command:

```
service-policy global_policy global
```

Examples

The following example shows how to enable the inbound_policy policy map on the outside interface:

```
hostname(config)# service-policy inbound_policy interface outside
```

The following commands disable the default global policy, and enables a new one called new_global_policy on all other ASA interfaces:

```
hostname(config)# no service-policy global_policy global
hostname(config)# service-policy new_global_policy global
```

Related Commands

Command	Description
clear configure service-policy	Clears service policy configurations.
clear service-policy	Clears service policy statistics.
service-policy (class)	Applies a hierarchical policy under another policy map.
show running-config service-policy	Displays the service policies configured in the running configuration.
show service-policy	Displays the service policy statistics.

session

To establish a Telnet session from the ASA to a module, such as an IPS SSP or a CSC SSM, to access the module CLI, use the **session** command in privileged EXEC mode.

session *id*

Syntax Description

id	Specifies the module ID: • Physical module—**1** (for slot number 1) • Software module, IPS—**ips** • Software module, ASA CX—**cxsc**

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.6(1)	Added the **ips** module ID for the IPS SSP software module.
9.1(1)	Support for the ASA CX module was added (the **cxsc** keyword).

Usage Guidelines

This command is only available when the module is in the Up state. See the **show module** command for state information.

To end a session, enter **exit** or **Ctrl-Shift-6,** then the **x** key.

Note This command is not available for the ASA CX hardware module; it is only available for the ASA CX software module.

Examples

The following example sessions to a module in slot 1:

```
hostname# session 1
Opening command session with slot 1.
Connected to slot 1. Escape character sequence is 'CTRL-^X'.
```

Related Commands

Command	Description
debug session-command	Shows debugging messages for sessions.

session console

To establish a virtual console session from the ASA to a software module, such as an IPS SSP software module, use the **session console** command in privileged EXEC mode. This command might be useful if you cannot establish a Telnet session using the **session** command because the control plane is down.

session *id* **console**

Syntax Description

id	Specifies the module ID; either **ips** or **cxsc**.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
8.6(1)	This command was introduced.
9.1(1)	Support for the ASA CX module was added (the **cxsc** keyword).

Usage Guidelines

To end a session, enter **Ctrl-Shift-6,** then the **x** key.

Do not use this command in conjunction with a terminal server where **Ctrl-Shift-6, x** is the escape sequence to return to the terminal server prompt. **Ctrl-Shift-6, x** is also the sequence to escape the module console and return to the ASA prompt. Therefore, if you try to exit the module console in this situation, you instead exit all the way to the terminal server prompt. If you reconnect the terminal server to the ASA, the module console session is still active; you can never exit to the ASA prompt. You must use a direct serial connection to return the console to the ASA prompt.

Use the **session** command instead.

Examples

The following example creates a console session to the IPS module:

```
hostname# session ips console

Establishing console session with slot 1
Opening console session with module ips.
Connected to module ips. Escape character sequence is 'CTRL-SHIFT-6 then x'.

sensor login: service
Password: test
```

Related Commands

Command	Description
session	Initiates a Telnet session to a module.
show module log console	Displays console log information.

session do

To establish a Telnet session and perform a command from the ASA to a module, such as an IPS SSP or a CSC SSM, use the **session do** command in privileged EXEC mode.

session *id* **do** *command*

Syntax Description

id	Specifies the module ID: • Physical module—**1** (for slot number 1) • Software module, IPS—**ips**
command	Performs a command on the module. Supported commands include: • **setup host ip** *ip_address*/*mask*,*gateway_ip*—Sets the management IP address and gateway. • **get-config**—Gets the module configuration. • **password-reset**—Resets the module password to the default.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.1(1)	This command was introduced.
8.6(1)	Added the **ips** module ID for the IPS SSP software module.
8.4(4.1)	We added support for the ASA CX module.

Usage Guidelines

This command is only available when the module is in the Up state. See the **show module** command for state information.

To end a session, enter **exit** or **Ctrl-Shift-6,** then the **X** key.

Examples

The following example sets the management IP address to 10.1.1.2/24, with a default gateway of 10.1.1.1:

```
hostname# session 1 do setup host ip 10.1.1.2/24,10.1.1.1
```

Related Commands

Command	Description
debug session-command	Shows debugging messages for sessions.

session ip

To configure logging IP addresses for the module, such as an IPS SSP or a CSC SSM, use the **session ip** command in privileged EXEC mode.

session *id* **ip** {**address** *address mask* | **gateway** *address*}

Syntax Description

id	Specifies the module ID: • Physical module—**1** (for slot number 1) • Software module, IPS—**ips**
address *address*	Sets the syslog server address.
gateway *address*	Sets the gateway to the syslog server.
mask	Sets the subnet mask.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.1(1)	This command was introduced.
8.4(4.1)	We added support for the ASA CX module.
8.6(1)	Added the **ips** module ID for the IPS SSP software module.

Usage Guidelines

This command is only available when the module is in the Up state. See the **show module** command for state information.

To end a session, enter **exit** or **Ctrl-Shift-6,** then the **X** key.

Examples

The following example sessions to a module in slot 1:

```
hostname# session 1 ip address
```

Related Commands

Command	Description
debug session-command	Shows debugging messages for sessions.

set connection

To specify connection limits within a policy map for a traffic class, use the **set connection** command in class configuration mode. To remove these specifications, thereby allowing unlimited connections, use the **no** form of this command.

set connection {[**conn-max** *n*] [**embryonic-conn-max** *n*] [**per-client-embryonic-max** *n*] [**per-client-max** *n*] [**random-sequence-number** {**enable** | **disable**}]}

no set connection {[**conn-max** *n*] [**embryonic-conn-max** *n*] [**per-client-embryonic-max** *n*] [**per-client-max** *n*] [**random-sequence-number** {**enable** | **disable**}]}

Syntax Description

conn-max *n*	Sets the maximum number of simultaneous TCP and/or UDP connections that are allowed, between 0 and 2000000. The default is 0, which allows unlimited connections. For example, if two servers are configured to allow simultaneous TCP and/or UDP connections, the connection limit is applied to each configured server separately. When configured under a class, this argument restricts the maximum number of simultaneous connections that are allowed for the entire class. In this case, one attack host can consume all the connections and leave none of the rest of the hosts matched in the access list under the class.
embryonic-conn-max *n*	Sets the maximum number of simultaneous embryonic connections allowed, between 0 and 2000000. The default is 0, which allows unlimited connections.
per-client-embryonic-max *n*	Sets the maximum number of simultaneous embryonic connections allowed per client, between 0 and 2000000. A client is defined as the host that sends the initial packet of a connection (that builds the new connection) through the ASA. If an **access-list** is used with a **class-map** to match traffic for this feature, the embryonic limit is applied per-host, and not the cumulative embryonic connections of all clients that match the access list. The default is 0, which allows unlimited connections. This keyword is not available for management class maps.
per-client-max *n*	Sets the maximum number of simultaneous connections allowed per client, between 0 and 2000000. A client is defined as the host that sends the initial packet of a connection (that builds the new connection) through the ASA. If an **access-list** is used with a **class-map** to match traffic for this feature, the connection limit is applied per-host, and not the cumulative connections of all clients that match the access list. The default is 0, which allows unlimited connections. This keyword is not available for management class maps. When configured under a class, this keyword restricts the maximum number of simultaneous connections that are allowed for each host that is matched through an access list under the class.
random-sequence-number {enable | disable}	Enables or disables TCP sequence number randomization. This keyword is not available for management class maps. See the "Usage Guidelines" section for more information.

Defaults

For the **conn-max**, **embryonic-conn-max**, **per-client-embryonic-max**, and **per-client-max** parameters, the default value of *n* is 0, which allows unlimited connections.

Sequence number randomization is enabled by default.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.1(1)	The **per-client-embryonic-max** and **per-client-max** keywords were added.
8.0(2)	This command is now available for a Layer 3/4 management class map, for to-the-ASA management traffic. Only the **conn-max** and **embryonic-conn-max** keywords are available.
9.0(1)	The maximum number of connections was increased from 65535 to 2000000.

Usage Guidelines

Configure this command using Modular Policy Framework. First define the traffic to which you want to apply the timeout using the **class-map** command (for through traffic) or **class-map type management** command (for management traffic). Then enter the **policy-map** command to define the policy, and enter the **class** command to reference the class map. In class configuration mode, you can enter the **set connection** command. Finally, apply the policy map to an interface using the **service-policy** command. For more information about how Modular Policy Framework works, see the CLI configuration guide.

Note Depending on the number of CPU cores on your ASA model, the maximum concurrent and embryonic connections may exceed the configured numbers due to the way each core manages connections. In the worst case scenario, the ASA allows up to *n*-1 extra connections and embryonic connections, where *n* is the number of cores. For example, if your model has 4 cores, if you configure 6 concurrent connections and 4 embryonic connections, you could have an additional 3 of each type. To determine the number of cores for your model, enter the **show cpu core** command.

TCP Intercept Overview

Limiting the number of embryonic connections protects you from a DoS attack. The ASA uses the per-client limits and the embryonic connection limit to trigger TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination. TCP Intercept uses the SYN cookies algorithm to prevent TCP SYN-flooding attacks. A SYN-flooding attack consists of a series of SYN packets usually originating from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests. When the embryonic connection threshold of a connection is crossed, the ASA acts

as a proxy for the server and generates a SYN-ACK response to the client SYN request. When the ASA receives an ACK back from the client, it can then authenticate the client and allow the connection to the server.

Disabling TCP Intercept for Management Packets for Clientless SSL Compatibility

By default, TCP management connections have TCP Intercept always enabled. When TCP Intercept is enabled, it intercepts the 3-way TCP connection establishment handshake packets and thus deprives the ASA from processing the packets for clientless SSL. Clientless SSL requires the ability to process the 3-way handshake packets to provide selective ACK and other TCP options for clientless SSL connections. To disable TCP Intercept for management traffic, you can set the embryonic connection limit; only after the embryonic connection limit is reached is TCP Intercept enabled.

TCP Sequence Randomization Overview

Each TCP connection has two ISNs: one generated by the client and one generated by the server. The ASA randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predecting the next ISN for a new connection and potentially hijacking the new session.

TCP initial sequence number randomization can be disabled if required. For example:

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the ASA, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- You use a WAAS device that requires the ASA not to randomize the sequence numbers of connections.

Examples

The following is an example of the use of the **set connection** command configure the maximum number of simultaneous connections as 256 and to disable TCP sequence number randomization:

```
hostname(config)# policy-map localpolicy1
hostname(config-pmap)# class local_server
hostname(config-pmap-c)# set connection conn-max 256 random-sequence-number disable
hostname(config-pmap-c)#
```

The following is an example of the use of the **set connection** command in a service policy that diverts traffic to a CSC SSM. The **set connection** command restricts each client whose traffic the CSC SSM scans to a maximum of five connections.

```
hostname(config)# policy-map csc_policy
hostname(config-pmap)# class local_server
hostname(config-pmap-c)# set connection per-client-max 5
hostname(config-pmap-c)# csc fail-close
hostname(config-pmap-c)#
```

You can enter this command with multiple parameters or you can enter each parameter as a separate command. The ASA combines the commands into one line in the running configuration. For example, if you entered the following two commands in class configuration mode:

```
hostname(config-pmap-c)# set connection conn-max 600
hostname(config-pmap-c)# set connection embryonic-conn-max 50
```

the output of the **show running-config policy-map** command would display the result of the two commands in a single, combined command:

```
set connection conn-max 600 embryonic-conn-max 50
```

Related Commands

Command	Description
class	Specifies a class-map to use for traffic classification.
clear configure policy-map	Removes all policy-map configuration, except that if a policy-map is in use in a service-policy command, that policy-map is not removed.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Displays all current policy-map configurations.
show service-policy	Displays service policy configuration. Use the **set connection** keyword to view policies that include the **set connection** command.

set connection advanced-options

To customize TCP normalization, use the **set connection advanced-options** command in class configuration mode. To remove the TCP normalization options, use the **no** form of this command.

set connection advanced-options *tcp_mapname*

no set connection advanced-options *tcp_mapname*

Syntax Description

tcp_mapname	Name of a TCP map created by the **tcp-map** command.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

To enable TCP state bypass, use the Modular Policy Framework:

1. **tcp-map**—Identify the TCP normalization actions.
2. **class-map**—Identify the traffic on which you want to perform TCP normalization actions.
3. **policy-map**—Identify the actions associated with the class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced options**—Apply TCP normalization to the class map.
4. **service-policy**—Assigns the policy map to an interface or globally.

Examples

The following example shows the use of the **set connection advanced-options** command to specify the use of a TCP map named localmap:

```
hostname(config)# access-list http-server permit tcp any host 10.1.1.1
hostname(config)# class-map http-server
hostname(config-cmap)# match access-list http-server
hostname(config-cmap)# exit
hostname(config)# tcp-map localmap
hostname(config)# policy-map global_policy global
```

```
hostname(config-pmap)# description This policy map defines a policy concerning connection
to http server.
hostname(config-pmap)# class http-server
hostname(config-pmap-c)# set connection advanced-options localmap
hostname(config-pmap-c)#
```

Related Commands

Command	Description
class	Specifies a class-map to use for traffic classification.
class-map	Configures a traffic class by issuing at most one (with the exception of tunnel-group and default-inspection-traffic) match command, specifying match criteria, in the class-map configuration mode.
clear configure policy-map	Remove all policy-map configuration, except that if a policy-map is in use in a service-policy command, that policy-map is not removed.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Display all current policy-map configurations.

set connection advanced-options tcp-state-bypass

To enable TCP state bypass, use the **set connection advanced-options** command in class configuration mode. The class configuration mode is accessible from the policy-map configuration mode. To disable TCP state bypass, use the **no** form of this command.

set connection advanced-options tcp-state-bypass

no set connection advanced-options tcp-state-bypass

Syntax Description

This command has no arguments or keywords.

Defaults

By default, TCP state bypass is disabled.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
8.2(1)	This command was introduced.

Usage Guidelines

To enable TCP state bypass, use the Modular Policy Framework:

1. **class-map**—Identify the traffic on which you want to perform TCP state bypass.
2. **policy-map**—Identify the actions associated with the class map.
   a. **class**—Identify the class map on which you want to perform actions.
   b. **set connection advanced options tcp-state-bypass**—Apply traffic shaping to the class map.
3. **service-policy**—Assigns the policy map to an interface or globally.

Allowing Outbound and Inbound Flows through Separate Devices

By default, all traffic that goes through the ASA is inspected using the Adaptive Security Algorithm and is either allowed through or dropped based on the security policy. The ASA maximizes the firewall performance by checking the state of each packet (is this a new connection or an established connection?) and assigning it to either the session management path (a new connection SYN packet), the fast path (an established connection), or the control plane path (advanced inspection).

TCP packets that match existing connections in the fast path can pass through the ASA without rechecking every aspect of the security policy. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), can stand in the way of asymmetrical routing solutions: both the outbound and inbound flow of a connection must pass through the same ASA.

For example, a new connection goes to ASA 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through ASA 1, then the packets will match the entry in the fast path, and are passed through. But if subsequent packets go to ASA 2, where there was not a SYN packet that went through the session management path, then there is no entry in the fast path for the connection, and the packets are dropped.

If you have asymmetric routing configured on upstream routers, and traffic alternates between two ASAs, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic much as it treats a UDP connection: when a non-SYN packet matching the specified networks enters the ASA, and there is not a fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

Unsupported Features

The following features are not supported when you use TCP state bypass:

- Application inspection—Application inspection requires both inbound and outbound traffic to go through the same ASA, so application inspection is not supported with TCP state bypass.
- AAA authenticated sessions—When a user authenticates with one ASA, traffic returning via the other ASA will be denied because the user did not authenticate with that ASA.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The ASA does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- SSM functionality—You cannot use TCP state bypass and any application running on an SSM, such as IPS or CSC.

NAT Guidelines

Because the translation session is established separately for each ASA, be sure to configure static NAT on both ASAs for TCP state bypass traffic; if you use dynamic NAT, the address chosen for the session on ASA 1 will differ from the address chosen for the session on ASA 2.

Connection Timeout Guidelines

If there is no traffic on a given connection for 2 minutes, the connection times out. You can override this default using the **set connection timeout tcp** command. Normal TCP connections timeout by default after 60 minutes.

Examples

The following is an example configuration for TCP state bypass:

```
hostname(config)# access-list tcp_bypass extended permit tcp 10.1.1.0 255.255.255.224 any

hostname(config)# class-map tcp_bypass
hostname(config-cmap)# description "TCP traffic that bypasses stateful firewall"
hostname(config-cmap)# match access-list tcp_bypass

hostname(config-cmap)# policy-map tcp_bypass_policy
hostname(config-pmap)# class tcp_bypass
hostname(config-pmap-c)# set connection advanced-options tcp-state-bypass

hostname(config-pmap-c)# service-policy tcp_bypass_policy outside

hostname(config-pmap-c)# static (inside,outside) 209.165.200.224 10.1.1.0 netmask
255.255.255.224
```

Related Commands

Command	Description
class	Identifies a class map in the policy map.
class-map	Creates a class map for use in a service policy.
policy-map	Configures a policy map that associates a class map and one or more actions.
service-policy	Assigns a policy map to an interface.
set connection timeout	Sets the connection timeouts.

set connection decrement-ttl

To decrement the time to live value within a policy map for a traffic class, use the **set connection decrement-ttl** command in class configuration mode. To not decrement the time to live, use the **no** form of this command.

set connection decrement-ttl

no set connection decrement-ttl

Syntax Description

This command has no arguments or keywords.

Defaults

By default, the ASA does not decrement the time to live.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.2(2)	This command was introduced.

Usage Guidelines

This command, along with the **icmp unreachable** command, is required to allow a traceroute through the ASA that shows the ASA as one of the hops.

Examples

The following example enables time to live decrements and sets the ICMP unreachable rate limit:

```
hostname(config)# policy-map localpolicy1
hostname(config-pmap)# class local_server
hostname(config-pmap-c)# set connection decrement-ttl
hostname(config-pmap-c)# exit
hostname(config)# icmp unreachable rate-limit 50 burst-size 6
```

Related Commands

Command	Description
class	Specifies a class map to use for traffic classification.
clear configure policy-map	Removes all policy map configuration, except if a policy map is in use in a **service-policy** command, that policy map is not removed.
icmp unreachable	Controls the rate at which ICMP unreachables are allowed through the ASA.

policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
show running-config policy-map	Displays all current policy map configurations.
show service-policy	Displays service policy configuration.

set connection timeout

To specify connection timeouts within a policy map for a traffic class, use the **set connection timeout** command in class configuration mode. To remove the timeout, use the **no** form of this command.

set connection timeout {[**embryonic** *hh*:*mm*:*ss*] [**idle** *hh*:*mm*:*ss* [**reset**]] [**half-closed** *hh*:*mm*:*ss*] [**dcd** [*retry_interval* [*max_retries*]]]}

no set connection timeout {[**embryonic** *hh*:*mm*:*ss*] [**idle** *hh*:*mm*:*ss* [**reset**]] [**half-closed** *hh*:*mm*:*ss*] [**dcd** [*retry_interval* [*max_retries*]]]}

Syntax Description

dcd	Enables dead connection detection (DCD). DCD detects a dead connection and allows it to expire, without expiring connections that can still handle traffic. You configure DCD when you want idle, but valid connections to persist. After a TCP connection times out, the ASA sends DCD probes to the end hosts to determine the validity of the connection. If one of the end hosts fails to respond after the maximum retries are exhausted, the ASA frees the connection. If both end hosts respond that the connection is valid, the ASA updates the activity timeout to the current time and reschedules the idle timeout accordingly.
embryonic *hh*:*mm*:*ss*	Sets the timeout period until a TCP embryonic (half-open) connection is closed, between 0:0:5 and 1193:0:0. The default is 0:0:30. You can also set the value to 0, which means the connection never times out. A TCP connection for which a three-way handshake is not complete is an embryonic connection.
half-closed *hh*:*mm*:*ss*	Sets the idle timeout period until a half-closed connection is closed, between 0:5:0 (for 9.1(1) and earlier) or 0:0:30 (for 9.1(2) and later) and 1193:0:0. The default is 0:10:0. You can also set the value to 0, which means the connection never times out. Half-closed connections are not affected by DCD. Also, the ASA does not send a reset when taking down half-closed connections.
idle *hh*:*mm*:*ss*	Sets the idle timeout period after which an established connection of any protocol closes. The valid range is from 0:0:1 to 1193:0:0.
max_retries	Sets the number of consecutive failed retries for DCD before declaring the connection as dead. The minimum value is 1 and the maximum value is 255. The default is 5.
reset	For TCP traffic only, sends a TCP RST packet to both end systems after idle connections are removed.
retry_interval	Time duration in *hh*:*mm*:*ss* format to wait after each unresponsive DCD probe before sending another probe, between 0:0:1 and 24:0:0. The default is 0:0:15.

Defaults

The default **embryonic** timeout is 30 seconds.

The default **half-closed** idle timeout is 10 minutes.

The default **dcd** *max_retries* value is 5.

The default **dcd** *retry_interval* value is 15 seconds.

The default **tcp** idle timeout is 1 hour.

The default **udp** idle timeout is 2 minutes.

The default **icmp** idle timeout is 2 seconds.

The default **esp** and **ha** idle timeout is 30 seconds.

For all other protocols, the default idle timeout is 2 minutes.

To never time out, enter 0:0:0.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
7.2(1)	Support for DCD was added.
8.2(2)	The **tcp** keyword was deprecated in favor of the **idle** keyword, which controls the idle timeout for all protocols.
9.1(2)	The minimum **half-closed** value was lowered to 30 seconds (0:0:30).

Usage Guidelines

Configure this command using Modular Policy Framework. First define the traffic to which you want to apply the timeout using the **class-map** command. Then enter the **policy-map** command to define the policy, and enter the **class** command to reference the class map. In class configuration mode, you can enter the **set connection timeout** command. Finally, apply the policy map to an interface using the **service-policy** command. For more information about how Modular Policy Framework works, see the CLI configuration guide.

Enabling DCD changes the behavior of idle-timeout handling in the TCP normalizer. DCD probing resets the idle timeout on the connections that appear in the **show conn** command. To determine when a connection that has exceeded the configured timeout value in the timeout command but has been kept alive due to DCD probing, use the **show service-policy** command to include counters to show the amount of activity from DCD.

Examples

The following example sets the connection timeouts for all traffic:

```
hostname(config)# class-map CONNS
hostname(config-cmap)# match any
hostname(config-cmap)# policy-map CONNS
hostname(config-pmap)# class CONNS
hostname(config-pmap-c)# set connection timeout idle 2:0:0 embryonic 0:40:0 half-closed
0:20:0 dcd
hostname(config-pmap-c)# service-policy CONNS interface outside
```

You can enter **set connection** commands with multiple parameters, or you can enter each parameter as a separate command. The ASA combines the commands into one line in the running configuration. For example, if you entered the following two commands in class configuration mode:

```
hostname(config-pmap-c)# set connection timeout idle 2:0:0
hostname(config-pmap-c)# set connection timeout embryonic 0:40:0
```

Then the output of the **show running-config policy-map** command would display the result of the two commands in the following single, combined command:

```
set connection timeout tcp 2:0:0 embryonic 0:40:0
```

Related Commands

Command	Description
class	Specifies a class-map to use for traffic classification.
clear configure policy-map	Remove all policy-map configuration, except that if a policy-map is in use in a service-policy command, that policy-map is not removed.
policy-map	Configures a policy; that is, an association of a traffic class and one or more actions.
set connection	Configure connection values.
show running-config policy-map	Display all current policy-map configurations.
show service-policy	Displays counters for DCD and other service activity.

set metric

To set the metric value of a route for OSPF and other dynamic routing protocols in a route map, use the **set metric** command in route-map configuration mode. To return to the default metric value for OSPF and other dynamic routing protocols, use the **no** form of this command.

set metric *metric-value* | [*bandwidth delay reliability loading mtu*]

no set metric *metric-value* | [*bandwidth delay reliability loading mtu*]

Syntax Description

bandwidth	EIGRP bandwidth of a route, in kbps. Valid values range from 0 to 4294967295.
delay	EIGRP route delay, in tens of microseconds. Valid values range from 0 to 4294967295.
loading	Effective EIGRP bandwidth of a route expressed as a number from 0 to 255. The value 255 means 100 percent loading.
metric-value	Metric value of a route for OSPF and other dynamic routing protocols (except for EIGRP), expressed as a number. Valid values range from 0 to 4294967295.
mtu	Minimum MTU size of a route for EIGRP, in bytes. Valid values range from 0 to 4294967295.
reliability	Likelihood of successful packet transmission for EIGRP expressed as a number from 0 to 255. The value 255 means 100 percent reliability; 0 means no reliability.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
8.2(5)	Added the *bandwidth*, *delay*, *reliability*, *loading*, and *mtu* arguments to support EIGRP in a route map.
9.0(1)	Multiple context mode is supported.

Usage Guidelines

The **no set metric** command allows you to return to the default metric value for OSPF and other dynamic routing protocols. In this context, the *metric-value* argument is an integer from 0 to 4294967295.

Examples

The following example shows how to configure a route map for OSPF routing:

```
hostname(config)# route-map maptag1 permit 8
hostname(config-route-map)# set metric 5
hostname(config-route-map)# match metric 5
hostname(config-route-map)# show route-map
route-map maptag1 permit 8
set metric 5
match metric 5
```

The following example shows how to set the metric value for EIGRP in a route map:

```
hostname(config)# access-list route-out line 1 standard permit 10.1.1.0 255.255.255.0
hostname(config)# route-map rmap permit 10
hostname(config-route-map)# set metric 10000 60 100 1 1500
hostname(config-route-map)# show route-map rmap
route-map rmap, permit, sequence 10
  Match clauses:
    ip address (access-lists): route-out
  Set clauses:
    metric 10000 60 100 1 1500
hostname(config-route-map)# show running-config route-map
route-map rmap permit 10
 match ip address route-out
 set metric 10000 60 100 1 1500
```

Related Commands

Command	Description
match interface	Distributes any routes that have their next hop out of one of the interfaces specified,
match ip next-hop	Distributes any routes that have a next-hop router address that is passed by one of the access lists specified.
route-map	Defines the conditions for redistributing routes from one routing protocol into another.

set metric-type

To specify the type of OSPF metric routes, use the **set metric-type** command in route-map configuration mode. To return to the default setting, use the **no** form of this command.

set metric-type {**type-1** | **type-2**}

no set metric-type

Syntax Description

type-1	Specifies the type of OSPF metric routes that are external to a specified autonomous system.
type-2	Specifies the type of OSPF metric routes that are external to a specified autonomous system.

Defaults

The default is **type-2**.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Route-map configuration	•	—	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.
9.0(1)	Multiple context mode is supported.

Examples

The following example shows how to configure a route map for OSPF routing:

```
hostname(config)# route-map maptag1 permit 8
hostname(config-route-map)# set metric 5
hostname(config-route-map)# match metric 5
hostname(config-route-map)# set metric-type type-2
hostname(config-route-map)# show route-map
route-map maptag1 permit 8
  set metric 5
  set metric-type type-2
  match metric 5
hostname(config-route-map)# exit
hostname(config)#
```

Related Commands

Command	Description
match interface	Distributes any routes that have their next hop out one of the interfaces specified,
route-map	Defines the conditions for redistributing routes from one routing protocol into another.
set metric	Specifies the metric value in the destination routing protocol for a route map.

setup

To configure a minimal configuration for the ASA using interactive prompts, enter the **setup** command in global configuration mode.

setup

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.4(1)	In routed mode for the ASA 5510 and higher, the interface configured is now the Management *slot*/*port* interface, and not the "inside" interface. For the ASA 5505, the interface configured is the VLAN 1 interface, not "inside".
9.0(1)	The default configuration prompt was changed, and Ctrl + Z to exit the setup process was enabled.

Usage Guidelines

The setup prompt automatically appears at boot time if there is no startup configuration in flash memory.

The **setup** command walks you through minimal configuration to establish ASDM connectivity. This command is designed for a unit that has either no configuration or a partial configuration. If your model supports a factory default configuration, we recommend using the factory default configuration instead of the **setup** command (to restore the default configuration, use the **configure factory-default** command).

The **setup** command requires an already-named interface called "management".

When you enter the **setup** command, you are asked for the information in Table 43-1. If there is already a configuration for the listed parameter, it appears in brackets, so you can either accept it as the default or override it by entering a new value. The exact prompts available may differ per model. The system **setup** command includes a subset of these prompts.

Table 43-1 Setup Prompts

Prompt	Description
`Pre-configure Firewall now through interactive prompts [yes]?`	Enter **yes** or **no**. If you enter **yes**, the setup continues. If **no**, the setup stops and the global configuration prompt (hostname(config)#) appears.
`Firewall Mode [Routed]:`	Enter **routed** or **transparent**.
`Enable password:`	Enter an enable password. (The password must have at least three characters.)
`Allow password recovery [yes]?`	Enter **yes** or **no**.
`Clock (UTC):`	You cannot enter anything in this field. The UTC time is used by default.
`Year:`	Enter the year using four digits, for example, 2005. The year range is 1993 to 2035.
`Month:`	Enter the month using the first three characters of its name, for example, **Sep** for September.
`Day:`	Enter the day of the month, from 1 to 31.
`Time:`	Enter the hour, minutes, and seconds in 24-hour time format, for example, enter **20:54:44** for 8:54 p.m and 44 seconds.
`Host name:`	Enter the hostname that you want to display in the command line prompt.
`Domain name:`	Enter the domain name of the network on which the ASA runs.
`IP address of host running Device Manager:`	Enter the IP address of the host that needs to access ASDM.
`Use this configuration and save to flash (yes)?`	Enter **yes** or **no**. If you enter **yes**, the inside interface is enabled and the requested configuration is written to the Flash partition. If you enter **no**, the setup prompt repeats, beginning with the first question: `Pre-configure Firewall now through interactive prompts [yes]?` Enter **Ctrl + Z** to exit the setup or **yes** to repeat the prompt.

Examples

The following example shows how to complete the **setup** command:

```
hostname(config)# setup
Pre-configure Firewall now through interactive prompts [yes]? yes
Firewall Mode [Routed]: routed
Enable password [<use current password>]: writer
Allow password recovery [yes]? yes
Clock (UTC):
   Year: 2005
   Month: Nov
   Day: 15
   Time: 10:0:0
Inside IP address: 192.168.1.1
Inside network mask: 255.255.255.0
Host name: tech_pubs
```

```
Domain name: example.com
IP address of host running Device Manager: 10.1.1.1

The following configuration will be used:
Enable password: writer
Allow password recovery: yes
Clock (UTC): 20:54:44 Sep 17 2005
Firewall Mode: Routed
Inside IP address: 192.168.1.1
Inside network mask: 255.255.255.0
Host name: tech_pubs
Domain name: example.com
IP address of host running Device Manager: 10.1.1.1

Use this configuration and write to flash? yes
```

Related Commands

Command	Description
configure factory-default	Restores the default configuration.

shape

To enable QoS traffic shaping, use the **shape** command in class configuration mode. If you have a device that transmits packets at a high speed, such as a ASA with Fast Ethernet, and it is connected to a low speed device such as a cable modem, then the cable modem is a bottleneck at which packets are frequently dropped. To manage networks with differing line speeds, you can configure the ASA to transmit packets at a fixed slower rate, called *traffic shaping*. To remove this configuration, use the **no** form of this command.

Note Traffic shaping is only supported on the ASA 5505, 5510, 5520, 5540, and 5550. Multi-core models (such as the ASA 5500-X) do not support shaping.

shape average *rate* [*burst_size*]

no shape average *rate* [*burst_size*]

Syntax Description

average *rate*	Sets the average rate of traffic in bits per second over a given fixed time period, between 64000 and 154400000. Specify a value that is a multiple of 8000. See the "Usage Guidelines" section for more information about how the time period is calculated.
burst_size	Sets the average burst size in bits that can be transmitted over a given fixed time period, between 2048 and 154400000. Specify a value that is a multiple of 128. If you do not specify the *burst_size*, the default value is equivalent to 4-milliseconds of traffic at the specified average rate. For example, if the average rate is 1000000 bits per second, 4 ms worth = 1000000 * 4/1000 = 4000.

Defaults

If you do not specify the *burst_size*, the default value is equivalent to 4-milliseconds of traffic at the specified average rate. For example, if the average rate is 1000000 bits per second, 4 ms worth = 1000000 * 4/1000 = 4000.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Class configuration	•	•	•	—	—

Command History

Release	Modification
7.2(4)/8.0(4)	This command was introduced.

Usage Guidelines

To enable traffic shaping, use the Modular Policy Framework:

1. **policy-map**—Identify the actions associated with the **class-default** class map.
   a. **class class-default**—Identify the **class-default** class map on which you want to perform actions.
   b. **shape**—Apply traffic shaping to the class map.
   c. (Optional) **service-policy**—Call a different policy map in which you configured the **priority** command so you can apply priority queueing to a subset of shaped traffic.
2. **service-policy**—Assigns the policy map to an interface or globally.

Traffic Shaping Overview

Traffic shaping is used to match device and link speeds, thereby controlling packet loss, variable delay, and link saturation, which can cause jitter and delay.

- Traffic shaping must be applied to all outgoing traffic on a physical interface or in the case of the ASA 5505, on a VLAN. You cannot configure traffic shaping for specific types of traffic.
- Traffic shaping is implemented when packets are ready to be transmitted on an interface, so the rate calculation is performed based on the actual size of a packet to be transmitted, including all the possible overhead such as the IPsec header and L2 header.
- The shaped traffic includes both through-the-box and from-the-box traffic.
- The shape rate calculation is based on the standard token bucket algorithm. The token bucket size is twice the burst size value. See the CLI configuration guide for more information about the token bucket.
- When bursty traffic exceeds the specified shape rate, packets are queued and transmitted later. Following are some characteristics regarding the shape queue (for information about hierarchical priority queueing, see the **priority** command):
  - The queue size is calculated based on the shape rate. The queue can hold the equivalent of 200-milliseconds worth of shape rate traffic, assuming a 1500-byte packet. The minimum queue size is 64.
  - When the queue limit is reached, packets are tail-dropped.
  - Certain critical keep-alive packets such as OSPF Hello packets are never dropped.
  - The time interval is derived by *time_interval* = *burst_size* / *average_rate*. The larger the time interval is, the burstier the shaped traffic might be, and the longer the link might be idle. The effect can be best understood using the following exaggerated example:

    Average Rate = 1000000

    Burst Size = 1000000

    In the above example, the time interval is 1 second, which means, 1 Mbps of traffic can be bursted out within the first 10 milliseconds of the 1-second interval on a 100 Mbps FE link and leave the remaining 990 milliseconds idle without being able to send any packets until the next time interval. So if there is delay-sensitive traffic such as voice traffic, the Burst Size should be reduced compared to the average rate so the time interval is reduced.

How QoS Features Interact

You can configure each of the QoS features alone if desired for the ASA. Often, though, you configure multiple QoS features on the ASA so you can prioritize some traffic, for example, and prevent other traffic from causing bandwidth problems.

See the following supported feature combinations per interface:

- Standard priority queuing (for specific traffic) + Policing (for the rest of the traffic).

  You cannot configure priority queueing and policing for the same set of traffic.
- Traffic shaping (for all traffic on an interface) + Hierarchical priority queueing (for a subset of traffic).

You cannot configure traffic shaping and standard priority queueing for the same interface; only hierarchical priority queueing is allowed. For example, if you configure standard priority queueing for the global policy, and then configure traffic shaping for a specific interface, the feature you configured last is rejected because the global policy overlaps the interface policy.

Typically, if you enable traffic shaping, you do not also enable policing for the same traffic, although the ASA does not restrict you from configuring this.

Examples

The following example enables traffic shaping for all traffic on the outside interface, and prioritizes traffic within VPN tunnel-grp1 with the DSCP bit set to ef:

```
hostname(config)# class-map TG1-voice
hostname(config-cmap)# match tunnel-group tunnel-grp1
hostname(config-cmap)# match dscp ef

hostname(config)# policy-map priority-sub-policy
hostname(config-pmap)# class TG1-voice
hostname(config-pmap-c)# priority

hostname(config-pmap-c)# policy-map shape_policy
hostname(config-pmap)# class class-default
hostname(config-pmap-c)# shape
hostname(config-pmap-c)# service-policy priority-sub-policy

hostname(config-pmap-c)# service-policy shape_policy interface outside
```

Related Commands

Command	Description
class	Identifies the class map on which you want to perform actions in a policy map.
police	Enables QoS policing.
policy-map	Identifies actions to apply to traffic in a service policy.
priority	Enables QoS priority queueing.
service-policy (class)	Applies a hierarchical policy map.
service-policy (global)	Applies a service policy to interface(s).
show service-policy	Shows QoS statistics.

CHAPTER 44

show aaa kerberos through show asdm sessions Commands

show aaa kerberos

To display all the Kerberos tickets cached on the ASA, use the **show aaa kerberos** command in webvpn configuration mode.

show aaa kerberos [**username** *user* | **host** *ip* | *hostname*]

Syntax Description

host	Specifies the specific host that you want to view.
hostname	Specifies the hostname.
ip	Specifies the IP address for the host.
username	Specifies the specific user that you want to view.

Defaults

No defaults exist for this command.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Webvpn configuration	•	—	•	—	—

Command History

Release	Modification
8.4(1)	This command was introduced.

Usage Guidelines

Use the **show aaa kerberos** command in webvpn configuration mode to view all the Kerberos tickets cached on the ASA. The **username** and **host** keywords are used to view the Kerberos tickets of a specific user or host.

Examples

The following example shows the usage of the **show aaa kerberos** command:

```
hostname(config)# show aaa kerberos

Default Principal      Valid Starting Expires        Service Principal
kcduser@example.com    06/29/10 17:33:00 06/30/10 17:33:00 asa$/mycompany.com@example.com
kcduser@example.com    06/29/10 17:33:00 06/30/10 17:33:00
http/owa.mycompany.com@example.com
```

Related Commands

Command	Description
clear aaa kerberos	Clears all the Kerberos tickets cached on the ASA.

clear configure aaa-server	Removes all AAA command statements from the configuration.
show running-config aaa-server	Displays AAA server statistics for all AAA servers, for a particular server group, for a particular server within a particular group, or for a particular protocol.

show aaa local user

To show the list of usernames that are currently locked, or to show details about the username, use the show **aaa local user** command in global configuration mode.

show aaa local user [**locked**]

Syntax Description

locked	(Optional) Shows the list of usernames that are currently locked.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Global configuration	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

If you omit the optional keyword **locked**, the ASA displays the failed-attempts and lockout status details for all AAA local users.

You can specify a single user by using the **username** option or all users with the **all** option.

This command affects only the status of users that are locked out.

The administrator cannot be locked out of the device.

Examples

The following example shows use of the **show aaa local user** command to display the lockout status of all usernames:

This example shows the use of the **show aaa local user** command to display the number of failed authentication attempts and lockout status details for all AAA local users, after the limit has been set to 5:

```
hostname(config)# aaa local authentication attempts max-fail 5
hostname(config)# show aaa local user
Lock-time  Failed-attempts      Locked  User
    -                   6       Y       test
    -                   2       N       mona
    -                   1       N       cisco
    -                   4       N       newuser
hostname(config)#
```

This example shows the use of the **show aaa local user** command with the **lockout** keyword to display the number of failed authentication attempts and lockout status details only for any locked-out AAA local users, after the limit has been set to 5:

```
hostname(config)# aaa local authentication attempts max-fail 5
hostname(config)# show aaa local user
Lock-time  Failed-attempts      Locked  User
    -                  6       Y       test
hostname(config)#
```

Related Commands

Command	Description
aaa local authentication attempts max-fail	Configures the maximum number of times a user can enter a wrong password before being locked out.
clear aaa local user fail-attempts	Resets the number of failed attempts to 0 without modifying the lockout status.
clear aaa local user lockout	Clears th e lockout status of the specified user or all users and sets their failed attempts counters to 0.

show aaa-server

To display AAA server statistics for AAA servers, use the **show aaa-server** command in privileged EXEC mode.

show aaa-server [**LOCAL** | *groupname* [**host** *hostname*] | **protocol** *protocol*]

Syntax Description

LOCAL	(Optional) Shows statistics for the LOCAL user database.
groupname	(Optional) Shows statistics for servers in a group.
host *hostname*	(Optional) Shows statistics for a particular server in the group.
protocol *protocol*	(Optional) Shows statistics for servers of the following specified protocols: • **kerberos** • **ldap** • **nt** • **radius** • **sdi** • **tacacs+**

Defaults

By default, all AAA server statistics display.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.1(1)	The http-form protocol was added.
8.0(2)	The server status shows if the status was changed manually using the **aaa-server active** command or **fail** command.

Examples

The following is sample output from the **show aaa-server** command:

```
hostname(config)# show aaa-server group1 host 192.68.125.60
Server Group:  group1
Server Protocol: RADIUS
Server Address:  192.68.125.60
Server port:  1645
Server status: ACTIVE. Last transaction (success) at 11:10:08 UTC  Fri Aug 22
Number of pending requests        20
```

```
Average round trip time           4ms
Number of authentication requests 20
Number of authorization requests  0
Number of accounting requests     0
Number of retransmissions         1
Number of accepts                 16
Number of rejects                 4
Number of challenges              5
Number of malformed responses     0
Number of bad authenticators      0
Number of timeouts                0
Number of unrecognized responses  0
```

The following table shows field descriptions for the **show aaa-server** command:

Field	Description
Server Group	The server group name specified by the **aaa-server** command.
Server Protocol	The server protocol for the server group specified by the **aaa-server** command.
Server Address	The IP address of the AAA server.
Server port	The communication port used by the ASA and the AAA server. You can specify the RADIUS authentication port using the **authentication-port** command. You can specify the RADIUS accounting port using the **accounting-port** command. For non-RADIUS servers, the port is set by the **server-port** command.
Server status	The status of the server. One of the following values appears: • ACTIVE—The ASA will communicate with this AAA server. • FAILED—The ASA cannot communicate with the AAA server. Servers that are put into this state remain there for some period of time, depending on the policy configured, and are then reactivated. If the status is followed by "(admin initiated)," then the server was manually failed or reactivated using the **aaa-server active** command or **fail** command. The date and time of the last transaction appear in the following form: **Last transaction ({success | failure}) at** *time timezone date* If the ASA has never communicated with the server, the message shows as the following: **Last transaction at Unknown**
Number of pending requests	The number of requests that are still in progress.
Average round trip time	The average time that it takes to complete a transaction with the server.
Number of authentication requests	The number of authentication requests sent by the ASA. This value does not include retransmissions after a timeout.

Field	Description
Number of authorization requests	The number of authorization requests. This value refers to authorization requests due to command authorization, authorization for through-the-box traffic (for TACACS+ servers), or for WebVPN and IPsec authorization functionality enabled for a tunnel group. This value does not include retransmissions after a timeout.
Number of accounting requests	The number of accounting requests. This value does not include retransmissions after a timeout.
Number of retransmissions	The number of times a message was retransmitted after an internal timeout. This value applies only to Kerberos and RADIUS servers (UDP).
Number of accepts	The number of successful authentication requests.
Number of rejects	The number of rejected requests. This value includes error conditions as well as true credential rejections from the AAA server.
Number of challenges	The number of times the AAA server required additional information from the user after receiving the initial username and password information.
Number of malformed responses	N/A. Reserved for future use.
Number of bad authenticators	The number of times that one of the following occurs: • The "authenticator" string in the RADIUS packet is corrupted (rare). • The shared secret key on the ASA does not match the one on the RADIUS server. To fix this problem, enter the correct server key. This value only applies to RADIUS.
Number of timeouts	The number of times the ASA has detected that a AAA server is not responsive or otherwise misbehaving and has declared it offline.
Number of unrecognized responses	The number of times that the ASA received a response from the AAA server that it could not recognize or support. For example, the RADIUS packet code from the server was an unknown type, something other than the known "access-accept," "access-reject," "access-challenge," or "accounting-response" types. Typically, this means that the RADIUS response packet from the server was corrupted, which is rare.

Related Commands

Command	Description
show running-config aaa-server	Displays statistics for all servers in the indicated server group or for a particular server.
clear aaa-server statistics	Clears the AAA server statistics.

show access-list

To display the hit counters and a timestamp value for an access list, use the **show access-list** command in privileged EXEC mode.

show access-list *id_1* [...[*id_2*]] [**brief**]

Syntax Description

brief	(Optional) Displays the access list identifiers, the hit count, and the timestamp of the last rule hit, all in hexadecimal format.
id_1	A name or set of characters that identifies an existing access list.
id_2	(Optional) A name or set of characters that identifies an existing access list.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
8.0(2)	Support for the **brief** keyword was introduced.
8.3(1)	Modified ACE show pattern to display ACL timestamp.

Usage Guidelines

You can display multiple access lists at one time by entering the access list identifiers in one command.

You can specify the **brief** keyword to display access list hit count, identifiers, and timestamp information in hexadecimal format. The configuration identifiers displayed in hexadecimal format are presented in three columns, and they are the same identifiers used in syslogs 106023 and 106100.

Clustering Guidelines

When using ASA clustering, if traffic is received by a single unit, the other units may still show a hit count for the ACL due to the clustering director logic. This is an expected behavior. Because the unit that did not receive any packets directly from the client may receive forwarded packets over the cluster control link for an owner request, the unit may check the ACL before sending the packet back to the receiving unit. As a result, the ACL hit count will be increased even though the unit did not pass the traffic.

Examples

The following examples show brief information about the specified access policy in hexadecimal format (ACEs in which the hitcount is not zero). The first two columns display identifiers in hexadecimal format, the third column lists the hit count, and the fourth column displays the timestamp value, also in hexadecimal format. The hit count value represents the number of times the rule has been hit by traffic. The timestamp value reports the time of the last hit. If the hit count is zero, no information is displayed.

The following is sample output from the **show access-list** command and shows the access list name "test," which is applied on an outside interface in the "IN" direction:

```
hostname# show access-list test
access-list test; 3 elements; name hash: 0xcb4257a3
access-list test line 1 extended permit icmp any any (hitcnt=0) 0xb422e9c2
access-list test line 2 extended permit object-group TELNET-SSH object-group S1
object-group D1 0x44ae5901
  access-list test line 2 extended permit tcp 100.100.100.0 255.255.255.0 10.10.10.0
255.255.255.0 eq telnet (hitcnt=1) 0xca10ca21
  access-list test line 2 extended permit tcp 100.100.100.0 255.255.255.0 10.10.10.0
255.255.255.0 eq ssh(hitcnt=1) 0x5b704158
```

The following is sample output from the **show access-list** command when **object-group-search** group is not enabled:

```
hostname# show access-list KH-BLK-Tunnel
access-list KH-BLK-Tunnel; 9 elements
access-list KH-BLK-Tunnel line 1 extended permit ip object-group KH-LAN object-group
BLK-LAN 0x724c956b
   access-list KH-BLK-Tunnel line 1 extended permit ip 192.168.97.0 255.255.255.0

   access-list KH-BLK-Tunnel line 1 extended permit ip 13.13.13.0 255.255.255.0 14.14.14.0
255.255.255.0 (hitcnt=0) 0x9a2f1c4d
access-list KH-BLK-Tunnel line 2 extended permit ospf interface pppoe1 host 87.139.87.200
(hitcnt=0) 0xb62d5832
access-list KH-BLK-Tunnel line 3 extended permit ip interface pppoe1 any (hitcnt=0)
0xa2c9ed34
access-list KH-BLK-Tunnel line 4 extended permit ip host 1.1.1.1 any (hitcnt=0) 0xd06f7e6b
access-list KH-BLK-Tunnel line 5 extended deny ip 1.1.0.0 255.255.0.0 any (hitcnt=0)
0x9d979934
access-list KH-BLK-Tunnel line 6 extended permit ip 1.1.1.0 255.255.255.0 any (hitcnt=0)
0xa52a0761
```

The following is sample output from the **show access-list** command when **object-group-search** group is enabled:

```
hostname# show access-list KH-BLK-Tunnel
access-list KH-BLK-Tunnel; 6 elements
access-list KH-BLK-Tunnel line 1 extended permit ip object-group KH-LAN(1) object-group
BLK-LAN(2)(hitcount=16) 0x724c956b
access-list KH-BLK-Tunnel line 2 extended permit ospf interface pppoe1 host 87.139.87.200
(hitcnt=0) 0xb62d5832
access-list KH-BLK-Tunnel line 3 extended permit ip interface pppoe1 any (hitcnt=0)
0xa2c9ed34
access-list KH-BLK-Tunnel line 4 extended permit ip host 1.1.1.1 any (hitcnt=0) 0xd06f7e6b
access-list KH-BLK-Tunnel line 5 extended deny ip 1.1.0.0 255.255.0.0 any (hitcnt=0)
0x9d979934
access-list KH-BLK-Tunnel line 6 extended permit ip 1.1.1.0 255.255.255.0 any (hitcnt=0)
0xa52a0761
```

The following is sample output from the **show access-list brief** command when Telnet traffic is passed:

```
hostname (config)# sh access-list test brief
access-list test; 3 elements; name hash: 0xcb4257a3
ca10ca21 44ae5901 00000001 4a68aa7e
```

The following is sample output from the **show access-list brief** command when SSH traffic is passed:

```
hostname (config)# sh access-list test brief
access-list test; 3 elements; name hash: 0xcb4257a3
ca10ca21 44ae5901 00000001 4a68aa7e
5b704158 44ae5901 00000001 4a68aaa9
```

The following is sample output from the **show access-list** command and shows the access list name "test," which is applied on an outside interface in the "IN" direction, with ACL Optimization enabled:

```
hostname# show access-list test
access-list test; 3 elements; name hash: 0xcb4257a3
access-list test line 1 extended permit icmp any any (hitcnt=0) 0xb422e9c2
access-list test line 2 extended permit object-group TELNET-SSH object-group S1
object-group D1 0x44ae5901
  access-list test line 2 extended permit tcp object-group S1(1) object-group D1(2) eq
telnet (hitcnt=1) 0x7b1c1660
  access-list test line 2 extended permit tcp object-group S1(1) object-group D1(2) eq ssh
(hitcnt=1) 0x3666f922
```

The following is sample output from the **show access-list brief** command when Telnet traffic is passed:

```
hostname (config)# sh access-list test brief
access-list test; 3 elements; name hash: 0xcb4257a3
7b1c1660 44ae5901 00000001 4a68ab51
```

The following is sample output from the **show access-list brief** command when SSH traffic is passed:

```
hostname (config)# sh access-list test brief
access-list test; 3 elements; name hash: 0xcb4257a3
7b1c1660 44ae5901 00000001 4a68ab51
3666f922 44ae5901 00000001 4a68ab66
```

Related Commands

Command	Description
access-list ethertype	Configures an access list that controls traffic based on its EtherType.
access-list extended	Adds an access list to the configuration and configures policy for IP traffic through the firewall.
clear access-list	Clears an access list counter.
clear configure access-list	Clears an access list from the running configuration.
show running-config access-list	Displays the current running access-list configuration.

show activation-key

To display the permanent license, active time-based licenses, and the running license, which is a combination of the permanent license and active time-based licenses. use the **show activation-key** command in privileged EXEC mode. For failover units, this command also shows the "Failover cluster" license, which is the combined keys of the primary and secondary units.

show activation-key [detail]

Syntax Description

detail	Shows inactive time-based licenses.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command.

	Firewall Mode		Security Context		
				Multiple	
Command Mode	**Routed**	**Transparent**	**Single**	**Context**	**System**
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
8.0(4)	The **detail** keyword was added.
8.2(1)	The output was modified to include additional licensing information.
8.3(1)	The output now includes whether a feature uses the permanent or time-based key, as well as the duration of the time-based key in use. It also shows all installed time-based keys, both active and inactive.
8.4(1)	Support for No Payload Encryption models.

Usage Guidelines

Some permanent licenses require you to reload the ASA after you activate them. Table 44-1 lists the licenses that require reloading.

Table 44-1 Permanent License Reloading Requirements

Model	License Action Requiring Reload
ASA 5505 and ASA 5510	Changing between the Base and Security Plus license.
All models	Changing the Encryption license.
All models	Downgrading any permanent license (for example, going from 10 contexts to 2 contexts).

If you need to reload, then the **show activation-key** output reads as follows:

```
The flash activation key is DIFFERENT from the running key.

The flash activation key takes effect after the next reload.
```

If you have a No Payload Encryption model, then when you view the license, VPN and Unified Communications licenses will not be listed.

Examples

Example 44-1 Standalone Unit Output for show activation-key

The following is sample output from the **show activation-key** command for a standalone unit that shows the running license (the combined permanent license and time-based licenses), as well as each active time-based license:

```
hostname# show activation-key

Serial Number:  JMX1232L11M
Running Permanent Activation Key: 0xce06dc6b 0x8a7b5ab7 0xa1e21dd4 0xd2c4b8b8 0xc4594f9c
Running Timebased Activation Key: 0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285
Running Timebased Activation Key: 0xyadayad2 0xyadayad2 0xyadayad2 0xyadayad2 0xyadayad2

The flash permanent activation key is the SAME as the running permanent key.

Active Timebased Activation Key:
0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285
Botnet Traffic Filter           : Enabled    39 days

Inactive Timebased Activation Key:
0xyadayada3 0xyadayada3 0xyadayada3 0xyadayada3 0xyadayada3
SSL VPN Peers                   : 100        7 days
```

Example 44-3 Primary Unit Output in a Failover Pair for show activation-key detail

The following is sample output from the **show activation-key detail** command for the primary failover unit that shows:

- The primary unit license (the combined permanent license and time-based licenses).
- The "Failover Cluster" license, which is the combined licenses from the primary and secondary units. This is the license that is actually running on the ASA. The values in this license that reflect the combination of the primary and secondary licenses are in bold.
- The primary unit permanent license.
- The primary unit installed time-based licenses (active and inactive).

```
hostname# show activation-key detail

Serial Number:  P3000000171
Running Permanent Activation Key: 0xce06dc6b 0x8a7b5ab7 0xa1e21dd4 0xd2c4b8b8 0xc4594f9c
Running Timebased Activation Key: 0xa821d549 0x35725fe4 0xc918b97b 0xce0b987b 0x47c7c285

Licensed features for this platform:

Total UC Proxy Sessions         : 100        14 days
```

Example 44-4 Secondary Unit Output in a Failover Pair for show activation-key detail

The following is sample output from the **show activation-key detail** command for the secondary failover unit that shows:

- The secondary unit license (the combined permanent license and time-based licenses).
- The "Failover Cluster" license, which is the combined licenses from the primary and secondary units. This is the license that is actually running on the ASA. The values in this license that reflect the combination of the primary and secondary licenses are in bold.
- The secondary unit permanent license.
- The secondary installed time-based licenses (active and inactive). This unit does not have any time-based licenses, so none display in this sample output.

```
hostname# show activation-key detail

Serial Number:  P3000000011

Intercompany Media Engine      : Disabled       perpetual

The flash permanent activation key is the SAME as the running permanent key.
```

Related Commands

Command	Description
activation-key	Changes the activation key.

show ad-groups

To display groups that are listed on an Active Directory server, use the **show ad-groups** command in privileged EXEC mode:

show ad-groups *name* [**filter** *string*]

Syntax Description

name	The name of the Active Directory server group to query.
string	A string within quotes specifying all or part of the group name to search for.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC mode	•	—	•	—	—

Command History

Release	Modification
8.0(4)	This command was introduced.

Usage Guidelines

The **show ad-groups** command applies only to Active Directory servers that use the LDAP protocol to retrieve groups. Use this command to display AD groups that you can use for dynamic access policy AAA selection criteria.

When the LDAP attribute type = LDAP, the default time that the ASA waits for a response from the server is 10 seconds. You can adjust this time using the **group-search-timeout** command in aaa-server host configuration mode.

Note If the Active Directory server has a large number of groups, the output of the **show ad-groups** command may be truncated based on limitations of the amount of data the server can fit into a response packet. To avoid this problem, use the **filter** option to reduce the number of groups reported by the server.

Examples

```
hostname# show ad-groups LDAP-AD17
Server Group   LDAP-AD17
Group list retrieved successfully
Number of Active Directory Groups     46
Account Operators
Administrators
APP-SSL-VPN CIO Users
Backup Operators
Cert Publishers
CERTSVC_DCOM_ACCESS
Cisco-Eng
DHCP Administrators
DHCP Users
Distributed COM Users
DnsAdmins
DnsUpdateProxy
Doctors
Domain Admins
Domain Computers
Domain Controllers
Domain Guests
Domain Users
Employees
Engineering
Engineering1
Engineering2
Enterprise Admins
Group Policy Creator Owners
Guests
HelpServicesGroup
```

The next example shows the same command with the **filter** option:

```
hostname(config)# show ad-groups LDAP-AD17 filter "Eng"
.
Server Group   LDAP-AD17
Group list retrieved successfully
Number of Active Directory Groups     4
Cisco-Eng
Engineering
Engineering1
Engineering2
```

Related Commands

Command	Description
ldap-group-base-dn	Specifies a level in the Active Directory hierarchy where the server begins searching for groups that are used by dynamic group policies.
group-search-timeout	Adjusts the time the ASA waits for a response from an Active Directory server for a list of groups.

show admin-context

To display the context name currently assigned as the admin context, use the **show admin-context** command in privileged EXEC mode.

show admin-context

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	—	—	•

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show admin-context** command. The following example shows the admin context called “admin” and stored in the root directory of flash:

```
hostname# show admin-context
Admin: admin flash:/admin.cfg
```

Related Commands

Command	Description
admin-context	Sets the admin context.
changeto	Changes between contexts or the system execution space.
clear configure context	Removes all contexts.
mode	Sets the context mode to single or multiple.
show context	Shows a list of contexts (system execution space) or information about the current context.

show arp

To view the ARP table, use the **show arp** command in privileged EXEC mode.

show arp

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(8)/7.2(4)/8.0(4)	Added dynamic ARP age to the display.

Usage Guidelines

The display output shows dynamic, static, and proxy ARP entries. Dynamic ARP entries include the age of the ARP entry in seconds. Static ARP entries include a dash (-) instead of the age, and proxy ARP entries state “alias.”

Examples

The following is sample output from the **show arp** command. The first entry is a dynamic entry aged 2 seconds. The second entry is a static entry, and the third entry is from proxy ARP.

```
hostname# show arp
        outside 10.86.194.61 0011.2094.1d2b 2
        outside 10.86.194.1 001a.300c.8000 -
        outside 10.86.195.2 00d0.02a8.440a alias
```

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
clear arp statistics	Clears ARP statistics.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

show arp-inspection

To view the ARP inspection setting for each interface, use the **show arp-inspection** command in privileged EXEC mode.

show arp-inspection

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	—	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show arp-inspection** command:

```
hostname# show arp-inspection
interface               arp-inspection         miss
-----------------------------------------------------
inside1                 enabled                flood
outside                 disabled                -
```

The **miss** column shows the default action to take for non-matching packets when ARP inspection is enabled, either “flood” or “no-flood.”

Related Commands

Command	Description
arp	Adds a static ARP entry.
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
clear arp statistics	Clears ARP statistics.
show arp statistics	Shows ARP statistics.
show running-config arp	Shows the current configuration of the ARP timeout.

show arp statistics

To view ARP statistics, use the show arp statistics command in privileged EXEC mode.

show arp statistics

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Examples

The following is sample output from the **show arp statistics** command:

```
hostname# show arp statistics
        Number of ARP entries:
        ASA : 6
        Dropped blocks in ARP: 6
        Maximum Queued blocks: 3
        Queued blocks: 1
        Interface collision ARPs Received: 5
        ARP-defense Gratuitous ARPS sent: 4
        Total ARP retries: 15
        Unresolved hosts: 1
        Maximum Unresolved hosts: 2
```

Table 2 shows each field description.

Table 44-2 show arp statistics Fields

Field	Description
Number of ARP entries	The total number of ARP table entries.
Dropped blocks in ARP	The number of blocks that were dropped while IP addresses were being resolved to their corresponding hardware addresses.
Maximum queued blocks	The maximum number of blocks that were ever queued in the ARP module, while waiting for the IP address to be resolved.

Table 44-2 show arp statistics Fields (continued)

Field	Description
Queued blocks	The number of blocks currently queued in the ARP module.
Interface collision ARPs received	The number of ARP packets received at all ASA interfaces that were from the same IP address as that of an ASA interface.
ARP-defense gratuitous ARPs sent	The number of gratuitous ARPs sent by the ASA as part of the ARP-Defense mechanism.
Total ARP retries	The total number of ARP requests sent by the ARP module when the address was not resolved in response to first ARP request.
Unresolved hosts	The number of unresolved hosts for which ARP requests are still being sent out by the ARP module.
Maximum unresolved hosts	The maximum number of unresolved hosts that ever were in the ARP module since it was last cleared or the ASA booted up.

Related Commands

Command	Description
arp-inspection	For transparent firewall mode, inspects ARP packets to prevent ARP spoofing.
clear arp statistics	Clears ARP statistics and resets the values to zero.
show arp	Shows the ARP table.
show running-config arp	Shows the current configuration of the ARP timeout.

show asdm history

To display the contents of the ASDM history buffer, use the **show asdm history** command in privileged EXEC mode.

show asdm history [**view** *timeframe*] [**snapshot**] [**feature** *feature*] [**asdmclient**]

Syntax Description

asdmclient	(Optional) Displays the ASDM history data formatted for the ASDM client.
feature *feature*	(Optional) Limits the history display to the specified feature. The following are valid values for the *feature* argument: • **all**—Displays the history for all features (default). • **blocks**—Displays the history for the system buffers. • **cpu**—Displays the history for CPU usage. • **failover**—Displays the history for failover. • **ids**—Displays the history for IDS. • **interface** *if_name*—Displays the history for the specified interface. The *if_name* argument is the name of the interface as specified by the **nameif** command. • **memory**—Displays memory usage history. • **perfmon**—Displays performance history. • **sas**—Displays the history for Security Associations. • **tunnels**—Displays the history for tunnels. • **xlates**—Displays translation slot history.
snapshot	(Optional) Displays only the last ASDM history data point.
view *timeframe*	(Optional) Limits the history display to the specified time period. Valid values for the *timeframe* argument are: • **all**—all contents in the history buffer (default). • **12h**—12 hours • **5d**—5 days • **60m**—60 minutes • **10m**—10 minutes

Defaults

If no arguments or keywords are specified, all history information for all features is displayed.

Command Modes

The following table shows the modes in which you can enter the command:

Command Mode	Firewall Mode		Security Context		
				Multiple	
	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show pdm history** command to the **show asdm history** command.

Usage Guidelines

The **show asdm history** command displays the contents of the ASDM history buffer. Before you can view ASDM history information, you must enable ASDM history tracking using the **asdm history enable** command.

Examples

The following is sample output from the **show asdm history** command. It limits the output to data for the outside interface collected during the last 10 minutes.

```
hostname# show asdm history view 10m feature interface outside

hostname#
```

The following is sample output from the **show asdm history** command. Like the previous example, it limits the output to data for the outside interface collected during the last 10 minutes. However, in this example the output is formatted for the ASDM client.

```
hostname# show asdm history view 10m feature interface outside asdmclient

Related Commands

Command	Description
asdm history enable	Enables ASDM history tracking.

show asdm image

To the current ASDM software image file, use the show **asdm image** command in privileged EXEC mode.

show asdm image

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	—	•

Command History

Release	Modification
7.0(1)	This command was changed from the **show pdm image** command to the **show asdm image** command.

Examples

The following is sample output from the **show asdm image** command:

```
hostname# show asdm image

Device Manager image file, flash:/ASDM
```

Related Commands

Command	Description
asdm image	Specifies the current ASDM image file.

show asdm log_sessions

To display a list of active ASDM logging sessions and their associated session IDs, use the **show asdm log_sessions** command in privileged EXEC mode.

show asdm log_sessions

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was introduced.

Usage Guidelines

Each active ASDM session has one or more associated ASDM logging sessions. ASDM uses the logging session to retrieve syslog messages from the ASA. Each ASDM logging session is assigned a unique session ID. You can use this session ID with the **asdm disconnect log_session** command to terminate the specified session.

Note Because each ASDM session has at least one ASDM logging session, the output for the **show asdm sessions** and **show asdm log_sessions** may appear to be the same.

Examples

The following is sample output from the **show asdm log_sessions** command:

```
hostname# show asdm log_sessions

0 192.168.1.1
1 192.168.1.2
```

Related Commands

Command	Description
asdm disconnect log_session	Terminates an active ASDM logging session.

show asdm sessions

To display a list of active ASDM sessions and their associated session IDs, use the **show asdm sessions** command in privileged EXEC mode.

show asdm sessions

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	—

Command History

Release	Modification
7.0(1)	This command was changed from the **show pdm sessions** command to the **show asdm sessions** command.

Usage Guidelines

Each active ASDM session is assigned a unique session ID. You can use this session ID with the **asdm disconnect** command to terminate the specified session.

Examples

The following is sample output from the **show asdm sessions** command:

```
hostname# show asdm sessions

0 192.168.1.1
1 192.168.1.2
```

Related Commands

Command	Description
asdm disconnect	Terminates an active ASDM session.

CHAPTER 45

show asp cluster counter through show asp table vpn-context Commands

show asp cluster counter

To debug global or context-specific information in a clustering environment, use the **show asp cluster counter** command in privileged EXEC mode.

show asp cluster counter

Syntax Description

This command has no arguments or keywords.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
9.0(1)	This command was introduced.

Usage Guidelines

The **show asp cluster counter** command shows the global and context-specific DP counters, which might help you troubleshoot a problem. This information is used for debugging purposes only, and the information output is subject to change. Consult the Cisco TAC to help you debug your system with this command.

Examples

The following is sample output from the **show asp cluster counter** command:

```
hostname# show asp cluster counter

Global dp-counters:

Context specific dp-counters:

MCAST_FP_TO_SP                  361136
MCAST_SP_TOTAL                  361136
MCAST_SP_PKTS                   143327
MCAST_SP_PKTS_TO_CP             143327
MCAST_FP_CHK_FAIL_NO_HANDLE     217809
MCAST_FP_CHK_FAIL_NO_ACCEPT_IFC 81192
MCAST_FP_CHK_FAIL_NO_FP_FWD     62135
```

Related Commands

Command	Description
show asp drop	Shows the accelerated security path counters for dropped packets.

show asp drop

To debug the accelerated security path dropped packets or connections, use the **show asp drop** command in privileged EXEC mode.

show asp drop [**flow** [*flow_drop_reason*] | **frame** [*frame_drop_reason*]]

Syntax Description

flow [*flow_drop_reason*]	(Optional) Shows the dropped flows (connections). You can specify a particular reason by using the *flow_drop_reason* argument. Valid values for the *flow_drop_reason* argument are listed in the "Usage Guidelines" section.
frame [*frame_drop_reason*]	(Optional) Shows the dropped packets. You can specify a particular reason by using the *frame_drop_reason* argument. Valid values for the *frame_drop_reason* argument are listed in the "Usage Guidelines" section.

Defaults

No default behavior or values.

Command Modes

The following table shows the modes in which you can enter the command:

	Firewall Mode		Security Context		
				Multiple	
Command Mode	Routed	Transparent	Single	Context	System
Privileged EXEC	•	•	•	•	•

Command History

Release	Modification
7.0(1)	This command was introduced.
7.0(8)/7.2(4)/8.0(4)	Output includes a timestamp indicating when the counters were last cleared (see the **clear asp drop** command). It also displays the drop reason keywords next to the description, so you can easily use the **capture asp-drop** command with the associated keyword.

Usage Guidelines

The **show asp drop** command shows the packets or connections dropped by the accelerated security path, which might help you troubleshoot a problem. See the CLI configuration guide for more information about the accelerated security path. This information is used for debugging purposes only, and the information output is subject to change. Consult Cisco TAC to help you debug your system with this command.

The following sections include each drop reason name and description, including recommendations:

- Frame Drop Reasons, page 45-5
- Flow Drop Reasons, page 45-60

Frame Drop Reasons

```
-----------------------------------------------------------------
Name: natt-keepalive
NAT-T keepalive message:
    This counter will increment when the appliance receives an IPSec NAT-T keepalive
message.  NAT-T keepalive messages are sent from the IPSec peer to the appliance to keep
NAT/PAT flow information current in network devices between the NAT-T IPSec peer and the
appliance.

 Recommendation:
    If you have configured IPSec NAT-T on your appliance, this indication is normal and
doesn't indicate a problem.  If NAT-T is not configured on your appliance, analyze your
network traffic to determine the source of the NAT-T traffic.

 Syslogs:
    None

-----------------------------------------------------------------
Name: ipsecudp-keepalive
IPSEC/UDP keepalive message:
    This counter will increment when the appliance receives an IPSec over UDP keepalive
message. IPSec over UDP keepalive messages are sent from the IPSec peer to the appliance
to keep NAT/PAT flow information current in network devices between the IPSec over UDP
peer and the appliance. Note - These are not industry standard NAT-T keepalive messages
which are also carried over UDP and addressed to UDP port 4500.
 Recommendation:
    If you have configured IPSec over UDP on your appliance, this indication is normal and
doesn't indicate a problem.  If IPSec over UDP is not configured on your appliance,
analyze your network traffic to determine the source of the IPSec over UDP traffic.

 Syslogs:
    None

-----------------------------------------------------------------
Name: bad-ipsec-prot
IPSec not AH or ESP:
    This counter will increment when the appliance receives a packet on an IPSec
connection which is not an AH or ESP protocol. This is not a normal condition.

 Recommendation:
    If you are receiving many IPSec not AH or ESP indications on your appliance, analyze
your network traffic to determine the source of the traffic.

 Syslogs:
    402115

-----------------------------------------------------------------
Name: ipsec-ipv6
IPSec via IPV6:
    This counter will increment when the appliance receives an IPSec ESP packet, IPSec
NAT-T ESP packet or an IPSec over UDP ESP packet encapsulated in an IP version 6 header.
The appliance does not currently support any IPSec sessions encapsulated in IP version 6.

 Recommendation:
    None

 Syslogs:
    None
```

```
-------------------------------------------------------------
Name: bad-ipsec-natt
BAD IPSec NATT packet:
    This counter will increment when the appliance receives a packet on an IPSec
connection which has negotiated NAT-T but the packet is not addressed to the NAT-T UDP
destination port of 4500 or had an invalid payload length.

 Recommendation:
    Analyze your network traffic to determine the source of the NAT-T traffic.

 Syslogs:
    None

-------------------------------------------------------------
Name: bad-ipsec-udp
BAD IPSec UDP packet:
    This counter will increment when the appliance receives a packet on an IPSec
connection which has negotiated IPSec over UDP but the packet has an invalid payload
length.

 Recommendation:
    Analyze your network traffic to determine the source of the NAT-T traffic.

 Syslogs:
    None

-------------------------------------------------------------
Name: inspect-srtp-encrypt-failed
Inspect SRTP Encryption failed:
    This counter will increment when SRTP encryption fails.

Recommendation:
    If error persists even after a reboot please call TAC to see why SRTP encryption is
failing in the hardware crypto accelerator.

Syslogs:
    337001.

-------------------------------------------------------------
Name: inspect-srtp-decrypt-failed
Inspect SRTP Decryption failed:
    This counter will increment when SRTP decryption fails.

Recommendation:
    If error persists even after a reboot please call TAC to see why SRTP decryption is
failing in the hardware crypto accelerator.

Syslogs:
    337002.

-------------------------------------------------------------
Name: inspect-srtp-validate-authtag-failed
Inspect SRTP Authentication tag validation failed:
    This counter will increment when SRTP authentication tag validation fails.

Recommendation:
    No action is required. If error persists SRTP packets arriving at the firewall are
being tampered with and the administrator has to identify the cause.

Syslogs:
```

```
    337003.

----------------------------------------------------------------
Name: inspect-srtp-generate-authtag-failed
Inspect SRTP Authentication tag generation failed:
    This counter will increment when SRTP authentication tag generation fails.

Recommendation:
    No action is required.

Syslogs:
    337004.

----------------------------------------------------------------
Name: inspect-srtp-no-output-flow
Inspect SRTP failed to find output flow:
    This counter will increment when the flow from the Phone proxy could not be created or
if the flow has been torn down

Recommendation:
    No action is required. The flow creation could have failed because of low memory
conditions.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-srtp-setup-srtp-failed
Inspect SRTP setup in CTM failed:
    This counter will increment when SRTP setup in the CTM fails.

Recommendation:
    No action is required. If error persists call TAC to see why the CTM calls are
failing.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-srtp-one-part-no-key
Inspect SRTP failed to find keys for both parties:
    This counter will increment when Inspect SRTP finds only one party's keys populated in
the media session.

Recommendation:
    No action is required. This counter could increment in the beginning phase of the call
but eventually when the call signaling exchange completes both parties should know their
respective keys.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-srtp-no-media-session
Inspect SRTP Media session lookup failed:
    This counter will increment when SRTP media session lookup fails.

Recommendation:
```

```
    No action is required. The media session is created by Inspect SIP or Skinny when the
IP address is parsed as part of the signaling exchange. Debug the signaling messages to
figure out the cause.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-srtp-no-remote-phone-proxy-ip
Inspect SRTP Remote Phone Proxy IP not populated:
    This counter will increment when remote phone proxy IP is not populated

Recommendation:
    No action is required. The remote phone proxy IP address is populated from the
signaling exchange. If error persists debug the signaling messages to figure out if ASA is
seeing all the signaling messages.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-srtp-client-port-not-present
Inspect SRTP client port wildcarded in media session:
    This counter will increment when client port is not populated in media session

Recommendation:
    No action is required. The client port is populated dynamically when the media stream
comes in from the client. Capture the media packets to see if the client is sending media
packets.

Syslogs:
    None.

----------------------------------------------------------------
Name: ipsec-need-sa
IPSec SA not negotiated yet:
    This counter will increment when the appliance receives a packet which requires
encryption but has no established IPSec security association. This is generally a normal
condition for LAN-to-LAN IPSec configurations. This indication will cause the appliance to
begin ISAKMP negotiations with the destination peer.

 Recommendation:
    If you have configured IPSec LAN-to-LAN on your appliance, this indication is normal
and doesn't indicate a problem.  However, if this counter increments rapidly it may
indicate a crypto configuration error or network error preventing the ISAKMP negotiation
from completing. Verify that you can communicate with the destination peer and verify your
crypto configuration via the 'show running-config' command.

 Syslogs:
    None

----------------------------------------------------------------
Name: ipsec-spoof
IPSec spoof detected:
    This counter will increment when the appliance receives a packet which should have
been encrypted but was not. The packet matched the inner header security policy check of a
configured and established IPSec connection on the appliance but was received unencrypted.
This is a security issue.

 Recommendation:
```

```
    Analyze your network traffic to determine the source of the spoofed IPSec traffic.

 Syslogs:
    402117

----------------------------------------------------------------
Name: ipsec-clearpkt-notun
IPSec Clear Pkt w/no tunnel:
    This counter will increment when the appliance receives a packet which should have
been encrypted but was not.  The packet matched the inner header security policy check of
a configured and established IPSec connection on the appliance but was received
unencrypted. This is a security issue.

 Recommendation:
    Analyze your network traffic to determine the source of the spoofed IPSec traffic.

 Syslogs:
    402117

----------------------------------------------------------------
Name: ipsec-tun-down
IPSec tunnel is down:
    This counter will increment when the appliance receives a packet associated with an
IPSec connection which is in the process of being deleted.

 Recommendation:
    This is a normal condition when the IPSec tunnel is torn down for any reason.

 Syslogs:
    None

----------------------------------------------------------------
Name: mp-svc-delete-in-progress
SVC Module received data while connection was being deleted:
    This counter will increment when the security appliance receives a packet associated
with an SVC connection that is in the process of being deleted.

Recommendation:
    This is a normal condition when the SVC connection is torn down for any reason. If
this error occurs repeatedly or in large numbers, it could indicate that clients are
having network connectivity issues.

Syslogs:
    None.

----------------------------------------------------------------
Name: mp-svc-bad-framing
SVC Module received badly framed data:
    This counter will increment when the security appliance receives a packet from an SVC
or the control software that it is unable to decode.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC. The SVC or
security appliance could be at fault.

Syslogs:
    722037 (Only for SVC received data).

----------------------------------------------------------------
```

```
Name: mp-svc-bad-length
SVC Module received bad data length:
    This counter will increment when the security appliance receives a packet from an SVC
or the control software where the calculated and specified lengths do not match.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC. The SVC or
security appliance could be at fault.

Syslogs:
    722037 (Only for SVC received data).

----------------------------------------------------------------
Name: mp-svc-unknown-type
SVC Module received unknown data frame:
    This counter will increment when the security appliance receives a packet from an SVC
where the data type is unknown.

Recommendation:
    Validate that the SVC being used by the client is compatible with the version of
security appliance software.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-addr-renew-response
SVC Module received address renew response data frame:
    This counter will increment when the security appliance receives an Address Renew
Response message from an SVC. The SVC should not be sending this message.

Recommendation:
    This indicates that an SVC software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-no-prepend
SVC Module does not have enough space to insert header:
    This counter will increment when there is not enough space before the packet data to
prepend a MAC header in order to put the packet onto the network.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-no-channel
SVC Module does not have a channel for reinjection:
    This counter will increment when the interface that the encrypted data was received
upon cannot be found in order to inject the decrypted data.

Recommendation:
    If an interface is shut down during a connection, this could happen; re-enable/check
the interface. Otherwise, this indicates that a software error should be reported to the
Cisco TAC.
```

```
Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-no-session
SVC Module does not have a session:
    This counter will increment when the security appliance cannot determine the SVC
session that this data should be transmitted over.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-session-lock-failure
SVC Module failed to acquire the session lock:
    This counter will increment when the security appliance cannot grab the lock for the
SVC session that this data should be transmitted over.

Recommendation:
    This condition should never be encountered during normal operation and     may
indicate a software problem with the appliance.  Contact the Cisco     Technical
Assistance Center (TAC) if this error occurs.

Syslogs:
    None.

----------------------------------------------------------------
Name: mp-svc-decompres-error
SVC Module decompression error:
    This counter will increment when the security appliance encounters an error during
decompression of data from an SVC.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC. The SVC or
security appliance could be at fault.

Syslogs:
   722037.

----------------------------------------------------------------
Name: mp-svc-compress-error
SVC Module compression error:
    This counter will increment when the security appliance encounters an error during
compression of data to an SVC.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC. The SVC or
security appliance could be at fault.

Syslogs:
   722037.

----------------------------------------------------------------
Name: mp-svc-no-mac
SVC Module unable to find L2 data for frame:
```

```
    This counter will increment when the security appliance is unable to find an L2 MAC
header for data received from an SVC.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-invalid-mac
SVC Module found invalid L2 data in the frame:
    This counter will increment when the security appliance is finds an invalid L2 MAC
header attached to data received from an SVC.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-invalid-mac-len
SVC Module found invalid L2 data length in the frame:
    This counter will increment when the security appliance is finds an invalid L2 MAC
length attached to data received from an SVC.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-flow-control
SVC Session is in flow control:
    This counter will increment when the security appliance needs to drop data because an
SVC is temporarily not accepting any more data.

Recommendation:
    This indicates that the client is unable to accept more data. The client should reduce
the amount of traffic it is attempting to receive.

Syslogs:
   None.

----------------------------------------------------------------
Name: mp-svc-no-fragment
SVC Module unable to fragment packet:
    This counter is incremented when a packet to be sent to the SVC is not permitted to be
fragmented or when there are not enough data buffers to fragment the packet.

Recommendation:
    Increase the MTU of the SVC to reduce fragmentation. Avoid using applications that do
not permit fragmentation. Decrease the load on the device to increase available data
buffers.

Syslogs:
    None.
```

```
------------------------------------------------------------------
Name: vpn-handle-error
VPN Handle Error:
    This counter is incremented when the appliances is unable to create a VPN handle
because the VPN handle already exists.

 Recommendation:
    It is possible to see this counter increment as part of normal operation However, if
the counter is rapidly incrementing and there is a major malfunction of vpn-based
applications, then this may be caused by a software defect. Contact the Cisco TAC to
investigate the issue further.

 Syslogs:
    None.

------------------------------------------------------------------
Name: ipsec-lock-error
IPSec locking error:
    This counter is incremented when an IPSec operation is attempted but fails due to an
internal locking error.

Recommendation:
    This condition should never be encountered during normal operation and may indicate a
software problem with the appliance. Contact the Cisco Technical Assistance Center (TAC)
if this error occurs.

Syslogs:
    None.

------------------------------------------------------------------
Name: vpn-handle-mismatch
VPN Handle Mismatch:
    This counter is incremented when the appliance wants to forward a block and the flow
referred to by the VPN Handle is different than the flow associated with the block.

 Recommendation:
    This is not a normal occurrence. Please perform a "show console-output" and forward
that output to CISCO TAC for further analysis.

 Syslogs:
    None.

------------------------------------------------------------------
Name: vpn-reclassify-failed
VPN Reclassify Failed:
    This counter is incremented when a packet for a VPN flow is dropped due to the flow
failing to be reclassified after a VPN state change.

 Recommendation:
    This counter is incremented when a packet for a VPN flow arrives that requires
reclassification due to VPN CLI or Tunnel state changes. If the flow no longer matches the
existing policies, then the flow is freed and the packet dropped.

 Syslogs:
    No new syslogs accompany this event.

------------------------------------------------------------------
Name: punt-rate-limit
Punt rate limit exceeded:
```

```
    This counter will increment when the appliance attempts to forward a layer-2 packet to
a rate-limited control point service routine and the rate limit (per/second) is now being
exceeded. Currently, the only layer-2 packets destined for a control point service routine
which are rate limited are ARP packets. The ARP packet rate limit is 500 ARPs per second
per interface.

Recommendation:
    Analyze your network traffic to determine the reason behind the high rate of ARP
packets.

 Syslogs:
    322002, 322003

----------------------------------------------------------------
Name: punt-no-mem
Punt no memory:
    This counter is incremented and the packet is dropped when there is no memory to
create data structure for punting a packet to Control Point.

Recommendation:
    No action needs to be taken if this condition is transient. If this condition persists
due to low memory, then system upgrade might be necessary.

Syslogs:
    None

----------------------------------------------------------------
Name: punt-queue-limit
Punt queue limit exceeded:
    This counter is incremented and the packet is dropped when punt queue limit is
exceeded, an indication that a bottle-neck is forming at Control Point.

Recommendation:
    No action needs to be taken.  This is a design limitation.

Syslogs:
    None

----------------------------------------------------------------
Name: flow-being-freed
Flow is being freed:
    This counter is incremented when the flow is being freed and all packets queued for
inspection are dropped.

Recommendation:
    No action needs to be taken.

Syslogs:
    None

----------------------------------------------------------------
Name: invalid-encap
Invalid Encapsulation:
    This counter is incremented when the security appliance receives a frame belonging to
an unsupported link-level protocol or if the L3type specified in the frame is not
supported by the appliance. The packet is dropped.

Recommendation:
    Verify that directly connected hosts have proper link-level protocol settings.
```

```
Syslogs:
    None.

----------------------------------------------------------------
Name: invalid-ip-header
Invalid IP header:
    This counter is incremented and the packet is dropped when the appliance receives an
IP packet whose computed checksum of the IP header does not match the recorded checksum in
the header.

Recommendation:
    The packet corruption may be caused by a bad cable or noise on the line. It may also
be that a peer is sending corrupted packets and an attack is in progress. Please use the
packet capture feature to learn more about the origin of the packet.

Syslogs:
    None

----------------------------------------------------------------
Name: unsupported-ip-version
Unsupported IP version:
    This counter is incremented when the security appliance receives an IP packet that has
an unsupported version in version field of IP header. Specifically, if the packet does not
belong to version 4 or version 6. The packet is dropped.

Recommendation:
    Verify that other devices on connected network are configured to send IP packets
belonging to versions 4 or 6 only.

Syslogs:
    None.

----------------------------------------------------------------
Name: invalid-ip-length
Invalid IP Length:
    This counter is incremented when the security appliance receives an IPv4 or IPv6
packet in which the header length or total length fields in IP header are not valid or do
not conform to the received packet length.

Recommendation:
    None.

Syslogs:
    None.

----------------------------------------------------------------
Name: invalid-ethertype
Invalid Ethertype:
    This counter is incremented when the fragmentation module on the security appliance
receives or tries to send a fragmented packet that does not belong IP version 4 or version
6. The packet is dropped.

Recommendation:
    Verify mtu of device and other devices on connected network to determine why the
device is processing such fragments.

Syslogs:
    None.
```

```
------------------------------------------------------------------
Name: invalid-tcp-hdr-length
Invalid TCP Length:
    This counter is incremented when the security appliance receives a TCP packet whose
size is smaller than minimum-allowed header length or does not conform to the received
packet length.

Recommendation:
    The invalid packet could be a bogus packet being sent by an attacker.
Investigate the traffic from source in the following syslog.

Syslogs:
    500003.

------------------------------------------------------------------
Name: invalid-udp-length
Invalid UDP Length:
    This counter is incremented when the security appliance receives a UDP packet whose
size as calculated from the fields in header is different from the measured size of packet
as received from the network.

Recommendation:
    The invalid packet could be a bogus packet being sent by an attacker.

Syslogs:
    None.

------------------------------------------------------------------
Name: no-adjacency
No valid adjacency:
    This counter is incremented when the security appliance has tried to obtian an
adjacency and could not obtain mac-address for next hop. The packet is dropped.

Recommendation:
    Configure a capture for this drop reason and check if a host with specified
destination address exists on connected network or is routable from the device.

Syslogs:
   None.

------------------------------------------------------------------
Name: unexpected-packet
Unexpected packet:
    This counter is incremented when the appliance in transparent mode receives a non-IP
packet, destined to its MAC address, but there is no corresponding service running on the
appliance to process the packet.

Recommendation:
    Verify if the appliance is under attack. If there are no suspicious packets, or the
device is not in transparent mode, this counter is most likely being incremented due to a
software error. Attempt to capture the traffic that is causing the counter to increment
and contact the Cisco TAC.

Syslogs:
    None

------------------------------------------------------------------
Name: no-route
No route to host:
```

```
    This counter is incremented when the security appliance tries to send a packet out of
an interface and does not find a route for it in routing table.

Recommendation:
    Verify that a route exists for the destination address obtained from the generated
syslog.

Syslogs:
   110002, 110003.

----------------------------------------------------------------
Name: rpf-violated
Reverse-path verify failed:
    This counter is incremented when ip-verify is configured on an interface and the
security appliance receives a packet for which the route lookup of source-ip did not yield
the same interface as the one on which the packet was received.

Recommendation:
    Trace the source of traffic based on source-ip printed in syslog below and investigate
why it is sending spoofed traffic.

Syslogs:
    106021.

----------------------------------------------------------------
Name: acl-drop
Flow is denied by configured rule:
    This counter is incremented when a drop rule is hit by the packet and gets dropped.
This rule could be a default rule created when the box comes up, when various features are
turned on or off, when an acl is applied to interface or any other feature etc. Apart from
default rule drops, a packet could be dropped because of:
     1) ACL configured on an interface
     2) ACL configured for AAA and AAA denied the user
     3) Thru-box traffic arriving at management-only ifc
     4) Unencrypted traffic arriving on a ipsec-enabled interface

Recommendation:
    Note if one of ACLs listed below are fired.

Syslogs:
    106023, 106100, 106004

----------------------------------------------------------------
Name: unable-to-create-flow
Flow denied due to resource limitation:
    This counter is incremented and the packet is dropped when flow creation fails due to
a system resource limitation.  The resource limit may be either:
       1) system memory
       2) packet block extension memory
       3) system connection limit
    Causes 1 and 2 will occur simultaneously with flow drop reason "No memory to complete
flow".

Recommendation:
    - Observe if free system memory is low.
    - Observe if flow drop reason "No memory to complete flow" occurs.
    - Observe if connection count reaches the system connection limit with the command
"show resource usage".

Syslogs:
    None
```

```
----------------------------------------------------------------
Name: unable-to-add-flow
Flow hash full:
    This counter is incremented when a newly created flow is inserted into flow hash table
and the insertion failed because the hash table was full. The flow and the packet are
dropped. This is different from counter that gets incremented when maximum connection
limit is reached.

Recommendation:
    This message signifies lack of resources on the device to support an operation that
should have been successful. Please check if the connections in the 'show conn' output
have exceeded their configured idle timeout values. If so, contact the Cisco Technical
Assistance Center (TAC).

Syslogs:
    None.

----------------------------------------------------------------
Name: np-sp-invalid-spi
Invalid SPI:
    This counter will increment when the appliance receives an IPSec ESP packet addressed
to the appliance which specifies a SPI (security parameter index) not currently known by
the appliance.

 Recommendation:
    Occasional invalid SPI indications are common, especially during rekey processing.
Many invalid SPI indications may suggest a problem or DoS attack. If you are experiencing
a high rate of invalid SPI indications, analyze your network traffic to determine the
source of the ESP traffic.

 Syslogs:
    402114

----------------------------------------------------------------
Name: unsupport-ipv6-hdr
Unsupported IPv6 header:
    This counter is incremented and the packet is dropped if an IPv6 packet is received
with an unsupported IPv6 extension header. The supported IPv6 extension headers are: TCP,
UDP, ICMPv6, ESP, AH, Hop Options, Destination Options, and Fragment. The IPv6 routing
extension header is not supported, and any extension header not listed above is not
supported.  IPv6 ESP and AH headers are supported only if the packet is through-the-box.
To-the-box IPv6 ESP and AH packets are not supported and will be dropped.

Recommendation:
    This error may be due to a misconfigured host. If this error occurs repeatedly or in
large numbers, it could also indicate spurious or malicious activity such as an attempted
DoS attack.

Syslogs:
    None.

----------------------------------------------------------------
Name: tcp-not-syn
First TCP packet not SYN:
    Received a non SYN packet as the first packet of a non intercepted and non nailed
connection.

Recommendation:
```

```
    Under normal conditions, this may be seen when the appliance has already closed a
connection, and the client or server still believe the connection is open, and continue to
transmit data.  Some examples where this may occur is just after a 'clear local-host' or
'clear xlate' is issued. Also, if connections have not been recently removed, and the
counter is incrementing rapidly, the appliance may be under attack. Capture a sniffer
trace to help isolate the cause.

Syslogs:
    6106015

----------------------------------------------------------------
Name: bad-tcp-cksum
Bad TCP checksum:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP packet whose computed TCP checksum does not match the recorded checksum in TCP header.

Recommendation:
    The packet corruption may be caused by a bad cable or noise on the line. It may also
be that a TCP endpoint is sending corrupted packets and an attack is in progress. Please
use the packet capture feature to learn more about the origin of the packet. To allow
packets with incorrect TCP checksum disable checksum-verification feature under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: bad-tcp-flags
Bad TCP flags:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP packet with invalid TCP flags in TCP header. Example a packet with SYN and FIN TCP
flags set will be dropped.

Recommendations:
    The packet corruption may be caused by a bad cable or noise on the line. It may also
be that a TCP endpoint is sending corrupted packets and an attack is in progress. Please
use the packet capture feature to learn more about the origin of the packet.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-reserved-set
TCP reserved flags set:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP packet with reserved flags set in TCP header.

Recommendations:
    The packet corruption may be caused by a bad cable or noise on the line. It may also
be that a TCP endpoint is sending corrupted packets and an attack is in progress. Please
use the packet capture feature to learn more about the origin of the packet. To allow such
TCP packets or clear reserved flags and then pass the packet use reserved-bits
configuration under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-bad-option-list
TCP option list invalid:
```

```
    This counter is incremented and the packet is dropped when the appliance receives a
TCP packet with a non-standard TCP header option.

Recommendations:
    To allow such TCP packets or clear non-standard TCP header options and then allow the
packet, use tcp-options configuration under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-mss-exceeded
TCP data exceeded MSS:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP packet with data length greater than the MSS advertized by peer TCP endpoint.

Recommendations:
    To allow such TCP packets use exceed-mss configuration under tcp-map

Syslogs:
    4419001

----------------------------------------------------------------
Name: tcp-synack-data
TCP SYNACK with data:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP SYN-ACK packet with data.

Recommendations:
    The packet corruption may be caused by a bad cable or noise on the line. It may also
be that a TCP endpoint is sending corrupted packets and an attack is in progress. Please
use the packet capture feature to learn more about the origin of the packet.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-syn-data
TCP SYN with data:
    This counter is incremented and the packet is dropped when the appliance receives a
TCP SYN packet with data.

Recommendations:
    To allow such TCP packets use syn-data configuration under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-dual-open
TCP Dual open denied:
    This counter is incremented and the packet is dropped when the appliance recevies a
TCP SYN packet from the server, when an embryonic TCP connection is already open.

Recommendations:
    None

Syslogs:
    None
```

```
------------------------------------------------------------------
Name: tcp-data-past-fin
TCP data send after FIN:
    This counter is incremented and the packet is dropped when the appliance recevies new
TCP data packet from an endpoint which had sent a FIN to close the connection.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-3whs-failed
TCP failed 3 way handshake:
    This counter is incremented and the packet is dropped when appliance receives an
invalid TCP packet during three-way-handshake. Example SYN-ACK from client will be dropped
for this reason.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-rstfin-ooo
TCP RST/FIN out of order:
    This counter is incremented and the packet is dropped when appliance receives a RST or
a FIN packet with incorrect TCP sequence number.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-seq-syn-diff
TCP SEQ in SYN/SYNACK invalid:
    This counter is incremented and the packet is dropped when appliance receives a SYN or
SYN-ACK packet during three-way-handshake with incorrect TCP sequence number.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-ack-syn-diff
TCP ACK in SYNACK invalid:
    This counter is incremented and the packet is dropped when appliance receives a
SYN-ACK packet during three-way-handshake with incorrect TCP acknowledgement number.

Recommendations:
    None

Syslogs:
```

```
    None

------------------------------------------------------------------
Name: tcp-syn-ooo
TCP SYN on established conn:
    This counter is incremented and the packet is dropped when appliance receives a TCP
SYN packet on an established TCP connection.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-synack-ooo
TCP SYNACK on established conn:
    This counter is incremented and the packet is dropped when appliance receives a TCP
SYN-ACK packet on an established TCP connection.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-seq-past-win
TCP packet SEQ past window:
    This counter is incremented and the packet is dropped when appliance receives a TCP
data packet with sequence number beyond the window allowed by the peer TCP endpoint.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-invalid-ack
TCP invalid ACK:
    This counter is incremented and the packet is dropped when appliance receives a TCP
packet with acknowledgement number greater than data sent by peer TCP endpoint.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcp-fo-drop
TCP replicated flow pak drop:
    This counter is incremented and the packet is dropped when appliance receives a TCP
packet with control flag like SYN, FIN or RST on an established connection just after the
appliance has taken over as active unit.

Recommendations:
    None
```

```
Syslogs:
    None

----------------------------------------------------------------
Name: tcp-discarded-ooo
TCP ACK in 3 way handshake invalid:
    This counter is incremented and the packet is dropped when appliance receives a TCP
ACK packet from client during three-way-handshake and the sequence number is not next
expected sequence number.

Recommendations:
    None

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-buffer-full
TCP Out-of-Order packet buffer full:
    This counter is incremented and the packet is dropped when appliance receives an
out-of-order TCP packet on a connection and there is no buffer space to store this packet.
Typically TCP packets are put into order on connections that are inspected by the
appliance or when packets are sent to SSM for inspection. There is a default queue size
and when packets in excess of this default queue size are received they will be dropped.

Recommendations:
    On ASA platforms the queue size could be increased using queue-limit configuration
under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-global-buffer-full
TCP global Out-of-Order packet buffer full:
    This counter is incremented and the packet is dropped when the security appliance
receives an out-of-order TCP packet on a connection and there are no more global buffers
available. Typically TCP packets are put into order on connections that are inspected by
the security appliance or when packets are sent to the SSM for inspection. When the global
Out-of-Order buffer queue is full, the packet will be dropped and this counter will
increment.

Recommendations:
    This is a temporary condition when all global buffers are used. If this counter is
constantly incrementing, then please check your network for large amounts of Out-of-Order
traffic, which could be caused by traffic of the same flow taking different routes through
the network.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-buffer-timeout
TCP Out-of-Order packet buffer timeout:
    This counter is incremented and the packet is dropped when a queued out of order TCP
packet has been held in the buffer for too long.Typically, TCP packets are put into order
on connections that are inspected by the security appliance or when packets are sent to
the SSM for inspection. When the next expected TCP packet does not arrive within a certain
period, the queued out of order packet is dropped.
```

```
Recommendations:
    The next expected TCP packet may not arrive due to congestion in the network which is
normal in a busy network. The TCP retransmission mechanism in the end host will retransmit
the packet and the session will continue.

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-rst-syn-in-win
TCP RST/SYN in window:
    This counter is incremented and the packet is dropped when appliance receives a TCP
SYN or TCP RST packet on an established connection with sequence number within window but
not next expected sequence number.

Recommendations:
    None

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-acked
TCP DUP and has been ACKed:
    This counter is incremented and the packet is dropped when appliance receives a
retransmitted data packet and the data has been acknowledged by the peer TCP endpoint.

Recommendations:
    None

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-dup-in-queue
TCP dup of packet in Out-of-Order queue:
    This counter is incremented and the packet is dropped when appliance receives a
retransmitted data packet that is already in our out of order packet queue.

Recommendations:
    None

Syslogs:
    None

----------------------------------------------------------------
Name: tcp-paws-fail
TCP packet failed PAWS test:
    This counter is incremented and the packet is dropped when TCP packet with timestamp
header option fails the PAWS (Protect Against Wrapped Sequences) test.

Recommendations:
    To allow such connections to proceed, use tcp-options configuration under tcp-map to
clear timestamp option.

Syslogs:
    None
```

```
------------------------------------------------------------------
Name: tcp-conn-limit
TCP connection limit reached:
    This reason is given for dropping a TCP packet during TCP connection establishment
phase when the connection limit has been exceeded. The connection limit is configured via
the 'set connection conn-max' action command.

Recommendation:
    If this is incrementing rapidly, check the syslogs to determine which host's
connection limit is reached. The connection limit may need to be increased if the traffic
is normal, or the host may be under attack.

Syslogs:
    201011

------------------------------------------------------------------
Name: conn-limit
Connection limit reached:
    This reason is given for dropping a packet when the connection limit or host
connection limit has been exceeded. If this is a TCP packet which is dropped during TCP
connection establishment phase due to connection limit, the drop reason 'TCP connection
limit reached' is also reported.

Recommendation:
    If this is incrementing rapidly, check the syslogs to determine which host's
connection limit is reached. The connection limit may need to be increased if the traffic
is normal, or the host may be under attack.

Syslogs:
    201011

------------------------------------------------------------------
Name: tcp_xmit_partial
TCP retransmission partial:
    This counter is incremented and the packet is dropped when check-retranmission feature
is enabled and a partial TCP retransmission was received.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcpnorm-rexmit-bad
TCP bad retransmission:
    This counter is incremented and the packet is dropped when check-retranmission feature
is enabled and a TCP retranmission with different data from the original packet was
received.

Recommendations:
    None

Syslogs:
    None

------------------------------------------------------------------
Name: tcpnorm-win-variation
TCP unexpected window size variation:
```

```
    This counter is incremented and the packet is dropped when window size advertized by
TCP endpoint is drastically changed without accepting that much data.

Recommendations:
    In order to allow such packet, use the window-variation configuration under tcp-map.

Syslogs:
    None

----------------------------------------------------------------
Name: rate-exceeded
QoS rate exceeded:
    This counter is incremented when rate-limiting (policing) is configured on an
egress/ingress interface and the egress/ingress traffic rate exceeds the burst rate
configured. The counter is incremented for each packet dropped.

Recommendation:
    Investigate and determine why the rate of traffic leaving/entering the interface is
higher than the configured rate. This may be normal, or could be an indication of virus or
attempted attack.

Syslogs:
    None.

----------------------------------------------------------------
Name: queue-removed
Rate-limiter queued packet dropped:
    When QoS config is changed or removed, the existing packets in the output queues
awaiting transmission are dropped and this counter is incremented.

Recommendation:
    Under normal conditions, this may be seen when the QoS configuration has been changed
by the user. If this occurs when no changes to QoS config were performed, please contact
Cisco Technical Assistance Center (TAC).

Syslogs:
   None.

----------------------------------------------------------------
Name: bad-crypto
Bad crypto return in packet:
    This counter will increment when the appliance attempts to perform a crypto operation
on a packet and the crypto operation fails. This is not a normal condition and could
indicate possible software or hardware problems with the appliance

 Recommendation:
    If you are receiving many bad crypto indications your appliance may need servicing.
You should enable syslog 402123 to determine whether the crypto errors are hardware or
software errors. You can also check the error counter in the global IPSec statistics with
the 'show ipsec stats' CLI command. If the IPSec SA which is triggering these errors is
known, the SA statistics from the 'show ipsec sa detail' command will also be useful in
diagnosing the problem.

 Syslogs:
    402123

----------------------------------------------------------------
Name: ctm-error
CTM returned error:
```

```
    This counter will increment when the appliance attempts to perform a crypto operation
on a packet and the crypto operation fails. This is not a normal condition and could
indicate possible software or hardware problems with the appliance.

 Recommendation:
    If you are receiving many bad crypto indications your appliance may need servicing.
You should enable syslog 402123 to determine whether the crypto errors are hardware or
software errors. You can also check the error counter in the global IPSec statistics with
the 'show ipsec stats' CLI command. If the IPSec SA which is triggering these errors is
known, the SA statistics from the 'show ipsec sa detail' command will also be useful in
diagnosing the problem.

 Syslogs:
    402123

----------------------------------------------------------------
Name: send-ctm-error
Send to CTM returned error:
    This counter is obsolete in the appliance and should never increment.

 Recommendation:
    None

 Syslogs:
    None

----------------------------------------------------------------
Name: security-failed
Early security checks failed:
    This counter is incremented and packet is dropped when the security appliance :
    - receives an IPv4 multicast packet when the packets multicast MAC address doesn't
match the packets multicast destination IP address
    - receives an IPv6 or IPv4 teardrop fragment containing either small offset or
fragment overlapping
    - receives an IPv4 packet that matches an IP audit (IPS) signature

Recommendation:
    Contact the remote peer administrator or escalate this issue according to your
security policy
    For detailed description and syslogs for IP audit attack checks please refer the ip
audit signature section of command reference guide

Syslogs:
    106020
    400xx in case of ip audit checks

----------------------------------------------------------------
Name: sp-security-failed
Slowpath security checks failed:
    This counter is incremented and packet is dropped when the security appliance is:
    1) In routed mode receives a through-the-box:
       - L2 broadcast packet
       - IPv4 packet with destination IP address equal to 0.0.0.0
       - IPv4 packet with source IP address equal to 0.0.0.0
    2) In routed or transparent mode and receives a through-the-box IPv4 packet with:
       - first octet of the source IP address equal to zero
       - source IP address equal to the loopback IP address
       - network part of source IP address equal to all 0's
       - network part of the source IP address equal to all 1's
       - source IP address host part equal to all 0's or all 1's
```

```
    3) In routed or transparent mode and receives an IPv4 or IPv6 packet with same source
and destination IP addresses

Recommendation:
    1 and 2) Determine if an external user is trying to compromise the protected network.
Check for misconfigured clients.
    3) If this message counter is incrementing rapidly, an attack may be in progress. Use
the packet capture feature to capture type asp packets, and check the source MAC address
in the packet to see where they are coming from.

Syslogs:
    1 and 2) 106016
    3) 106017

-------------------------------------------------------------------
Name: ipv6_sp-security-failed
IPv6 slowpath security checks failed:
    This counter is incremented and the packet is dropped for one of the following
reasons:
1) IPv6 through-the-box packet with identical source and destination address.
2) IPv6 through-the-box packet with linklocal source or destination address.
3) IPv6 through-the-box packet with multicast destination address.

Recommendation:
    These packets could indicate malicious activity, or could be the result of a
misconfigured IPv6 host.  Use the packet capture feature to capture type asp packets, and
use the source MAC address to identify the source.

Syslogs:
    For identical source and destination address, syslog 106016, else none.

-------------------------------------------------------------------
Name: invalid-ip-option
IP option drop:
    This counter is incremented when any unicast packet with ip options or a multicast
packet with ip-options that have not been configured to be accepted, is received by the
security appliance. The packet is dropped.

Recommendation:
    Investigate why a packet with ip options is being sent by the sender.

Syslogs:
    None.

-------------------------------------------------------------------
Name: lu-invalid-pkt
Invalid LU packet:
    Standby unit received a corrupted Logical Update packet.

Recommendation:
    The packet corruption could be caused by a bad cable, interface card, line noise, or
software defect. If the interface appears to be functioning properly, then report the
problem to Cisco TAC.

Syslogs:
    None

-------------------------------------------------------------------
Name: fo-standby
Dropped by standby unit:
```

```
    If a through-the-box packet arrives at an appliance or context in a Standby state and
a flow is created, the packet is dropped and the flow removed. This counter will increment
each time a packet is dropped in this manner.

Recommendation:
    This counter should never be incrementing on the Active appliance or context. However,
it is normal to see it increment on the Standby appliance or context.

Syslogs:
    302014, 302016, 302018

----------------------------------------------------------------
Name: dst-l2_lookup-fail
Dst MAC L2 Lookup Failed:
    This counter will increment when the appliance is configured for transparent mode and
the appliance does a Layer 2 destination MAC address lookup which fails. Upon the lookup
failure, the appliance will begin the destination MAC discovery process and attempt to
find the location of the host via ARP and/or ICMP messages.

 Recommendation:
    This is a normal condition when the appliance is configured for transparent mode. You
can also execute (show mac-address-table) to list the L2 MAC address locations currently
discovered by the appliance.

 Syslogs:
    None

----------------------------------------------------------------
Name: l2_same-lan-port
L2 Src/Dst same LAN port:
    This counter will increment when the appliance/context is configured for transparent
mode and the appliance determines that the destination interface's L2 MAC address is the
same as its ingress interface.

 Recommendation:
    This is a normal condition when the appliance/context is configured for transparent
mode.  Since the appliance interface is operating in promiscuous mode, the
appliance/context receives all packets on the local LAN seqment.

 Syslogs:
    None

----------------------------------------------------------------
Name: flow-expired
Expired flow:
    This counter is incremented when the security appliance tries to inject a new or
cached packet belonging to a flow that has already expired.It is also incremented when the
appliance attempts to send an rst on a tcp flow that has already expired or when a packet
returns from IDS blade but the flow had already expired. The packet is dropped

Recommendation:
    If valid applications are getting pre-empted, investigate if a longer timeout is
needed.

Syslogs:
   None.

----------------------------------------------------------------
Name: inspect-icmp-out-of-app-id
ICMP Inspect out of App ID:
```

```
    This counter will increment when the ICMP inspection engine fails to allocate an 'App
ID' data structure. The structure is used to store the sequence number of the ICMP packet.

Recommendation:
    Check the system memory usage. This event normally happens when the system runs short
of memory.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-icmp-bad-code
ICMP Inspect bad icmp code:
    This counter will increment when the ICMP code in the ICMP echo request or reply
message is non-zero.

Recommendation:
    No action required if it is an intermittent event.  If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313009.

----------------------------------------------------------------
Name: inspect-icmp-seq-num-not-matched
ICMP Inspect seq num not matched:
    This counter will increment when the sequence number in the ICMP echo reply message
does not match any ICMP echo message that passed across the appliance earlier on the same
connection.

Recommendation:
    No action required if it is an intermittent event. If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313004

----------------------------------------------------------------
Name: inspect-icmp-error-no-existing-conn
ICMP Error Inspect no existing conn:
    This counter will increment when the appliance is not able to find any established
connection related to the frame embedded in the ICMP error message.

Recommendation:
    No action required if it is an intermittent event.  If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313005

----------------------------------------------------------------
Name: inspect-icmp-error-nat64-error
ICMP NAT64 Error Inspect XLATE Error:
    This counter will increment when the appliance is unable to translate ICMP error
messages between IPv6 and IPv4.

Recommendation:
    No action required if it is an intermittent event.  If the cause is an attack, you can
deny the host using the ACLs.
```

```
Syslogs:
    313005

----------------------------------------------------------------
Name: inspect-icmp-nat64-frag
ICMP NAT64 Inspect Fragmentation Error:
    This counter will increment when the appliance is unable to translate ICMP messages
between IPv6 and IPv4 due to fragmentation.  Per RFC-6145, ICMP packet fragments will not
be translated.

Recommendation:
    No action required.

Syslogs:
    313005

----------------------------------------------------------------
Name: inspect-icmp-error-different-embedded-conn
ICMP Error Inspect different embedded conn:
    This counter will increment when the frame embedded in the ICMP error message does not
match the established connection that has been identified when the ICMP connection is
created.

Recommendation:
    No action required if it is an intermittent event.  If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313005

----------------------------------------------------------------
Name: inspect-icmpv6-error-invalid-pak
ICMPv6 Error Inspect invalid packet:
    This counter will increment when the appliance detects an invalid frame embedded in
the ICMPv6 packet. This check is the same as that on IPv6 packets. Examples: Incomplete
IPv6 header; malformed IPv6 Next Header; etc.

Recommendation:
    No action required.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-icmpv6-error-no-existing-conn
ICMPv6 Error Inspect no existing conn:
    This counter will increment when the appliance is not able to find any established
connection related to the frame embedded in the ICMPv6 error message.

Recommendation:
    No action required if it is an intermittent event. If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    313005

----------------------------------------------------------------
Name: inspect-dns-invalid-pak
DNS Inspect invalid packet:
```

```
    This counter will increment when the appliance detects an invalid DNS packet.
Examples: A DNS packet with no DNS header; the number of DNS resource records not matching
the counter in the header; etc.

Recommendation:
    No action required.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-dns-invalid-domain-label
DNS Inspect invalid domain label:
    This counter will increment when the appliance detects an invalid DNS domain name or
label. DNS domain name and label is checked per RFC 1035.

Recommendation:
    No action required. If the domain name and label check is not desired, disable the
protocol-enforcement parameter in the DNS inspection policy-map (in supported releases).

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-dns-pak-too-long
DNS Inspect packet too long:
    This counter is incremented when the length of the DNS message exceeds the configured
maximum allowed value.

Recommendation:
    No action required.  If DNS message length checking is not desired, enable DNS
inspection without the 'maximum-length' option, or disable the 'message-length maximum'
parameter in the DNS inspection policy-map (in supported releases).

Syslogs:
    410001

----------------------------------------------------------------
Name: inspect-dns-out-of-app-id
DNS Inspect out of App ID:
    This counter will increment when the DNS inspection engine fails to allocate a data
structure to store the identification of the DNS message.
Recommendation:
    Check the system memory usage. This event normally happens when the system runs short
of memory.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-dns-id-not-matched
DNS Inspect ID not matched:
    This counter will increment when the identification of the DNS response message does
not match any DNS queries that passed across the appliance earlier on the same connection.

Recommendation:
    No action required if it is an intermittent event. If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
```

```
    None.

----------------------------------------------------------------
Name: dns-guard-out-of-app-id
DNS Guard out of App ID:
    This counter will increment when the DNS Guard function fails to allocate a data
structure to store the identification of the DNS message.

Recommendation:
    Check the system memory usage.  This event normally happens when the system runs short
of memory.

Syslogs:
    None.

----------------------------------------------------------------
Name: dns-guard-id-not-matched
DNS Guard ID not matched:
    This counter will increment when the identification of the DNS response message does
not match any DNS queries that passed across the appliance earlier on the same connection.
This counter will increment by the DNS Guard function.

Recommendation:
    No action required if it is an intermittent event.  If the cause is an attack, you can
deny the host using the ACLs.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-rtp-invalid-length
Invalid RTP Packet length:
    This counter will increment when the UDP packet length is less than the size of the
RTP header.

Recommendation:
    No action required. A capture can be used to figure out which RTP source is sending
the incorrect packets and you can deny the host using the ACLs.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-rtp-invalid-version
Invalid RTP Version field:
    This counter will increment when the RTP version field contains a version other than
2.

Recommendation:
    The RTP source in your network does not seem to be sending RTP packets conformant with
the RFC 1889. The reason for this has to be identified and you can deny the host using
ACLs if required.

Syslogs:
    431001.

----------------------------------------------------------------
Name: inspect-rtp-invalid-payload-type
Invalid RTP Payload type field:
```

```
    This counter will increment when the RTP payload type field does not contain an audio
payload type when the signalling channel negotiated an audio media type for this RTP
secondary connection. The counter increments similarly for the video payload type.

Recommendation:
    The RTP source in your network is using the audio RTP secondary connection to send
video  or vice versa. If you wish to prevent this you can deny the host using ACLs.

Syslogs:
    431001.

----------------------------------------------------------------
Name: inspect-rtp-ssrc-mismatch
Invalid RTP Synchronization Source field:
    This counter will increment when the RTP SSRC field in the packet does not match the
SSRC which the inspect has been seeing from this RTP source in all the RTP packets.

Recommendation:
    This could be because the RTP source in your network is rebooting and hence changing
the SSRC or it could be because of another host on your network trying to use the opened
secondary RTP connections on the firewall to send RTP packets. This should be investigated
further to confirm if there is a problem.

Syslogs:
    431001.

----------------------------------------------------------------
Name: inspect-rtp-sequence-num-outofrange
RTP Sequence number out of range:
    This counter will increment when the RTP sequence number in the packet is not in the
range expected by the inspect.

Recommendation:
    No action is required because the inspect tries to recover and start tracking from a
new sequence number after a lapse in the sequence numbers from the RTP source.

Syslogs:
    431001.

----------------------------------------------------------------
Name: inspect-rtp-max-outofseq-paks-probation
RTP out of sequence packets in probation period:
    This counter will increment when the out of sequence packets when the RTP source is
being validated exceeds 20. During the probation period, the inspect looks for 5
in-sequence packets to consider the source validated.

Recommendation:
    Check the RTP source to see why the first few packets do not come in sequence and
correct it.

Syslogs:
    431001.

----------------------------------------------------------------
Name: inspect-rtcp-invalid-length
Invalid RTCP Packet length:
    This counter will increment when the UDP packet length is less than the size of the
RTCP header.

Recommendation:
```

```
    No action required. A capture can be used to figure out which RTP source is sending
the incorrect packets and you can deny the host using the ACLs.

Syslogs:
    None.

----------------------------------------------------------------
Name: inspect-rtcp-invalid-version
Invalid RTCP Version field:
    This counter will increment when the RTCP version field contains a version other than
2.

Recommendation:
    The RTP source in your network does not seem to be sending RTCP packets conformant
with the RFC 1889. The reason for this has to be identified and you can deny the host
using ACLs if required.

Syslogs:
    431002.

----------------------------------------------------------------
Name: inspect-rtcp-invalid-payload-type
Invalid RTCP Payload type field:
    This counter will increment when the RTCP payload type field does not contain the
values 200 to 204.

Recommendation:
    The RTP source should be validated to see why it is sending payload types outside of
the range recommended by the RFC 1889.

Syslogs:
    431002.

----------------------------------------------------------------
Name: cxsc-request
Flow terminated by CXSC:
This reason is given for terminating a flow as requested by CXSC module. Recommendations:
Check syslogs and alerts on CXSC module.
Syslogs: 429002

----------------------------------------------------------------
Name: cxsc-fail
CXSC config removed for connection:
    This counter is incremented and the packet is dropped when CXSC configuration is not
found for a particular connection.

Recommendations:
   check if any configuration changes have been done for CXSC.

Syslogs:
   None

----------------------------------------------------------------
Name: cxsc-fail-close
CXSC fail-close:
    This reason is given for terminating a flow since CXSC card is down and fail-close
option was used with CXSC action.

Recommendations:
```

```
    Check and bring up CXSC card.

Syslogs:
    429001

----------------------------------------------------------------
Name: cxsc-bad-tlv-received
CXSC Module requested drop:
    This counter is incremented and the packet is dropped as requested by CXSC module when
the packet has bad TLV's.

Recommendations:
    Check syslogs and alerts on CXSC module.

Syslogs:
    None

----------------------------------------------------------------
Name: cxsc-ha-request
CXSC HA replication drop:
    This counter is incremented when the security appliance receives a CXSC HA request
packet, but could not process it and the packet is dropped.

Recommendation:
    This could happen occasionally when CXSC does not have the latest ASA HA state, like
right after ASA HA state change. If the counter is constantly increasing however, then it
can be because CXSC and ASA are out of sync. If that happens, contact Cisco TAC for
assistance.

Syslogs:
    None.

----------------------------------------------------------------
Name: cxsc-invalid-encap
CXSC invalid header drop:
    This counter is incremented when the security appliance receives a CXSC packet with
invalid messsage header, and the packet is dropped.

Recommendation:
    This should not happen. Contact Cisco TAC for assistance.

Syslogs:
    None.

----------------------------------------------------------------
Name: cxsc-malformed-packet
CXSC Module requested drop:
    This counter is incremented and the packet is dropped as requested by CXSC module when
the packet is malformed.

Recommendations:
    Check syslogs and alerts on CXSC module.

Syslogs:
    None

----------------------------------------------------------------
Name: ips-request
IPS Module requested drop:
```

```
    This counter is incremented and the packet is dropped as requested by IPS module when
the packet matches a signature on the IPS engine.

Recommendations:
    Check syslogs and alerts on IPS module.

Syslogs:
    420002

----------------------------------------------------------------
Name: ips-fail-close
IPS card is down:
    This counter is incremented and the packet is dropped when IPS card is down and
fail-close option was used in IPS inspection.

Recommendations:
    Check and bring up the IPS card.

Syslogs:
    420001

----------------------------------------------------------------
Name: ips-fail
IPS config removed for connection:
    This counter is incremented and the packet is dropped when IPS configuration is not
found for a particular connection.

Recommendations:
   check if any configuration changes have been done for IPS.

Syslogs:
   None

----------------------------------------------------------------
Name: ips-no-ipv6
Executing IPS software does not support IPv6:
    This counter is incremented when an IPv6 packet, configured to be directed toward IPS
SSM, is discarded since the software executing on IPS SSM card does not support IPv6.

Recommendations:
   Upgrade the IPS software to version 6.2 or later.

Syslogs:
   None

----------------------------------------------------------------
Name: l2_acl
FP L2 rule drop:
    This counter will increment when the appliance denies a packet due to a layer-2 ACL.
By default, in routed mode the appliance will PERMIT:
    1) IPv4 packets
    2) IPv6 packets
    3) ARP packets
    4) L2 Destination MAC of FFFF:FFFF:FFFF (broadcast)
    5) IPv4 MCAST packet with destination L2 of 0100:5E00:0000-0100:5EFE:FFFF
    6) IPv6 MCAST packet with destination L2 of 3333:0000:0000-3333:FFFF:FFFF

    By default, in Transparent mode permits the routed mode ACL and PERMITS:

    1) BPDU packets with destination L2 of 0100:0CCC:CCCD
```

```
    2) Appletalk packets with destination L2 of 0900:0700:0000-0900:07FF:FFFF

    The user can also configure ethertype ACL(s) and apply them to an interface to permit
other types of L2 traffic.

    The default L2 ACL can be seen in routed and transparent mode with the show asp table
classify domain permit command.

    Note - Packets permitted by L2 ACLs may still be dropped by L3-L4 ACLs.

 Recommendation:
    If your running the appliance/context in transparent mode and your non-IP packets are
dropped by the appliance, you can configure an ethertype ACL and apply the ACL to an
access group. Note - the appliance ethertype CLI only supports protocol types and not L2
destination MAC addresses.

 Syslogs:
    106026, 106027

----------------------------------------------------------------
Name: intercept-unexpected
Intercept unexpected packet:
    Either received data from client while waiting for SYNACK from server or received a
packet which cannot be handled in a particular state of TCP intercept.

Recommendation:
    If this drop is causing the connection to fail, please have a sniffer trace of the
client and server side of the connection while reporting the issue. The box could be under
attack and the sniffer traces or capture would help narrowing down the culprit.

Syslogs:
    None.

----------------------------------------------------------------
Name: no-mcast-entry
FP no mcast entry:
    A packet has arrived that matches a multicast flow, but the multicast service is no
longer enabled, or was re-enabled after the flow was built.
    - OR -
    A multicast entry change has been detected after a packet was punted to the CP, and
the NP can no longer forward the packet since no entry is present.

Recommendation:
    Reenable multicast if it is disabled.
    - OR -
    No action required.

Syslogs:
    None

----------------------------------------------------------------
Name: no-mcast-intrf
FP no mcast output intrf:
    All output interfaces have been removed from the multicast entry.
    - OR -
    The multicast packet could not be forwarded.

Recommendation:
    Verify that there are no longer any receivers for this group.
    - OR -
    Verify that a flow exists for this packet.
```

```
Syslogs:
    None

----------------------------------------------------------------
Name: fragment-reassembly-failed
Fragment reassembly failed:
    This counter is incremented when the appliance fails to reassemble a chain of
fragmented packets into a single packet. All the fragment packets in the chain are
dropped. This is most probably because of failure while allocating memory for the
reassembled packet.

Recommendation:
    Use the show blocks command to monitor the current block memory.

Syslogs:
    None

----------------------------------------------------------------
Name: ifc-classify
Virtual firewall classification failed:
    A packet arrived on a shared interface, but failed to classify to any specific context
interface.

Recommendation:
    For software versions without customizable mac-address support, use the "global" or
"static" command to specify the IPv4 addresses that belong to each context interface.  For
software versions with customizable mac-address support, enable "mac-address auto" in
system context.  Alternatively, configure unique MAC addresses for each context interfaces
residing over a shared interface with "mac-address" command under each context interface
submode.

Syslogs:
    None.

----------------------------------------------------------------
Name: connection-lock
Connection locking failed:
    While the packet was waiting for processing, the flow that would be usedwas destroyed.

Recommendation:
    The message could occur from user interface command to remove connection in an device
that is actively processing packet.  Otherwise, investigate flow drop counter.  This
message may occur if the flow are forced dropped from error.

Syslogs:
    None.

----------------------------------------------------------------
Name: interface-down
Interface is down:
    This counter will increment for each packet received on an interface that is shutdown
via the 'shutdown' interface sub-mode command. For ingress traffic, the packet is dropped
after security context classification and if the interface associated with the context is
shut down. For egress traffic, the packet is dropped when the egress interface is shut
down.

Recommendation:
    No action required.
```

```
Syslogs:
    None.

-----------------------------------------------------------------
Name: invalid-app-length
Invalid App length:
    This counter will increment when the appliance detects an invalid length of the Layer
7 payload in the packet.  Currently, it counts the drops by the DNS Guard function only.
Example: Incomplete DNS header.

Recommendation:
    No action required.

Syslogs:
    None.

-----------------------------------------------------------------
Name: loopback-buffer-full
Loopback buffer full:
    This counter is incremented and the packet is dropped when packets are sent from one
context of the appliance to another context through a shared interface and there is no
buffer space in loopback queue.

Recommendations:
    Check system CPU to make sure it is not overloaded.

Syslogs:
    None

-----------------------------------------------------------------
Name: non-ip-pkt-in-routed-mode
Non-IP packet received in routed mode:
    This counter will increment when the appliance receives a packet which is not IPv4,
IPv6 or ARP and the appliance/context is configured for routed mode. In normal operation
such packets should be dropped by the default L2 ACL configuration.

 Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

 Syslogs:
    106026, 106027

-----------------------------------------------------------------
Name: host-move-pkt
FP host move packet:
    This counter will increment when the appliance/context is configured for transparent
and source interface of a known L2 MAC address is detected on a different interface.

 Recommendation:
    This indicates that a host has been moved from one interface (i.e. LAN segment) to
another. This condition is normal while in transparent mode if the host has in fact been
moved. However, if the host move toggles back and forth between interfaces, a network loop
may be present.

 Syslogs:
    412001, 412002, 322001

-----------------------------------------------------------------
Name: tfw-no-mgmt-ip-config
```

```
No management IP address configured for TFW:
    This counter is incremented when the security appliance receives an IP packet in
transparent mode and has no management IP address defined. The packet is dropped.

Recommendation:
    Configure the device with management IP address and mask values.

Syslogs:
    322004

----------------------------------------------------------------
Name: shunned
Packet shunned:
    This counter will increment when a packet is received which has a source IP address
that matches a host in the shun database.

Recommendation:
    No action required.

Syslogs:
    401004

----------------------------------------------------------------
Name: rm-conn-limit
RM connection limit reached:
    This counter is incremented when the maximum number of connections for a context or
the system has been reached and a new connection is attempted.

 Recommendation:
    The device administrator can use the commands 'show resource usage' and 'show resource
usage system' to view context and system resource limits and 'Denied' counts and adjust
resource limits if desired.

 Syslogs:
    321001

----------------------------------------------------------------
Name: rm-conn-rate-limit
RM connection rate limit reached:
    This counter is incremented when the maximum connection rate for a context or the
system has been reached and a new connection is attempted.

 Recommendation:
    The device administrator can use the commands 'show resource usage' and 'show resource
usage system' to view context and system resource limits and 'Denied' counts and adjust
resource limits if desired.

 Syslogs:
    321002

----------------------------------------------------------------
Name: np-socket-closed
Dropped pending packets in a closed socket:
    If a socket is abruptly closed, by the user or software, then any pending packets in
the pipeline for that socket are also dropped. This counter is incremented for each packet
in the pipeline that is dropped.

Recommendation:
```

```
    It is common to see this counter increment as part of normal operation. However, if
the counter is rapidly incrementing and there is a major malfunction of socket-based
applications, then this may be caused by a software defect. Contact the Cisco TAC to
investigate the issue further.

Syslogs:
    None.

----------------------------------------------------------------
Name: mp-pf-queue-full
Port Forwarding Queue Is Full:
       This counter is incremented when the Port Forwarding application's internal queue
is full and it receives another packet  for transmission.

Recommendation:
    This indicates that a software error should be reported to the Cisco TAC.

Syslogs:
    None.

----------------------------------------------------------------
Name: ssm-dpp-invalid
Invalid packet received from SSM card:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when the security appliance receives a packet from the internal data plane
interface but could not find the proper driver to parse it.

Recommendation:
    The data plane driver is dynamically registered depending on the type of SSM installed
in the system. So this could happen if data plane packets arrive before the security
appliance is fully initialized. This counter is usually 0. You should not be concerned if
there are a few drops. However, if this counter keeps rising when system is up and
running, it may indicate a problem. Please contact Cisco Technical Assistance Center (TAC)
if you suspect it affects the normal operation of your the security appliance.

Syslogs:
    None.

----------------------------------------------------------------
Name: ssm-asdp-invalid
Invalid ASDP packet received from SSM card:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when the security appliance receives an ASA SSM Dataplane Protocol (ASDP)
packet from the internal data plane interface, but the driver encountered a problem when
parsing the packet. ASDP is a protocol used by the security appliance to communicate with
certain types of SSMs, like the CSC-SSM. This could happen for various reasons, for
example ASDP protocol version is not compatible between the security appliance and SSM, in
which case the card manager process in the control plane issues system messages and CLI
warnings to inform you of the proper version of images that need to be installed; the ASDP
packet belongs to a connection that has already been terminated on the security appliance;
the security appliance has switched to the standby state (if failover is enable) in which
case it can no longer pass traffic; or any unexpected value when parsing the ASDP header
and payload.

Recommendation:
    The counter is usually 0 or a very small number. But user should not be concerned if
the counter slowly increases over the time, especially when there has been a failover, or
you have manually cleared connections on the security appliance via CLI. If the counter
increases drastically during normal operation, please contact Cisco Technical Assistance
Center (TAC).
```

```
Syslogs:
    421003
    421004

------------------------------------------------------------------
Name: ssm-app-request
Service module requested drop:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when the application running on the SSM requests the security appliance to
drop a packet.

Recommendation:
    More information could be obtained by querying the incident report or system messages
generated by the SSM itself. Please consult the documentation that comes with your SSM for
instructions.

Syslogs:
    None.

------------------------------------------------------------------
Name: ssm-app-fail
Service module is down:
    This counter only applies to the ASA 5500 series adaptive security appliance. It is
incremented when a packet to be inspected by the SSM is dropped because the SSM has become
unavailable. Some examples of this are: software or hardware failure, software or
signature upgrade, or the module being shut down.

Recommendation:
    The card manager process running in the security appliance control plane would have
issued system messages and CLI warning to inform you of the failure. Please consult the
documentation that comes with the SSM to trouble shoot the SSM failure. Contact Cisco
Technical Assistance Center (TAC) if needed.

Syslog:
    None.

------------------------------------------------------------------
Name: wccp-return-no-route
No route to host for WCCP returned packet:
    This counter is incremented when a packet is returned from the Cache Engine and the
security appliance does not find a route for the original source of the packet.

Recommendation:
    Verify that a route exists for the source ip address of the packet returned from Cache
Engine.

Syslogs:
    None.

------------------------------------------------------------------
Name: wccp-redirect-no-route
No route to Cache Engine:
    This counter is incremented when the security appliance tries to redirect a packet and
does not find a route to the Cache Engine.

Recommendation:
    Verify that a route exists for Cache Engine.

Syslogs:
   None.
```

```
----------------------------------------------------------------
Name: telnet-not-permitted
Telnet not permitted on least secure interface:
    This counter is incremented and packet is dropped when the appliance receives a TCP
SYN packet attempting to establish a TELNET session to the appliance and that packet was
received on the least secure interface.

 Recommendation:
    To establish a Telnet session to the appliance via the least secure interface, first
establish an IPSec tunnel to that interface and then connect the Telnet session over that
tunnel.

 Syslogs:
    402117

----------------------------------------------------------------
Name: ipv6-sp-security-failed
IPv6 slowpath security checks failed:
    This counter is incremented and the packet is dropped for one of the following
reasons:
1) IPv6 through-the-box packet with identical source and destination address.
2) IPv6 through-the-box packet with linklocal source or destination address.
3) IPv6 through-the-box packet with multicast destination address.

Recommendation:
    These packets could indicate malicious activity, or could be the result of a
misconfigured IPv6 host.  Use the packet capture feature to capture type asp packets, and
use the source MAC address to identify the source.
Syslogs:
    For identical source and destination address, syslog 106016, else none.

----------------------------------------------------------------
Name: ipv6-eh-inspect-failed
IPv6 extension header is detected and denied:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet but extension header could not be inspected due to memory allocation failed.

 Recommendation:
Also check 'show memory' output to make sure appliance has enough memory to operate.

 Syslogs:
    None

----------------------------------------------------------------
Name: ipv6-bad-eh
Bad IPv6 extension header is detected and denied:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with bad extension header.

 Recommendation:
Check 'verify-header type' of 'parameters' in 'policy-map type ipv6'. Remove
'verify-header type' if the header conformance can be skipped.

 Syslogs:
    325005

----------------------------------------------------------------
Name: ipv6-bad-eh-order
```

```
IPv6 extension headers not in proper order is detected and denied:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with extension headers not in proper order.

 Recommendation:
Check 'verify-header order' of 'parameters' in 'policy-map type ipv6'. Remove
'verify-header order' if the header order can be arbitrary.

 Syslogs:
    325005

----------------------------------------------------------------
Name: ipv6-mobility-denied
IPv6 mobility extension header is denied by user configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with mobility extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header mobility' in 'policy-map type ipv6'. Remove action
'drop' if mobility should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-mobility-type-denied
IPv6 mobility type extension header is denied by user configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with mobility type extension header which is denied by the user configuration rule.

 Recommendation:
    Check action of 'match header mobility type' in 'policy-map type ipv6'. Remove action
'drop' if mobility should be allowed.

 Syslogs:
    325004

----------------------------------------------------------------
Name: ipv6-fragment-denied
IPv6 fragmentation extension header is denied by user configuration:
    This counter is incremented and packet is dropped when the appliance receives a IPv6
packet with fragmentation extension header which is denied by the user configuration rule.

 Recommendation:
